The first full-scale development Amraam missile was fired successfully at the White Sands Missile Range in New Mexico. The missile was launched from a U.S. Air Force F-16 at 40,000 feet at a speed of Mach 1.2. It flew a preprogrammed course designed to evaluate the missile's control system and separation from the launch aircraft. It did not have a seeker but instead was programmed through its autopilot to fly a prescribed route. The advanced medium-range air-to-air missile is in full-scale development at Hughes Aircraft Company for the U.S. Air Force and Navy

Infrared-guided Maverick missiles scored 11 direct hits in 11 launches over a seven-day period as the U.S. Air Force tested the air-to-surface weapon under typical combat conditions. Ten launches were part of the Follow-On Test and Evaluation (FOT&E) series, designed to determine whether missiles off a production line are ready for operational deployment. The other was a telemetry round not counted as part of the FOT&E series. The Mavericks were fired from F-111 and F-16 aircraft against a variety of moving and stationary targets, including tanks and armored personnel carriers. Three launches occurred at night. In other evaluations conducted by the Air Force, the Hughes missiles met or surpassed reliability and maintainability standards.

TOW missiles are being modified to have an even greater armor-piercing capability. The Improved TOW, or ITOW, carries a five-inch diameter warhead incorporating advanced technology. The improved wire-guided missile has approximately the same weight and size as the basic TOW, but includes a probe on the nose of the missile for standoff detonation. The ITOW warhead can be retrofitted on all basic missiles and requires no changes in the launcher or guidance hardware. Hughes builds missiles in the ITOW family for the U.S. Army and Marine Corps and over 30 nations.

U.S. Marine Corps A-4M Skyhawk attack aircraft are as much as three times more effective when equipped with the Angle Rate Bombing Set (ARBS), according to pilots who participated in the first overseas operational deployment of such aircraft. ARBS is a computerized bombing system that can be used with bombs, gunfire, and rockets. Its dual-mode TV and laser tracker locks onto and tracks targets either identified by the pilot on a cockpit display or designated by a laser device. Marine Attack Squadron 311 pilots using ARBS in bombing exercises concentrated bomb hits 50% to 75% closer to targets than did pilots using previous manual techniques. These tests demonstrated how the Hughes-built ARBS can cut the number of missions over enemy territory and improve the A-4M's primary close air support mission of attacking targets located near friendly troops.

The Amraam missile may become the next-generation weapon for protecting U.S. Navy surface ships against threats that have slipped through the outer defense shields. Sea Amraam, under study for ship self-defense, would be essentially the same as the advanced medium-range air-to-air missile in full-scale development by Hughes for the U.S. Air Force and Navy. However, compared to existing missiles, Sea Amraam would increase a ship's firepower because the missile's guidance system is much less dependent on the ship's radars. Many missiles could be fired at different targets simultaneously, and they could home in even if the targets were outside the field of the ship's radar systems. Sea Amraam is also faster, more maneuverable, and can fly farther than current ship self-defense systems.

We have the lead...

. . . IN TOWED ARRAY TECHNOLOGY
Design and development authority for the most effective underwater detection systems available today.

Ameeco can provide Towed Arrays for ships and submarines of all sizes plus coastal defence systems. Ameeco also manufacture a range of sophisticated cable penetrators including fibre optic types plus connectors and cable terminations.

Ameeco have the underwater detection technology to provide the solutions you're searching for.

The lowdown on the lowdown

Sea skimmers like Exocet come in low and fast.

They're small radar targets - often 0.1 m^2 or less. They hide in sea clutter. And they're usually accompanied by jamming, chaff or both.

Marconi's combat-proven experience in point defence systems provides the answer. Marconi's new ST1802 is a second generation tracker radar derived from the highly successful 800 series in service with the Royal Navy and other navies worldwide.

The ST1802 combines full random frequency agility with the most advanced techniques of moving target indication. ST1802 will supplement the ship's main surveillance sensor at low level, providing initial sub-clutter detection before automatically entering the tracking mode.

Control is instantly transferred to a co-mounted infrared/TV and laser system if any distortion is experienced when tracking low-level targets.

Marconi ST1802 tracker radar. Proven peformance. State-of-the-art technology. Frequency agility with digital MTI. Infrared/TV and laser support. For any warship down to 75 tonnes displacement.

Please ask for details from Marconi Radar Systems Limited, Writtle Road, Chelmsford CM1 3BN, England.
Telephone: 0245 267111.
Telex: 99108.

ADATS on Target

The Air Defence Anti Tank System...

...ADATS is a cost-effective high technology missile system specially designed to provide

Flexibility

- Mission
  - air defence of rear area assets, light or heavy manœuvre forces
  - long range antitank role
- Targets
  - low flying aircraft
  - attack helicopter
  - RPV
  - main battle tank
- Integration on
  - tracked vehicle
  - wheeled vehicle
  - shelter

Availability

- day/night operation
- adverse weather capability
- ECM immunity
- transportability
- built-in test equipment
- advanced logistic support

Efficiency

- high velocity missile (Mach 3+)
- heavy dual purpose warhead

Complete system performance has been demonstrated during the ADATS flight test program at Eglin Air Force Base, Florida and White Sands Missile Range, New Mexico

Direct hit of an ADATS missile against a drone type QF-86

The effect of the ADATS missile hit on the M47 tank

FULL SCALE DRONE AIRCRAFT

QF-86

FSI currently modifies F-86 to QF-86 aircraft for the U.S. Army. Subsequent to modification, FSI provides maintenance and operation in support of Army Test Programs.

QF-100

In 1984 FSI won the Air Force production contract for modification of F-100's to QF-100's. The effort is accomplished at the FSI facility, Mojave, California.

OTHER AIRCRAFT

The FSI drone conversion designs can be adapted to other high performance fighter aircraft. FSI has the experience in providing total system capability; design and development, test and operational support of the target system.

MISSION MASTERY PROVEN.

In the challenging combat arenas of recent battles. Computerized tank fire control. Passive night vision. IR thermal imaging system. IR warning systems. Laser rangefinding. Avionics. From El-Op — high performance systems based on advanced technologies. Launched from the perspective of combat feedback. Systems that are targeted at the future. To make your forces the masters of the combat arena.

EW Simulation. The all-U.K. solution.

The sophistication within the spectrum of the electronic battlefield continues to increase as technologies evolve.

Rapid growth in the areas of digital microelectronics, microwave, millimetre wave, and electro-optics continues to have significant impact on EW threats and their ECCM capabilities.

Yet this increasing threat sophistication is only part of the problem. The operational readiness of the free world's defence forces depends on the knowledge that EW equipment is properly maintained and personnel are properly trained in the use of sophisticated EW equipment.

At Walmore Defence Systems we understand these critical requirements. We produce software controlled scenario simulators for the electromagnetic environment which offer viable solutions to the problems of test evaluation and validation of threat warning systems; jamming systems; reconnaissance and surveillance equipment; as well as the training of personnel in the effective use of this equipment.

Our simulators also provide cost-effective alternatives to escalating operational expenses.

If you need to know more, or have special requirements in the spectrum of threat simulation, call or write to us today:

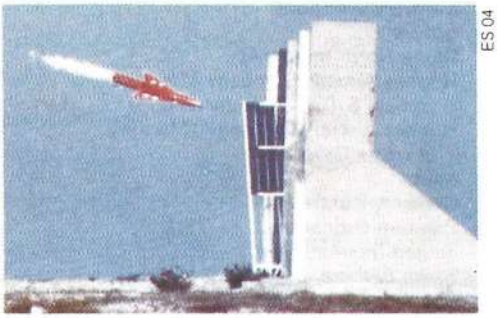
with telling accuracy... from 10 kilometers away!



In 1944, Flying Fortresses had to drop hundreds of tons of bombs to knock out a single bridge. Today the use of such massive force is unnecessary.

A missile exists that can strike a bridge's central piling directly, with virtually surgical precision. Aerospatiale builds it. We call it the AS 30 Laser. The AS 30 Laser is fired at a range of 10 kilometers from a jet fighter flying at 1 000 Kph, at tree top level.

Using laser guidance to reach its target, the AS 30 Laser can rip through 2 meters of concrete before exploding.

Unmatched precision of the laser guidance system, low altitude supersonic flight, very powerful final efficiency: the AS 30 Laser is the best offensive weapon system against pin point and hardened targets, such as bunkers or concrete shelters.

Go for Integration...

There are solid reasons for integrating your multi-sensor fire controls and your power generators with the firing unit.

Even if several firing units have to be deployed together to give the required defence there's no sense in them all being forced to fire at the same target. With modern proximity fuzed ammunition a certain kill is obtainable with one burst from one barrel. But the accuracy required is only obtainable with an integrated gun/fire control.

With integrated power generators a battery of guns becomes a flexible combat unit capable of being redeployed or dispersed several times a day – and better capable of being concealed. This gives a far wider coverage.

And you still have the full possibility of obtaining target indication from a central search radar. The gun's integrated fire control sensors can remain signal silent right up until the actual engagement, thus avoiding suppression.

The BOFI system fires the combined proximity/impact fuzed prefragmented Mk 2 ammunition. One single type of ammunition only, PFHE Mk 2, is required for engagement of all types of aerial target.

BOFI – Combat-effective integration

how to give your infantry tank fire support — without the tanks

Ground troops these days are up against all sorts of threats: tanks, armored fighting vehicles, fortifications and attack helicopters are some of them. To fight back they need the kind of fire support tanks give, but it's just not possible to field that many tanks.

To meet this problem, Israel Military Industries has developed a hyper-velocity 60 mm gun system, complete with armored turret, auto-loading, controls and ammunition. The system is ready to be mounted on fighting vehicles, old or new, tracked or wheeled, as well as on those light tanks you've been thinking of scrapping.

In its towed version, it is ideal for airborne and airdropped operations.

The system's APFS-DS round will penetrate modern armor at long range and its HE shell is big enough to inflict great damage on soft targets. It is called the HVMS — High Velocity Medium Support — 60mm Weapon System and it will give your infantry the fire support they need at a price you can afford.

Penetration of 120/60° NATO mediu single plate, at approx. 2000 m.

If you would like to know more about the HVMS, let us know.

ISCB-1
THE NEW AREA DENIAL WEAPON CERTIFIED FOR THE WORLD'S LEADING FIGHTERS.

Deny access to a SAM site for up to 24 hours. Discourage troops from repairing cratered runways. Prohibit light vehicles from crossing the bridge your troops require to complete the mission.

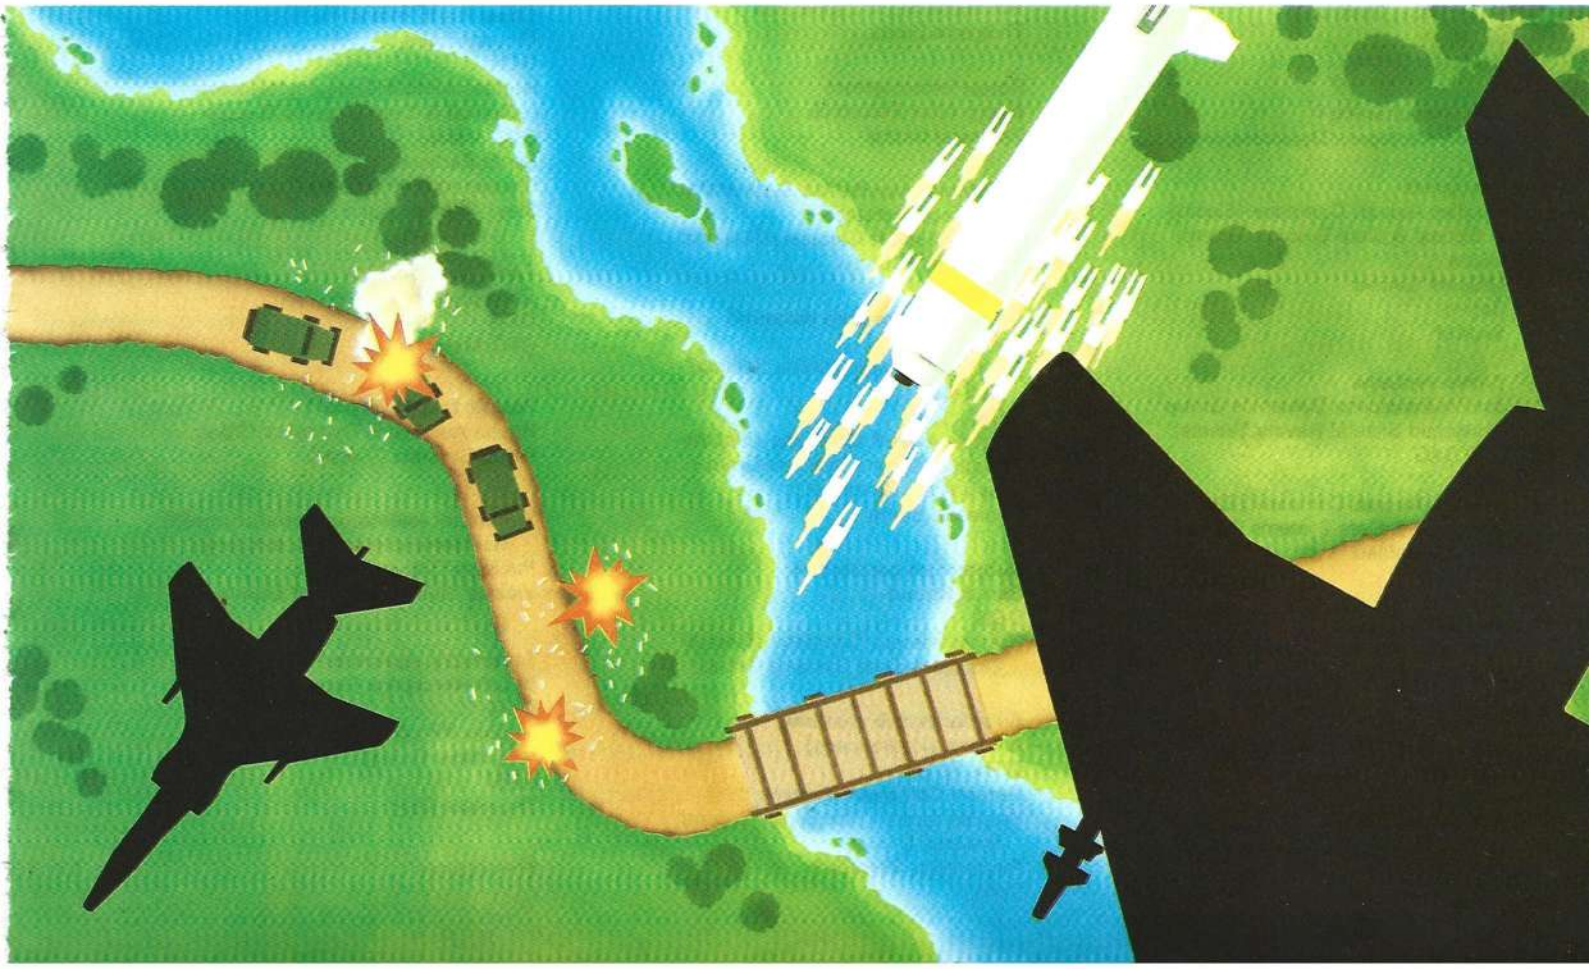
And do it all using a weapon dropped from the world's most advanced, battle-proven tactical aircraft.

Aircraft-certified, mission-ready

Introducing the ISCB-1—the first air-delivered, individually programmable area-denial cluster mine. It's as new as tomorrow. Yet, because it uses the same MK 7 dispenser as the proven Rockeye Cluster Bomb, the ISCB-1 is aircraft-certified and mission-ready for every fighter shown at right.

In fact, any aircraft equipped to carry 500-pound bombs can carry the ISCB-1 without modification. And any pilot trained to drop a conventional bomb can deliver the ISCB-1.

Area-denial for up to 24 hours



Each ISCB-1 contains 160 electronically-timed mines that you program to suit your tactics. Program them up to the moment of take-off to detonate at impact, or in 10-second increments for up to 24 hours.

The ISCB-1. It's your assurance of air-delivered area-denial.

For complete information contact: ISC Technologies, Inc., Tactical Systems, 3700 Electronics Way, P.O. Box 3040, Lancaster, Pennsylvania U.S.A. 17604-3040. Telephone: 717/285-7911. Telex: 68-55310 ISCINTL.

IN THE HEART OF THE ACTION

C³I SYSTEMS

On today's battlefield, Commanding Officers must affront the formidable combination of powerful weapons and advanced technology. CIMSA can help them to meet the challenge.

CIMSA provides Command with the means to reduce information processing time and facilitates their access to all available data, thus enabling them to base their decisions on an overall, clear and up-to-date view of the situation.

The Command Systems developed by CIMSA are modular, easy to use and adaptable to all levels of hierarchy.

Defence technology from a single source. Ferranti.

There is almost no problem in defence electronics to which Ferranti cannot offer solutions.

In avionics we are in our element. In naval systems we have been afloat for more than 20 years. In army equipment we know the ground.

Our products and systems have been proven in armed forces worldwide.

We supply radar for the Lynx, Sea Harrier and Tornado. Inertial navigation for the Jaguar, Tornado, Sea Harrier, Harrier, Nimrod, Buccaneer, GR5 and Mitsubishi F-1.

COMED horizontal situation display for the Naval F/A-18 Hornet of the US, Canada and Australia.

Lasers for the Harrier, Jaguar, Draken, Tornado and US Navy's Seafire programme, and stabilised sighting systems for helicopters.

Computers for Nimrod, and air traffic control systems and simulators for military and civil use.

On land, both the Laser Target Marker and Ranger and PADS (Position and Azimuth Determining System) are in service with the British Army, whilst Ferranti microprocessors and serial signalling systems are being used in British armoured fighting vehicles.

At sea, Ferranti is principal supplier of action information and weapon control systems for the Royal Navy and allied navies.

For all services, Ferranti has led the way in fuzes and safety and arming devices for over 40 years.

Wherever there is a defence requirement you'll find Ferranti defence capability one move ahead.

MIN

MINE IDENTIFICATION AND NEUTRALIZATION SYSTEM FOR MH VESSELS

Min is a system developed by Elsag and Riva Calzoni joined in the SMIN Consortium offering the highest kill-probability against modern mines laid near the approaches to harbours, in coastal waters and shipping lanes.
The system, adopted by the Italian Navy consists of a wire-guided underwater vehicle being able to approach a submerged target, to identify it and neutralize it, should it turn to be either a bottom or a moored mine.
To achieve this, the underwater vehicle can release a highly destructive charge in the case of the bottom mine or cut the mooring rope of the moored mine, using a small charge secured to a cutting device.
The most outstanding features of the system are:

- Propulsion system capable of ensuring high manoeuvrability and ease in positioning the vehicle in the proximity of a mine.
- Low acoustic signature.
- Low magnetic signature of the vehicle by the use of hydraulic systems fed from a hydraulic source in oleopneumatic accumulators (power pack) onboard the vehicle.
- Use of a closed loop TV system suitable for operation with good levels of brightnees, and of an electronic sonar capable of providing a true image of the mine.
- Short turnround time for the vehicle, principally resulting from the use of the oleopneumatic accumulator recharge system.

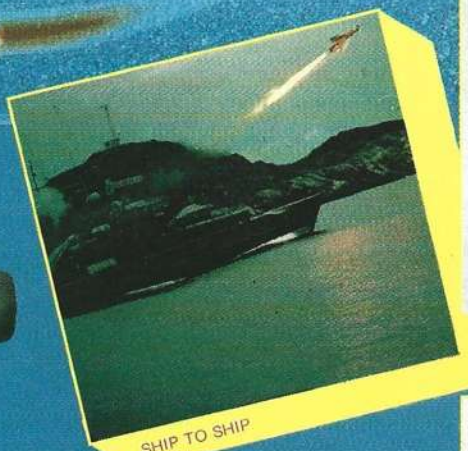
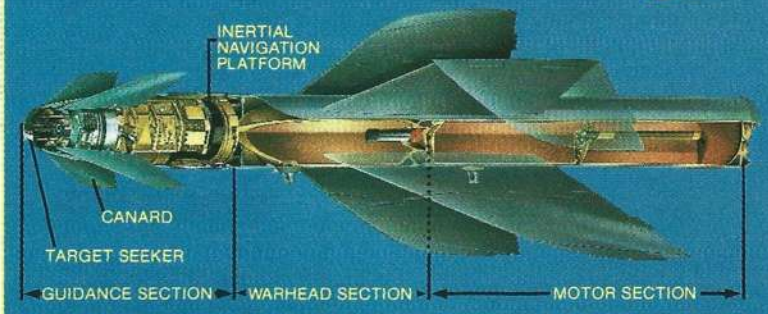
dp DANIEL PIGAT RÉALISATIONS



PENGUIN, A Cost Effective Stand Off Anti-Ship Missile For Different Platforms.



The ship launched PENGUIN is now operational on 76 frigates and fast attack craft in 4 navies. The latest version with folding wings is presently being adapted to the SH-60B Seahawk helicopter of the US Navy LAMPS III program. The air launched PENGUIN has been developed for fixed wing aircraft, and is being evaluated on the F-16 Fighting Falcon.

SHIP TO SHIP

AIRCRAFT TO SHIP

SHORE TO SHIP

The PENGUIN missile consists of a common guidance and warhead section, with interchangeable motor and wing sections for the various applications, providing a common logistics system for all users.

A/S Kongsberg Våpenfabrikk is a manufacturer and supplier of fully integrated modern weapon systems. These are computerbased systems providing navigation, command, control and information.

The Untowed Story.

Helicopter MAD systems — to tow or not to tow. Once this wasn't a matter of choice . . . now there is the CAE Advanced Integrated MAD System — AIMS. With the advent of AIMS, towed MAD systems for ASW helicopters have become yesterday's technology — because CAE AIMS permits the magnetometer to be installed in a fixed position on the aircraft.

There's much more to the CAE AIMS story than eliminating a cable. The full story of AIMS includes many outstanding benefits, because CAE AIMS is one of the most significant developments in ASW technology since the introduction of MAD systems in the early 1940's. AIMS permits rapid transition from dipping sonar; AIMS is extremely sensitive and accurate, with the best detection range available; AIMS is light and compact, a fact that will be appreciated by helicopter personnel used to cumbersome reeling systems and cables; AIMS has automated signal processing to relieve operator workload; AIMS can be compensated quickly with a minimum of discomfort to the crew; and AIMS eliminates the hazards of towing MAD.

CAE AIMS is competitively-priced, with a system reliability that yields extremely low life-cycle costs. And — although we're talking helicopters — we want the fixed-wing community to know that AIMS on their aircraft is an unbeatable combination.

CAE AIMS is the finest MAD system available. We've given you just the outline . . . now get the full story by contacting us soon.

TWIN 40 L 70 FIELD MOUNTING

The Weapon Interfacing Any F.C.S.

This powerful point defence system is the first able to effectively engage, with minimum reaction time, not only aircraft but also missiles.

- *Useful intercept at very high ranges is possible, owing to the exceptional system accuracy and firing proximity fuzed ammunition.*
- *Performance has recently been improved even further by the introduction of Mark 2 Proximity Fuzed Ammunition.*
- *With a rate of fire of 1200 r.p.m. from a Twin 40 L 70 Field Mounting Unit, linked to a F.C.S., air launched and cruise type missiles can be defeated in saturation attacks, aided by large ready-to-fire magazines.*

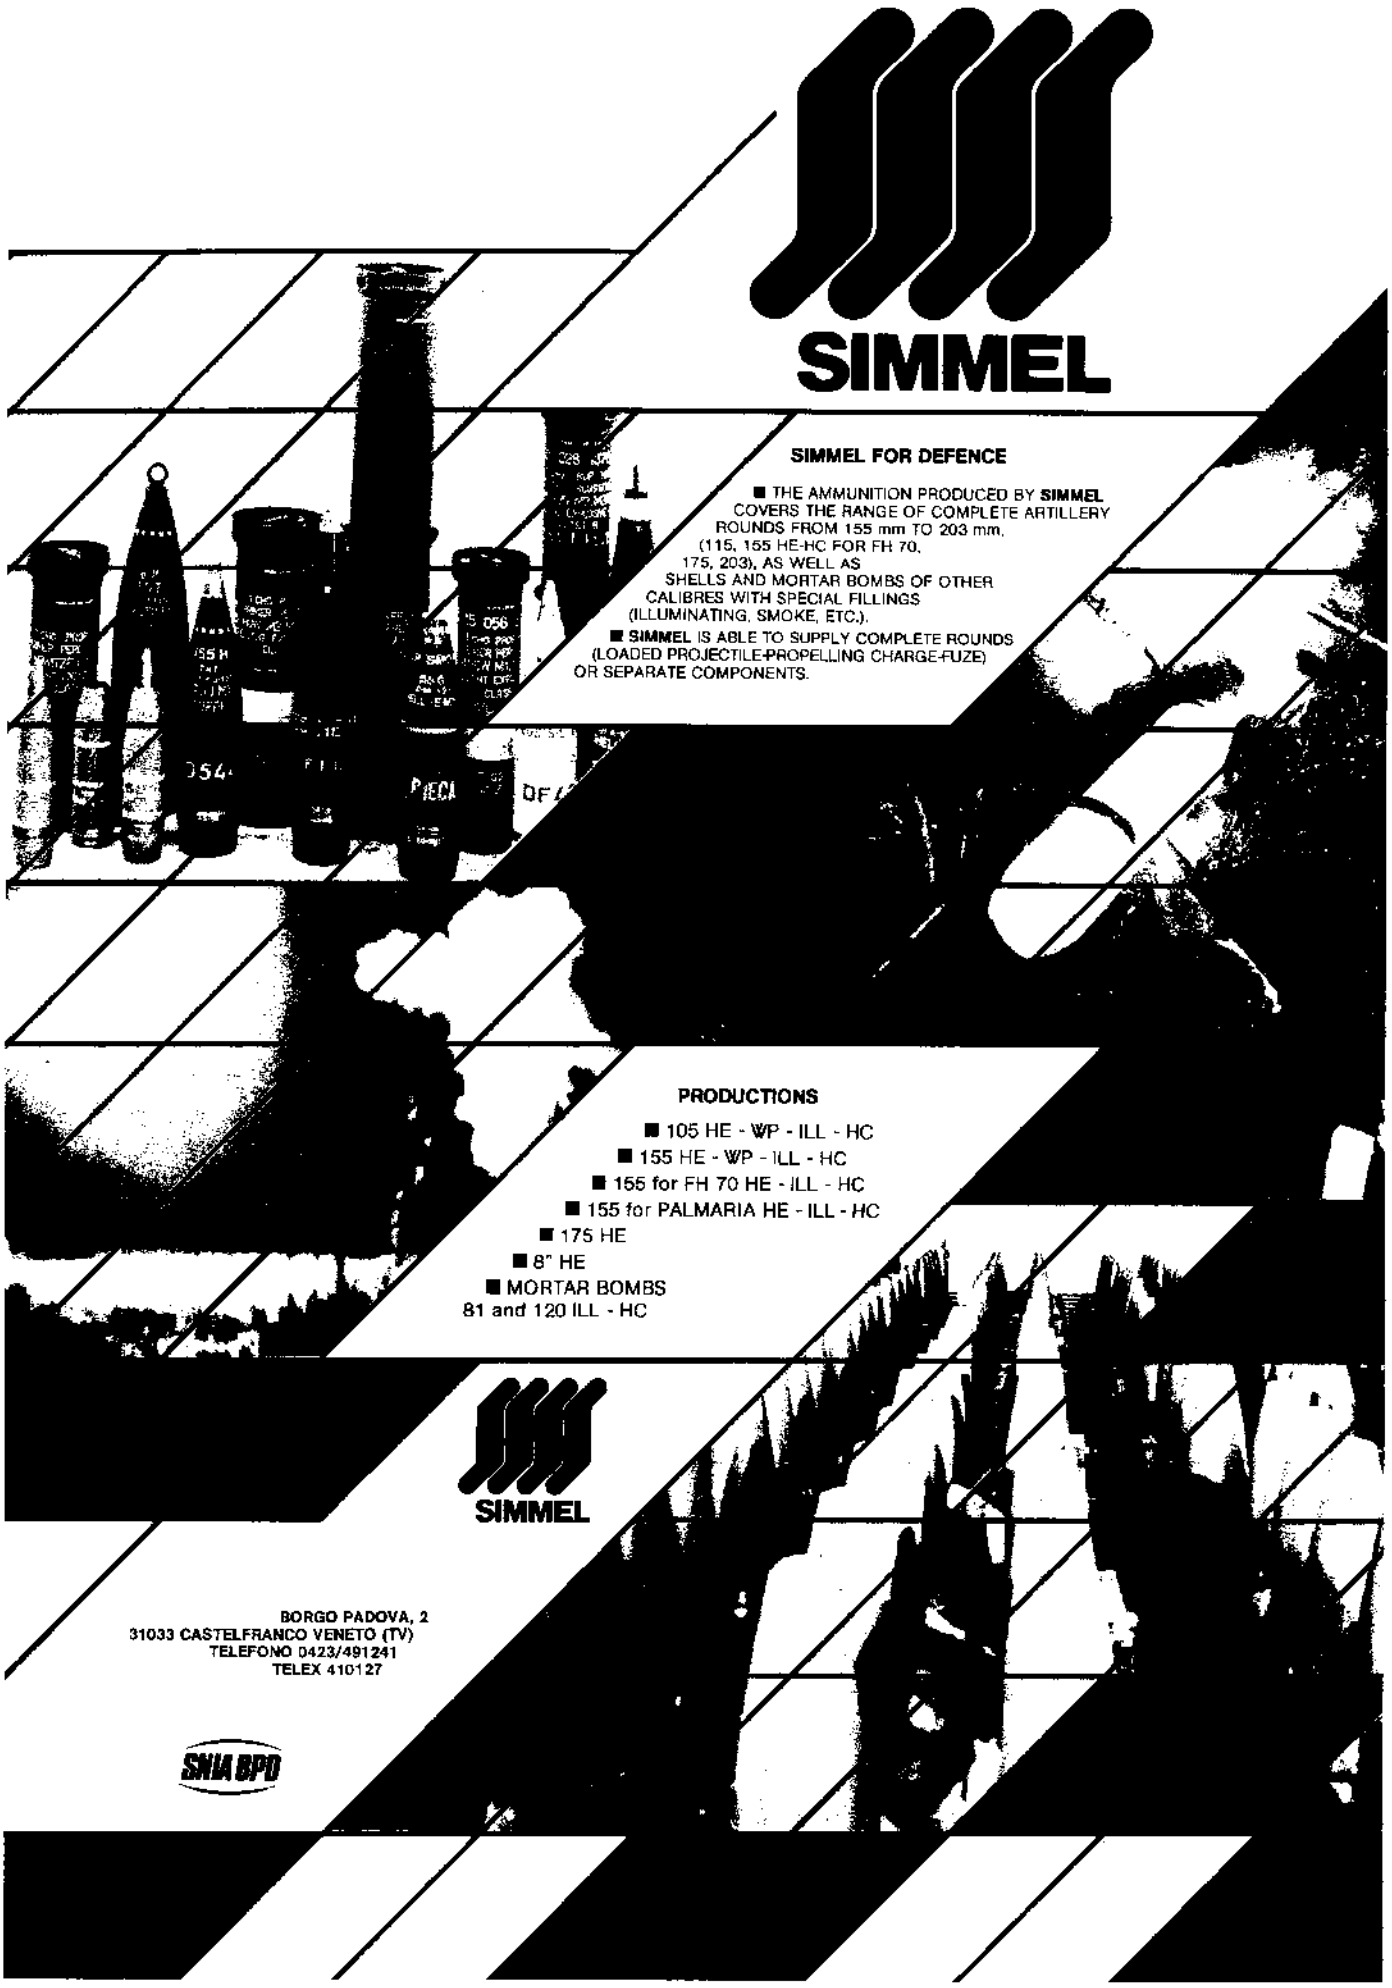
Oldelft thermal imaging systems reveal the unseen in detail.



