This is a PDF file of an unedited manuscript that has been accepted for publication. As a service to our customers we are providing this early version of the manuscript. The manuscript will undergo copyediting, typesetting, and review of the resulting proof before it is published in its final form. Please note that during the production process errors may be discovered which could affect the content, and all legal disclaimers that apply to the journal pertain.

1

2 • "Krokodil" was produced mimicking street synthesis followed by addicts

3 • Desomorphine was synthesized using the hydriodic acid/red phosphorous reduction

4 • Qualitative and quantitative analysis of desomorphine was performed by GC-EI/MS

5 • Dihydromorphine-3,6-dideoxy and morphinan-4,5-epoxy-3-ol were also obtained

1 **Full Title:** THE CHEMISTRY BEHIND “KROKODIL”: STREET-LIKE SYNTHESIS
2 AND PRODUCT ANALYSIS

3
4 **Running Head:** “krokodil” synthesis and analysis

5
6 **ABSTRACT**

7
8 “Krokodil” is the street name for a drug, which has been attracting media and
9 researchers attention due to its increasing spread and extreme toxicity. “Krokodil” is a
10 homemade injectable mixture being used as a cheap substitute for heroin. Its use begun
11 in Russia and Ukraine, but it is being spread throughout other countries. The starting
12 materials for “krokodil” synthesis are tablets containing codeine, caustic soda, gasoline,
13 hydrochloric acid, iodine from disinfectants and red phosphorus from matchboxes, all of
14 which are easily available in a retail market or drugstores. The resulting product is a
15 light brown liquid that is injected without previous purification. Herein, we aimed to
16 understand the chemistry behind “krokodil” synthesis by mimicking the steps followed
17 by abusers. The successful synthesis was assessed by the presence of desomorphine and
18 other two morphinans. An analytical gas chromatography-electron impact/mass
19 spectrometry (GC-EI/MS) methodology for quantification of desomorphine and codeine
20 was also developed and validated. The methodologies presented herein provide a
21 representative synthesis of “krokodil” street samples and the application of an effective
22 analytical methodology for desomorphine quantification, which was the major
23 morphinan found. Further studies are required in order to find other hypothetical
24 byproducts in “krokodil” since these may help to explain signs and symptoms presented
25 by abusers.

26
27 *Keywords:* Opioid abuse; desomorphine; “krokodil” synthesis; GC-EI/MS analysis.

1 INTRODUCTION

2
3 “Krokodil” is the street name for an injectable mixture that has been used as a
4 cheap substitute for heroin and is attracting media and researchers attention due to its
5 spreading and extreme toxicity [1-5]. “Krokodil” first appeared around 2002/3 in Russia
6 and Ukraine [1-4]. It is obtained from codeine tablets after a homemade process aimed
7 to synthesize desomorphine, as a low cost option for heroin addicts. Data about the
8 homemade synthesis of “krokodil” are related to a Nagai and “Moscow” methods, both
9 commonly used for methamphetamine [1, 6-8]. Thereby, precursors are chemical
10 products easily purchased in supermarkets, pharmacies and hardware stores [4]. As
11 refereed, the morphinan starting material is codeine usually extracted from analgesic
12 and antitussive medicines sold in the form of tablet or syrup, which may also contain
13 other substances such as paracetamol, acetylsalicylic acid and caffeine [1]. The other
14 chemicals used in the synthesis, iodine and red phosphorus, are readily available as
15 components of medical tinctures and matchboxes, respectively [1]. The process requires
16 very little equipment and is usually undertaken in unsanitary conditions.

17 The manufacture of “krokodil” involves two steps [6, 8]. Firstly, a simple acid-base
18 extraction of codeine from the tablets, using gasoline as organic solvent is performed.
19 The second step is the reduction reaction of codeine to desomorphine, using iodine and
20 red phosphorus [8]. The resulting mixture is light brown liquid and has a strong acidic
21 pH. Some users reported the use of cigarette ashes or sodium bicarbonate to increase the
22 pH value of the mixture [4]. The obtained product is filtered, using cotton wool or a
23 cigarette filter, to remove suspended particles. After filtration, the resulting mixture is
24 usually directly injected without further purification.

25 By definition, in “krokodil”, desomorphine is believed to be the main active opioid
26 [1, 2, 9-11]. However, descriptions of possible by-products in the catalytic reduction
27 from codeine to desomorphine at different conditions of their synthesis was previously
28 described in samples from syringes and biological fluids of Russian users [12].

