ABSTRACT

Objective Peritoneal or mesenteric tumours may correspond to several tumour types or tumour-like conditions, some of them being represented by histiocytosis. This rare condition often poses diagnostic difficulties that can lead to important time delay in targeted therapies. Our aim was to describe main features of histiocytoses with mesenteric localisation that can improve the diagnostic process.

Design We performed a retrospective study on 22 patients, whose peritoneal/mesenteric biopsies were infiltrated by histiocytes.

Results Abdominal pain was the revealing symptom in 10 cases, and 19 patients underwent surgical biopsies. The diagnosis of histiocytosis was proposed by initial pathologists in 41% of patients. The other initial diagnoses were inflammation (n=7), sclerosing mesenteritis (n=4) and liposarcoma (n=1). The CD163/CD68+CD11a-histiocytes infiltrated subserosa and/or deeper adipose tissues in 16 and 14 cases, respectively. A *BRAF*^{V600E} mutation was detected within the biopsies in 11 cases, and two others were *MAP2K1* mutated. The final diagnosis was histiocytosis in 18 patients, 15 of whom had Erdheim-Chester disease. The median diagnostic delay of histiocytosis was 9 months. Patients treated with *BRAF* or *MEK* inhibitors showed a partial response or a stable disease. One patient died soon after surgery, and five died by the progression of the disease.

Conclusion Diagnosis of masses arising in the mesentery should be carefully explored as one of the possibilities in histiocytosis. This diagnosis is frequently missed on mesenteric biopsies. Molecular biology for detecting the mutations in *BRAF* or in genes of the MAP kinase pathway is a critical diagnostic tool.

Summary box

What is already known about this subject?

- Only few case reports with peritoneal or mesenteric histiocytosis have been published as yet.
- Revealing symptoms, as well as the main clinical, pathological and molecular characteristics are not well described.

What are the new findings?

- Revealing symptoms of half of the patients was abdominal pain, and 19/22 patients underwent surgical biopsies.
- For half of them the first histopathological diagnosis was not histiocytosis (unspecific inflammation, sclerosing mesenteritis or liposarcoma).
- A *BRAF* or *MAP2K1* mutation was detected in the majority of cases, and happens to be an important tool to achieve the diagnosis.

How might it impact on clinical practice in the foreseeable future?

- Gastroenterologists, digestive surgeons and oncologists will consider histiocytosis among the possible diagnoses of peritoneal/mesenteric tumours.
- Avoid surgical biopsy in some cases.
- Achieve the correct diagnosis, or achieve the final diagnosis in a shorter delay.
- Propose efficient targeted therapies.

INTRODUCTION AND OBJECTIVES

Peritoneal or mesenteric tumours detected by imaging may correspond to carcinomatosis or sarcomatosis of a previously unsuspected tumour, or to a primitive mesothelioma. It may also reveal atypical proliferations such as abdominal desmoid tumour, inflammatory pseudotumour, infections

such as tuberculosis or be a manifestation of a systemic auto-immune or inflammatory disease, such as amyloidosis, Castleman disease or IgG4-related disease. Some of such rare conditions have been described as mesenteric panniculitis, mesenteric lipodystrophy or retractile mesenteritis before being gathered into a single entity: sclerosing mesenteritis.¹ A few cases of histiocytosis associated with peritoneal/mesenteric tumours have been reported.²⁻⁹

CT scans or MRI are good imaging modalities for the detection of peritoneal/

What are the side effects? Should I use Dianabol? When it comes to steroids, the name that comes up more than any other is Dianabol. It's the most popular and most widely used anabolic steroid, especially amongst bodybuilders. Some call it the "grand-daddy" of steroids, and not without good reason.

Dementia: Hearing loss causes structural changes in the brain

STRUCTURAL CHANGES

Alzheimer's disease spreads through the brain, causing a progressive loss of the connections between neurons (synapses), and then neurons themselves. In the later stages of the condition, the brain is noticeably shrunk — the cerebral cortex appears shrivelled and the fluid-filled ventricles are expanded.

MICROSCOPIC CHANGES

Two hallmarks of Alzheimer's disease are visible only under the microscope.

Accumulations of the peptide amyloid- β , known as plaques, form between neurons. Microtubule-associated protein tau aggregates into neurofibrillary tangles inside neurons, and these structures persist after neurons have died.