Oldelft's thermal imaging techniques give you a well defined view of your surroundings, by daylight under bad weather conditions, or in the black of night, even when there's no light at all. Smoke and fog scarcely make any difference to the penetration capabilities. Camouflaged objects are revealed while the observer remains concealed. All this without the use of actively light-emitting search beams. From the early sixties, Oldelft has been involved in the development and production of thermal imaging equipment: the most advanced way of observing a scene under the worst possible conditions. Oldelft's thermal imaging systems are used for mobile and non-mobile observation applications for surveillance purposes as well as in infantry armoured vehicles and in tanks. It's the safe way to see without being seen.

D4

GET A GUN AHEAD.

1. The CREUSOT-LOIRE 100 mm "Compact" gun mount was designed and developed to efficiently combat air threats, in particular 1985/1990 generation missiles, as well as for firing on surface and shore targets. Now in production, it is the most versatile combat weapon on the market, with the capability to exactly meet all operational requirements.
2. The 100 mm "Compact" gun mount is a powerful weapon for the navies, providing all the units, from patrol boats to aircraft carriers, with unparalleled offensive and defensive capabilities :
– extremely high firing power with a fire rate of 90 rounds/minute.
– remarkable firing efficiency, especially against missiles, with automated ammunition selection inside the turret.

The 100 mm "Compact"

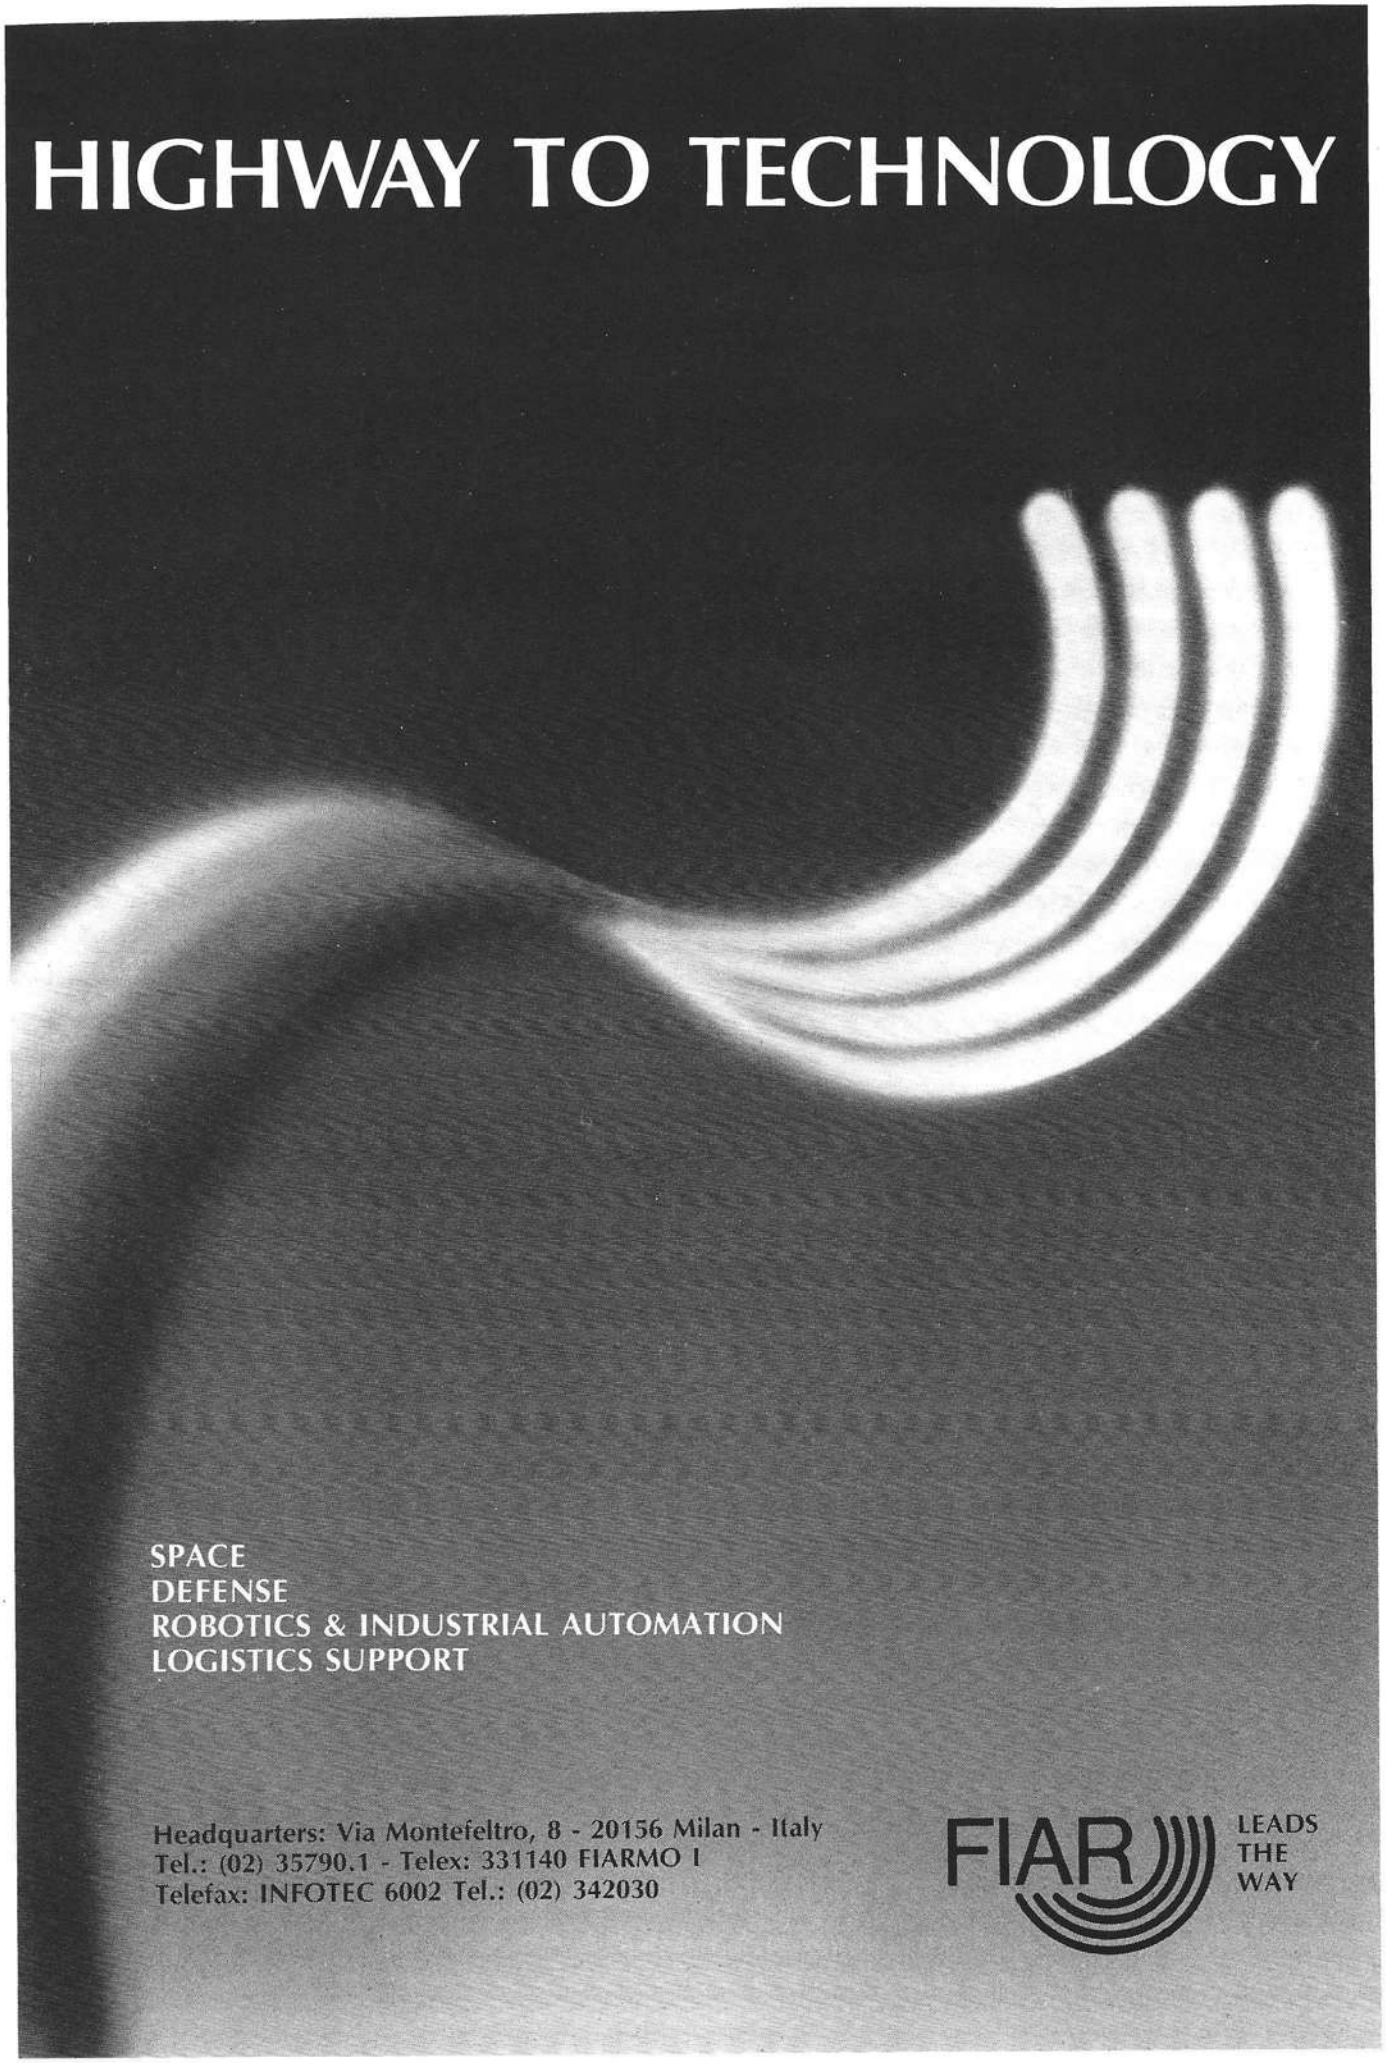
ARMBRUST.
The Short-Range Anti-Tank and Self-Defense Weapon.

ARMBRUST is a light, ballistic, expendable weapon. It has a combat range of up to 300 m (547 yd) with the AT projectile. Its shaped charge penetrates heavy armor.

ARMBRUST's unique features:



- Smokeless firing
- No flash or blast
- Lower report than a pistol shot
- Firing from small enclosed rooms without endangering or discomforting the gunner
- Expendable
- Maintenance-free

ARMBRUST equipped with LATAM – Laser Target Marker – also provides night combat capability against tanks and armored vehicles.

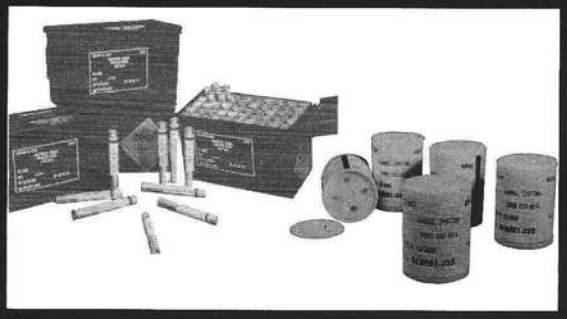
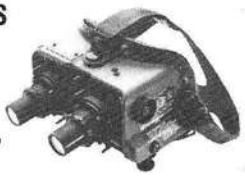
FIAR LEADS THE WAY



PRACTICE BOMBS

These practice bombs accurately and realistically duplicate the ballistic performance of all conventional and nuclear free fall ordnance.



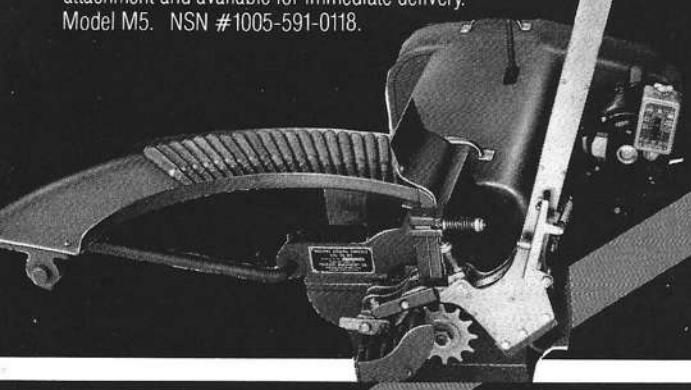
CXU-3/CXU-4 SIGNAL CARTRIDGES

These practice bomb signal cartridges are based on recent signal technology. They contain a chemical agent which reacts with atmospheric moisture (up to 80,000 feet altitude) to produce a cloud of dense, white smoke to mark the impact of the practice munition on the range. CXU-3 fits all Navy and Air Force sub-calibre practice bombs. CXU-4 fits the BDU45 500 lb. practice bomb.

AN/PVS-5A NIGHT VISION GOGGLES

These lightweight headmounted battery-powered goggles are for general purpose after dark use, which includes night driving, patrols, security surveillance, detection of IR sources and low level helicopter operations. Equipment maintenance and map reading can be made possible by a built-in infrared LED light source. Each unit comes complete with carrying case, storage case, demist shield, batteries and instruction manual. Adapter permits operation in temperature below −20°F.

AN/PVS-4 INDIVIDUAL-SERVED WEAPONSIGHT
AN/TVS-5 CREW-SERVED WEAPONSIGHT

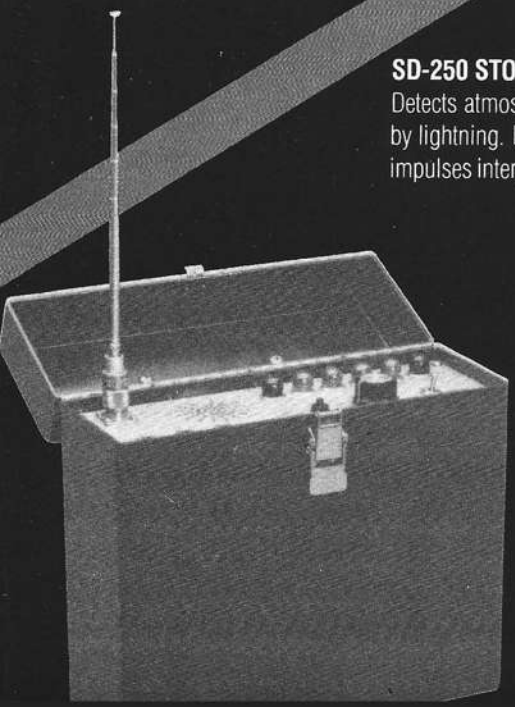


These Night Vision Weaponsights are portable, battery-operated electro-optical instruments used for observation and aimed fire of weapons at night. They amplify reflected light, such as moonlight, starlight and skyglow, so that the viewed scene becomes clearly visible to the operator. The sight does not emit visible or infrared light (except from the eyepiece) that can be detected by the enemy.

2.75″ (70MM) WTU-1/B PRACTICE WARHEAD

The 2.75″ (70mm) WTU-1/B is an inexpensive and accurate practice warhead which simulates a number of warheads, all of which fit the Mk4 and Mk40 2.75″ rocket motors.

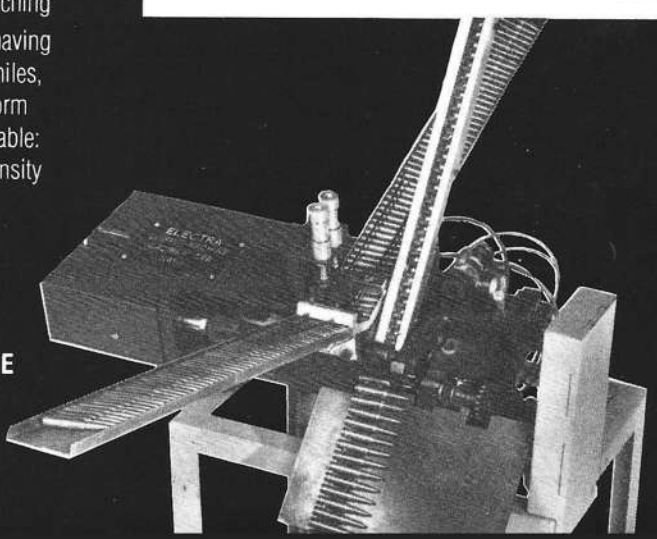
ELECTRICALLY OPERATED .50 CALIBER (12.7MM) AMMUNITION LINKING MACHINE



Compact, yet features heavy-duty construction for an all-around military use. Each unit is complete with Delinker M7 attachment and available for immediate delivery. Model M5. NSN #1005-591-0118.

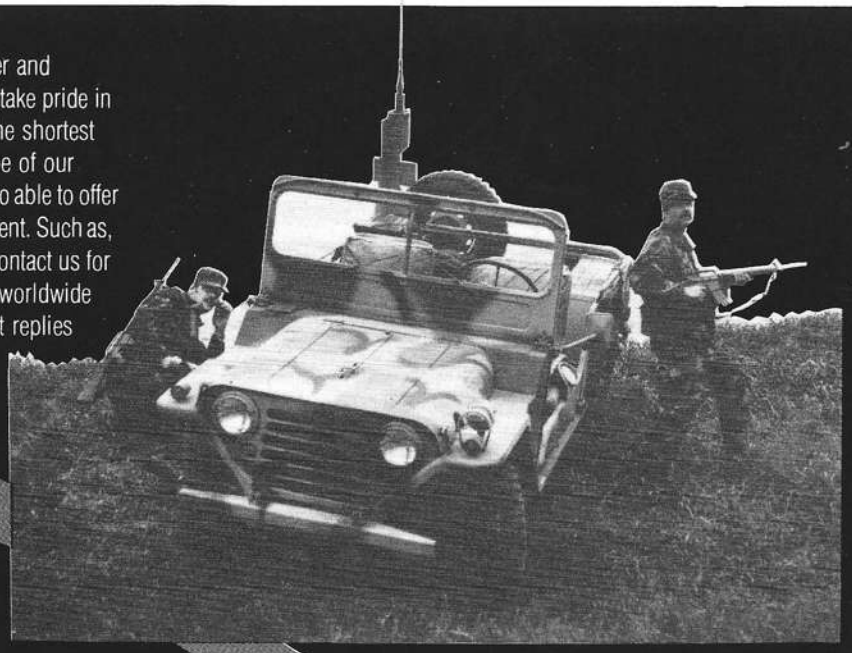
SPARTANICS WEAPONEER MARKSMANSHIP TRAINING SYSTEM

The Weaponeer (U.S. Army Trainer 7-57), is now in 'Hands-On' diagnostic simulator for rifle marksmansh and sound. The Weaponeer can be adapted to any mi for each round on a video monitor with printout for



SD-250 STORM ALERT LIGHTNING DETECTOR

Detects atmospheric static electricity that has been caused by lightning. It keeps a constant count of large electrical impulses interpreted as bursts of lightning from approaching thunderstorms. The range selector, having four range settings from 12 to 100 miles, determines the distance from the storm the alarm will activate. Options available: Battery Charger, Chart Recorder, Intensity Meter & Antenna.

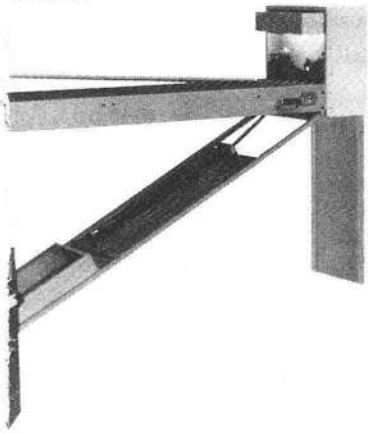


PNEUMATICALLY OPERATED 7.62 NATO CALIBER AMMUNITION LINKING MACHINE

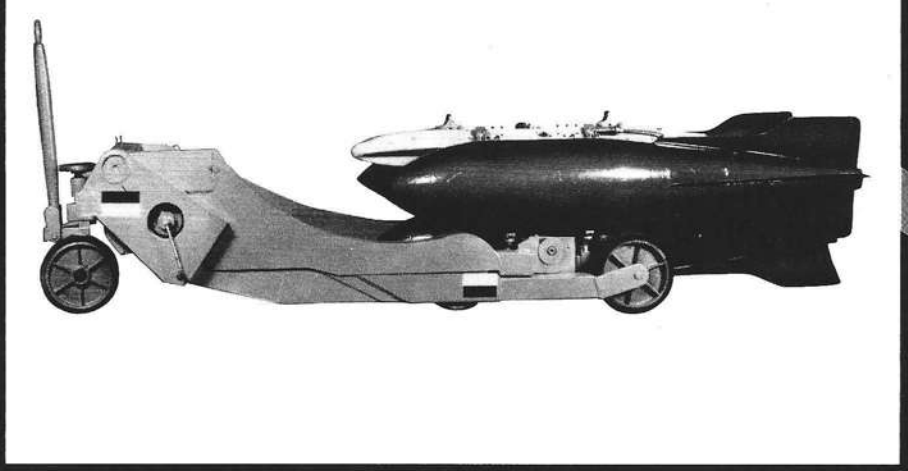
Linking Capacity: 60 Rds. per minute
Operates at Air Pressure: 100 PSI
Feed: Manual
Compact size. Heavy-duty construction. Immediate delivery.

THE WORLD'S SUPPLIER OF DEFENSE EQUIPMENT

We are the largest private domestic supplier and international exporter of ordnance material. We take pride in supplying materials of the highest quality, in the shortest possible delivery time. Not only does the scope of our activities cover the ordnance field, but we are also able to offer the latest in U.S. Government issue field equipment. Such as, uniforms, combat boots, canteens, tents, etc. Contact us for all your military requirements or for exclusive worldwide distributorships. You can be assured of prompt replies and immediate deliveries.



M781C, 40MM PRACTICE CARTRIDGE

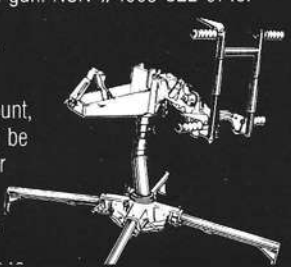


This cartridge is a fixed, practice-type ammunition designed as a commercial replacement for the M407 40mm Practice Cartridge to be utilized in the 40mm Grenade Launchers M79 and M203.

This cartridge consists of a thermoplastic injection molded projectile body with a rotating band filled with a high visibility yellow-orange dye. Upon impact the frangible projectile ruptures releasing the high visibility orange dye which gives the appearance of explosive impact.

ce with the U.S. Army worldwide. The Weaponeer is a hich exactly duplicates weapon functions to include recoil rifle. This system displays the aiming point of the trainee nstructor.

MINI MCT



The Mini MCT is a compact fighter-aircraft loading trolley that minimizes turnaround time between missions. It consists of two separate components: the movable cradle and the handling system to create fast-access storage, rapid transport and immediate, efficient loading.

M3 .50 CALIBER MACHINE GUN TRIPOD MOUNT

A lightweight, portable folding mount for use with the Browning M2 .50 Cal. Machine Gun. Three telescoping tubular legs join in a tripod head for full front support of gun. NSN #1005-322-9716.

M63 AA .50 CALIBER MACHINE GUN MOUNT

Four-legged, low silhouette, medium weight, portable mount, used for antiaircraft fire. Can be easily disassembled into four compact assemblies. Used primarily with Machine Gun, Caliber .50: Browning, M2,

SIMRAD LP100

A NEW LASER RANGEFINDER SIGHT FOR MOUNTING ON DIRECT FIRING WEAPONS

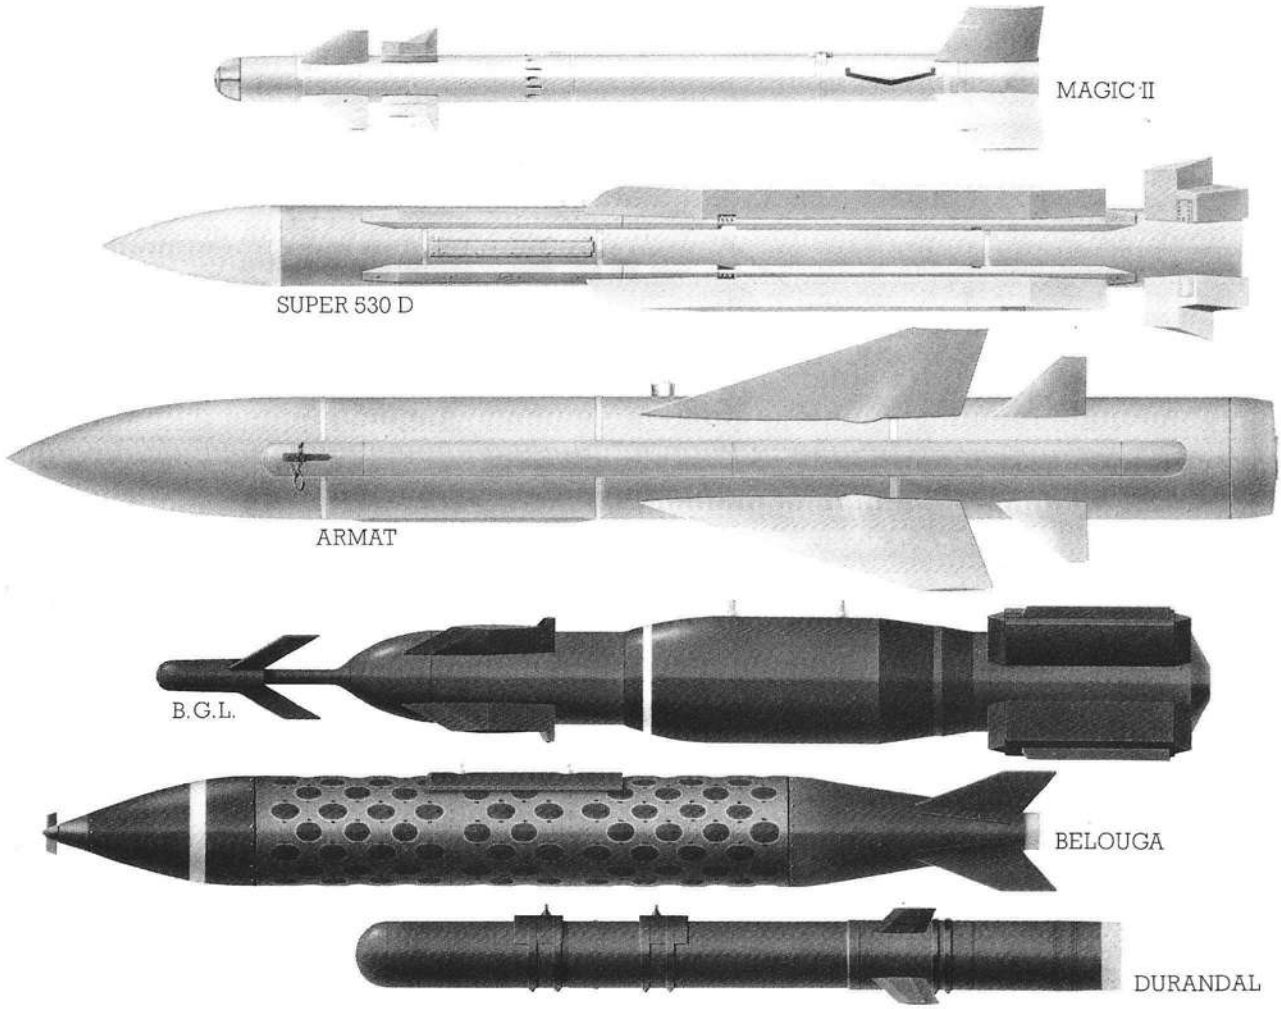
This compact instrument replaces the traditional weapon sights normally used, providing accurate range information and increased hit probability.

A built-in ballistic computer, programmed for the type of weapon and ammunition used, calculates superelevation and sets up a LED aiming mark. Another LED indicates the flight time, enabling the gunner to estimate the lead angle.

Operational range is 5000 m, and the resolution is 5 m.

The reticle pattern can be designed to comply with various types of weapon and ammunition.

Weapon mounting hardware is provided according to user's requirements.



Other products manufactured by Simrad Optronics are:

- Laser rangefinders for use by artillery, infantry and mechanized troops, as well as for air defence and navy
- Laser rangefinder modules for integration in sights
- Laser threat warning receivers
- IR thermal imager for navy and coastal artillery
- Night observation devices for various applications

JANE'S FIGHTING SHIPS

1985/86 EDITION PUBLISHED AUGUST

"It remains the one truly comprehensive compendium of world naval resources. When you have it you need look at no other."
"Extremely difficult to fault" (Defence Attache).
In its 88th year of publication, **JANE'S FIGHTING SHIPS** is the only annually updated and wholly revised publication in its field.

"The most desirable approach to maintaining a comprehensive catalogue of the ships and craft possessed by the worlds navies is the annual addition of new information to, and deletion of, superseded data from a solid core of annually confirmed date . . . . . only Jane's and Captain Moore attempt it . . . . " (National Defense — April 1985)

The Foreword surveys naval matters worldwide, particularly their strategic, political and financial aspects. Summary tables provide information on current naval armament, aircraft and radar, including comparative strengths and compositions of major fleets.
Illustrated throughout with photographs, line drawings, and silhouettes only Jane's Fighting Ships 1985/86 can keep you informed of the latest developments and movement on all the world's navies.