29 The availability of real samples of “krokodil” is very scarce, which hampers
30 analytical studies and the elucidation of the toxicity of this drug. Therefore, this study
31 aims to follow a procedure for the synthesis of “krokodil”, by mimicking the street
32 conditions used in its preparation as reported by abusers, namely the raw materials and
33 home equipment. The process of synthesis was filmed and reproduced in laboratory.

1 Moreover, considering the absence of documented validation method for detection and
2 quantification of desomorphine and codeine in “krokodil” samples, a gas
3 chromatography-mass spectrometry with electron impact ionization (GC-EI/MS)
4 method was fully developed and validated. In addition, this methodology was applied
5 for the identification of sub-products of the synthesis.

6 7 8 **MATERIAL AND METHODS**

9 10 *Reagents and standards*

11
12 For “krokodil” synthesis gasoline, alkali solutions for cleaning pipes and
13 matchboxes were purchased from local retail stores in Porto, Portugal. Hydrochloric
14 acid 37% was purchased from VWR Prolabo[®]. Codeine-containing capsules, iodine
15 tinctures, hydrogen peroxide and, commercial ethanol 96% were purchased from local
16 pharmacies in Porto, Portugal.

17 For GC-EI/MS analysis, ethyl acetate and sodium sulphate were purchased from
18 Carlo Erba (Milan, Italy), *N*-methyl-*N*-trimethylsilyltrifluoroacetamide (TMSFA) was
19 purchased from Sigma-Aldrich (St Louis, MO, USA). Phenacetin (internal standard for
20 GC-EI/MS, IS), codeine and desomorphine were purchased from Lipomed AG
21 (Arlesheim, Switzerland). Helium C-60 (99.99%) was obtained from Gasin (Portugal).
22 Nitrogen was supplied by AirLiquid (Algés, Portugal). For GC-EI/MS analysis, all the
23 reagents used were of analytical grade or from the highest available grade. For High-
24 Performance Liquid Chromatography with Diode-Array (HPLC-DAD) analysis,
25 methanol, hexane, ethyl acetate and triethylamine (TEA) of HPLC grade were obtained
26 from Sigma-Aldrich.

27 28 *Synthesis of “krokodil”*

29 30 Extraction of codeine

31 Codeine was extracted from analgesic capsules containing 30 mg of codeine
32 phosphate, using an alkali solution obtained from commercial pipe cleaning products in
33 proportion of 20% (m/v), gasoline and hydrochloric acid (37%). The solvents were

1 chosen according to clandestine synthesis information obtained by inquiring abusers.
2 For each extraction, the entire content of five codeine-containing capsules was mixed
3 with 20 mL of alkali solution and 200 mL gasoline, respectively. The organic phase was
4 transferred to another bottle and hydrochloric acid 37% and water (30 mL) were added
5 until pH 1, and mixture was agitated for 5 minutes. The aqueous phase was then
6 removed with a syringe, transferred into a plate and evaporated using a water bath.

7 8 Extraction of iodine from iodine tincture

9 Iodine tincture (30 mL, 6%), hydrochloric acid 37% (15 mL,) and hydrogen
10 peroxide 10 volumes (30 mL, 3%) were mixed together with swirling. The mixture was
11 left to stand for 30 minutes. The mixture was filtered to obtain the iodine crystals.

12 13 Extraction of red phosphorus from matchboxes

14 Matchboxes sides were soaked in ethanol 96% (2 mL) and scrapped with fingers.
15 The mixture was stored at ambient temperature and left to dry.

16 17 Nagai type reaction

18 A mixture of codeine hydrochloride obtained from the extraction and red
19 phosphorus was transferred to an injection flask containing iodine and heated in a
20 candle flame. Water was added on the final step and the obtained solution was filtered
21 using a syringe filter and stored.

22 23 Preparation of blank “krokodil” samples

24 Blank “krokodil” samples were obtained performing the above procedures in the
25 absence of capsules containing codeine.

