Fake Mail to Protect Your Identity

When you sign up to use any of your favorite websites, such as Facebook or Pinterest, you need to provide an email address in order to set up your account. Even though you may not give it much thought, this can be risky since anyone with your email address and password would have full access to all of your private accounts, personal photos, and more. If you're concerned about identity theft and privacy, then [fakemail](#) could be the right solution for you! Here's how temporary email works and how it can keep your information safe from malicious hackers and other cyber criminals.

How fake mail works

When you sign up for [fake mail](#), you'll first create a username and password. Then, whenever you need a disposable email address for a specific online application, click on your fake mail inbox and choose from one of your addresses. The email is sent from that address but not by it—the company sending your message thinks they're using your name or personal information, but they aren't. No one can see what's inside your email accounts; they're completely private. Fake mail means nobody else has access to your information either—no cybercriminals with their eyes on your bank account or identity thieves after Social Security numbers that can be used later on in life.

How temporary email can help you out

Fake mail is a temporary email service that allows you to generate a realistic-looking email address and website address (with a corresponding domain name) at no cost. These are important because they can protect your identity and privacy online, allowing you to access real emails and keep your personal info separate from someone else who might be monitoring it. There are a variety of services out there; one great option is FakeMail, which allows you to create an unlimited number of email addresses that will forward all incoming messages directly back to your inbox or send them directly to another email address if that's what you want. For example, if you don't want potential customers finding your private Gmail account, create a temporary (and totally fake) one using FakeMail.

How it prevents hacking attempts

Temporary email keeps your real email address a secret. Fake mail is an effective way to protect your identity on and off line. Hackers will typically not go through extra effort for temporary emails, and if they are dedicated, then a new [fakemail](#) account can be created quickly. Using fake mail when signing up for accounts can also prevent other types of hacking attempts that try to harvest information from social media or identify theft forums/websites by tying together email addresses in their databases.

Hackers won't know you exist

One way hackers can get your passwords is by guessing what they are. One method for doing so is called a brute force attack—basically, trying millions of combinations until it gets it right. Temporary email addresses prevent them from even knowing if their guesses are correct by giving you an account that lasts just one hour and a new one each time. That means there's no chance a brute force attack could succeed as long as you don't use your fake email address for any other purpose than logging into insecure sites. If a hacker tries to guess your password on another site, that hack will be thwarted immediately because he or she will only have access for sixty minutes and then be locked out of your account completely!

Bypass spam filters

Be sure your fake mail provider allows you to send mail from a browser on your computer and from a mobile device, such as an iPhone or Android. The more versatility they offer, the better it is for protecting your identity. If all you're doing is sending emails via your desktop computer, stick with Gmail. You don't need anything more sophisticated than that. With Google Inbox, you can respond without ever downloading an app.

Create throwaway accounts without an IP address

Are you worried that creating an email account could provide a digital breadcrumb trail leading back to your physical location? Even if you're using a VPN and a fake IP address, it can be easy for snoops to figure out who you are. If that's something that concerns you, try setting up throwaway accounts. With most services, all you need is an email address—you don't have to register with personal information such as your name or even your real email address. You also have more flexibility with throwaway accounts: If one gets caught in a spam filter, simply create another one and move on with your life.

Works on desktop and mobile devices

As our online personas get more and more involved, it's easier than ever for others to use our private information against us. Whether it's a romantic interest who gets suspicious after seeing too many emails from you or your stalker who somehow finds your personal information and then starts sending threats through that channel. For times like these, there are temporary email services designed specifically with these situations in mind! You can generate an anonymous email address that doesn't link back to you at all, allowing you to communicate without revealing anything about yourself.