● Major Matters ● Pennant List ● Naval Strengths ● Naval Equipment
● Recognition Silhouettes ● Ship Reference Section

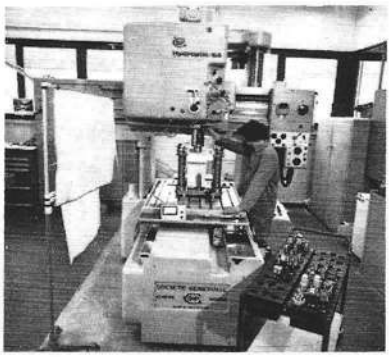
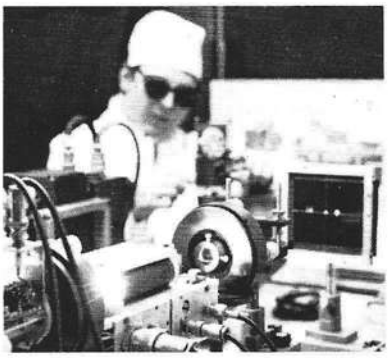
40 YEARS EXPERIENCE



SMA is a flexible company founded in 1943. Since 1948 is active in design, development and production of electronic equipments for defence. Main activities are radars for ground, shipborne, airborne, missile applications and related display systems. The company broad spectrum permits the supply of turnkey systems taylored to the end-user needs.

SMA

SEGNALAMENTO MARITTIMO ED AEREO



SMA's basic product lines and business sectors include: High definition and discrimination **coastal radar control stations**, both for maritime traffic management systems and military application (anti intrusion, coastal defence, mine splash detection); **Shipborne navigation/ search radars** devoted to low, very-low air coverage (anti sea skimmers); **Missile active homing heads**, provided with a variety of ECCM devices, for SSM (OTOMAT MK1, MK2) and ASM (Marte MK2) aplications; **360° coverage search and navigation airborne radars** for helicopters and maritime patrol aircraft; **Standard Pod contained search radars** for fixed wing aircraft that can be employed in conjunction with ASM; **Integrated search and tracking radars for A/A defence** to be employed both on specialized trucks (OTOMATIC) or on semi-mobile/fixed station for point defence; applied research aimed toward millimetric waves (up to 100 GHz) in **active and passive sensors** (radiometer); **Duct analisys** and electromagnetic propagation forecast.

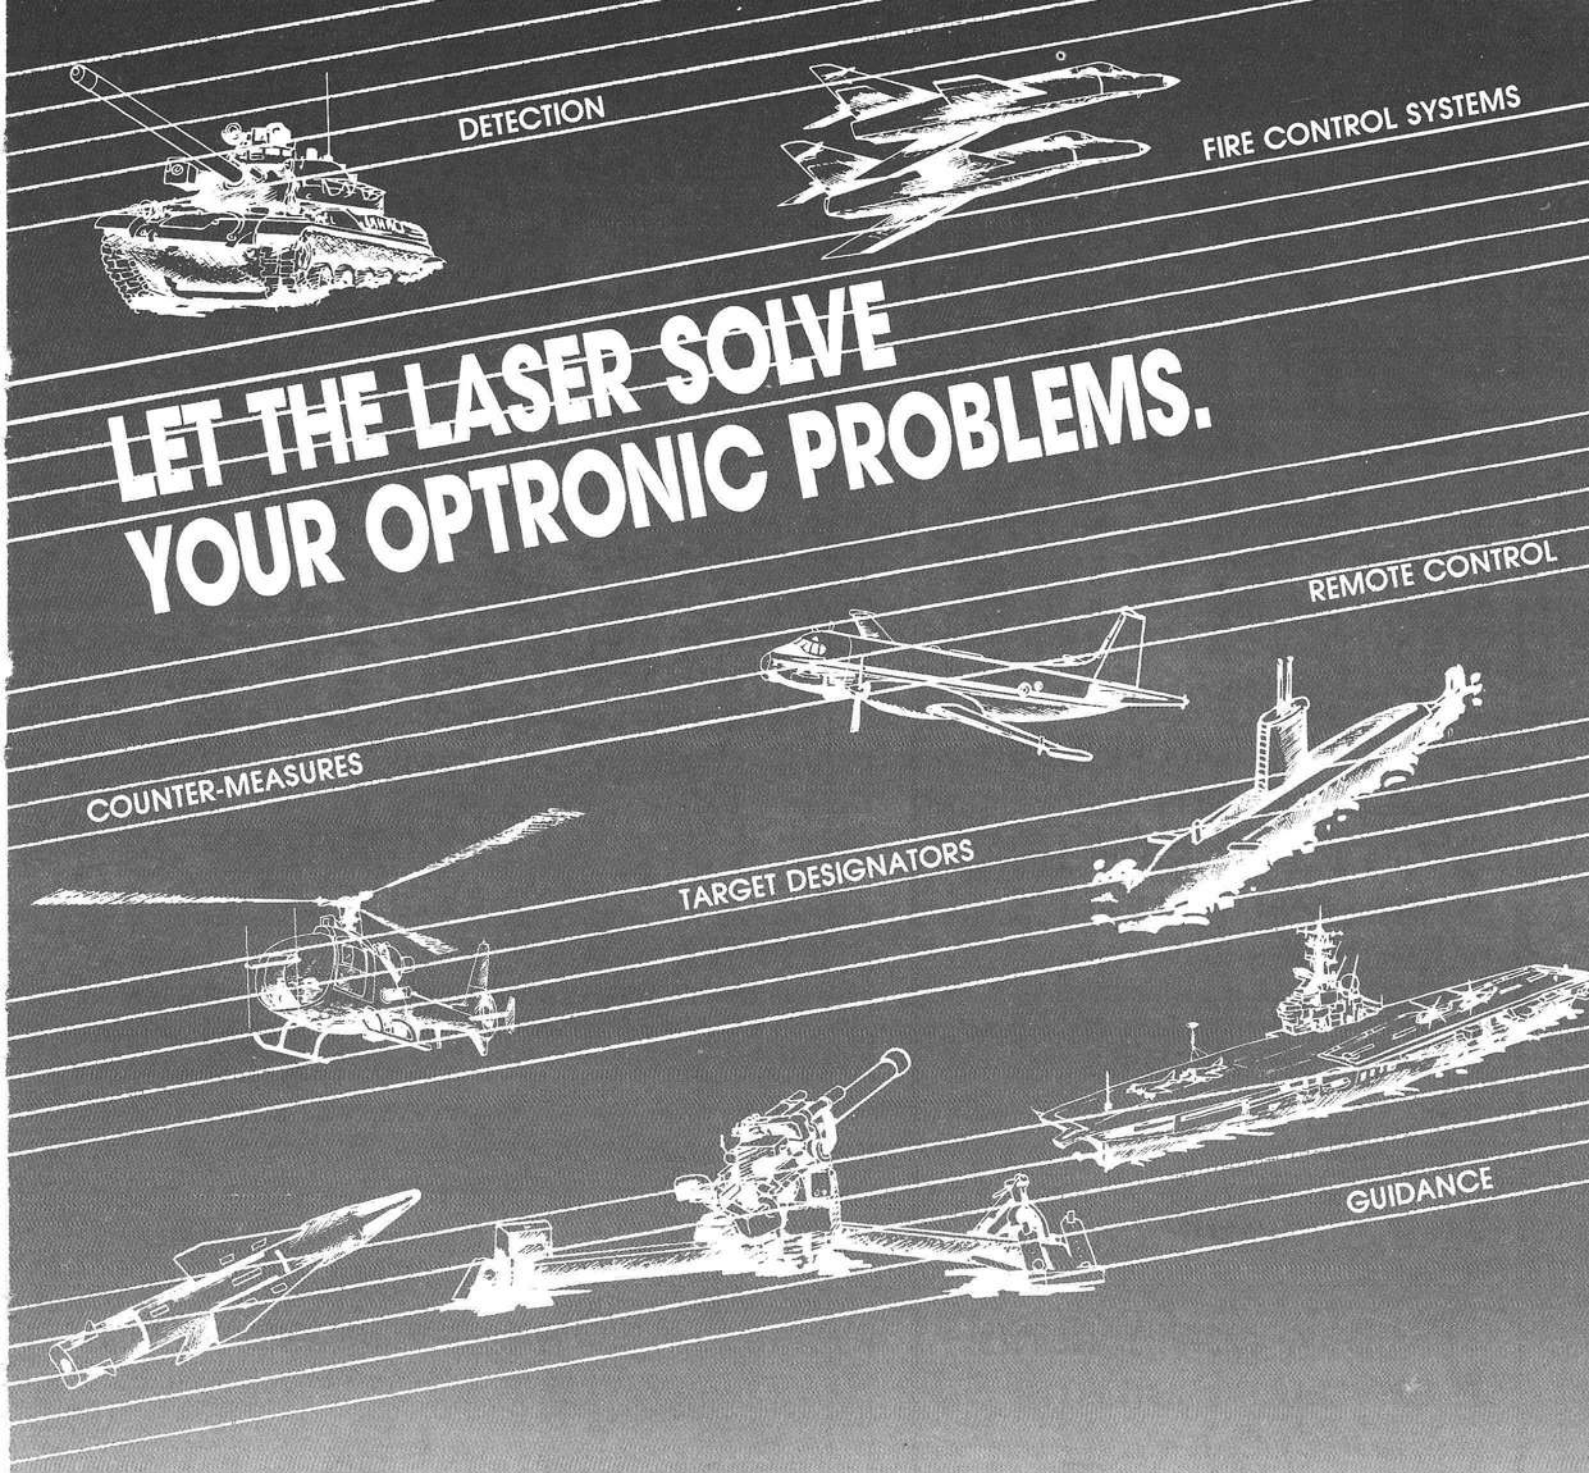
ELTRO
know how and cooperation

Years spent on research and development, the successful transfer of know-how and cooperation in both national and international military programs have accounted for Eltro's achievements in the field of optronics.



We specialize in:

- **Solid-state, semiconductor and gas lasers for rangefinding, target illumination and target tracking**
- **Thermal detection units**

– IR-missile guidance – Image intensifier and converter units – Fire suppression systems – Mobile workshops for maintenance service – NC-automats, high-precision measuring and test installations, modern air-conditioned workshops and qualified personnel assure the quality standard called out for military equipment.

Eltro OPTRONIK

ELTRO GmbH, Gesellschaft für Strahlungstechnik
Postfach 102120, 6900 Heidelberg 1/W.-Germany

LET THE LASER SOLVE YOUR OPTRONIC PROBLEMS.

You are designing optronics for the future.

The laser has enormous potential in the development of fire control systems, target designators, guidance, detection, remote control, power and information transmission and counter measures.

The leading laser manufacturer in Europe.

Cilas Alcatel posseses all the laser techniques from infra-red to ultra-violet, as well as signal processing. Under the aegis of the Compagnie Générale d'Électricité (200 000 people), Cilas Alcatel, with its 350 employees is the optronic specialist of an industrial enterprise of world renown.

Backed by the work carried out at Marcoussis Laboratories, the research unit of the CGE, Cilas Alcatel leads in advanced technology.

We understand and can meet your aspirations.

Cilas Alcatel knows how to evaluate system performance and constraints and has the industrial capability necessary to design the interface with the optical sub-assemblies.

Cilas Alcatel follows the Quality Control procedures, provides logistic support, maintenance of the equipment and training for the personnel.

How the laser contribution succeeds.

Participation in a programme implies the assumption of responsibility and of knowing how to play one's part in a complex system.

The expertise of Cilas Alcatel is exemplified by having its laser in :
- fire control systems of the AMX range
- airbone missile guidance illuminators
- gyrostabilized sights for helicopters
- naval fire control optical posts, etc...

Let Cilas Alcatel help you in your most ambitious projects.

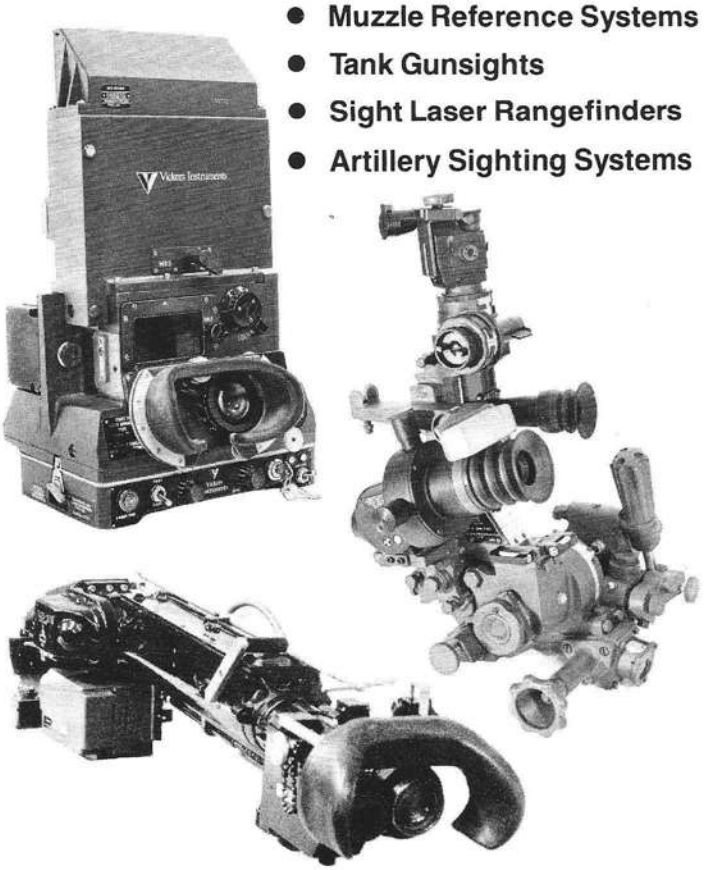
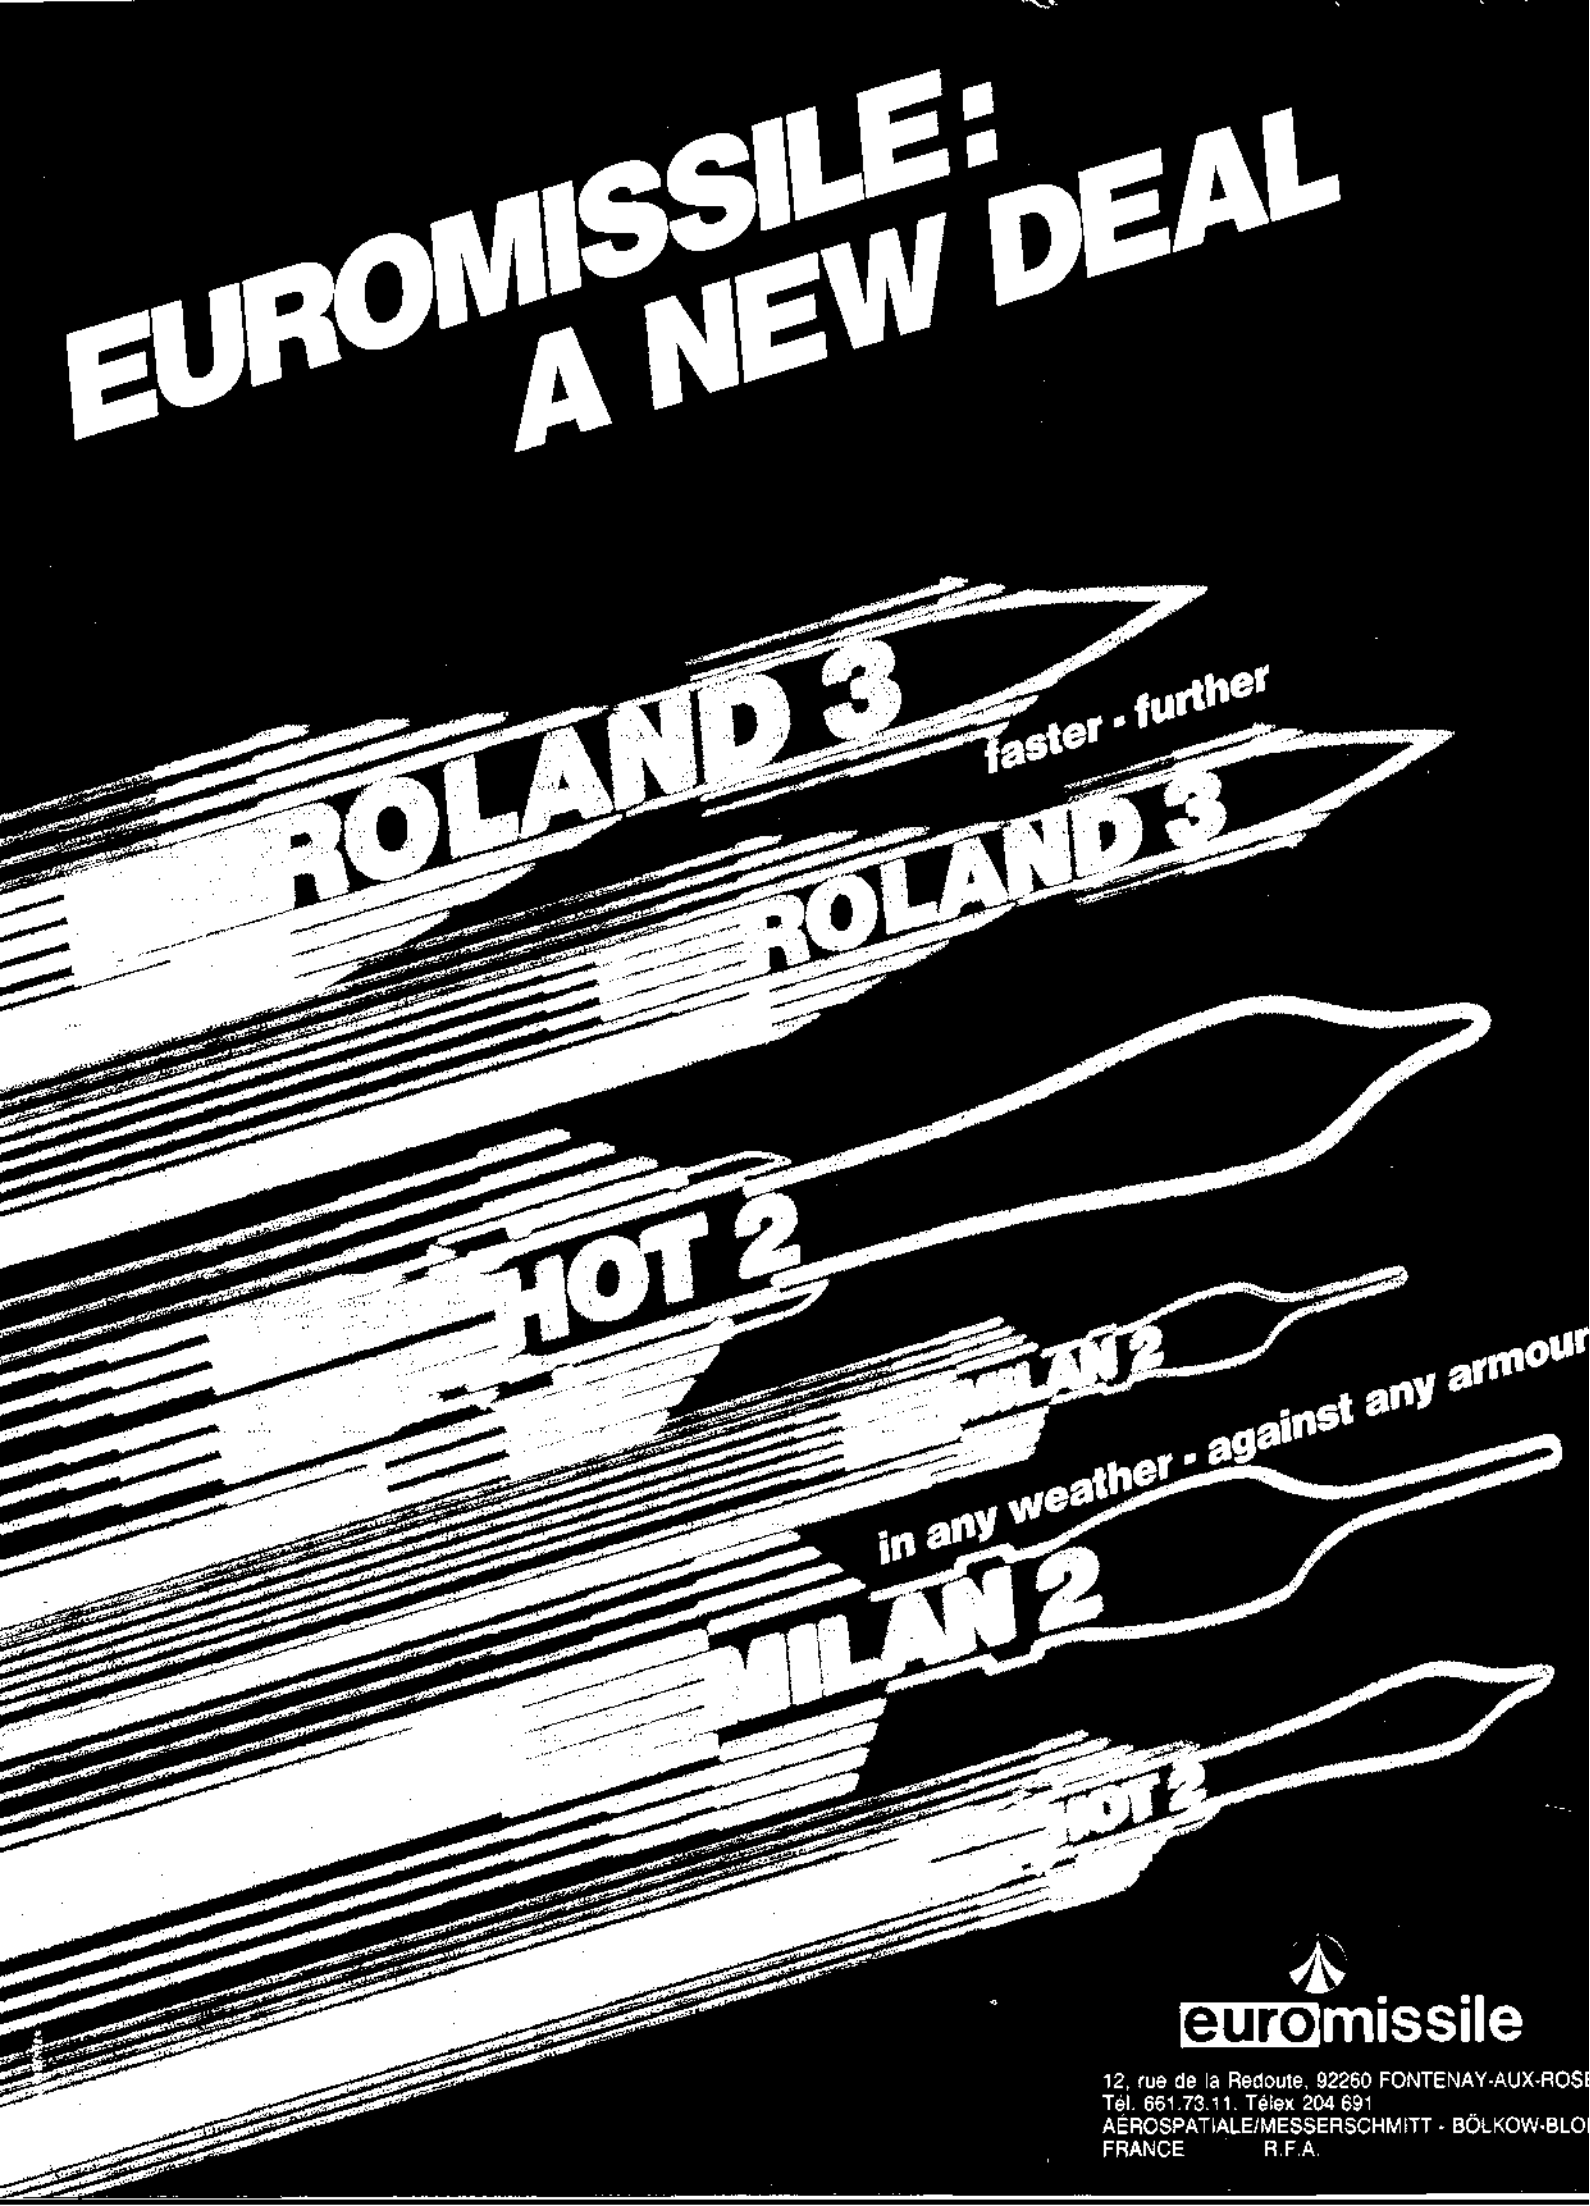
WE HAVE OUR SIGHTS ON YOUR TARGETS



On the battlefield, survival and success depend upon the fast and reliable supply of accurate information on the enemy's position and range.

Vickers Instruments use their depth of expertise in optical design and manufacture to meet your need for operational precision at the most critical moments.

Vickers Instruments military sighting systems include:-



- **Muzzle Boresights**
- **Muzzle Reference Systems**
- **Tank Gunsights**
- **Sight Laser Rangefinders**
- **Artillery Sighting Systems**

BIRD OF PREY ?

... no, it's the McDonnell Douglas-BAe AV-8B in the USMC derivative version, just one of the many aircraft covered in detail in the new edition of Jane's All the World's Aircraft.
The 76th edition of this popular publication is packed with information on aircraft worldwide synonymous only with Jane's experience and reputation for accuracy and research.
And as a perfect complement to our year-books, Jane's Defence Weekly will keep you totally informed on the latest developments in this particular field and on all defence matters internationally the instant they happen.

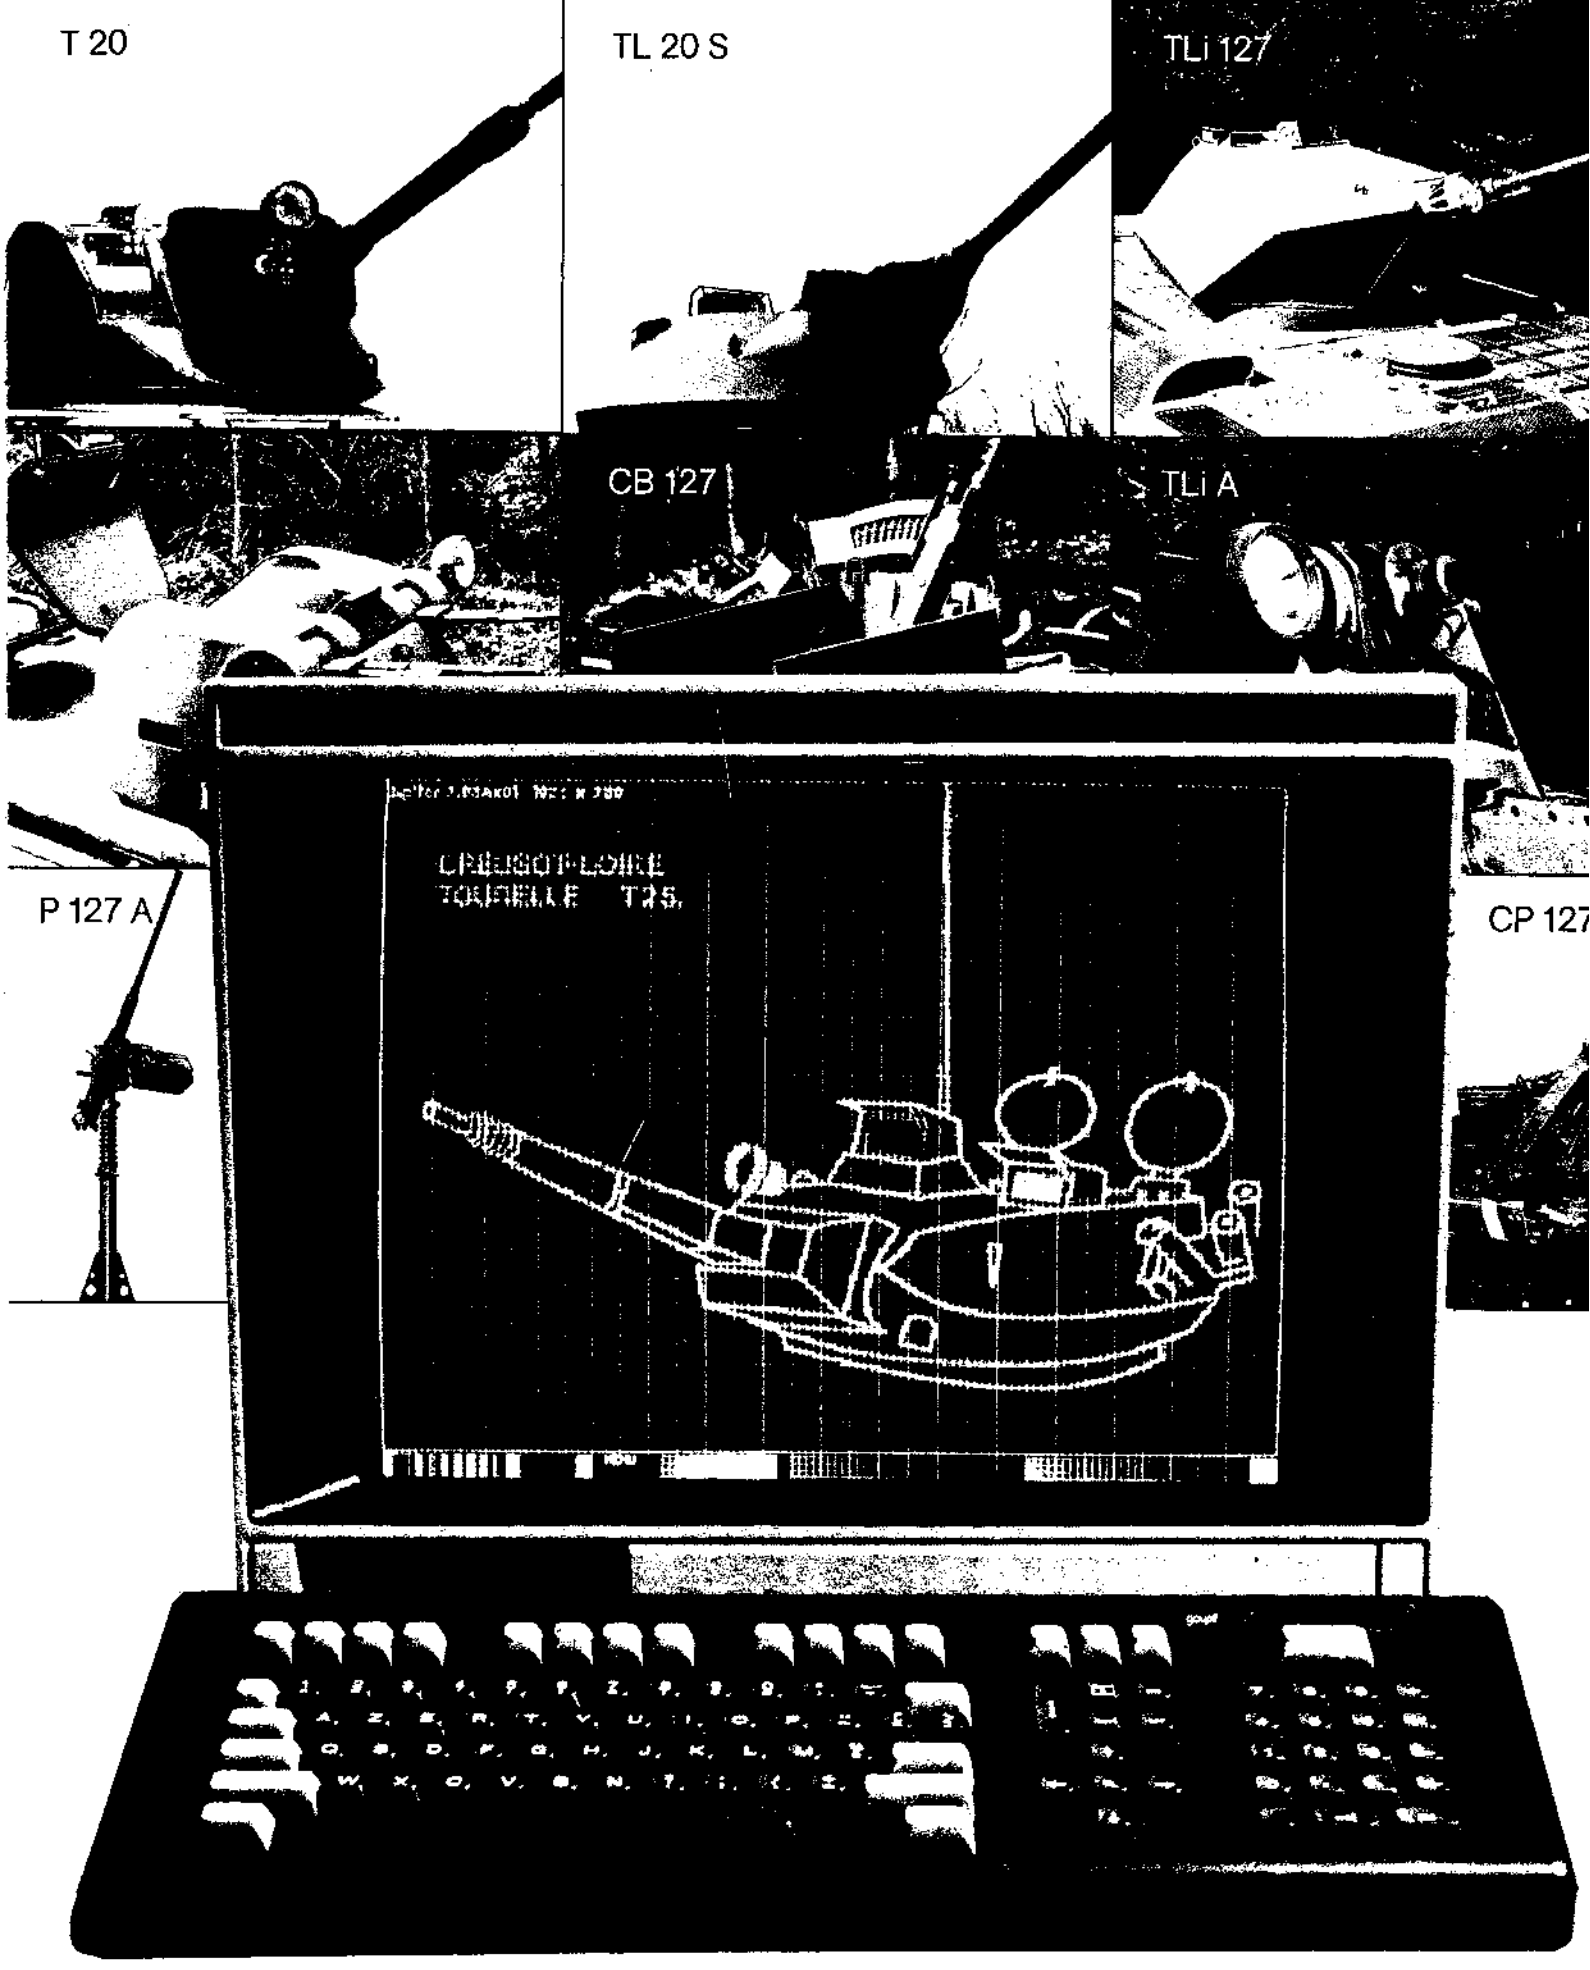
JANE'S DEFENCE WEEKLY

BE INFORMED...