26 27 *Quantitative and qualitative analysis of “krokodil”*

28 29 Preparation of stock and working standard solutions of codeine and desomorphine

30 Stock solutions of the desomorphine and codeine and IS were prepared in methanol
31 at the concentration of 1 mg/mL. Desomorphine and codeine concentrations of working
32 standard solutions for the calibration curve were prepared at different concentrations by
33 diluting stock solutions in ethyl acetate (0.625, 1.25, 2.5, 5.0 and 10.0 µg/mL). A

1 working solution of the IS at 4 $\mu\text{g}/\text{mL}$ was also prepared in ethyl acetate. Working
2 solutions were prepared fresh daily and stock solutions were stored at -80°C prior use.
3 “Krokodil” blank samples were spiked with different standards working solutions to
4 validation curves.

6 Sample Preparation

7 Synthesized “krokodil” samples (100 μL) were diluted in deionized water (1:10)
8 and basified using one drop of NaOH 0.1N (Fig. 1). An aliquot of 200 μL of the diluted
9 solution was extracted with 600 μL of ethyl acetate. The organic layer was dried over
10 Na_2SO_4 , transferred to another vial and evaporated to dryness under a gentle stream of
11 nitrogen (Fig. 1). 60 μL of *N*-methyl-*N*-trimethylsilyltrifluoroacetamide (TMSFA) was
12 added and samples heated at 80° for 30 min to accomplish derivatization (silylation). An
13 aliquot of 1 μL of the derivatized extract was injected into the GC-EI/MS system (Fig.
14 1).

16 Gas chromatography-mass spectrometry conditions

17 Quantitative and qualitative GC-EI/MS analyses were performed on a Trace GC
18 2000 Series ThermoQuest gas chromatography equipped with ion-trap GCQ Plus
19 ThermoQuest Finnigan mass detector. Chromatographic separation was achieved using
20 a capillary column (30m \times 0.25 mm \times 0.25 μm , cross-linked 5% diphenyl and 95%
21 dimethyl polysiloxane) from Restek[®] and high-purity helium C-60 was used as carrier
22 gas maintained at 1.0 mL/min. An initial temperature of 80°C was maintained for 1 min,
23 increased to 300°C at $10^\circ\text{C}/\text{min}$, and held for 5 min giving a total run time of 28 min.
24 The injector temperature was set at 280°C . Quantitative analyses were performed in
25 selected ion monitoring mode with splitless injection (1 μL). The designated ions were
26 m/z 148, 286 and 271 for desomorphine, 178, 229 and 280 for codeine, and 162, 236
27 and 251 for IS. Qualitative analyses were performed in the full-scan mode in the range
28 of m/z 50-650.

30 Liquid chromatography conditions

31 Qualitative HPLC-DAD analyses were performed on a Finnigan Surveyor (Thermo
32 Electron Corporation, USA) equipped with an AutoSampler Plus and a diode array
33 detector TSP UV6000LP (Thermo Separation Products, USA). The separation was

1 carried out on a 250 × 4.6 mm i.d. Hypersil silica 3 mm, pore size 120 Å, (Hichrom,
2 UK). LC analysis was performed by gradient elution, with mobile phase consisting of
3 hexane as solvent A, methanol as solvent B and ethyl acetate with 0.005% of
4 triethylamine as solvent C. The gradient elution program was as follows: 100% of A
5 from 0 to 30 min, 0% to 100% C from 30 to 90 min, isocratic 100% C from 90 to 100
6 min, 1:1 (B:C) from 100 to 140 min, isocratic on this condition from 140 to 150 min,
7 50% to 100% C from 150 to 180 min. The injected volume was 20 mL and the elution
8 was monitored in UV/Vis at 254nm. Chromeleon 7.1 SR2 software Thermo Fisher
9 Scientific managed chromatographic data. Prior to use, mobile phase solvents were
10 degassed in an ultrasonic bath for 15 min. The identification of desomorphine was
11 established based on the comparison with standard retention time under the same
12 chromatographic conditions and UV/Vis spectrum.

13

14 ³¹P NMR conditions

15 ³¹P liquid state NMR spectra were performed and recorded on a Brücker DRX-300
16 spectrometer, using deuterated methanol (CD₃OD) or deuterium oxide (D₂O) as
17 solvents from Deutero GmbH®.

18

19 Method validation

20 The validation of the method was performed accordingly to European Medicines
21 Agency [13] and other authors [14-16]. The evaluated parameters were selectivity, limit
22 of detection (LOD), lower limit of quantification (LLOQ), precision, accuracy, recovery
23 and linearity of the method. The calibration curves were prepared by spiking blank
24 “krokodil” samples with proper volumes of standard solutions of desomorphine and
25 codeine as described above.