Dianabol, chemically known as Methandrostenolone, is a widely recognized anabolic steroid that athletes and bodybuilders utilize to promote muscle growth, enhance strength, and improve overall athletic performance.

ABSTRACT

Background Tumors rewire their metabolism to achieve robust anabolism and resistance against therapeutic interventions like cisplatin treatment. For example, a prolonged exposure to cisplatin causes downregulation of pyridoxal kinase (PDXX), the enzyme that generates the active vitamin B6, and upregulation of poly ADP-ribose (PAR) polymerase-1 (PARP1) activity that requires a supply of nicotinamide (vitamin B3) adenine dinucleotide. We investigated the impact of the levels of PDXX and PAR on the local immunosurveillance (ie, density of the antigen presenting cells and adaptive immune response by CD8 T lymphocytes) in two different tumor types.

Methods Tumors from patients with locally advanced cervical carcinoma (LACC) and non-small cell lung cancer (NSCLC) were stained for PAR, PDXX, dendritic cell lysosomal associated membrane glycoprotein (DC-LAMP) and CD8 T cell infiltration. Their correlations and prognostic impact were assessed. Cisplatin-resistant NSCLC cell clones isolated from Lewis-lung cancer (LLC) cells were evaluated for PAR levels by immunoblot. Parental (PAR^{wt}) and cisplatin-resistant (PAR^{rr}) clones were subcutaneously injected into the flank of C57BL/6 mice. Tumors were harvested to evaluate their immune infiltration by flow cytometry.

Results The infiltration of tumors by CD8 T and DC-LAMP⁺ cells was associated with a favorable overall survival in patients with LACC ($p=0.006$ and $p=0.008$, respectively) and NSCLC ($p<0.001$ for both CD8 T and DC-LAMP cells). We observed a positive correlation between PDXX expression and the infiltration by DC-LAMP⁺ ($R=0.44$, $p=0.02$ in LACC, $R=0.14$, $p=0.057$ in NSCLC), and a negative correlation between PAR levels and CD8 T lymphocytes ($R=-0.39$, $p=0.034$ in LACC, $R=-0.18$, $p=0.017$ in NSCLC). PARP1 is constitutively hyperactivated in cisplatin-resistant LLC cells manifesting elevated intracellular levels of polyADP-ribosylated proteins (PAR^{rr}). Tumors formed by such cancer cells injected into immunocompetent mice were scarcely infiltrated by CD8 T ($p=0.028$) and antigen presenting cells ($p=0.086$).

Conclusions Oncometabolic features can impact local immunosurveillance, providing new functional links between cisplatin resistance and therapeutic failure.

INTRODUCTION

Cancer cell-intrinsic properties drive alterations in the microecosystem that is composed by malignant cells, stromal elements as well as tumor-infiltrating leukocytes. This latter point has been neglected for a long time, yet spurred ever expanding interest since the discoveries that (i) the presence of certain immune effectors, in particular CD8⁺ cytotoxic T lymphocytes (CTLs) and activated dendritic cells (DCs) have a major prognostic impact in most extracranial cancer types¹ and (ii) immunotherapy with antibodies neutralizing the cytotoxic T-lymphocyte associated protein 4 (CTLA-4) and programmed cell death protein 1 (PD-1)/programmed cell death ligand 1 (PD-L1) has the potential to become a close-to-universal antineoplastic treatment.² Today, it is common knowledge that tumors, to become truly life threatening, must fulfill a compendium of conditions including malignancy (ie, the unrestrained proliferation and dissemination of neoplastic cells) and escape from immunosurveillance (ie, camouflage of tumor cells to become invisible to the immune system and/or active immunosuppression).³

The metabolic features of tumors may also be interpreted in the sense of a constant dialog between malignant and immune cells. In essence, tumor cells must rewire their metabolisms to produce biomass, initially often in a hostile context with scarce supply of growth factors, glucose, amino acids and oxygen. Beyond these anabolic capacities and an increased capacity to 'capture' nutrients from the environment, oncometabolism also may subvert immunosurveillance (and hence interfere with immunometabolism). For example, lactate produced by malignant cells and low extracellular pH interfere with T cell