No weekly Defence Magazine brings you the news faster



JANE'S DEFENCE WEEKLY is the first defence journal with both the authority and ability to provide an objective assessment of developments in world defence and the frequency of publication to keep you constantly informed of the latest changes in the defence scene worldwide. Building on the international recognition won by its predecessor, Jane's Defence Review, **JANE'S DEFENCE WEEKLY** is available **only** on subscription.

Full subscription details on application.

We also make turrets to measure. Please send us your inquiries.

CREUSOT-LOIRE

The military vehicle of the year?

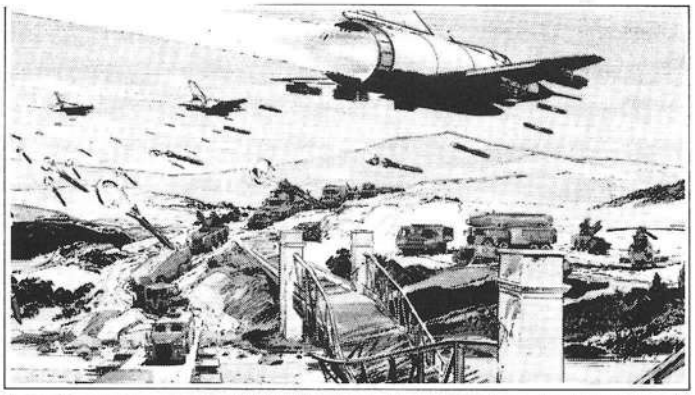
Once again from Iveco Defence Vehicle Division.

Once again, Iveco has scored a bullseye.

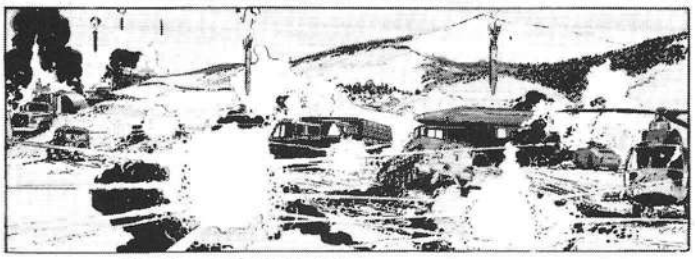
For its wide selection of military vehicles – a galaxy of different models and versions – now has a new star: the 40-10 WM.

The 40-10 WM, the most advanced example of Iveco technology, is the product of co-operation with military authorities all over the world.

The 40-10 WM offers technological innovations never before found together in the same product, and combines the comfort and performance of an off-road vehicle with the toughness and payload of a light truck.



Add to this its speed and its adaptability to a wide range of weapon systems, and the 40-10 WM obviously has a great deal to offer in meeting both tactical and strategic military requirements.



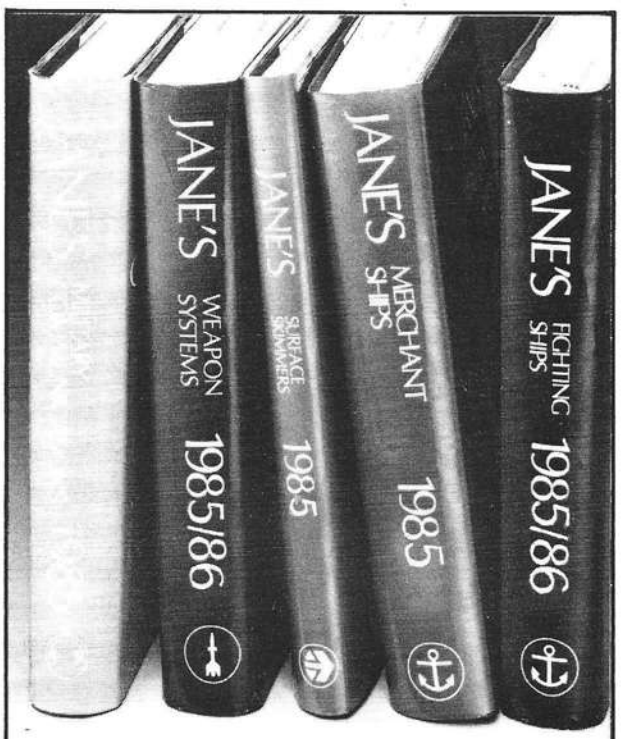
Moreover – to stress a point that is as vital as ever – the 40-10 WM is economical to operate.

All in all, another brilliant solution from Iveco Defence Vehicle Division.

IVECO

FIAT MAGIRUS UNIC

tactical support bomb



BAT 120

To neutralize the columns of mechanized units as they travel along their axes of advance (roads, railway-tracks) before they deploy over the combat-zone.

- Optimal aircraft loading: 18 bombs under just one pylon (735 kg on a single carrying point). Other carrying points available for fuel, ECM, air-to-air missiles.
- Weapon-system adaptable to all combat-aircraft, including the lightest, whether they are fitted with a fire control system or not.
- Two weapon-systems in one:
  – with no adjustment, the adaptors installed on the aircraft can accommodate the BAT 120 or BAP 100 (cratering bomb) indifferently;
  – in both cases less than 10 min is required to load the bombs on the aircraft.
- Weapon-system in service with the French Air Force.

JANE'S

Quality that lasts

The Steyr SK 105 "Kürassier" – fast, highly manoeuvrable, air-transportable

A light, fast and highly manoeuvrable tank with tactically advantageous dimensions and weights. Overall width no more than 2.50 m, head-on profile 2.50 x 2.50 m, ground pressure 968 kg/cm², climbing ability 75%, fording depth 1 m, top speed 70 km/h. Its small front silhouette in conjunction with its high manoeuvrability offers significant practical advantages in rough terrain. In action, the turret with top-mounted gun enables optimal use to be made of the terrain. Its large radius of action and its suitability for air transport make this tank one of the most highly mobile armoured vehicles available today.

Its fire power is optimized by the 105-mm gun, its target accuracy by means of laser range finders and its combat effectiveness at night by active and passive target acquisition devices.

The secondary armament fitted is a 7.62-mm machine-gun. The SK 105 "Kürassier" embodies up-to-date technology and has been designed for cost-cutting operation and maintenance.

SAGEM GYROSTABILIZED OPTRONIC SYSTEMS.

ON TARGET.

Sagem develops and manufactures a wide range of gyrostabilized optronic systems. Fire control systems for guns or missiles, use them for observation, identification and firing by day and night.

They are suited to land vehicles as well as helicopters and anti-aircraft batteries. Backed by a standing experience and a widely recognized competence, Sagem integrates and stabilizes several sensors, boresighting them with great accuracy.

All channels: optical, infra-red, FLIR and laser of the Sagem gyrostabilized optronic systems are thus aiming at the same target with an accuracy better than 100 microradians. Choose Sagem for effectiveness!

Naval electrical equipment from AEG sets the trend for technological progress.

A ship's state of readiness is to a great extent dependant on the reliability of its electrical outfit. Only systems which use state of the art technology can meet the constantly changing tactical and technical demands placed upon them. At the same time, the operators receive the vital support they need thus increasing the defence capability of the whole ship.
AEG has been producing naval systems for over a century for the most diverse types of vessels. Due to this comprehensive experience AEG is one of the worlds leading naval equipment suppliers. Our list of references ranges from supply ships over fast patrol boats to frigates and destroyers. In fact we have equipped all types of ships and to round out our program we also supply shore installations, such as magnetic ranges, training centers and maintenance facilities. Our service is complete; from the very first concept to type testing and trials, from production to installation and acceptance testing of the series equipment and systems. We prepare the technical documentation, train the operators and maintenance technicians and take care of material support. The result is high technology equipment in the hands of a well trained crew.
A prime example of this is the frigate class 122. We provided the electrical power plants and electrical distribution system. These systems together with the propulsion plants and ancillary and auxiliary systems are all controlled and monitored from the machinery control room by a centralized control and monitoring system which we also especially designed and built. Planning and realization of ships electrical systems are only one example of innovative capabilities and production capacity of AEG. Further major areas include degaussing systems, steering gears, stabilizers, minesweeping systems, anti-corrosion equipment and electronic counter measure systems. We will be glad to provide you detailed information on the many opportunities and decisive advantages offered by us.

Allowance for all attack configurations, intelligent systems, coordination of weaponry... are all part of the Flexible Force, enabling the Electronic Systems Division to offer the best possible response to today's air attacks.

The Electronic Systems Division analyses and develops the basic approaches to defence against low and very low altitude air threats, and tailors the results to each partner's specific situation. Modular design of systems and ready compatibility mean the best suitable response. Analysis of all hypotheses has given the Division considerable simulation experience and, to ensure continuing dialogue with the user, we offer staff training and technical back-up services.

For any configuration on the international chessboard, the Electronic Systems Division offers the skills that make its strength, to checkmat any form of threat.

THOMSON-CSF

THE SYSTEMS APPROACH

SDI Precursor – Lockheed's non-nuclear Homing Overlay Experiment (HOE) interceptor lifts off from Meck Island in the Pacific to engage a dummy warhead launched by two stages of a Minuteman ICBM from California about 4000 nautical miles away. Tracked by radars on Kwajalein Atoll, the HOE vehicle with its 'umbrella spoke' nose successfully met the incoming dummy warhead head-on at more than 10 000 miles an hour, at an altitude of over 160 kilometres. Originally part of the US Army ABM programme, HOE and other major space defence projects are now combined within the American Strategic Defense Initiative (SDI) which has won the popular title of 'Star Wars' – it is less popular with the USSR.

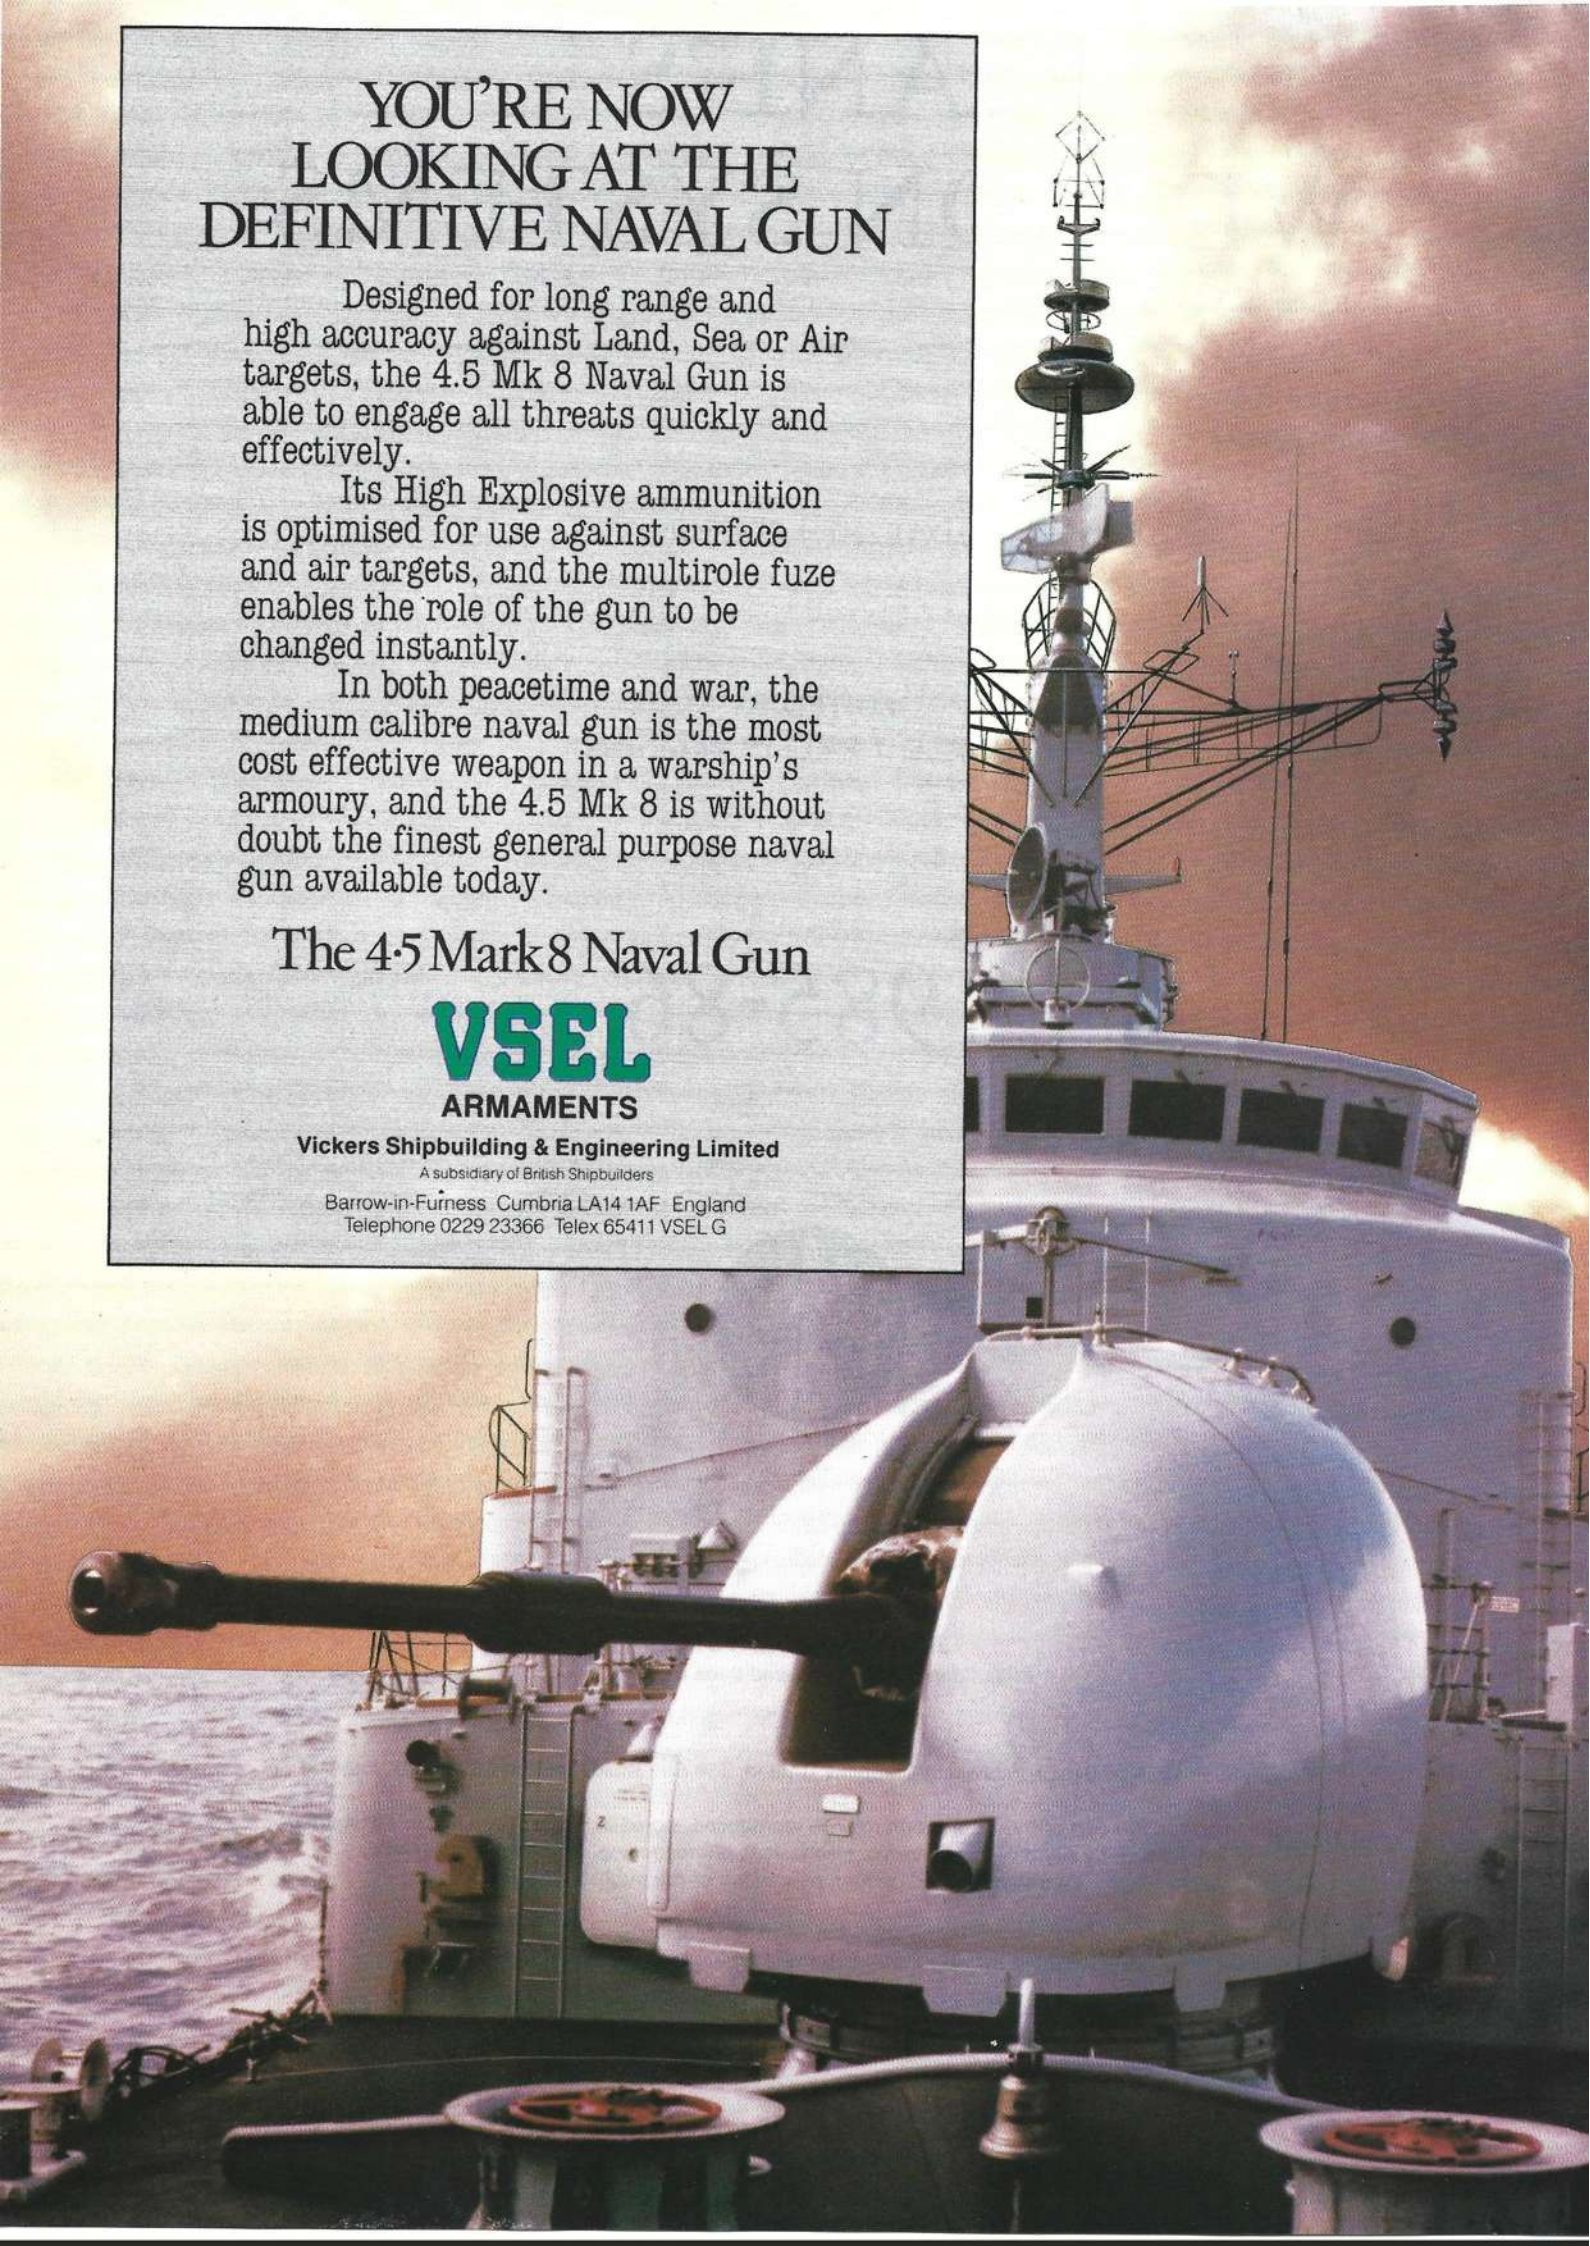
YOU'RE NOW LOOKING AT THE DEFINITIVE NAVAL GUN

Designed for long range and high accuracy against Land, Sea or Air targets, the 4.5 Mk 8 Naval Gun is able to engage all threats quickly and effectively.



Its High Explosive ammunition is optimised for use against surface and air targets, and the multirole fuze enables the role of the gun to be changed instantly.

In both peacetime and war, the medium calibre naval gun is the most cost effective weapon in a warship's armoury, and the 4.5 Mk 8 is without doubt the finest general purpose naval gun available today.

Foreword

Star Wars or SDI?

Writing at the time of the 40th anniversary of the first use of atomic weapons in the history of warfare, (and sharing the universal fear of any repetition) it seems that the world is on the threshold of another new era of military technology in the shape of President Reagan's Strategic Defence Initiative (SDI). This, like the awful confirmation of the practicality of nuclear weapons visited on Hiroshima and Nagasaki forty years ago, appears to have the potential to change the nature of warfare and dramatically influence the way in which international affairs are conducted.

It is no surprise that SDI is already of burning interest to the media – nor that both superpowers, and some other states, have seen the topic as a useful vehicle for their own particular propaganda exercises. The 'space' and 'nuclear' connotations have naturally been irresistible to headline writers whose duty is to serve those sections of the popular press and broadcasting where immediacy and impact are key words, so that the convenient and popular title 'Star Wars' was virtually inevitable. No criticism is implied by pointing out the very different impact that each term (official and popular) for the same thing can generate in the minds of the world's populations: 'Star Wars' suggests manned spacecraft slugging it out with ray guns and undreamt of spectacular weapons over our heads in the dark reaches of outer space; while the Strategic Defence Initiative expression has as its principal noun the word 'defence', giving practically the opposite meaning.

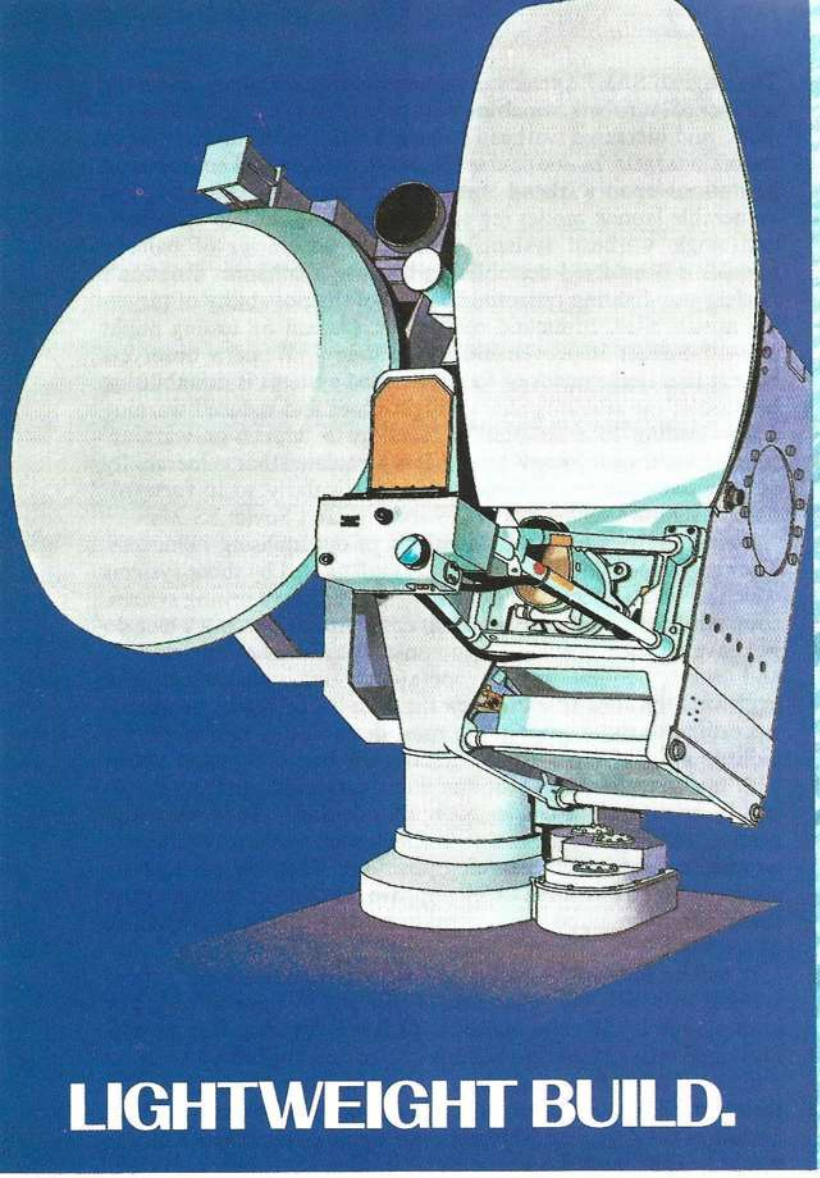
Rather than occupy readers' time debating this point, we offer the suggestion that the most significant word used in the American President's title for the project is 'initiative'. Initiative is what both parties to the resumed Strategic Arms Limitation Talks (SALT) now in progress are really concerned about. It is an essential element of their endeavours to secure the advantage for their respective political philosophies and forms of government, that is, a continuation of the communism versus capitalism/democracy struggle.

"Initiative, once gained, must never be lost; only in this way will the enemy be made to dance to your tune. If you lose the initiative against a good enemy you will very soon be made to react to his thrusts; and once this happens you may well lose the battle." Though admittedly writing in the narrower context of 'generalship', Field Marshal Viscount Montgomery of Alamein would hardly have objected to the extension of this view to the wider context of international politics. There is little doubt either that both the superpowers are equally convinced of the value of the initiative, or that each is dedicated to the struggle to obtain/maintain whatever initiatives are achievable. Depending on viewpoint, individual readers' perceptions of the relative successes of the Eastern Bloc powers and those of the West will vary considerably in all probability, and examples in support of both sides can be found in the recent history of the exchanges between the Warsaw Pact and NATO.