26

27 *Stability of “krokodil”*

28

29 In order to evaluate the stability of the synthesized “krokodil” samples,
30 desomorphine was quantified after freeze/thawed three times in different moments (in
31 the first three consecutive days, one week and one month after the synthesis). Moreover,
32 each sample was submitted to three different storage temperatures (*i.e.* room

1 temperature, 4°C and -20°C) to evaluate the thermal stability of the products and the
2 mixture obtained.

3

4

5 **RESULTS AND DISCUSSION**

6

7 *Synthesis of “krokodil”*

8

9 The need of samples for analytical purposes and toxicological analysis was the
10 main reason for the synthesis of “krokodil” in the present work. The method used for
11 the synthesis was based on what is known to be followed by “krokodil” users in
12 Georgia. Preparation was recorded and later reproduced in our laboratory. The synthesis
13 method resemblances Nagai route, firstly used to synthesize methamphetamine from
14 ephedrine or pseudoephedrine. Indeed, both syntheses use the hydriodic acid (HI)
15 formed *in situ* by the reaction between red phosphorus and iodine as catalyst of the
16 reduction reaction to obtain the final product. Therefore, data regarding the by-products
17 formed during Nagai route [8, 17, 18], could be useful to hypothesize which impurities
18 may be present in “krokodil” samples.

19 Usually, codeine is commercially available as a phosphate salt. Its extraction was
20 performed by liquid-liquid extraction, based on acid-base chemistry. 65.13% of codeine
21 was recovered, which is acceptable once the extraction process was totally homemade.
22 Firstly, a strong base was added to form the codeine free base, which was dissolved in
23 the organic phase. The strong base was usually obtained from commercial available
24 products that contain sodium hydroxide and are used to clean pipes. The organic solvent
25 was usually gasoline, although some addicts also reported using paint thinner [4]. The
26 water-soluble compounds associated with codeine in the tablets were washed away in
27 this step. Subsequently, the organic extract was acidified with hydrochloric acid,
28 obtained from industrial products found in supermarkets, and then water was added.
29 After the separation of the phases, codeine was back-extracted into the aqueous layer as
30 its hydrochloride salt. The aqueous solution containing codeine can be used directly or
31 evaporated. Even though, being aware of the street procedure limitations, our protocol
32 mimics precisely the steps undertaken by “krokodil” abusers.

1 After these extraction steps, the reduction of codeine to desomorphine was
2 performed. Taking into account the reagents used in the manufacture of “krokodil”, the
3 proposed mechanism of its synthesis is described in Figure 2. Iodine and red
4 phosphorus react to form phosphorus triiodide (PI₃) [19]. PI₃ usually reacts, by a SN₂
5 mechanism, with primary and secondary alcohols, displacing the hydroxyl group which
6 is replaced by iodine, to produce an alkyl iodide [20]. We propose that PI₃ promotes the
7 nucleophilic substitution of the hydroxyl group at C(6) of codeine forming α-
8 iodocodeine (6-iodocodeine) [19]. Subsequently, in the presence of water, PI₃ is
9 converted to HI, which promotes the acidic ether cleavage [21] of the methoxyl group
10 and the dehalogenation of 6-iodocodeine to 6-deoxymorphine (or dehydro-
11 desomorphine) [19]. HI is also responsible for the reduction of the double bond at C(7)
12 and C(8) [22], leading to the formation of desomorphine. Iodine released in the
13 dehalogenation of 6-iodocodeine reacts again with red phosphorus, initiating a new
14 redox cycle [19].

15 In Figure 2 is also showed the formation of phosphorous acid (H₃PO₃) as a product
16 of the nucleophilic substitution of the alcohol and as a product of the reaction of PI₃
17 with water. Phosphorous acid produces phosphoric acid (H₃PO₄) and phosphine (PH₃),
18 once the reaction is conducted at high temperature (a gas flame is used for heating, T >
19 200 °C).

20 Approximately 45 minutes after the beginning of the extraction, “krokodil” is ready
21 to be injected. The obtained product has a dark brown color, probably a result of iodine
22 formed during the reaction of a strong acid with iodide ion [23], and a characteristic
23 acid odor. The measured pH was 1.15±0.30. The physical appearance and the found pH
24 values are in accordance with literature [1]. Usually, each user injects 1 mL of
25 “krokodil” into different parts of body. The most common route of administration is
26 intravenous, but intramuscular or even intradermal was also reported.