A persuasive proposal is that by attempting to change the whole ground of superpower military competition from one of amassing more and more offensive weaponry (conventionally known as being for mutually assured destruction – MAD) to the (theoretically) less damaging one of 'mutual assured security', President Reagan is bidding for fresh bargaining 'high ground'. The Soviet Union was prompt to recognise this as a valuable initiative and to take steps to wrest it back by throwing out the challenge that such a doctrine would destabilise the nuclear strategic balance.

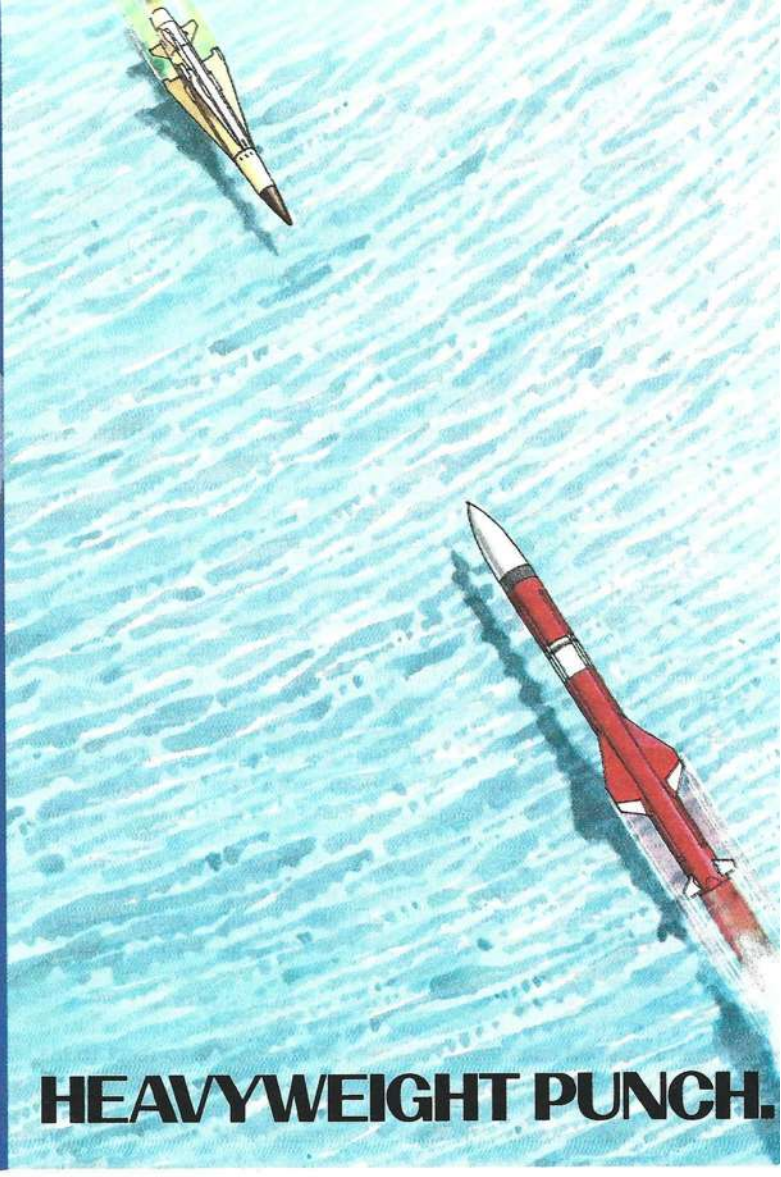
In attempting to assess the merits of these alternative views of SDI, it is interesting to note that in the course of the 10 to 15 years that saw the signing of the Anti-Ballistic Missile (ABM) Treaty of 1972 and which form the backdrop against which US and Soviet developments leading to the present situation occurred, the American and Russian standpoints each seem to have undergone a complete reversal in respect of what constitutes a destabilising influence. In the initial discussion preceding the ABM Treaty of 1972, the USSR argued that, since an ABM system was defensive, it must be acceptable, while the USA pointed out the de-stabilising consequences of ABM development. (At that time the Soviet Union was carrying out 'killer' satellite tests, and the USA had yet to perfect its Safeguard ABM system, preparatory to dismantling it in 1975). Now it can be seen that each side has apparently reversed its original position; the reasons surrounding these changes provide fruitful ground for discussion. The net result is that at present there is no common agreement between East and West on what is destabilising.

The West thinks mostly in terms of technological development. The original SALT agreement laid down simple limitations on the number of launchers, which encouraged multiple warhead development, and increased warhead-to-target ratios with missile silos as the main targets. In due course this led to the SALT II emphasis on limitations upon warhead and launcher numbers, favouring less vulnerable launch modes (eg submarines, land-mobile launchers, and single warhead systems). Increased accuracies of ballistic missiles is considered destabilising because it enhances a nation's nuclear war-fighting potential because of the possibility of targeting missile silos, command centres etc. (A ban on testing might prevent further improvements in accuracy). Western observers believe that deployment of forward-based systems is destabilising because of the resulting shorter flight times and reduced warning times, leading to a temptation to adopt a 'launch-on-warning' posture, or 'trigger-happy' stance. It is postulated that vulnerability of offensive systems is destabilising, particularly so in forward-based examples such as NATO Pershings and Soviet SS-22s.



Soviet analysts have a different list of destabilising influences. They argue that stability is primarily endangered by those systems which are most effective in destroying the defence warning system, command posts, and staffs and their communications, but which do not have sufficiently reliable communications with headquarters . . . and which require special operational measures which can aggravate tensions (for instance the take-off of heavy bombers). According to these criteria, the most destabilising means are the ballistic missiles deployed on submarines; heavy bombers armed with stealth technology; long-range cruise missiles; and the Pershing II missile deployed in forward positions. They therefore propose restraint on the extent to which such western systems can be manoeuvred into threatening positions. They are particularly concerned with measures which improve the control of events, and the effective command and control over nuclear arms in the course of a crisis.

It will be noted that each side describes as destabilising those systems in which the other side is thought to have a lead. For example the USSR cites bombers, SLBMs, Pershing II (and now SDI), and the USA cites Soviet heavy missiles. The USA also sees a number of other Soviet strategic developments as threatening and these perceptions are summarised in this edition, together with an outline of the American SDI response. Some of the reactions these moves have prompted, and the events leading up to them are briefly discussed in the paragraphs that follow.



Both the Soviet Union and the USA relate their arguements for and against SDI to the provisions of the 1972 ABM Treaty. The relevant parts of this can be summarised: "Each party undertakes not to develop, test, or deploy ABM systems or components which are sea-based, air-based, space-based or mobile land-based." It goes on to argue that if work on ABM defence progresses beyond the research phase to testing, the actual provisions of the Treaty may well be infringed. Here it has been pointed out that the American President's National Security Decision Directive No. 119 (January 1984) directs the SDI programme manager to conduct four major demonstrations of critical missile defence technologies before 1990. It is also stated that "a party has the right to withdraw from the Treaty after six months' notice, if it decides that extraordinary events related to the subject matter of this Treaty have jeopardised its supreme interests . . . Such notice shall include a statement of the extraordinary events the notifying party regards as having jeopardised its supreme interests."

The essence of the US presentation of SDI is as follows: SDI would replace or supplant the deterrent strategy of mutual assured destruction (MAD) by a doctrine of 'mutual asssured security' – thus it would be the adequacy of defence rather than the threat of retaliation that would prevent an attack from taking place. This is coupled with the suggestion that eventually SDI technology would be shared with the USSR. The criticism that there is little likelihood of providing ballistic missile defence for civilian populations is accepted to a certain degree, but SDI is proposed as a means of enhancing deterrence by adding protection for missile sites, command centres etc, rather than replacing deterrence, thereby reducing the risks of a first-strike attack. It is also emphasised that SDI is officially presented as a research programme only.

Official versions of the US conception of what SDI is and is meant to be differ slightly in emphasis and detail, as do Soviet interpretations of them. The joint Chiefs of Staff (US) Military Posture Statement, FY 1986 said: "Under the SDI, the United States is conducting an intensive research effort focused on advanced defensive technologies capable of defeating ballistic

LIGHTWEIGHT BUILD.

HEAVYWEIGHT PUNCH.

The Marconi Radar 805 SW.

A new, lightweight dual frequency fire control radar specially designed for use in major warships and smaller craft.

Chosen by the Royal Navy to direct the lethal punch of the Seawolf missile, and backed by the technology and experience of the largest radar manufacturer in Europe, the Marconi 805 system combats the threat of low level attack from air or sea once and for all.

A WHOLE NEW GENERATION OF THINKING.

missiles. A number of concepts, involving a wide range of technologies are being examined. The effort does not represent a departure from the fundamental US support for deterrence". (This carries with it the inevitable implications that the USA is preserving its option to continue offensive strategic weapon development as a hedge against failure of the SDI – a point which is not lost on the Soviet Union. Ed.) The Posture Statement goes on: "No single concept of technology has been identified as most appropriate. Initial research indicates that it is feasible to increase stability through employment of a multi-layered defence capable of engaging enemy missiles and re-entry vehicles in all stages of flight. The SDI effort is also examining technologies with potential against short-range ballistic missiles, which could extend protection against nuclear and conventional attack to the allies.

The SDI is addressing the protection of both civilian and military assets. The research seeks to exploit the *inevitable technological evolution* and is a prudent response to active Soviet research and development activities in ballistic missile defence."

The US authorities believe the Soviet Union is moving towards providing a nationwide ABM system, and later in the Statement we read, "The Soviet Union has already deployed a BMD system, which is permitted under the 1972 ABM Treaty. The Soviets are also engaged in research and development of a rapidly deployable ABM system within the next decade in violation of the ABM Treaty. The (SDI) programme also provides a prudent hedge against a possible Soviet breakout from the ABM Treaty, holds the promise of a better way to deter aggression, strengthens stability, and increases US and Allied security."

From the Soviet side it is argued that SDI does not seem to have brought with it any lessening of interest in US offensive strategic system developments (Eg. MX, Midgetman, Trident II, and various cruise missile applications), and SDI is therefore seen in the USSR as offering increased potential for a first strike capability against the Soviet Union. In their view the BMD would be used to deal with any Soviet retaliatory ballistic missiles left after a US first strike.

Some reactions to these and similar Soviet charges were given by Ambassador Edward L Rowny, Chairman of the US START delegation, and formerly as General Rowny the US Joint Chiefs of Staff representative to the SALT I and II negotiations from 1973 onward, in an interview organised by *Jane's Defence Weekly*, last August. He was asked, "Why are Soviets so anti-SDI?" and he responded:

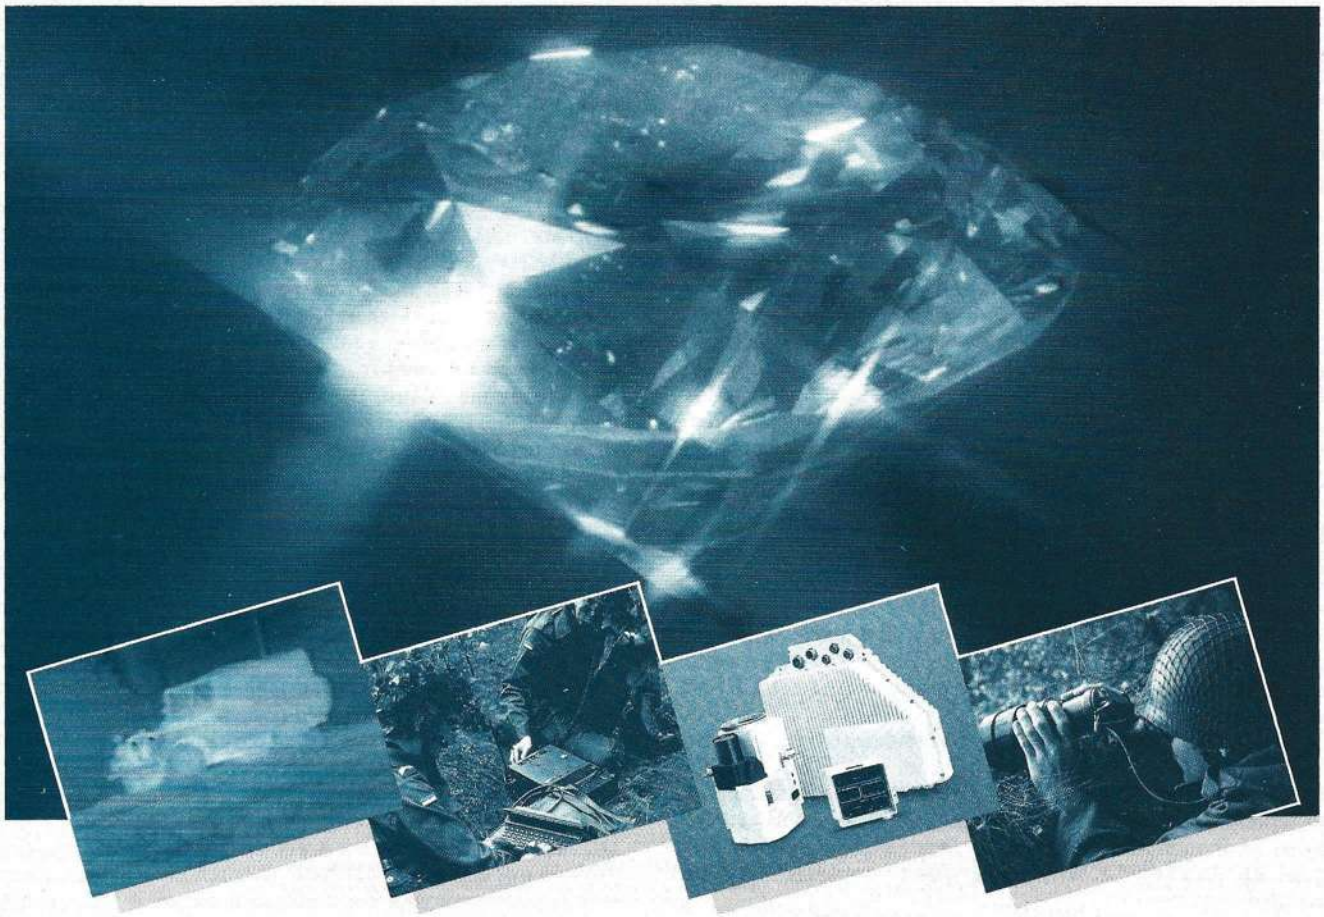
"Well there are two or three reasons. Primarily they complement one another; one reason is they're very fearful of western technology. They know that they have good basic scientists and they know that they can have the same break-throughs, and may be even better (but) they don't compete with us (USA/the West) on basic knowledge, basic research. But they cannot turn it into hardware in a hurry and make it work, and make it reliable. They fear our prowess in the West of being able to put science in application, to apply science. Therefore they see their land-based systems, their fixed land-based systems at risk. Now they're hedging against that by their SS-X-24 and SS-X25 (rail-mobile and silo-based, and mobile and silo-based ICBMs, respectively. Ed) developments. They are going global with some of their systems, a little more to sea, at least larger and longer-range systems, powerful systems at sea.

So on the one hand they fear our technology, fear what it might do to the heavy investment they have in fixed land bases, and on the other hand it is a marvelous propaganda theme, particularly in Europe. They lost out on their SS-20/Pershing II deal and put this huge system together to sell this and market it, and they think that they are having some success in Europe with their arguments, and that this is somehow going to decouple Europe from the USA, and that Europe will be naked and that the US will not come to the defence of Europe. Or the US is building a defensive system so that it can provide sanctuary for its own first strike capability. We don't have a first strike capability and are really not building one. 50 MXs, (the Peacekeeper silo-based ICBM beginning deployment in 1986. Ed.) not even 200, would give you a first strike capability. So they use those arguments, plus the fact that we have got to talk about these in order to get public support and legislative support for this huge defence research programme. They talk about it as though they (new US weapon systems, Ed.) were here now and most are only at development stages and it will be at least six or seven years on before they really know if these are really feasible or not."

Destabilising

Asked what is the US argument against the charge that SDI is destabilising, the General replied: "Well we can say that it is not because a combination of defence and offence will be more stabilising than pure offence against offence. That throughout history (we have) always had the spear and the shield and you can only throw away your shield if you throw away your spears or reduce the spears to the same size. The Soviets have not reduced, we've thrown away most of our shields; these days we don't have an ABM system (but) they have one of sorts. . . But the ABM Treaty was entered into with the understanding that within five years there would be an agreement on offensive weapons. As a matter of fact, we went further than that, we said that if there is not an agreement on offensive systems we reserve the right to activate the ABM, so that in 1977 we looked at that as the first five years' review and we warned the Soviets about the necessity of coming down on offensive weapons. In 1982 we had the second five year review and we warned them again, so the argument was, 'As you, the Soviets, said in 1971 and 1972, defensive systems can be stabilised. They don't hurt anybody, they don't kill anybody and they will contribute to stability.' We are using a lot of their original argument."

Commenting on the Soviet perceptions of SDI presented for public consumption, General Rowny had this to say, "I made a trip to a couple of capitals here in Europe about two months ago. I found there were two broad misconceptions about SDI. The first I've already mentioned; that its here, now. Like it's about to be deployed, and it's not; it is in the research mode. The second is that the United States has as a near-term goal a 100 per cent perfected shield or dome over the United States and that's wrong because we don't have that capability and know it, won't have it for years and years. Its not leak-proof; its going to leak and we know it. But the argument is used, that somehow the US will be so protected that it is, or will be, 100 per cent protected, thereby allowing even a limited capability so as to be able to be used when the Soviets cannot deter us. I say that's wrong, it just can't be done and won't be done."



SDI is scheduled to cost $26 billion over 5 years, with the declared initial objective to establish whether ballistic missile defence is feasible. If it is judged to be so, then the intention of the present US Administration is to deploy it; it has been said that the technology would be made internationally available. The scale of research in the Soviet Union is not known. Some observers say that the Soviet Union is more threatened than the USA by possible attack from aircraft, and it is acknowledged to spend a great deal on anti-aircraft defence. It has basic research programmes concerned with laser technologies, for example. But there is little evidence, in this view, of the vigorous development of new ABM systems. The United States authorities and others, however, place a different interpretation on matters of this kind taking place in the USSR.

When trying to assess the overall strategic balance between the two superpowers in the context of SDI and a nation's overall defensive posture, it must be borne in mind that ballistic missiles are not the only available delivery system for nuclear weapons: any effective total defence would have to provide protection from cruise missiles and aircraft as well. Given new cruise missile technologies, and the development of 'stealth' characteristics for aircraft, this protection would also be very costly. This is a point of particular relevance to Europe, where many nuclear delivery systems are short range. If we ask: "How is SDI expected to deal with the threats from conventional strategic bombers, cruise missiles and 'in-atmosphere' nuclear weapon delivery vehicles?", the answer at this stage must surely be: "It probably will not", but at least threats of this kind would favour the defender to the extent that they take longer to reach their targets than other threats such as ICBMs etc, and are more suitable for engagement by 'conventional' defensive means such as interceptor aircraft, SAMs, etc.

"The SDI programme (and ideology) is extraordinarily radical. It is beginning to force open a debate about the fundamental structure and relationship of US and Soviet nuclear forces and doctrines. Depending on how much the plans will be translated into actual systems, it either re-defines or overthrows the fact of mutual deterrence. President Reagan and other SDI supporters have claimed that strategic defences would provide an alternative to a MAD doctrine . . . " But as it has been pointed out by strategic experts, MAD is not a policy or a doctrine but rather a fact of life. It simply descends like a medieval plague – a seemingly inevitable consequence of the enormous destructive power of nuclear weapons, of rockets that could hurl themselves across almost half the globe in 30 minutes and of the importance of political institutions in the face of such momentous technological innovations.

It is held in certain quarters that by the turn of the decade, the SDI programme (as planned at present) will almost certainly be in contravention of the ABM Treaty, which does not just ban

PHILIPS USFA

HAS MANY FACETS

Yes, Philips Usfa has many facets. Many unique skills. Many products. All reflecting Usfa's high technology expertise in electronics, physics, electro-chemistry, opto-electronics and cryogenics.

Expertise not only in these technologies, but also in systems application and design, and in manufacture. Manufacture under a regime that ensures unparalleled reliability in the field.

Usfa's product range includes:

- **Thermal imaging systems**
  Vision, by thermal contrast, penetrating mist, fog, smoke, camouflage, by day and night. For aiming and observation systems, thermal cameras for naval applications, surveillance sensors.
- **Night vision equipment**
  High performance multi-use night sights, weapon sights, driver's periscopes, observation and gunnery periscopes.
- **Secure Communications**
  Highly specialised crypto-graphic equipment including teleprinter terminal, voice encryption systems, bulk encryption equipment, rugged portable short burst terminals.
- **Proximity fuzes**
  Fuzes for use with the new generation of naval armament and field artillery, especially against incoming low level, sea-skimming targets.
- **Stirling-cycle cryogenic coolers**
  Modular, highly reliable miniature coolers, to suit any Dewar/detector, also available in split-configuration.
- **Special reserve batteries**
  Extraordinarily long storage life, instant activation, with stable output, over a very wide temperature range.

PHILIPS

deployment, but also development and testing of ABM systems. Because of this, it has been suggested that the SALT I and SALT II agreements (which would have expired by that time in any case) would be unlikely to be renewed. This would lead to an unchecked growth in the numbers of nuclear strategic weapons, eg, ICBMs, SLBMs and cruise missiles for various launch modes. This appears to be the eventuality that the Soviets are preparing for, if US assessments of cruise missile and other advanced weapon developments in the USSR are well-founded.

Because at present the Soviet Union says it will not consider an agreement on strategic offensive weapons unless "something is done" about the control of 'space weapons', it is necessary to be able to differentiate between SDI and its use of a space-borne element, and anti-satellite weapons which are more or less generally accepted as being destabilising. For example, part of the SDI concept of ABM defence, as so far propounded, involves the use of space vehicles to carry the defensive weapons intended to disable/destroy attacking ballistic missiles, and these elements would form a logical target for an attacker/enemy's anti-satellite capability. The attacker's weapon in space would be regarded as merely an embellishment of an offensive weapon system, whereas the defender's space-borne weapon could be argued as entirely defensive and therefore 'stabilising' as opposed to 'destabilising'. Whichever way one chooses to interpret this riddle in an endeavour to resolve the apparent dichotomy, past experience suggests that the ultimate result in practice might well be yet another round of the techno-military competition that has kept the pages of this book (and contemporary volumes) filled for some decades past.

SDI, if successful, would render the principle of deterrence obsolete, and the hardware and investment in deterrence would also represent wasted money and resources. What of the other nations and their aspirations? Possibly the most affected are the leading European states, though history suggests that no situation remains unchanged for very long and there are other potential centres of economic, military and political power which might be expected to expand and wish to exert an influence on international affairs – in ways which would not necessarily be agreeable to the two superpowers.

Although the SDI programme did not become a major issue in the US presidential campaign of 1984, arms control and defence analysts are lining up in support or opposition to the proposed programme. The attention focused on SDI by the Soviet Union has also coincided with Administration arguments that it was the fear of 'Star Wars' and the strategic offensive build-up that brought the Soviets back to the negotiating table. The reality is certainly much more complex.

From an early stage, once SDI had been made public, there was steady pressure on America's European allies, at both the public and diplomatic levels, to give their support to this initiative, and this has been matched by a similar campaign to win public and corporate backing at home.

Further afield, the British Prime Minister appeared to support the idea and UK industry seems keen on the idea of participating in the research programme, but Sir Geoffrey Howe, the UK Foreign Secretary, publicly disagreed with Mrs Thatcher and seemed to espouse the current doctrine of MAD, which, to borrow a simile employed by General Rowny, is like a man who has no shield but relies on a sword to retaliate. Howe is quoted as saying, the "risks (of SDI) may outweigh the benefits." Meanwhile the French, having agreed initially with West Germany and the UK, to participate in SDI, later, in company with Denmark and Norway, decided against it. Instead, France countered with their Eureka project, which, it emerged, had not a great deal to do with SDI objectives directly. (However, in the interests of 'European unity' and maybe those of their home scientific and industrial communities, the British and Germans gave their support to Eureka. Whereupon the EEC sought to involve itself and started to draw up its own list of suitable 'high-tech' projects). Britain and West Germany reserved the option of SDI participation, and the latter weighed the possible research benefits against the political hazards. In the German view this poses the following principal questions: what are the foreign policy implications? how would it affect the NATO alliance? and what are the military strategy implications? If satisfactory answers to the first group of questions are found, the prospect for technological co-operation is thought highly attractive to West German interests. On the other hand, the German authorities are keeping their options open at this stage. One unattributable official summarised the position as follows: 'You can't expect that we would be so foolish as to make a decision now. (March 1985, Ed.) We don't want to jump on the wrong horse, if indeed we jump on at all.'

If US support for SDI is far less restrained than in Europe, it is by no means universal, nor unqualified. For instance, the Scowcroft Commission report, of March 1984, concluded that the "strategic implications of ballistic missile defence and the criticality of the ABM Treaty to further arms control agreements dictate extreme caution in proceeding to engineering development in this sensitive area." While a background paper by the Office of Technology Assessment, 24 April 1984 contained the damning passage: "The prospect that emerging 'Star Wars' technologies, when further developed, will provide a perfect or near-perfect defence system literally removing from the hands of the Soviet Union the ability to do socially mortal damage to the United States with nuclear weapons, is so remote that it should not serve as the basis of public expectation or national policy about ballistic missile defence."

This theme was taken up by two former US Defence Secretaries: James Schlesinger estimated the cost at at least $1 trillion while saying that "There is no serious likelihood of removing the nuclear threat from our cities in our lifetime or the lifetime of our children." And Harold Brown, said, ". . . technology does not offer even a reasonable prospect of a successful population defence", at the same time calling on President Reagan to: "publicly acknowledge that there is no realistic prospect for a successful population defence certainly for many decades and probably never."

The defence and high technology industries generally have adopted a more pragmatic attitude toward both SDI and the less well-defined French Eureka: in other words 'business is business'! Nevertheless the possible commercial implications of the undoubtedly enormous technical problems to be overcome are just as clear to would-be contractors as the potential gains from participation through technological spin-off, production orders, research and development work and so on. This cautious interest was illustrated in the editorial column of a leading British computer journal by the following passage:

". . . readers are being buffeted from all sides, whether it is Star Wars or Eureka, whether it is Cocom regulations attempting to stem the flow of technology to the Eastern bloc or technology transfer between the US and its allies. They might rightly ask: 'Why do I need to know about all of this?'."

At a simple and fairly straightforward level, all developments having to do with computers have the potential to affect directly or indirectly computer users. On that basis, the 'politics' of the computer industry is of background interest to all involved with information technology.

'Star Wars', or more correctly the Strategic Defence Iniative, takes the issues on to a new plane, and does, we think, demand a contribution to the debate from all sectors of the computer industry. The arguments over 'Star Wars' are mainly among politicians who, in general, have little understanding of either the limits or the possibilities of technology.

Computer professionals may have some insight into the complexity of designing a computerised space-based defence system with the millions of lines of 'error proof' code that would entail.

In the US, a section of the university research establishment is attempting to organise a boycott of 'Star Wars' research. With an overall SDI budget of $26 billion, and plans to spend $600 million with US universities over the next five years, such a boycott would be a brave action.

But at the University of Illinois, for instance, an overwhelming majority of the faculty at what is considered one of the most prestigious physics departments in the country has condemned SDI as 'technically dubious and politically unwise', and vowed not to do 'Star Wars' research.

Similar plans for a boycott are being organised at other major US universities. Many defence experts scoff at the technical criticisms, saying those who criticise Star Wars are simply afraid of new ideas. Even if the programme is feasible, however, it is sure that it will exert an enormous drain on other research efforts.

If the SDI gamble can be pulled off, it has an obvious and highly powerful popular appeal. The logic of this was expressed by Senator Fred Ikle, US Under Secretary of Defense for policy, in June 1985, when appearing before House of Representatives Republican Study Committee:

"It is not warranted to criticise SDI for upsetting an existing stability. There is not now stability existing in that (missile) competition or that (US/USSR) relationship. Why should we lock ourselves into a dead-end street? Why shouldn't we try to find an alternative to continuing this endless competition in offensive arms, which is what we are suggesting?"

Military use of space

While not directly part of the SDI programme but nevertheless very

Wheels or tracks, large or small,
U.S. or foreign-built...

Guess what they've all got in common.

The most versatile combat vehicles in the world have one thing in common. They can all mount the combat-effective 25mm M242 BUSHMASTER automatic cannon.

In fact, over 2,500 BUSHMASTERs are now in service with the U.S. armed forces, and each month 80 more roll off the line at Hughes Helicopters, currently the free world's largest producer of automatic cannons.

BUSHMASTER performance exceeds military requirements and goals on all counts...reliability, availability, maintainability, durability, accuracy and lethality. Join the growing ranks and put the lethal BUSHMASTER on your combat vehicle.

much in the 'Star Wars' context (the relevance to 'the military use of space' is certainly to the forefront of official Soviet minds) two other American projects have been much in the news recently. These are the ASAT, anti-satellite programme that is intended to launch missiles from aircraft to intercept and destroy low-orbit satellites in orbit, and the homing overlay experiment (HOE) in which a ground rocket is used to take the HOE vehicle carrying a guidance sensor and a non-nuclear kill (NNK) payload into space where it detects an incoming missile re-entry vehicle and steers itself onto a collision course. The latter project originated as part of the US Army's ballistic missile defence (BMD) programme, and will probably be incorporated into the broader SDI effort. The fourth test HOE flight took place successfully in June 1984 when two stages from a Minuteman ICBM boosted the HOE vehicle from Meck Island, Kwajalein (see frontispiece) to a height of over 100 hundred miles where it was manoeuvred onto a collision course with an ICBM launched from Vandenberg AFB, California, over 4000 nautical miles away. In the nose of the HOE vehicle a sensor detected the missile's RV and corrected the HOE trajectory, then a radial net, wrapped around the HOE interceptor's nose unfurled like an umbrella several metres in diameter before the two bodies collided and destroyed each other. The Army was highly satisfied with the result, which was likened to hitting a bullet with a bullet.

The second of these two projects, the seven-year old ASAT programme, seems to be getting a rougher ride. The first of twelve planned tests took place in December 1982, when it was demonstrated that an F-15 aircraft could safely carry the two-stage ASAT missile; a test launch followed in January 1984, with second test launch later that year in November. This was meant to be followed by a further flight to test the ASAT's tracking system, but after a series of deferrments it still had not been launched in July 1985. The programme is now having to fight for its funds having come in for criticism from several quarters. For example, it has been argued that delays due to technical problems have rendered it obsolete in the face of new space technology and that it should be replaced by a new project using more advanced laser technologies. In May 1985 a study was ordered to find ways of improving the ASAT programme in the light of fresh assessment of the threat, and in Washington that summer critics of the programme were peddling their views in whatever centres of influence accessible to them. Whatever the outcome (here it is a brave man who attempts to forecast) the Air Force and the contractors seemingly still believe in the concept, and their ability to overcome whatever problems there are with the 30 or so 'technical concerns' voiced by the US General Accounting Office that hinder ASAT's progress. It has been contended that ASAT was originally intended for use as a 'bargaining chip' in negotiations with the Soviet Union by President Carter, and there is little doubt that the idea is one that gained considerable official Soviet interest, which surely cannot be entirely bad?

The past year saw much press comment about the alledgedly extravagant funding practices of the US defence procurement processes, tellingly illustrated by the oft-told tales of the F-14's $529 seat cushion or the $659 aircraft ashtrays! Entertaining though this may have been to read, the funding of America's defence programmes is actually subject to more official and public debate and discussion than probably any other nation's in the western world – elsewhere there is no discussion! There are things to be said both for and against this, but by and large the overall situation must be for the better. Nevertheless the total budget and authorisation is a lengthy and complicated proceedure, which is sometimes difficult to appreciate fully, particularly by foreigners who are not familiar with the American government structure or with the elaborate and highly professional Congressional and Senate committees that exercise powerful influences on defence affairs in the USA.

Peacekeeper (MX)

It is hardly surprising that things are not always what they seem to be when the copious reports, statements and mass of documentation that accompany the whole procedure are assessed by the public, informed or uninformed, US or foreign nationals. When Pentagon statements and reports, proceedings of Senate and Congressional defence committee hearings and so on are issued over a period of many weeks, it is sometimes a brave man who is prepared to say about a specific defence programme, "this is the situation as it stands today." For instance, while in mid-1985 the world gained the impression that despite seeking approval for the procurement of a force of 100 Peacekeeper (MX) ICBMs, the outcome of deliberations in the US House and Senate was that funding approval for a force of 50 missiles only was forthcoming. At one stage it looked like being only 40, but the slightly higher number was eventually approved. Nevertheless President Reagan and the US Air Force are still seeking a force of 100, and to this end the slightly unreal search for alternative basing modes that once was the best-known feature of the MX programme is being restarted. But as US Air Force Secretary, Verne Orr, pointed out, the Pentagon had examined 32 different basing modes before he took office, and he added, "They ranged from running them down rivers on rafts, to putting them on the Great Lakes, to bobbing them on lobster-pot type buoys out on the shallow waters of the oceans. I mean, you name it – south sides of cliffs facing away from the Soviets! We'll look at them all again, and we'll get the thinkers in and say, 'Is there a 33rd or 34th that nobody thought of?'. But unless the arguments change a lot, we'll probably come back and say we don't have any as good as the ones we've already looked at before." But significantly he concluded, "I think we're still with the President's programme of 100." This may yet be possible, because it has been pointed out that the Chairman of the House-Senate conference committee, Republican Les Aplin, while stating the 50 MX limit permitted USAF purchase of test and spare MX missiles, which it is estimated could be sufficient for a total purchase of 125 missiles. The MX story has seldom been a tame one!

The basing debate which surrounded the American MX programme for so long served to concentrate minds on the relative merits of the various possibilities, and the advantages of mobile basing compared with silo bases for ICBMs was examined afresh, doubtless on both sides of the Iron Curtain. It cannot be said with any certainty that the Soviet SS-X-24 and SS-X-25 ICBMs which are expected by the US authorities to become operational soon are a direct result of Soviet studies of America's MX, nor would it be true to say that the projected US Small ICBM (popularly known as Midgetman), which will be a mobile system, has been prompted specifically as a response to the Soviet SS-20 system. Estimates of deployments of the latter suggest well over 400 currently, whereas in the USA the mobile basing philosophy is accepted less readily and this, taken with possible technical difficulties suggests that funding may prove to be a problem with the programme. There are domestic fears that the Midgetman SICBM project may get drawn into the same sort of long-running basing debate that dogged MX/Peacekeeper.

Of the other nations with a nuclear strategic ballistic missile capability, the People's Republic of China revealed in the closing months of 1984 that the pace of developments in this field is being maintained, with examples of CSS-3 ICBMs and their first SLBM, the CSS-NX-3 intended for 'Xia'-class submarines, on the October 1st National Day Parade; the French M4 MIRVed SLBM (French initials MSBS) moved towards operational status in the submarine, *L'Inflexible*, which has tubes for 16 of these 4000+ km range weapons; and Britain continued to fret over the costs of its Polaris/Chevaline payload and Trident II SLBM deterrent programmes. As this edition was being prepared for printing, the latest official figures for the latter programme were hovering around the £10 billion mark, with £300 million spent and a long haul ahead. To date the first of the new PWR2 nuclear power plants for a new 15 000-ton class of submarine (each expected to cost between £500 and £600 million) is about to start tests at a shore establishment.

Other Weapons

If strategic matters and potential military competition in space more readily reaches and holds popular attention, and if these affairs have been discussed at some length here, this is not to say that things have been at a standstill in the rest of the defence industry, and in addition to the entries in the volume that record strategic system developments there are hundreds that deal with tactical weapons of many sorts and the equipment required for their implementation and operation. Progress along these lines during the past twelve months has called for almost 300 new entries in this edition, of which approaching one third deal with weapon system developments.

'Theatre', or to use an older expression, battlefield weapons continue to receive the lion's share of R & D investment resources, yielding some impressive and innovative results. A typical example is artillery delivered anti-armour weapons of which several versions are included in this edition, which use cargo carrying shells to carry target locating self-forging projectiles and/or A/T mines for instance. Another recent approach to the threat of armoured formation attack is the homing mortar projectile as exemplified by the American GAMP (guided anti-armour mortar projectile) programme, Swedish Strix A/T grenade, and the British Merlin 81 mm anti-tank mortar bomb. Of course these are not the only new ideas. Another, which first appeared in Sweden, was the RBS 56 Bill missile, developed for the Swedish Army which features a 30 degree

UNEQUALLED UNBEATABLE AND UNDER WAY

ELISRA NAVAL EW SYSTEMS

ELISRA series NS-9000 EW systems. Built by front-line experts. Proven flawless under battle conditions. These advanced naval EW systems were designed to pinpoint, process and jam signals from the most sophisticated far-range emitters, instantaneously.

ELISRA naval EW systems. Built to be compatible with other shipboard systems. And configured to fit most vessel types. Including small and full-size patrol boats, frigates, destroyers and other combat ships.

NS-9001 The latest generation ELINT gathering system, offering rapid and accurate analysis of virtually all radar emitters, including "exotic" type radar signals.

NS-9003 and NS-9010 Our most advanced ESM systems that automatically respond to the latest-generation weaponry providing: instant radar interception, platform identification, and effective signal jamming via our NS-9005 or other similar systems.

NS-9005 A unique ECM system providing noise and deception jamming techniques for effective engagement of multiple threats.

NS-9009 A compact, cost-effective system for small patrol boats capable of immediately analyzing and identifying sophisticated radar emitters.

Our NS-9000 series does not stop here. It also includes retrofit systems that convert manual ESM/ECM equipment to automatic power-management suites.

ELISRA Naval EW systems. Powerful, computerized systems. Designed to confuse the enemy and debilitate his equipment. Put them to work for you... today!

WORKING FOR YOU. elisra electronic systems ltd.

downward-directed warhead designed for attacking the lighter top armour of tanks. A new system called Volcano is under development by the US Army to enable helicopters and/or ground vehicles to dispense mines in large quantities; for example one SH-60A Black Hawk helicopter with four launcher racks could sow a total of 828 mines in one load.

Among the surface-launched tactical weapons at the heavier end of this category worthy of note this year, the Soviet Union's replacement for the FROG (free rocket over ground) series, the SS-21 battlefield support missile, has now been photographed and externally appears to be roughly equivalent to NATO's Lance. The USSR also has what are reported to be replacements for the larger, longer range, SS-1 (Scud) and SS-12 (Scaleboard) systems, in the SS-22 and SS-23 missiles, which, regrettably, have not yet appeared as photographs. Photographs have been obtained for another new Warsaw Pact surface-launched missile system for a somewhat different tactical role. This is the SSC-3 mobile/transportable coastal defence missile system which is operational in East Germany, Yugoslavia, and it is believed Syria. The actual missile is thought to be essentially a version of the long-serving SS-N-2 Styx, in this role coupled with a new land-mobile launcher and radar/command and control unit. The People's Republic of China also employs its own version of Styx, as the HY-2, in the coastal defence role, and is now offering its system for export. Three guidance system options are offered: active radar, active radar with a radio altimeter, and passive IR homing.

The People's Republic of China also claims to have been using the C801 anti-ship missile (an Exocet-like weapon) for some years, probably for coastal defence purposes since no ship fittings have been seen or reported to date. It appeared in public for the first time in a 1984 military parade with a container launcher similar to that seen with early MM 38 Exocets, carried on trailers behind military trucks. Arriving too late for inclusion in the main part of this book, a photograph and a few details have been received of the long-rumoured surface-launched version of the indigenous Japanese ASM-1 anti-ship missile. For this role the normally air-launched weapon is fitted with a booster rocket.

Another new photograph that has arrived in time for the Addenda is that of Taiwan's Tien Kung (Sky Arrow) land-based SAM. From this photograph (very little else has appeared as yet) it appears to be an American Patriot missile 'look-alike', but until the associated radar(s) and other ancillaries are seen further details will have to remain conjecture. In this category until this year, there was almost nothing new other than Patriot in the West and in recent Forewords we have commented on this apparent gap in the West's future inventory. We wonder if perhaps Taiwan is contemplating entering this market sector.

The air threat, worldwide, has not declined in recent years, (if it has not actually become much more serious). Many more third world countries now feel themselves threatened in this area and have a requirement for a moderately sophisticated SAM system. In addition, it must be admitted that most of the SAM systems operated by the West (Patriot excepted) have come to look decidedly elderly beside introductions from the Soviet Union. Patriot is undeniably sophisticated, and is probably too costly for many would-be operators, so that there could be a highly promising market for a new SAM that comes between Patriot and older systems such as Bloodhound and Hawk in terms of performance and cost. Some such reasoning might have encouraged the French to undertake their ambitious SAAM family of weapons. As the major exporter of military equipment, after the USA and USSR, France is noted for its keen commercial eye and excellent judgement of what is needed and what will sell overseas. It also must be acknowledged that there could be useful replacement SAM contracts to be won from some of the NATO members who cannot afford Patriot.

Current NATO SAM systems continue to be the subject of refinement and updating programmes, particularly the less venerable types, and the medium-range Hawk, and shorter-range weapons like Rapier and Roland are good examples of this process. For still shorter range applications, a number of new weapons are now in or approaching service use, such as the Swedish RBS 70 RayRider, UK Javelin and the French Mistral. There is also a trend towards combining single or multiple launchers for these initially man-portable SAMs with AA guns of various calibres to obtain more flexible coverage and overall performance improvement. This is particularly the case with the last named (Mistral) which is proposed for a number of naval close-in weapon systems, where it appears co-mounted with a multiple barrel, or other type of high rate-of-fire gun, and a dedicated fire director system.

Turret mountings of this class of missile for both land use and naval applications are beginning to multiply. A recent example of the former category is the widely operated Stinger man-portable AA missile which is now finding vehicle-mounted uses such as the Boeing Avenger system. There are similar projects at varying stages based on other AA missiles from manufacturers of several countries.

Of the three principal categories of platform, land, sea and air it is perhaps the last which can be expected to exhibit the greatest flexibility in application. It is a lucky aircraft designer today who is asked to design an aircraft that is just a fighter, or a ground attack interdictor. Usually an equally important, or vital, secondary role is specified in addition to the main function. If versatility is the order of the day, the weapons developers are fully capable of keeping pace with aircraft evolution. European manufacturers are well to the fore in this, where battlefield/airfield attack weapons are concerned. Recent examples include the West German Vebal/Syndrom anti-tank weapon, the Franco-German Mobidic project which combines efforts that originated in the Apache/CWS collaboration and its forerunners, and several stand-off weapon programmes. At the other end of the air-to-surface missile scale, we hear that the Soviet Union's AS-15 reached operational status in the course of 1984. Credited with a 3000 km range, it is believed in official circles that the AS-15 may have two distinct roles, although what these are has not been divulged.

Equipment

Equipment developments that need to be reflected in this year's edition are less than startling. Many of the new additions to the market are updates of existing hardware. However, the following may be noted.

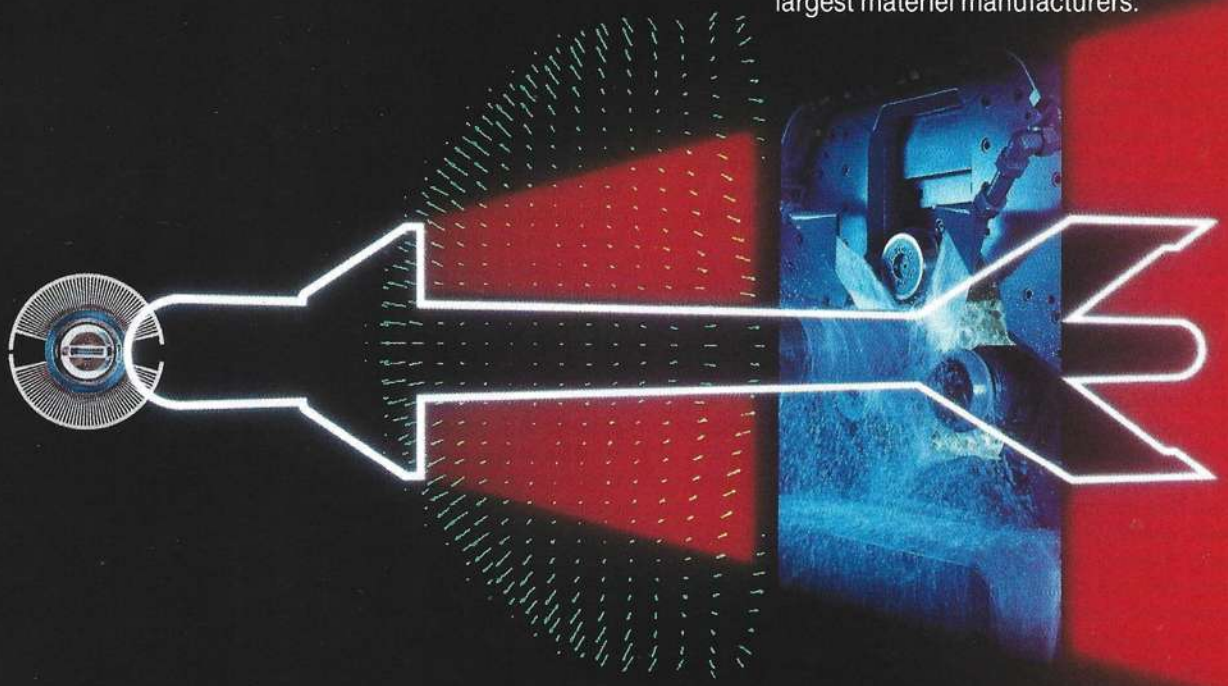
One of the more interesting aspects of the past year has been the emergence of more of the Chinese defence industry's activities and its growing participation at exhibitions around the globe. Major examples of this were the Defendory 84 exhibition in Athens, and the Paris Air Show in June 1985. Although no Chinese hardware was apparent, and what literature was available described only ageing Soviet weapons or equipment built in the People's Republic of China, it became clear that this country is engaged in an indigenous development programme of defence electronic equipments, in particular radar and EW systems. As yet no details have surfaced, but possibly in a year or two, more will be forthcoming. At least China seems to have decided to come out of its self-imposed isolation so far as defence equipment is concerned, and is now apparently interested, not only in developing an industry of its own, but also in the export markets to help support it. Third World states that have either little real need, or money, for the sophisticated systems of the West could well be a promising outlet for Chinese defence products.

On the ground radar front, the steadily increasing pace in the utilisation of electronically scanned arrays to achieve greater all-round performance and operational flexibility has now become quite clear, with more examples of such equipments, or fresh instances of their application with each new edition of this book. A last-minute example of this was the announcement by Hughes at the Paris Air Show last June that a modified version of its HADR radar had been selected for the update programme for the NATO air defence systems southern flank. The announcement apart, nothing more has been heard, the rumour was that Selenia was far from pleased and had made representations to the Italian government, and that other manufacturers of electronically scanned air defence radars in Europe were none too happy either. Hughes in recent years has achieved a prominent position internationally in air defence radar, although other market leaders in this field such as Westinghouse and GE in the USA, Thomson-CSF in France, and Plessey and Marconi in Britain all enjoy their successes around the world but perhaps without quite as much impact as Hughes. This leads us to wonder what changes General Motors' take-over of Hughes earlier this year will make in the next few years. Will Hughes still be as free to pursue the same sort of ambitious and adventurous R & D policies as those which gave the company so many 'break-throughs' in the past? Now is hardly the best time to slacken the push for new products, just when advancing component technology and other relevant radar techniques are reaching production status and finding their way into marketable hardware, and competitors are stepping up their sales efforts world-wide.

Another significant NATO radar contract that has still to be awarded as this book is being prepared for printing is the three-faced phased array radar that the US DoD has announced is to be constructed at the Fylingdales BMEWS site in Yorkshire, England, replacing the elderly mechanically scanned early warning space tracking radars currently in use. Some concern has been expressed

RAFAEL

battle-born development expertise



Rafael's unparalleled expertise can help you solve your most baffling development problems. Rafael meets the exacting demands of Israel's tough, active military.

Rafael is eminently successful in the field of defense systems development:

Total project capability, from conception to delivery—with a surprisingly short development-through-production cycle. Broad diversification. Efficient inter-disciplinary structure,

Rafael controls the most advanced technologies in guided and unguided weaponry and EW; electronics; electro-optics and thermal imaging; missile systems, including detection, propulsion and warheads; and a score of related areas.

Rafael shares its skills and techniques—in joint ventures with some of the world's largest matériel manufacturers.

that construction of this new facility may be cited by the Soviet Union as an infringment of the terms of the 1972 ABM Treaty, this sentiment possibly being triggered by a similar charge levelled by US interests that what could well be a comparable phased array radar has been constructed at Krasnoyarsk in the Soviet heartland, about 2000 miles east of Moscow. This, it is claimed, could be a sign of an impending Russian 'break-out' from the constraints of the Treaty, and indicative of a move towards implementation of the nationwide ABM system that the US fears. The Soviet contention is that the new radar is for scientific space tracking purposes, and at this stage it is probably unwise to speculate precisely where the truth lies.

Returning to the topic of more familiar types of radar, we note that agreement was at last reached on the new NATO IFF system – NATO Identification System (NIS). To nobody's surprise, the USA got its own way and virtually forced the West German government to accept the Mark XV development in the 1 to 2 GHz band. The UK, which at one stage was, in collaboration with West German industry, at the forefront of the development of a successor to the overstretched Mark 10/12 IFF, bowed to the seemingly inevitable and agreed, with reservations, to the US plan. Whether the reservations will be heeded is a different affair. In any event, Stage 2 development is already underway in the USA and Europe with systems likely to be operational in the early 1990s – if all goes well.

Another furore that won a fair share of media attention in the past year occurred in the airborne radar field, with accusations and recriminations being bandied about indiscriminately regarding delays in the entry into service of the AEW Nimrod, and in particular the GEC Avionics early warning radar with its distinctive bulbous nose and tail radomes. It is hard to sort sheep from goats in this argument: did GEC underestimate the scale of the task, or was the MoD guilty of the all too common crime of constantly advancing the system requirement to ensure that it remained ahead of the contractor's attainments? (This is not a uniquely British affliction, and one American development engineer has sworn to us that defence equipment procurement dogma holds that, "Specification development always moves 10-20 per cent faster than design implementation and production and IOC (initial operational capability) follow on later. If it ain't cancelled!). The Nimrod itself also seems to have drawn its fair share of criticism, the longer it is debated the more one is tempted to wonder if the right airframe was chosen in the first place! However, it would appear that GEC is now likely to get an overall contract to sort out the whole system – aircraft and equipment. How this is going to affect the updated NADGE set-up and communications equipment such as JTIDS is anybody's guess. In the meantime the weary old RAF Shackletons with their still older radars must hang on for a few more years.

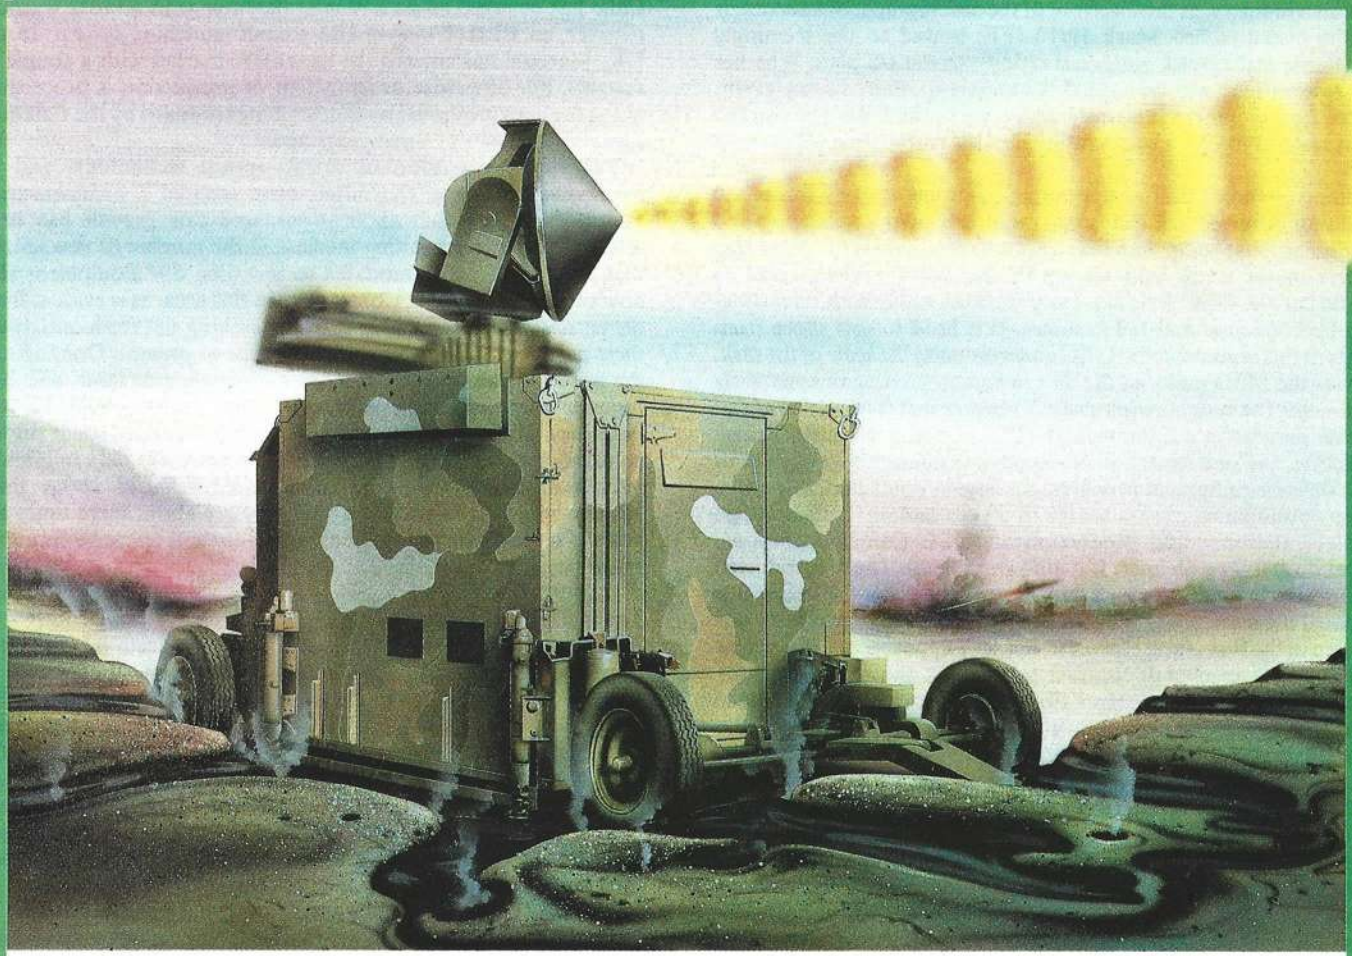
The much more modest American E-2C Hawkeye AEW meanwhile steadily builds up aircraft orders for Grumman and AN/APS-138 radar orders for General Electric from an increasing number of countries which require the added surveillance capabilities that an airborne radar provides, but which must also carefully consider initial procurement and operating costs when choosing a system.

Activity in the sonar sector of the defence electronics industry has been reported as lively though the North American section has been curiously silent, presumably for security reasons. In the UK the most important events have been the Royal Navy's selection of various new systems from Ferranti and Plessey mainly. These include the Types 2050 hull-mounted active sonar from Ferranti that is to be fitted in the Type 23 and some Type 22 frigates, and the Type 2051 by Plessey and Ferranti for the RN 'Oberon'-class submarine update. Another joint system from these companies, the Type 2054 integrated active/passive sonar has been selected for the new Trident-armed submarines. Plessey will supply the Type 2093 variable depth minehunting sonar for a new class of single-role minehunter. A new towed array sonar was revealed in 1985 by Marconi Underwater Systems, designated the Type 2052, and this is likely to be fitted to some earlier classes of UK nuclear-powered fleet submarines. A significant reshuffling of European underwater capabilities, which with the existing international co-operative arrangements that have been agreed will result in a powerful grouping, took place when Thomson-CSF combined its underwater activities with those of Sintra-Alcatel to form Thomson-Sintra Activities Sous-Marines. This combination of two major French underwater specialist groups should make for a formidable force in the European sonar and underwater weapons field.

Electronic warfare (EW) in recent years has assumed a far more 'visible' position within the defence equipment field, and there is now an obvious increase in the commercial activity associated with what is an important market sector, for both buyers and sellers. Nevertheless it is still true that reliable unrestricted information on products is normally hard to come by. Despite this, this area is responsible for a large proportion of the new entries in this edition. After this section of *Jane's Weapon Systems* expanded to almost 100 pages in the previous edition, it was decided to accommodate, the by then widely differing equipments the section contained into three sub-sections dedicated to land-, sea- and air-based items, respectively. This will provide improved facilities for readers to access the data they require.

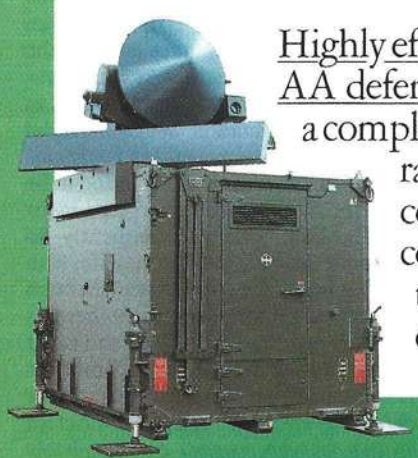
Since the previous edition, France has introduced a number of ECM and ESM equipments, mainly applicable to Mirage 2000 variants, and the US is busy developing INEWS. The latter is a joint USAF/USN project designed to provide an overall EW system for combat aircraft in the 1990s. At present it is very much at the conceptual design stage with a number of American company teams competing for the eventual development contract. Full production is foreseen in the early 1990s. From South America, Chile has emerged as an EW manufacturer with a radar warning receiver, an ELINT system and a chaff launching system. In the UK, Marconi has entered the naval EW market with a couple of systems, but otherwise development or production is proceeding along the lines prompted by shortcomings revealed by the Falkland Islands campaign of three years ago.

The steady extension of electro-optical technology, and its impressive perfection thereafter, have ensured a commensurate multiplication of E-O applications, and this growth has been reflected in a corresponding increase in the number of new entries that have to be accommodated in this (like EW Equipment also now three-part) section. Contractors in this area, as is evident from the entries, have been highly active in seeking out fresh outlets for their products and this remains very true at present. One topic in the minds of many of them is the carbon-dioxide laser, and it is thought that, although eventually this device could hit the headlines, at the moment so much money has been spent on the conventional Nd:YAG that defence ministries are only minimally interested. Much the same thing could be said about third generation image intensifier tubes: they are about three times the price of second generation tubes at the moment but are only about 25-30 per cent better.



Jane's Code Numbers

Within the last year, a normally carefully accurate and well respected organ of the news/entertainment media undertook to present *'The Jane's story'* to the public (with the Publisher's blessing and full co-operation), and this proved to be a moderately comprehensive, entertaining and basically accurate account of the founder (Fred T Jane) and his first book *(Jane's Fighting Ships)*, which led on naturally to later members of this family of military yearbooks. In attempting to place these works within their proper context, the producer of this broadcast programme included comment from both users and contemporaries in this field of publishing. This is where the oracle must have nodded!



One of the speakers observed that he found the entry numbering system employed in this book too complicated, and that finding what he wanted was sometimes difficult. (This is not in itself new, nor surprising when the average contents of a typical edition of *Jane's Weapon Systems* (JWS) amount to several thousand entries printed on around 1000 pages.) It has been suggested that his problem arose, not from the sheer volume of information which contained the item of interest, but rather that the JWS code number system somehow helped to hide it! We agree that seven-digit numbers do lack a certain 'individuality', but each one is unique, which surely makes for positive identification? This is one of the several reasons why the system was adopted for this reference volume from the very first edition. These advantages enabled the Janes editorial and production teams to manage the very considerable quantities of information involved, on a regular basis and fit in with the normal but hectic routine demands of commercial publishing.

As an aside, within Jane's, entry numbers are usually found to be more convenient than manufacturer's or operator's designation for a system or equipment item. The latter can and frequently do change in the course of the weapon's/system's operational life, with the inevitable difficulties in keeping track of a specific item through several or many editions. By allocating a discrete entry number this confusion is eliminated, and although commercial whims and other vagaries may change the title of an entry with time, its JWS number will always identify it. This is sometimes useful when by chance or design a marketing name is chosen by two contractors for different items/systems, which may in fact be very similar or completely

THE FLYCATCHER

Modern air attackers are fast and will mask their approach.
A defender hardly stands a chance.
The defender who relies on Flycatcher, does; it will catch all that flies.

Highly effective all-weather AA defence. Flycatcher is a complete, self-contained radar/weapon control unit. It can control several types of medium-calibre guns and guide short-range missiles.
The use of two separate radar bands ensures accurate tracking, also at low levels and under all weather conditions.

Flycatcher is easy to deploy by helicopter or truck and simple to operate. Flycatcher catches all that flies, by early detection and instant reaction. Ask for more information.

F2E

TACKLE THE FUTURE WITH SIGNAAL INTEGRATED SYSTEMS

different, 'Hawk' for example: this can either BAe's strike/advanced trainer aircraft, or Raytheon's Homing All the Way Killer SAM. Giving each its own number resolves the confusion.

For those who prefer not to use numerals, from the second edition of *Jane's Weapon Systems* onward a conventional alphabetical index has been included, giving readers the option of using whichever method they like best to find their way among the admittedly confusingly elaborate variety of subjects that have to comprise the contents. However those who have the patience to familiarise themselves with the JWS numbering system will find that it is capable of use for a number of additional research and collation functions to meet individual readers' needs.