27

28 *Method validation*

29 The analytical parameters of the developed method were discussed in the following
30 topics.

31 **Selectivity.** Six blank samples were analyzed to evaluate chromatographic
32 interferences. No interference peaks were detected, either in the retention times of
33 desomorphine or codeine or in the IS retention time (Fig. 3A).

1 **Carry-over.** During the validation process, injections of calibration standards
2 containing more than 10 times the concentration correspondent to the limit of
3 quantification were followed by blank sample injections of ethyl acetate, to ensure that
4 there was no carry-over from one injection to the next one. The obtained carry-over
5 results were <20% of the LLOQ and <5% for the IS, which were within the proposed
6 acceptance limits for this parameter [13].

7 **Linearity.** The weighted least squares linear regression equations and coefficients
8 of determination were calculated using three different curves of each analyte obtained
9 from independent sets of standards. The results obtained were showed in Table 1. The
10 determination coefficients (r^2) were >0.990 over the concentration range, showing good
11 linearity for all the analytes.

12 **Limit of Detection and Limit of Quantification.** LOD and LLOQ were
13 determined as following: $LOD=3.3\sigma/m$ and $LOD=10\sigma/m$ where σ is the standard
14 deviation of the response and m the slope of the calibration curve. Detection limits were
15 $0.150\pm 0.002 \mu\text{g/mL}$ for desomorphine and $0.170\pm 0.002 \mu\text{g/mL}$ for codeine in normal
16 autotune conditions. The quantification limit for was $0.490\pm 0.002 \mu\text{g/mL}$ for
17 desomorphine and $0.570\pm 0.002 \mu\text{g/mL}$ for codeine. The values of LOD and LLOQ are
18 listed on Table 1.

19 **Precision, Accuracy and Recovery.** The results obtained are showed in Table 1.
20 The %CV for desomorphine and codeine did not exceed 15% and the developed method
21 was considered precise for both analytes. Accuracies in the range of 101.3 – 110.2% for
22 desomorphine and 101.3 – 106.6% for codeine were obtained, which are within the
23 proposed acceptance limits for this parameter ($100\pm 15\%$, [13]). The recoveries were
24 89.42% and 92.88% for desomorphine and codeine, respectively. Associated with lower
25 %CV (0.49 – 11.6%), these results suggest that extraction was efficient for the three
26 different concentrations evaluated.

27 28 *Qualitative Analysis*

29
30 Our aim was to obtain “krokodil” real samples. The performed synthesis mimics
31 the street procedure and leads to a crude product that was not submitted for further
32 purification. Therefore, the gas chromatographic profile of the synthesized “krokodil”
33 was complex, revealing the presence of several compounds (Fig. 3B). Many of these

1 compounds belong to the raw materials used for the synthesis (excipients of the
2 formulation, plastics, gasoline etc.) or could arise from reactions between them. Our
3 focus was on the compounds with the morphinan nucleus.

4 Desomorphine was the predominant morphinan presented. Its identification was
5 established by the retention time and co-injection with a reference standard, as well as
6 by the interpretation of the mass spectral fragmentations (Fig. 1S). The mass spectral
7 fragmentations of desomorphine showed the molecular ion ($m/z = 343$), which was the
8 base peak, consistent with the molecular mass of the trimethylsilyl derivative (Fig.
9 1S). The ion with $m/z = 328$ [M-15]⁺ corresponded to the loss of the methyl group and
10 the ion $m/z = 286$ [M-57]⁺ is consistent with a possible loss of C₃H₇N fragment, which
11 resulted from the cleavage of the piperidine ring. The ion $m/z = 271$ [M-72]⁺
12 corresponded to the loss of the trimethylsilyl group followed by protonation.

13 The work developed by Savchuk, Barsegyan [12] pointed out that the procedure
14 and raw materials adopted in “krokodil” preparation would reflect the final chemical
15 composition, not only in terms of the amount of desomorphine, but also on the
16 presence/absence of other morphinans. Therefore, in order to assess how well the
17 followed procedure mimicked real samples, a further analysis was undertaken. The
18 synthesis method applied in the present study, revealed trace amounts of
19 dihydromorphine-3,6-dideoxy and morphinan-4,5- epoxy-3-ol in the “krokodil”
20 samples. These morphinans had also been found in street “krokodil” samples analyzed
21 previously by Savchuk, Barsegyan [12]. Their mass spectra (Fig. 1S) are in agreement
22 with NIST library for these compounds (please see the following website:
23 [http://webbook.nist.gov/cgi/cbook.cgi?ID=C427009&Units=SI&Mask=200#Mass-](http://webbook.nist.gov/cgi/cbook.cgi?ID=C427009&Units=SI&Mask=200#Mass-Spec)
24 [Spec](http://webbook.nist.gov/cgi/cbook.cgi?ID=C427009&Units=SI&Mask=200#Mass-Spec)). Taking into account chemical structure it was reasonable to consider they were
25 by-products from the same reaction that occurs between codeine, iodine and red
26 phosphorus.

27 In order to clarify the chemical composition of “krokodil”, the obtained extract was
28 analyzed with HPLC-DAD (Fig. 2S). The wide polarity range of the mobile phase
29 highlighted the large chemical diversity of the sample, which can be divided into three
30 categories according to its polarity. The apolar constituents were eluted within the first
31 minutes. Since the final products were not submitted to any purification step, we
32 hypothesized that these contaminants were derived from plasticizers family. The second

1 category was composed by compounds with intermediate polarity, which were eluted
2 almost at the end of one hour. Desomorphine was identified here with a retention time
3 of 50.13. It is expected that the other morphinans may be present within this category.
4 Finally, the third category, composed by the polar constituents of the mixture, were
5 eluted almost at the end of two hours. Due to the harsh reaction conditions at elevated
6 temperatures, it is expected that polar sub-products are obtained during the synthesis
7 procedure.

8 As phosphorus is a key element in “krokodil” preparation, we analyzed the
9 presence of phosphorus-containing molecules present on it by ^{31}P -NMR (Fig. S3). Four
10 phosphorous species are involved in the “krokodil” manufacture namely, H_3PO_3 ,
11 H_3PO_4 , PI_3 and PH_3 . PH_3 is a highly reactive and toxic gas that promptly reacts with
12 water and oxygen. PI_3 is the most unstable phosphorous trihalide and reacts easily with
13 water [24]. Considering the reduction mechanism using HI as catalyst, H_3PO_3 is formed
14 as a by-product of the SN_2 reaction that leads to 6-iodocodeine and by PI_3 hydrolysis.
15 As referred above, the formation of H_3PO_4 is explained by the thermal decomposition
16 ($T > 200^\circ\text{C}$) of H_3PO_3 . Apparently, H_3PO_3 and H_3PO_4 are not present in “krokodil”,
17 since their typical signals at δ 3.5 ppm and δ 0 ppm [25], respectively, were not
18 observed. ^{31}P NMR spectra usually cover the region between -500 ppm and 1400 ppm
19 [25]. However, all signals in the ^{31}P NMR spectrum of “krokodil” are present in a
20 narrow range (-11.74 ppm to 5.86 ppm). These absorptions are compatible with the
21 presence of phosphanes or phosphorous/phosphoric acid derivatives, such as phosphate
22 esters, phosphonate esters or phosphates salts [26]. Since H_3PO_3 and H_3PO_4 were not
23 evident in the ^{31}P NMR “krokodil” spectrum we could assume that they were converted
24 into its derivatives during the extremely harsh reaction.

25 26 *Quantitative Analysis*

27
28 Several chromatographic conditions, such as column oven temperatures and gas
29 flow rate, were tested in order to achieve the best peak separation of the analytes of
30 interest. These tests led to the optimized conditions presented above and the analytes of
31 interest were detected in 28 min. The retention time of desomorphine was 19.99
32 minutes, the retention time of codeine was 21.45 minutes and the retention time of the
33 IS was 12.78 minutes (Figure 3A). Despite Srimurugan and colleagues [27] had

1 synthesized a deuterated analogue for desomorphine, it was not available to purchase and
2 phenacetin was chosen as IS since it proved to be effective for opioids analysis [28].
3 The integration of the chromatographic peaks for quantitative analysis was performed
4 by Selective Ion Monitoring (SIM) mode, increasing selectivity and allowing more
5 precise peak integration, especially relevant when we led with small concentrations
6 [16].