If we briefly summarise how entry numbers are allocated, and the significance of the digits that go to make up the seven-figure number, this will assist in making maximum use of this book. It may be noted that the number consists of two parts: a four-digit number before the 'decimal point', and three more numerals after the point. The first part is discrete to the entry to which it refers, and generally is not changed in subsequent editions, thus identifying that particular item permanently. (Over a period of years, in rare instances, a topic is given a fresh number. This usually occurs if there has been a major alteration to some aspect(s) that materially affects the system or equipment described, calling for new or considerably modified text.)

It is the last three digits that are the most useful. These are code numbers and have no arithmetical significance whatsoever. The last figure of all denotes the section of the book in which a particular entry will be found. Thus it is always either '1', '2', '3' or '4', referring to the Systems, Platforms*, Equipment or Analysis Sections of *Jane's Weapon Systems*. These appear in that order in the book. This narrows the search for a given entry appreciably by limiting to one of four sections**.

Immediately after the 'decimal point' are two other digits, which, in the case of 'system' entries (ie. entry nos. ending in '1') describe the function of the entry described by means of the following code:

1 – Land
2 – Sea
3 – Air (including space)
4 – Underwater
5 – Data Acquisition
6 – Data Processing
7 – Display or Output
8 – Actuation, Direction or Guidance
9 – Miscellaneous
0 – Not Applicable

Thus, in the case of an air-to-air missile entry, its JWS number would be coded 'XXXX·331', and a submarine-launched ballistic missile 'XXXX·411', the first digit after the point indicating the missile's launch environment (ie. '3' for air-launched, or '4' for submarine-launched), and the next digit denotes the intended target environment ('3' for air, or '1' for land).

Where the system to be described in an entry is something other than a missile, eg. a naval tactical data handling system, the first digit after the 'point' will be used to denote the environment in which the system operates (in this case '2' on board a ship) and one of either '6', '7', or '8' will follow to indicate the predominant function of the system; 'data processing' (6) where computers form the basis of the system, 'display' (7) if a display console is the main element, or (8) if direction is the principal function of the system. A few minutes study of entries and the numbers they have been allocated will soon make the pattern clear.

In the case of Platform Section Entries (ie. those with a final digit '2') only the first digit after the point has any significance, when it indicates either a land vehicle (tank etc) when the figure '1' would be used, '2' for a ship entry, '3' for an aircraft, and '4' for a submarine. The next digit is always a '0'. Thus entry XXXX·302 would describe an aircraft or helicopter.

The coding applied to Equipment Section (final digit '3') is similar to that used for system entries in Section One, with the digits after the 'point' having the same significance as set out in the list above. In equipment entries though, the digit immediately after the 'point' is used to signify the environment in which the equipment operates, and the next figure is used to denote its main function. In practice this means that 'equipment' entries always have '3' as their last figure, and '1', '2', '3' or '4' as the first figure after the 'point'. Thus an airborne radar will be coded XXXX·353, a sonar XXXX·453, and a land-based electronic warfare equipment XXXX·193.

Readers who take the time to familiarise themselves with the system will appreciate the scope for additional uses of the code numbers for their own analysis purposes etc. For example, a list of all entries dealing with air-to-surface weapons could be readily complied by noting all entries with numbers that end '·311', '·321' or '·303'. Similarly, underwater display equipments, for instance, could be extracted by listing those entries ending '·473'.

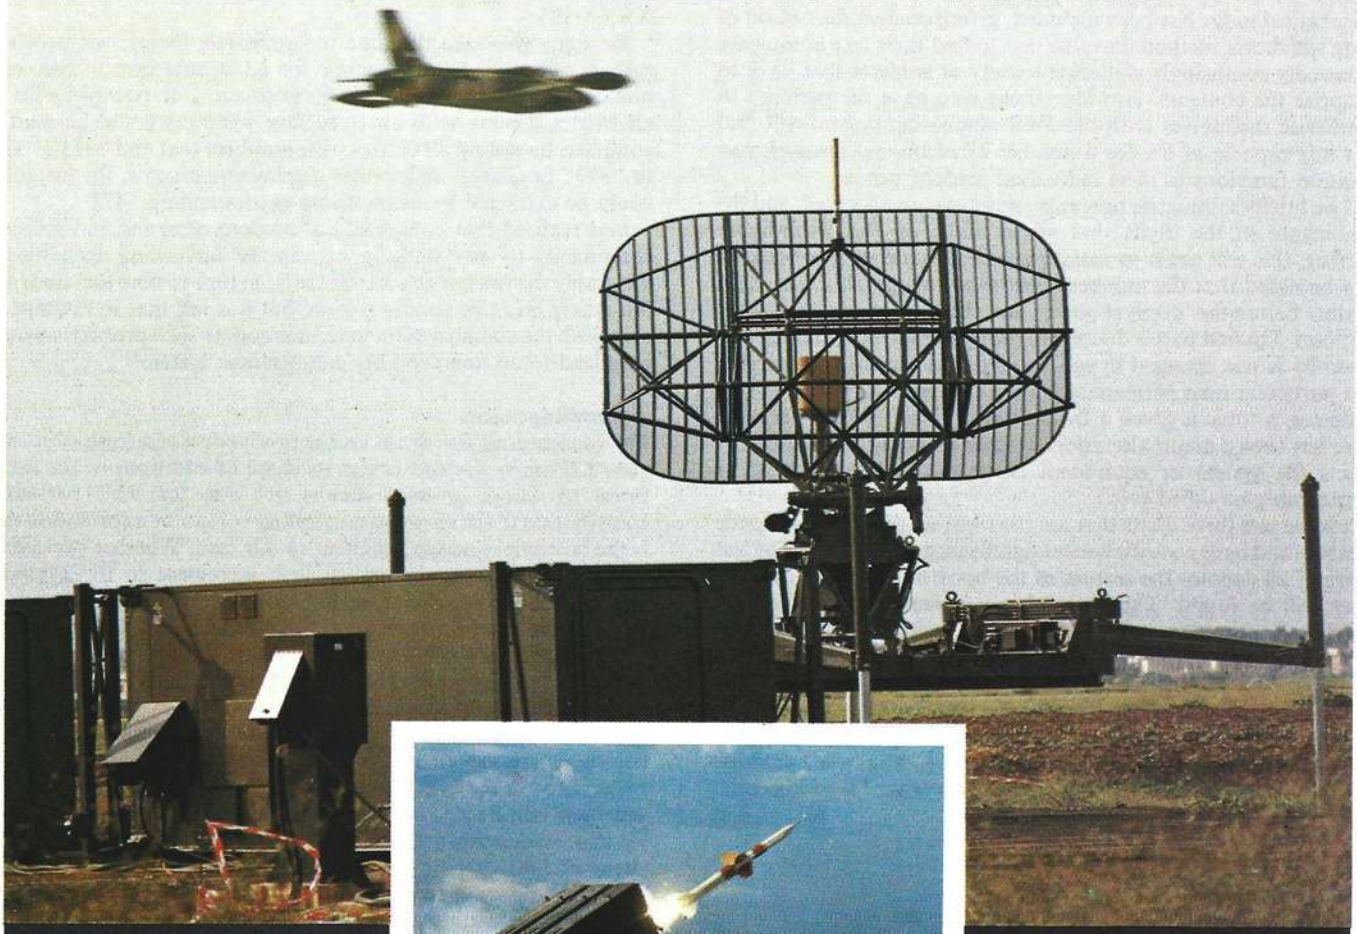
It is realised that complexity of modern weapons and military equipment, to say nothing of rapidly advancing technology, inevitably throws out new hardware from time to time that does not fall neatly into this coding system, but it is felt that to attempt to embellish the coding system to accommodate such problems would only lead to an unacceptably cumbersome system.

*Each platform category, land, sea and air, now has its own yearbook devoted entirely to that category of vehicle. Consequently, corresponding JWS platform sections were omitted some years ago although the salient data relating to each now appears in tabular form in section 4 of this book.

**Sections now number three only, now that the platform section no longer appears.

Acknowledgements

Each succeeding year spent on the production of a fresh edition of *Jane's Weapon Systems* brings its share of additions to the list of those to whom grateful thanks are due for their particular contribution to the sometimes daunting volume of information that is the customary accompaniment to our task. Whether occasional or frequent and regular, every such increment to the available aggregate of unprocessed information is greatly appreciated, as also are the helpful suggestions and comments that often accompany photographs or items of news. Many of those who help both the producers and readers of this book must remain anonymous for personal or professional reasons; we hope they will accept our assurances that, although publicly unacknowledged, their contributions are valued and greatly appreciated.



As noted in the Forward to the previous edition, Jane's defence yearbook editors now have access to a weekly defence journal, with all that association implies in the way of data exchanges, in the shape of *Jane's Defence Weekly*. We look forward to a continued growth in the scope of the collaboration between the two 'arms' of the Jane's organisation, and proffer our thanks to Robert Hutchinson, our 'contact' on 'the weekly', and his colleagues for their assistance. We hope our reciprocal endeavours have been as helpful. As ever, there is a familiar list of other 'in house' stalwarts who deserve special recognition for their particular contributions to this edition, among them: Christopher F Foss, editor of *Jane's Armour and Artillery*; Capt John Moore (RN) editor of *Jane's Fighting Ships*; John W R Taylor and Kenneth Munson of *Jane's All the World's Aircraft*; Bob Raggett editor of *Jane's Military Communications*; David F Rider, whose book *Jane's Airport Equipment* has a shared interest in certain ground radar equipment with this volume; and Terry Gander who undertakes the compilation of some inventory tables for this book in addition to co-editing *Jane's Military Vehicles and Ground Support Equipment*. The pressures of their responsibilities to their own books is well understood; their assistance and advice, whenever sought, is therefore greatly appreciated.

Other Jane's colleagues who manage to find time to seek out data for this book as well as performing their principal duties representing the advertising interests, include Anne McKrill and Arthur Browne in the United States, and Gillian Thompson in the course of her wide-ranging travels in many parts of the world. To these ladies and gentlemen our thanks for your efforts on our behalf. Always welcome are the regular consignments received from our official and unofficial correspondents abroad, and notable among them are our Washington correspondent Thomas DeFrank, Stefan Terzibatschitch, Juan Taibo, Osame Ooe, Kensuke Ebata, Wilhelm Donko, Steven Zaloga, Col James Loop and G J Jacobs, many of whom have provided photographs used in this edition. Once again we are indebted to Mr Michael Badrocke for specially drawn missile line diagrams, sometimes culled from the sketchiest of reference material and at short notice.

At the end of the day all these efforts have to be collated and prepared for the printers and bookbinders, after the editor's team of himself and staff compilers Bernard Blake and Roger Villar have dealt with the 'raw' material, by the 'in house' team under Christine Richards: Pat Taylor, Elizabeth Lye, Andrew Sharpe and Veronica Knapman.

R T Pretty — September 1985

SPADA AIR-DEFENCE SYSTEM

A new system, recently delivered to the Italian Air Force, has been added to the SELENIA weapon system products line: it's the SPADA ground-to-air missile system.
Among the others in existance SPADA is the first system designed from the beginning for the air-defence of objectives of vital importance from heavy ECM supported attacks carried out at high speed and very low altitude by highly manoeuvring aircraft or tactical air-to surface missiles.
The proven capability of SELENIA in the field of radars, both search and teacking, of C^3 systems as well as of missiles, allowed the design of a weapon system entirely now in operational concept.
Thanks to:

- The extended coverage of the PLUTO search radar and the munition used, the ASPIDE multirole missile, both fielded by a remarkable number of users.
- The high degree of ECM resistance, of system coordination, target identification capability and missile SSKP as well as the linking with higher level ADCs.

The SPADA effectiveness in reaction has been brought to the highest level to-day achievable.

AFAP	artillery-fired atomic projectile
AFATDS	advanced field artillery tactical data system
AFB	air force base
AFC	automatic frequency control
AFSARC	Air Force Systems Acquisition Review Council
AFSATCOM	Air Force satellite communications system
AFV	armoured fighting vehicle
AGC	automatic gain control
AGM	air-to-ground missile
AIAAM	advanced intercept air-to-air missile
AIM	air intercept missile
ALARM	air-launched anti-radiation missile
ALCC	airborne launch control centre
ALCM	air-launched cruise missile
ALCS	airborne launch control system
ALOC	air line of communication
ALWT	advanced lightweight torpedo
AM	amplitude modulation
AMCM	advanced mine counter-measures
AMRAAM	advanced medium-range air-to-air missile
ANG	Air National Guard
APC	armoured personnel carrier
ARINC	Aeronautical Radio Incorporated
ARM	anti-radiation missile
ARP	anti-radiation projectile
ARRADCOM	Army Armament Research and Development Command (USA)
ARS	automatic reporting system
ARSR	air route surveillance radar
ASAT	anti-satellite (weapon or system)
ASCM	anti-ship cruise missile
ASM	air-to-surface missile
ASPJ	airborne self-projection jammer
ASR	airport surveillance radar or air staff requirement
ASRAAM	advanced short-range air-to-air missile
ASROC	anti-submarine rocket
ASTAR	airborne search target attack radar
ASUW	anti-surface ship warfare
ASW	anti-submarine warfare
ASW/SOW	anti-submarine warfare/stand-off weapon
ATA	advanced test accelerator
ATAFCS	airborne target acquisition and fire control system
ATB	advanced technology bomber
ATC	air traffic control
ATE	automatic test equipment
ATF	advanced tactical fighter
ATGM	anti-tank guided missile
ATGW	anti-tank guided weapon
AUTODIN	automatic digital network
AWACS	airborne warning and control system
BADGE	base air defence ground equipment
BATES	battlefield artillery target engagement system
BCC	battery control centre
BCP	battery control post
BETA	battlefield exploitation and target acquisition
BITE	built-in test equipment
BMD	ballistic missile defence
BMEWS	ballistic missile early warning system
BUIC	back-up intercept control (for air defence)
BVR	beyond visual range
C^3	command, control and communications
C^3I	command, control, communications and intelligence
CAD	computer aided design
CADMAT	computer aided design, manufacture and test
CANE	computer aided navigation equipment
CAS	close air support
CASS	command active sonobuoy system
CASTOR	corps airborne stand-off radar
CBU	cluster bomb unit
CBW	chemical and biological warfare
CCIS	command and control information system
CCTV	closed-circuit television system
CD	civil defence
CEP	circular error, probable
CFAR	constant false alarm rate
CFV	cavalry fighting vehicle
CIA	Central Intelligence Agency
CINCEUR	Commander-in-chief, European Command
CINCLANT	Commander-in-chief, Atlantic
CINCPAC	Commander-in-chief, Pacific Command
CINCSAC	Commander-in-chief, Strategic Air Command

LCAC	landing craft, air cushion
LCC	launch control centre
LCP	launch control post

ELECTRONIC WARFARE

SATT is one of the oldest companies in Sweden as supplier of defence electronics.

In SATT Communications AB we specialize in custom designed ESM and ECM systems. Our range of products includes:

- Radar Warning Systems
- Surveillance Receiver Systems
- Microwave Jamming Systems
- Communications Jamming Systems
- EW Training Systems

SATT Communications AB
Box 32701, S-126 11 STOCKHOLM, SWEDEN. Tel. Int + 46-8-81 01 00. Telex 15325 SATCOM S

It's not just another weapon

The AMELI is the ultimate squad machine gun. Individually manned, its light weight (14.8 lbs), durability, easy handling, simplified maintenance and small size make this arm the versatile and reliable machine gun needed in today's world.

Its streamlined, pragmatic design, built-in features and attractive price for all it offers, have converted the AMELI in the automatic leader in its field.

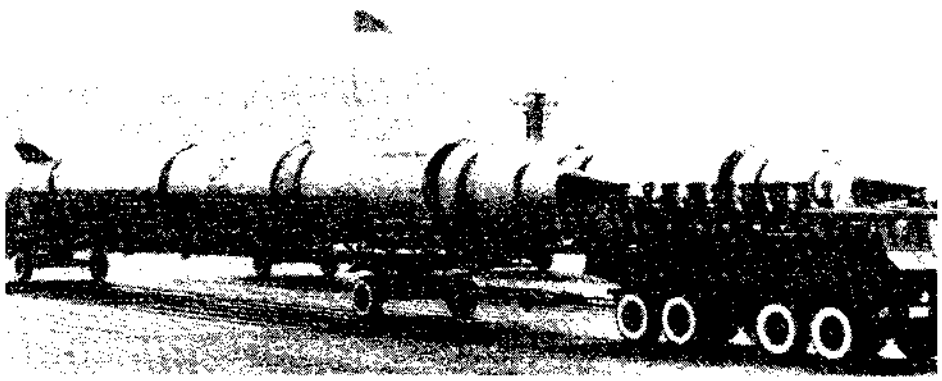
CHINA (PEOPLE'S REPUBLIC)

2010.111
CSS-1 MRBM

Liquid-fuelled medium-range ballistic missiles similar to the Soviet SS-3 MRBM have been operational in north-eastern and north-western China since 1970, although recent American reports claim operational use since 1966. Like the SS-3, Shyster, these missiles have a range of about 1100 km and it is understood that some 50 were initially deployed, a total which despite an increase of up to 100 anticipated at one time, seems to be still in the same region. The designation assigned by the American authorities is CSS-1. The first operational warheads are believed to be smaller than those carried by the Soviet missile; a figure of 20 KT has been suggested but a larger warhead may be fitted to some. In particular it is probable that those which have been most recently deployed carry thermo-nuclear warheads similar to those carried by the IRBM.

At one time it was thought that this missile would either be deployed in large numbers or be replaced by solid-fuel missiles. It now seems rather more likely, however, that the Chinese will put the majority of their effort into the ICBM and IRBM programmes and restrict the MRBM deployment to the minimum consistent with posing a significant threat to the Soviet Union while the other missiles are being deployed.



2049.111
CSS-2 IRBM

Although the Chinese IRBM and MRBM programmes have been subject to delays similar to those that appear to have affected their ICBM programme, it seems fairly clear that there has been a small-scale (15 to 20) deployment in China of a single-stage IRBM using a storable liquid propellant. This missile is understood to be similar to the first stage of the rocket which launched the first Chinese satellite in April 1970 and its range has been estimated as lying between 2500 and 4000 km. According to US sources, entry into operational service occurred in 1971 and it has been designated CSS-2.

Basing is understood to be on a basis of deployment at permanent sites from which targets in Central and Eastern Asia can be reached, although recent estimates suggest a capability for relocation of launch facilities without necessarily implying a mobile system. By late 1980 the estimated total in service had risen to about 70 missiles, with a possible national capability to add CSS-2s at a rate of between five and ten per year.

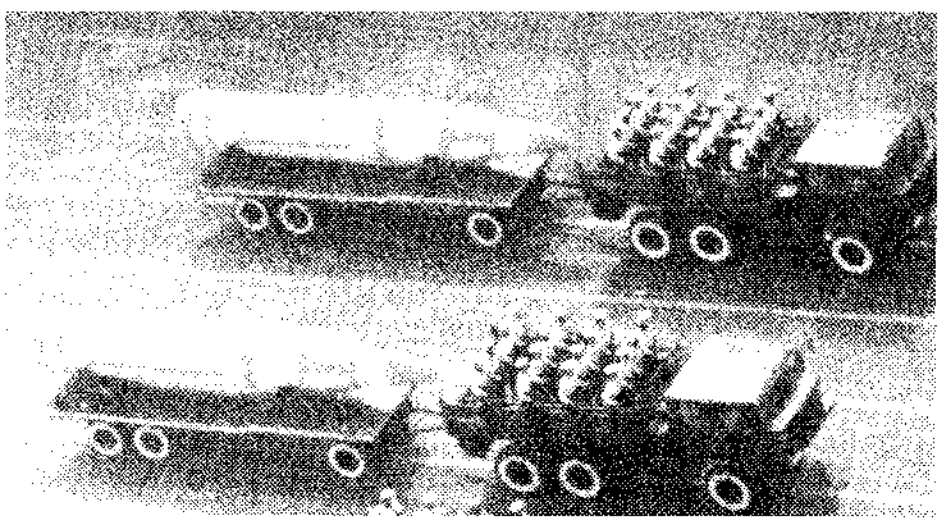
4210.111
CSS-3 ICBM

The Chinese CSS-3 long-range ballistic missile is a two-stage weapon believed to have a maximum range of around 7000 km carrying a warhead with an estimated yield of 2 MT. According to American defence analyses, two of these weapons had been deployed in silos between 1975 and 1980, by which time it was thought that another six were in the course of construction. The CSS-3 is approximately 25·5 m long and about 2·43 m in diameter and inertial guidance is assumed. Deployment is reported to be concentrated in western China from where targets in European USSR would be accessible.

CSS-3 Chinese ICBM on a ceremonial parade in Peking

Prognostications of Chinese strategic intentions and missile production and deployment should be treated with caution, as should the observation that current practice in this area of military technology appears to be keeping abreast of significant developments, while deferring inordinate expenditure on system implementation until circumstances demand otherwise. Just what these circumstances might be are grounds for speculation, but typical examples might include deterioration of relations with the super-power neighbour to the north, or a need for a strategic initiative perceived by the Chinese themselves at some future date. Notwithstanding such considerations the known evidence of the last 15 years or so does not indicate a Chinese stampede to achieve anything resembling nuclear parity in strategic terms with anyone.

4211.111
CSS-X-4 ICBM



In May 1980 China launched into an impact area in the Pacific Ocean two test rockets for what is provisionally understood to be a new strategic ICBM weapon designated CSS-X-4. The two launches achieved ranges of about 7000 km although the figures quoted by different observers vary quite appreciably, some higher (up to 13 800 km) and some lower, and the impact area was within the area bounded by the Solomon Islands, Fiji and the Gilbert Islands. No warheads were carried according to Chinese reports of the event, but an estimated payload weight of about 1200 kg suggests that a 5 MT warhead could be carried. Length of the CSS-X-4 has been estimated at about 33 m and two-stage liquid propulsion with inertial guidance is likely. US reports claim that CSS-X-4 missiles have been deployed in silos in central China, but this has not been confirmed. This missile is thought to bear the Chinese designation DF-5.

4893.411
CSS-NX-3 SUBMARINE-LAUNCHED BALLISTIC MISSILE

The People's Republic of China has been developing a new submarine-launched ballistic missile, believed to be for use with the new 'Xia' class of nuclear-powered submarine. The designation assigned provisionally to this weapon is CSS-NX-3.

It is thought to have been developed, to some extent, from the CSS-2 IRBM (**2049.111**) which has the Chinese designation DF-3. This suggests that the naval weapon will have a similar payload, probably a single 2 MT nuclear warhead and a maximum range of about 2800 km. Deployed aboard 'Xia'-class submarines (which some observers think may number 12), there will be 12 or possibly 16 launch tubes for the CSS-NX-3 SLBM in each boat.

Test firings were carried out in 1982 reportedly from a submerged pontoon (30 April 1982), and later on 12 October 1982. In 1985 it was estimated that the CSS-NX-3 system was nearing operational status, and a number of these missiles were ceremonially paraded in Peking in October 1984. At the earlier date it was claimed by Chinese sources that a number of nuclear submarines were operational with the Chinese Navy.

CSS-NX-3 SLBMs seen in public for the first time at a Peking ceremonial parade in October 1984

FRANCE

2163.111
SSBS INTERMEDIATE RANGE BALLISTIC MISSILE TYPE S-3

SSBS (Sol-Sol-Balistique-Stratégique) is a medium-range two-stage solid-propellant missile, with nuclear warhead, which is stored in and launched from an underground silo.

Launch areas are dispersed and hardened to reduce the effects of an enemy attack. Each includes the silo in which the missile is maintained in operational readiness, and an annexe housing the automatic launching equipment and servo mechanisms.

The original S-2 strategic missile force formed the main land-based element of the French 'force de frappe' from the early 1970s.

In 1973 a programme was initiated to develop the second-generation SSBS weapon system, the S-3. This programme entailed the renovation of the first two groups of S-2 silos and replacing the missiles with the S-3 model.

Retaining the same first stage as the S-2, the S-3 has a second stage of higher performance, namely, the P-6 originally developed for the MSBS. An advanced re-entry vehicle system is also included. This has a hardened thermonuclear charge and a re-entry vehicle which is hardened also against the effects of a high altitude nuclear explosion from an ABM. Other features are a new system of penetration aids designed to counter enemy defences, and a payload fairing to protect the RV during powered flight. The complete system is hardened against the effects of EMP (electro-magnetic pulse).

Improvements to the ground facilities include both equipment modernisation and system modifications to increase reliability and reduce maintenance costs.

CHARACTERISTICS

Type: Intermediate-range silo-launched, ballistic missile

Guidance: Inertial

Propulsion

First stage: SEP Type 902 motor. 4 gimballed nozzles for control. Thrust 45 000 kg

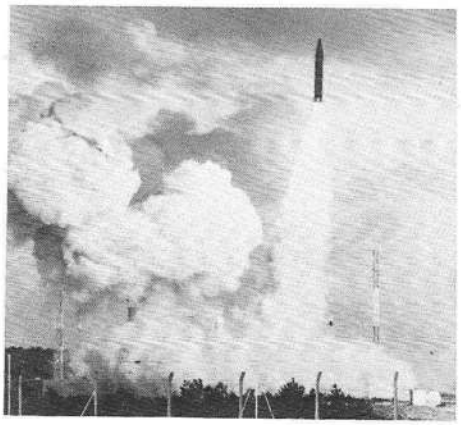
Second stage: SEP Rita II motor in wound fibreglass casing containing 6 tonnes of solid propellants. Thrust 32 000 kg. Thrust vector control by 4 freon injectors into a single fixed nozzle

Warhead: Thermonuclear (1·2 MT)

Dimensions

Length: 14 m

Diameter: 1·5 m

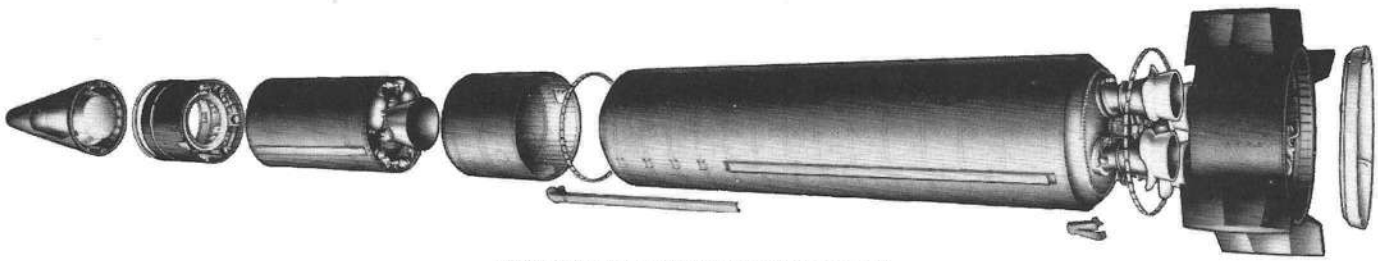


Range: Approx 1850 nm (>3000 km)

DEVELOPMENT

Development was covered by five contracts awarded to Aérospatiale spanning the six-year period 1974-80. Four contracts were from the Direction des Engins, and one from the Commissariat à l'Energie Atomique, and their combined value amounted to over $456 million. Aspects of the programme covered were: programme management; vector development; system development; experimentation and instruction for Air Force personnel; and studies, production, development, and testing related to the nuclear warhead.

STATUS



Development of the S-3 was completed and deployment began in 1980. The first group of nine S-3 missiles and their associated silo installations on the Plateau d'Albion was officially inaugurated in May 1980 and both groups of nine silos were operational by the end of 1982.

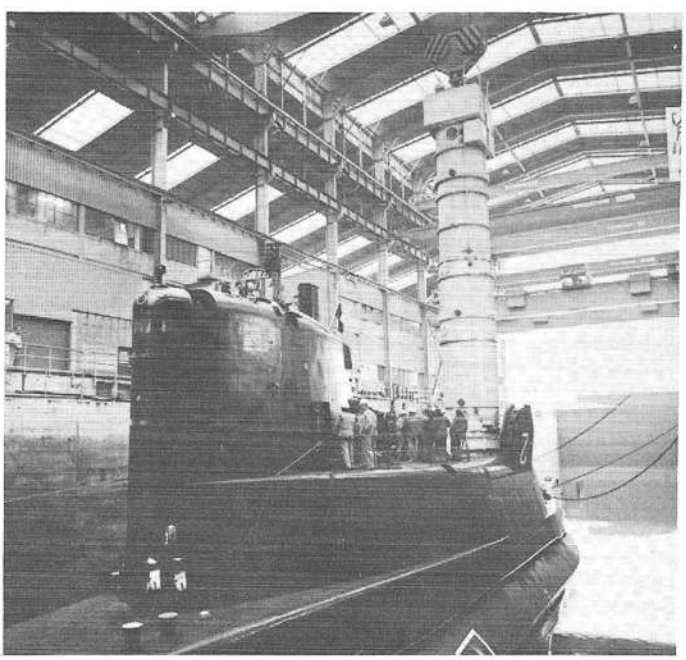
SSBS S-3 IRBM launch from the Landes test site (Aérospatiale)

CONTRACTORS

Aérospatiale is the prime contractor and integrator for the SSBS programme, and heads a team of some 200 French firms, under the overall authority of the Direction des Engins (a French Government body). The warhead and manufacture of the nuclear payload is the responsibility of the Commissariat à l'Energie Atomique.

SSBS S-3 constructional layout (Aérospatiale)

1134.411
MSBS SUBMARINE LAUNCHED BALLISTIC MISSILE



MSBS (Mer-Sol Balistique Stratégique) is a medium-range, two-stage submarine-launched weapon forming a vital part of the French nuclear deterrent force. In general concept it is similar to the American Polaris missile family.

The M-1 version went into service in 1971 but was phased out in favour of the M-2 in 1974 which by mid-1977 had itself been supplanted by the M-20.

The current MSBS force is based on six nuclear-powered submarines (SLNE - Sous-marines Nucléaire Lanceur d'Engins balistique), each able to carry and launch 16 missiles. The MSBS fleet will consist of the submarines, *Le Redoutable*, *Le Tonnant*, *Le Terrible*, *Le Foudroyant*, *l'Indomptable* and *l'Inflexible*. Construction of the last of these began in 1978 and it will join the fleet soon.

Logistical support for the MSBS system is provided by the Ile Longue Naval Base in Brest Bay where there are the assembly and storage facilities necessary to keep the missiles in operational readiness.

The M-20 has an upgraded re-entry vehicle system which includes a thermonuclear charge, hardening against the effects of an ABM explosion at high altitude and improved penetration aids, and is now being deployed.