7 To evaluate the efficacy of the synthesis, codeine and desomorphine concentrations
8 were analyzed in 10 synthesized “krokodil” samples. The concentration of codeine in
9 “krokodil” samples was residual and lower than the LLOQ of the method. On the other
10 hand, the medium desomorphine concentration was approximately to 0.56 (± 0.35)
11 mg/mL (yield of 5.5% ± 3.5). Due to the homemade character of synthesis, different
12 amounts of desomorphine were produced. This variability is also common in homemade
13 synthesis. Indeed, according to users’ skills, different “krokodil” batches may be
14 produced. These results proved that the synthesis procedure allows the consumption of
15 almost all the codeine present in the original tablets, but other compounds besides
16 desomorphine are formed (Figure 3B).

17 18 *Stability of “krokodil”*

19 Regarding “krokodil” stability, the best storage temperature was shown to be 4°C
20 since higher concentrations of desomorphine were observed (Table 1S). Stock solutions
21 are usually stored in freezer and, to make a working solution it is necessary to bring the
22 stock solution to room temperature [29]. Karinen, Oiestad [29] described the stability of
23 different substances in stock solution at room temperature, in the freezer and
24 refrigerator. Opioids were shown to be stable at different temperatures for at least one
25 year, except tramadol. There are no data describing the stability of desomorphine. The
26 short stability of desomorphine in “krokodil” samples might be explained by extremely
27 acidic pH of the final sample. Moreover we hypothesized that the lower stability at -
28 20°C when compared to 4°C may be justified by the freezing-thawing phenomenon that
29 occurs when a solution is stored at low temperatures.

30
31
32
33

1 CONCLUSIONS

2
3 “Krokodil” was produced mimicking street synthesis. The laboratory route for
4 desomorphine production from codeine is totally different since the reduction is
5 catalyzed by thionyl chloride. Despite both reaction methods are reductions, the by-
6 products are very different due to the starting materials used. A sensitive, reproducible
7 and simple GC-EI/MS method was developed and validated to screen and quantify
8 desomorphine and codeine in “krokodil” samples. The qualitative analysis of the
9 samples also showed the presence of other two morphinans (*i.e.* dihydromorphine-3,6-
10 dideoxy and morphinan-4,5-epoxy-3-ol) due to the highly reductive environment. It is
11 believe that the proposed analytical methodology will be a powerful tool for forensic
12 laboratories in cases where street samples require laboratorial analysis. Finally, a more
13 systematic investigation of the reaction conditions is needed in order to obtain
14 additional information about the chemistry behind “krokodil” synthesis. Indeed, despite
15 the fact that GC-EI/MS is a highly sensitive technique, the identification of other
16 morphinans is difficult namely due to non-volatile and unusual fragmentation patterns.
17 Further elucidation and identification of side-products might be possible by liquid
18 chromatography-high-resolution mass spectrometry and nuclear magnetic resonance.

19 There is no doubt that “krokodil” is an extremely dangerous mixture of compounds,
20 which contain desomorphine as its main psychoactive ingredient. The use of harmful
21 substances in the synthesis and the absence of proper purification methods before the
22 drug consumption results in the formation of a very damaging mixture. Chemical
23 content analysis of “krokodil” should provide the needed information about its active
24 ingredients and contaminants and about the chemical process undergoing its homemade
25 production. It has been reported by the media that the life expectancy of people who
26 inject the drug is reduced to about 2-3 years. Both consumers and service providers
27 suggest that skilled “cooks” can prepare a cleaner intravenous “krokodil” solution,
28 which causes less toxic effects.

29 Our group is dedicated to understand the complete toxicology of “krokodil”. We
30 initiated this work trying to obtain reliable samples of “krokodil”. The authors contacted
31 users to understand the synthesis process and to know all the social and legal issues that
32 lead a person to abuse “krokodil”. All this information was compiled and can be found
33 in a previous work [1]. To further understand “krokodil”-related toxic effects, a “clean”

1 (not homemade) synthesis using quality laboratorial starting materials would be
2 interesting. Moreover, biochemical and histological analysis aiming to compare to the
3 toxic alterations of blank samples (“krokodil” without codeine), “krokodil” samples and
4 “clean” krokodil need to be done. Indeed, we are in progress with *in vivo* experimental
5 studies using “krokodil” samples, aiming to understand its mechanism of toxicity and
6 the main target organs. Certainly, conjugating the chemical and *in vivo* toxicological
7 data it will be possible to understand which compounds are actually being responsible
8 for signs and symptoms of intoxication. Moreover, these findings should contribute to
9 preventive measures for reducing the harmful toxic effects of this drug. Ultimately,
10 specific therapeutic approaches for “krokodil” abusers can be proposed and developed.