Loading M-4 in experimental submarine Le Gymnote

CHARACTERISTICS - M-20 MISSILE

Height: 10·4 m

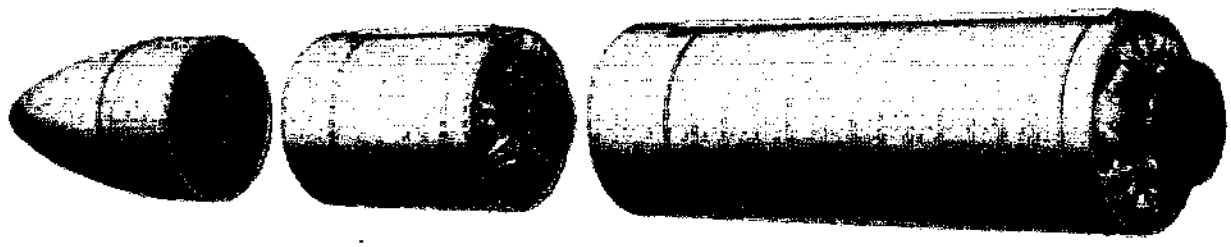
Diameter: 1·5 m

Weight: 20 tonnes (approx)

Guidance: Inertial

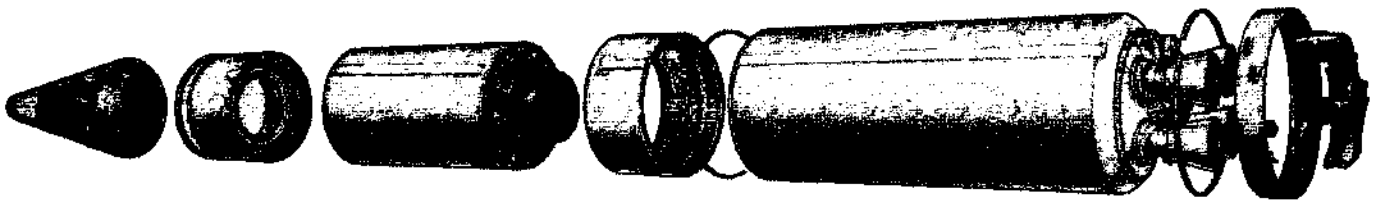
Propulsion

First stage: Type 904 motor in a flow-turned Vascojet 1000 structure. Control by 4 gimballed nozzles. 10 tonnes of solid propellant. Combustion time 50 s and thrust 45 000 kg



Second stage: Rita II motor in a wound glass fibre casing containing 6 tonnes of solid propellant. Internal thrust vector system of control using freon injection into single fixed nozzle. Combustion time 52 s and thrust 32 000 kg

Warhead: Thermonuclear 1 MT



Range: About 3000 km

A completely new generation of MSBS, designated the M-4, is at the development stage. The range will be significantly increased to over 4000 km and multiple thermonuclear warheads are planned. M-4 missiles will be deployed on existing submarines after certain modifications have been carried out.

A three-stage propulsion system is employed; the

New generation M-4 MSBS

Current M-20 MSBS

M-4 MSBS launch from submarine Le Gymnote

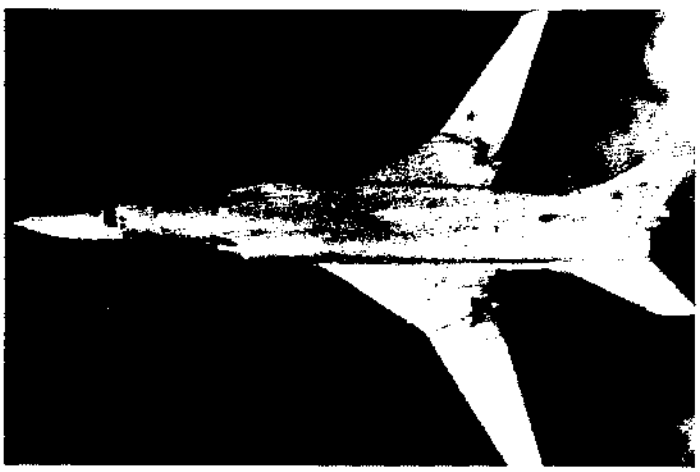
first stage (M-401) has a metal casing, while the other two motors (M-402 and M-403) have wound casings of Kevlar material produced in the USA.

The experimental submarine *Le Gymnote* was used for M-4 tests.

CHARACTERISTICS – M-4 MISSILE
Height: 11·05 m
Diameter: 1·93 m
Weight: 35 tonnes
Guidance: Inertial
Propulsion

First stage: Type 401 motor with 20 tonnes of solid propellant and 4 flexible nozzles

Second stage: Type 402 motor with 8 tonnes of solid propellant and 1 flexible nozzle



Third stage: Type 403 1·5 tonnes of solid propellant with flexible nozzle
Warhead: MRV
Range: >4000 km
STATUS
The M-20 is operational and the M-4 became operational in 1985. The first M-4 test launch took place (from the Landes Test Range near Biscarosse) in November 1980. The 12th firing took place from *Le Gymnote* in July 1983 with successful results. Despite its larger diameter, the M-4 missile can be carried in the tubes of first generation SNLEs after certain modifications, and the earlier submarines will be converted from the M-20 to the M-4 one at a time after the M-4 enters service in *l'Inflexible*, in 1985. It has been reported that an improved version, designated M-4C is being developed.
CONTRACTORS
As in the case of the SSBS, the governmental agency in control is the Direction des Engins and the industrial prime contractor is the Division des Systèmes Balistiques et Spatiaux of Aérospatiale (SNIAS) whose responsibilities, in addition to the missile itself, include the on-shore assembly and check-out operations at the naval base, as well as the command and control launch procedures aboard the submarines.

UNION OF SOVIET SOCIALIST REPUBLICS

2952.111
SS-4 (SANDAL) MRBM
Known also by the NATO code-name Sandal, the SS-4 is a low medium-range ballistic missile which is a developed version of the SS-3 (Shyster).

SS-4 was first shown in public in 1961, but was deployed originally in 1958; it became a standard MRBM in the Soviet armed forces. It was also the missile that lay at the root of the Cuban crisis in 1962. Depending on the weight of the warhead the missile has a range of between 1500 and 1800 km.

The complete weapon system comprises about 12 tractor vehicles with special trailers. Some 20 men are required to erect and launch the missile. Official US sources report that the SS-4 has a reload capacity when fired from soft sites; it is also deployed at hardened sites but without a reload capability. The guidance system employed was originally radio command, operating on guidance vanes in the efflux nozzles, but it was observed at the time of the Cuban crisis that a changeover to inertial guidance had taken place.
CHARACTERISTICS
Type: Medium-range ballistic missile
Guidance principle: Inertial
Guidance method: By control of elevators and of guidance vanes in the efflux nozzles
Accuracy: Typically 2400 m CEP
Propulsion: 1 liquid propellant sustainer
Warhead: Optional nuclear (1 MT) or HE

Backfire bomber can perform strategic nuclear or conventional bombing, reconnaissance, and other missions

Missile length: About 21 m
Missile diameter: About 160 cm
Launch weight: About 27 000 kg
Speed at burn-out: Mach 6 – 7
Range: About 1800 km
STATUS
The SS-4, and a considerably increased number of SS-20 mobile IRBMs, forms a major part of the armament of the Soviet Strategic Rocket Force. Since 1977, according to official US estimates, the proportion of SS-4 and SS-5 missiles has slowly declined as the SS-20 successor system is deployed, the SS-4 less rapidly than the SS-5. Nevertheless by 1985 it was estimated that there were only about 120 SS-4s remaining operational, while the SS-5 had to be completely withdrawn, apart from possibly a few training installations.

Map summary of principal Soviet strategic assets. Note: details of longer-range IRBM force deployments and strength appear in the text

---

4207.111
SS-11 (SEGO) ICBM

The SS-11 Sego ICBM has been reported in four distinct versions at one time known in official American publications as Mods 1, 2, 3 and 4 but now referred to in three models only. Although still remaining the most numerous of Soviet ICBMs, it is now regarded as a 'third generation' ICBM. Despite having given way to replacement by newer weapons to some extent, it remains a very common member of the Soviet Union's ample strategic armoury of land-based missiles. The basic missile is a two-stage storable liquid propellant rocket with a range of between 10 000 and 13 000 km, which when it entered service around 1966 carried a single warhead payload.

The Mod 2 is thought to have become operational in 1973, although at one time the absence of any evidence of operational testing was taken as indicative of cancellation. However, firings in the latter part of 1975 suggested crew training which implied deployment of this version. Like the Mod 1, a single RV is carried, but in the case of the Mod 2 this is accompanied by penetration aids. The Mod 3 version, when it was detected soon after the Mod 2, was noted for a different RV and warhead arrangement, in particular an MRV equipped with three warheads. No details of the size of these warheads have been discovered but it has been deduced that they are unlikely to be less than the 200 KT of each of the warheads carried by the US Minuteman III.

CHARACTERISTICS

Type: Silo-launched intercontinental ballistic missile
Guidance: Inertial
Propulsion: Storable liquid
Warhead: Single nuclear (Mod 1); single nuclear plus penaids (Mod 2); 3 MRVs probably about 200 KT each (Mod 3)
Dimensions: None available, but length believed to be about 20 m and diameter approx 2·5 m (max)
Range: 10 000 – 13 000 km

STATUS

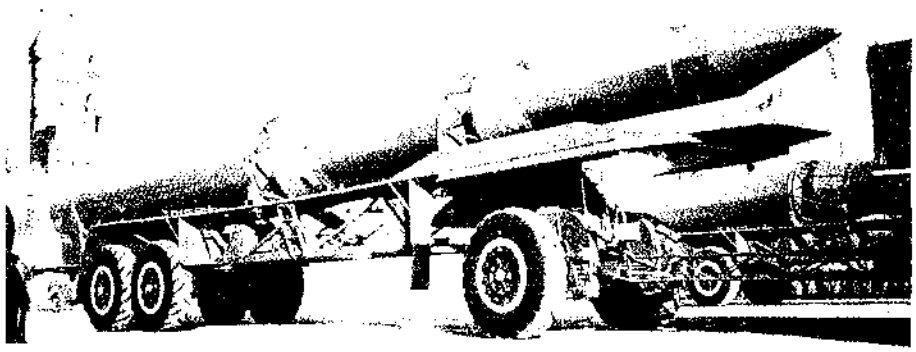
Widely deployed with the Soviet Strategic Rocket Forces from around 1970 in various versions, but since then many SS-11 silos have been converted to house SS-17 and SS-19 missiles. The SS-11 is still deployed extensively in many parts of the USSR, and in early 1981 there were about 500 deployed operationally altogether, mostly positioned opposite the Soviet Union's borders with China, Europe, Scandinavia, and the Middle East. The official US view in early 1984 was that there were 520 in all, made up of 100 Mod 1 S-11s and 420 Mod 2 and 3 versions. This situation still maintained at the beginning of 1985.

SS-11 Sego ICBM in its launch canister which is loaded into silo with the missile to aid reload and preparation for second launch

---

2958.111
SS-13 (SAVAGE) ICBM

First seen in public in 1965, this missile, which may be known to NATO as Savage, is a three-stage solid-propellant ICBM that has been said to be comparable with the US Minuteman.



The three stages of the missile shown here are separated by truss structures and each has four nozzles. The upper stages are believed to be identical with the two stages of the SS-14 Scapegoat missile (**2961.111**).

Although the missile has been in service for some time it has never been deployed statically on a large scale. So far as is known, moreover, it has never been equipped with other than a single warhead. One of the new generation of Soviet strategic missiles is said to resemble the SS-13 closely and this missile (the SS-16, **2990.111** in 1982-83 and earlier editions) has also been reported to be limited at present to a single warhead.

CHARACTERISTICS

Type: Intercontinental ballistic missile
Guidance principle: Presumed inertial
Propulsion: 3-stage, solid-propellant motors

Warhead: Nuclear, estimated 1 MT capability
Missile length: Overall 20 m (including interstages). 1st stage 8·7 m. 2nd stage 4 m. 3rd stage 3·5 m. Nose cone and re-entry vehicle 2·3 m
Missile body diameters: 1st stage 1·7 m. 2nd stage 1·4 m. 3rd stage 1 m. Nose cone and re-entry vehicle 1 m
Missile base diameters: 1st stage 2 m. 2nd stage 1·9 m. 3rd stage 1·4 m
Range: 8000 – 10 000 km
STATUS
Operational with about 60 deployed in early 1982. Most of these are believed to be based in two areas: one in the region around Ivanovo, to the north-east of Moscow; and in the neighbourhood of Yashkar O.a, between Gorki and Kazan.

Savage three-stage solid-propellant ICBM

2991.111
SS-17 ICBM
The SS-17 is thought to bear the designation RS-16 in the Soviet Union's own numbering system, but since (as usual) no confirmation or denial is forthcoming from official sources it is not proposed to use this designation at the present time. The information is included only in case it should be of possible use to readers in future. Described by official US sources (with the SS-18 and SS-19) as a 'fourth generation' Soviet ICBM, the SS-17 two-stage storable liquid-propellant ICBM is one of two Soviet missiles regarded as successors to the widely-deployed SS-11 missile (**2984.111** in 1980-81 and earlier editions). Both it and the other SS-11 replacement, the SS-19, have a MIRV payload capability, improved accuracy, increased throw-weight, and greater survivability than their predecessor. The SS-17 is slightly longer than the SS-11 and of increased volume. The cold-launch technique is used, whereby the missile is ejected from the silo by a gas generator before the main booster is ignited, whereas the SS-19 relies upon the conventional hot-launch technique. In a later assessment of this aspect of Soviet ICBM force practice, the US DoD states that all liquid-propellant ICBMs now deployed by the USSR are contained in a launch canister within the silo. This acts as a liner to minimise incidental damage to the silo during missile launch and to facilitate reloading.

The most important aspect of these new missile developments, however, is the introduction of MIRV-type warheads. Both the SS-17 and the SS-19 are reputed to have on-board computers and have been tested with such warheads; furthermore, since the SS-17 is credited with only a four-warhead MIRV capability whereas the SS-19 is said to be able to carry six MIRV warheads, it would seem that two different MIRV systems are involved. This lends colour to an official US view that the two missiles have been developed in competition with one another – although this seems to be a little out of keeping with normal Soviet practice. The SS-17 has been tested with a single, large RV which might be allied to the potential accuracy enhancement conferred by the post-boost vehicle to achieve an improved hard target capability.
CHARACTERISTICS
Type: Intercontinental ballistic missile
Guidance: Inertial. Computer-controlled RV arrangement
Propulsion: 2-stage storable liquid-propellant rocket motors. Cold-launch
Warhead: Nuclear. MIRV system of 4 – 6 warheads. Yield not known but probably not less than 200 KT each (Mod 1); single high-yield RV (Mod 2); four 750 KT MIRVs (Mod 3)
Dimensions: No details known. Length appears to be about 24 m and base diameter about 2·5 m but little reliance can be put on these figures
Range: 10 000 km (Mod 1); 11 000 km (Mod 2); 10 000 km (Mod 3)
STATUS
Operational. Tests are said to have been observed for the first time during the second half of 1972 and there was intensive testing during 1973 and early 1974. Deployment in converted and modernised SS-11 silos began in 1975. By 1980, 150 SS-17s were deployed operationally in converted SS-11 silos and this was considered to represent the total number under present Soviet modernisation plans. The estimated total of 150 SS-17s in early 1982 apparently still holds good, although the converted SS-11 silos are now thought to contain Mod 3 SS-17s with four warheads with MIRV payloads.

2992.111
SS-18 ICBM
The SS-18 has been reported as having the designation RS-20 in a Soviet identification series, but since this cannot be confirmed the information is included only as a matter of general interest and record.

Largest of the 'fourth generation' of Soviet intercontinental ballistic missiles, the SS-18 is said to be the functional successor to the SS-9 (**2962.111** in 1980-81 and earlier editions). It is a very large two-stage liquid-propellant missile with a considerable payload capacity which in one model includes a post-boost vehicle which may carry a bus-type MIRV system with an on-board digital computer. By 1983 four different versions of the SS-18 had been identified, each with a different payload/range ratio, as follows:

SS-18	Mod 1	Mod 2	Mod 3	Mod 4
Warheads	1	8/10	1	10
Max range (km)	12 000	11 000	16 000	11 000

The US authorities are sure that increased accuracy has been a major consideration in the development programme, presumably with the intention of enabling the missile to attack hardened targets successfully. Some of the more recent tests, moreover, have been carried out using a single RV, from which it is deduced that the USSR may have a continuing interest in a missile with a single very powerful warhead. However later official assessments have mentioned the possibility of directing two of the SS-18s MIRVs against the same ICBM silo target, in which case the tests with a single large warhead might have been part of a comparative test programme designed to establish the best way of countering silos of greater hardening levels. This would be a logical step if the Soviet authorities believed that America was following a similar ICBM modernisation programme as the USSR (ie. increased hardening of own silos and infra structure allied to improved ICBM accuracy).

SS-18 is transported in a canister that is also used to load the missile into its ICBM silo as shown in this US sketch

Like other current fourth generation Soviet ICBMs the SS-18 is deployed in a launch canister which is inserted into the silo with the missile. Its purpose is to provide some protection to the silo launch mechanism/structure during launches to enable the silo to be reloaded and used again with minimum delay after the first firing.
CHARACTERISTICS
Type: Intercontinental ballistic missile
Guidance: Inertial. Computer-controlled RV arrangement
Propulsion: 2-stage liquid-propellant rocket motors. Cold-launch
Warhead: Single nuclear (Mod 1); 8/10 MIRV < 1MT (Mod 2); single 20 MT (Mod 3); 10·5 MT (Mod 4)
Dimensions: No details available. Length appears to be about 35 m and base diameter about 3 m
Range: 12 000 km (Mod 1); 11 000 km (Mod 2); 16 000 km (Mod 3); 11 000 km (Mod 4)
STATUS
Deployed operationally in 1974 in former SS-9 silos and launch complexes converted and improved to accept SS-18s. By 1982 the task of converting SS-9 silos to house SS-18s was thought to have been completed and the number of SS-18s deployed then was estimated to be 308; the present level of deployment of this system. In late 1983 it was reported that SS-18 silos had been hardened to enable them to withstand an overpressure of 6000 psi. It was thought to have been achieved by using concrete reinforced by concentric steel rings. The geographical distribution within the Soviet Union (see map of strategic forces) suggests that SS-18s are mostly located centrally in the Dombarovskiy, Imeni Gastello, Aleysk, Zhangiz Tobe and Uzhur missile fields. The total number deployed is estimated as 308, the majority of which are thought to be Mod 4 missiles with ten MIRVs.

2993.111
SS-19 ICBM

The Soviet designation RS-18 has been ascribed to the SS-19 by some observers but as this cannot be confirmed at present, it is not proposed to use this designation for the time being.

The SS-19 is a two stage liquid-propellant weapon with an on board computer and MIRV warhead system.

With the cold-launch SS-17, the hot-launch SS-19 has been designed as a successor to the SS-11 missile (**2984.111** in 1980 81 and earlier editions). It has a throw weight three or four times that of the older missile. It is also of greater volume. Its guidance system is said to combine (inertia-?) navigation with a refinement of the traditional Soviet 'fly-the-wire' guidance technique. An on-board computer determines deviation from the pre-programmed course and directs correction to that course or plots a new course depending upon the attendant circumstances.

Slightly larger than the SS-17, it is also provided with a MIRV capability, reported by being able to disperse four or six RVs. There is also a single RV version, Mod 2, which appeared after the MIRV model. This suggests that the Mod 2 payload may be a high accuracy high yield design. A Mod 3 version, which is said to combine high accuracy with a MIRV payload, was reported to have entered service in 1980, this model having a payload of six 0·5 MT warheads.

Latest of the Soviet 'fourth generation' ICBMs now operational, although a hot launch system, the SS-19 is deployed in canister launch containers which are loaded into the silos to facilitate reload and refire capability in the same way as SS-17 and SS-18 ICBMs.

CHARACTERISTICS

Type: Silo-launched intercontinental ballistic missile.
Guidance: Inertial. Computer-controlled RV arrangement.
Propulsion: 2-stage liquid-propellant rocket motors.
Warhead: Nuclear. MIRV system of 4 or 6 warheads. Yield not known but probably 200 KT each (Mod 1); single advanced design RV (Mod 2); 6 × 500 KT MIRV (Mod 3).
Dimensions: Length about 25 m; base diameter about 2·75 m.
Range: 10 000 km.

STATUS

Deployed operationally in 1974. The first SS-19 test detected took place in April 1973. With the SS-17, this missile is replacing SS-11 ICBMs, the silos being improved at the same time as they are converted to receive the later type of missile.

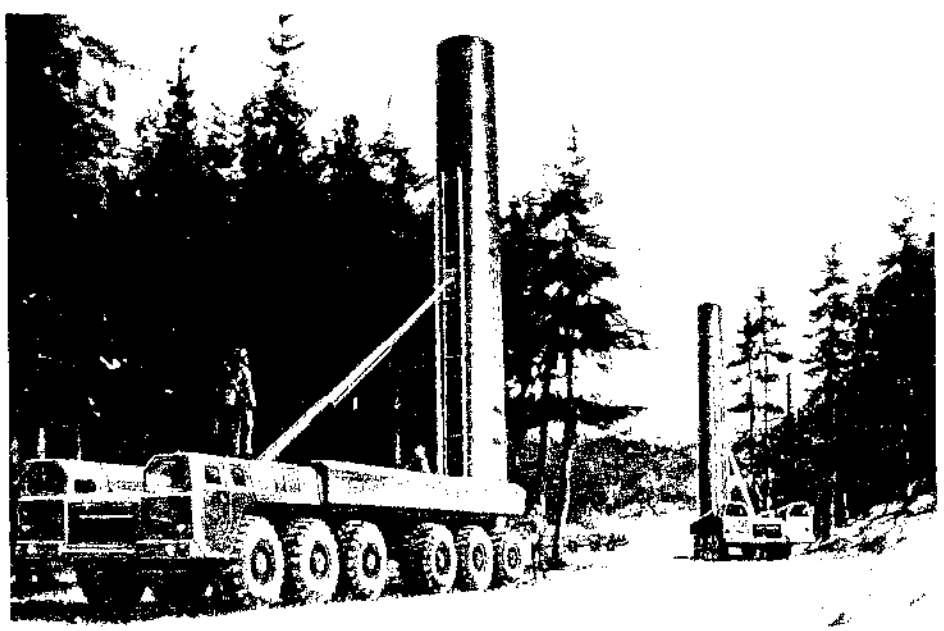
In 1984 it was estimated that there were 60 SS-19 Mod 2 missiles and 300 SS-19 Mod 3 missiles deployed in the Soviet Union, mostly in the major Derazhnya, Kozelsk, Pervomaysk and Tatishchevo missile fields.

3219.111
SS-20 MOBILE IRBM

The SS-20 is regarded as a replacement system for the elderly SS-4 and SS-5 IRBMs (**2952.111** and **2981.111**), and its origins are generally thought to consist of two stages of the SS-16 three-stage solid-propellant ICBM. SS-4, SS-5 and SS-20 deployment between 1978 and 1983 revealed a steady decrease in quantities of the first two types matched by comparable increase in SS-20 deployments, which tends to confirm the idea that the newer missile was designed as a replacement for the earlier types.

Whereas quite good photographs of its predecessors have been available for some time, photographic evidence about the SS-20 is extremely limited and generally of poor quality. Therefore open sources are mostly forced to rely upon fragmentary details culled from official (principally US) assessments when attempting to estimate the characteristics of this weapon. The SS-20 is a two-stage solid-propellant mobile IRBM about 16·4 metres long with a multiple warhead capability and a maximum range generally accepted as between 4000 and 5000 km, although this latter parameter is the subject of various opinions as will be mentioned. Inertial guidance is employed and a figure of 400 m CEP is usually accepted, although inevitably this must rest to a significant extent on the accuracy with which the initial launch site has been surveyed and with range. Some reports claim that there are a significant number of pre-surveyed launch sites in the USSR, but that this is not absolutely essential for operation of the SS-20.

The missile is fired from a transporter/erector/launcher vehicle which is probably of the wheeled type. Recent official US reports surmise that SS-20s are deployed in groups of nine missiles, probably with their supporting command and control and support vehicles as well as supply of reload missiles (one for each launcher). Among the support vehicles there may be a meteorological unit to provide accurate local wind and other atmospheric data affecting the launch site, in the interests of system accuracy. The SS-20 is said to be capable of refiring after launching the first missile, but considerable heat is involved in each launch so that it may not be possible to prepare for a second launch in less than a few hours, according to some authorities.



The payload of the SS-20 is another feature that is still debated. Most authorities suggest three MIRVs of 150 KT yield, with an alternative of a single larger warhead, while elsewhere the first of these is defined as the SS-20 Mod 1; SS-20 Mod 2 being the second alternative of a single 1·5 MT yield; and a third option (SS-20 Mod 3) being one 50 KT warhead with a maximum range capability of 7400 km. US intelligence estimates believe that each SS-20 battery contains nine launchers, each with one triple-warhead missile, plus a reload missile.

STATUS

First recorded deployments of the SS-20 took place in 1977 and by the end of 1980 it was estimated there were 180 operational launchers in use. From January 1981 onward, the pace of SS-20 base construction increased and in May 1983 official US estimates claimed there were 351 operational SS-20s in the Soviet Union of which 243 are based in the European portion of the USSR west of the Ural Mountains. The remainder are to the east of this range and are presumed to be targeted on China, Japan and South Korea. The total of 243 facing NATO remained the same until early 1984, apparently to substantiate the Soviet moratorium on deployments that lasted until the breakdown of the Geneva arms limitation talks. However, the overall total of SS-20 deployments according to US figures in February 1984 was 378 launchers (with some additional reload missiles). Other sources quoted even higher figures.

Specific areas where it is claimed SS-20 launch complexes have been noted include the Yecheva, Yurya, Verkhnaya Salda, Omsk, Caspian Sea area, Novosibirsk, Drouyanaya and Olovyannaya regions. The possibility that the Soviet authorities might decide to deploy SS-20s in the northeastern regions of the USSR to present a rapid threat to parts of the continental USA has been voiced by certain US observers.

Towards mid-1985 SS-20 deployments were quoted as having reached a total of 414 missiles, of which 243 were in the western part of the USSR. At that time it was reported that test flights had started of a new version of the SS-20 with a more accurate, possibly single warhead, payload. In January 1985, it was anticipated by official US sources that between 60 and 110 additional SS-20 deployments were planned.

US sources report SS-20 complexes of up to nine missiles, each with three nuclear warheads and with reloads for each launcher. Artist's impression shows typical deployment at unprepared sites

4778.111
SS-X-24 ICBM

The US code SS-X-24 has been assigned to a new type generation ICBM being developed by the USSR, possibly as an eventual successor to the existing SS-18 ICBM (**2992.111**). Few details beyond those revealed (or leaked) from US Intelligence assessments, are available to open sources. These indicate that the SS-X-24 is probably of about the same size as the American Peacekeeper (MX) advanced ICBM, with an estimated length of between 21 and 22 metres, and up to 10 RVs carrying payloads of unknown yield. As a successor to the SS-18 a range in the region of 12 000 to 16 000 km would be in order, but there is no evidence concerning this parameter of the new weapon. It has been presumed by official US observers that the SS-X-24 uses solid propulsion and three stages are assumed. The 'cold' launch technique is used.

Official DoD reports have stated that the SS-X-24 is probably more accurate than either the SS-18 Mod 4 (11 000 km range version) or the SS-19 Mod 3 (**2993.111**), and it is assumed that both this and the other new ICBM being developed in parallel, the SS-X-25 (**4779.111**) will have a greater hard target kill potential (HTKP) than their predecessors. In other words they are expected to be able to redress the balance of advantage against the effects of American silo hardening programmes.

It has been estimated that both mobile (transportable) and silo based versions of the SS-X-24 may appear, but the silo housed model is thought the most likely to be deployed with the mobile version several years later.

Mobile versions of the SS-X-24 are seen as being a Soviet attempt to match American defence thinking to

the extent that a rail-mobile version with the missile in a launcher container is carried on a railway vehicle ressembling a freight wagon for movement over the nation's rail network. Construction of a series of protective tunnels (*a la* MX, Peacekeeper) is reported to have been started. Another mobile model carried on a tracked chassis is also said to be in development.

STATUS

The first flight test reported in the West took place in October 1982, and under direction of the Plesetsk Test Centre, testing continued thereafter at a rapid pace so that the 10th test in September 1983 (a failure) narrowly preceeded a flight of November 1983 when eight RVs were launched, apparently successfully.

US sources expect first deployments to be in some existing SS-11 silos at first, possibly in 1986, with these being followed by the rail-mobile version within two years.

Rail-mobile basing is projected for new Soviet SS-X-24 ICBM; others include hardened silos and tracked cross-country vehicles

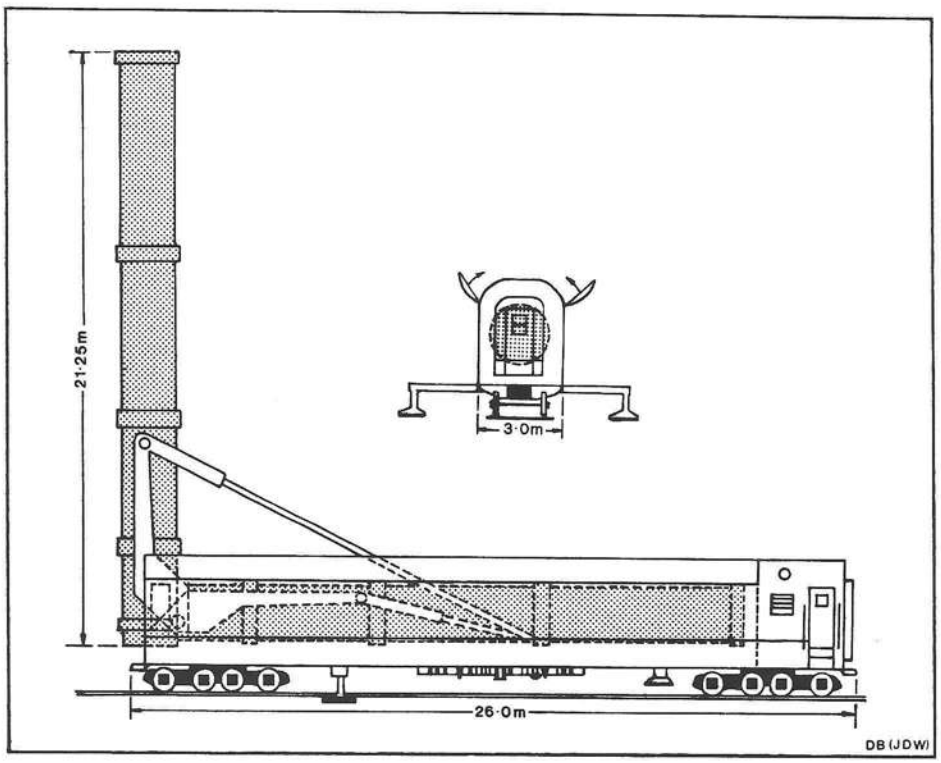


Diagram of rail-mobile SS-X-24 operation (Jane's Defence Weekly)

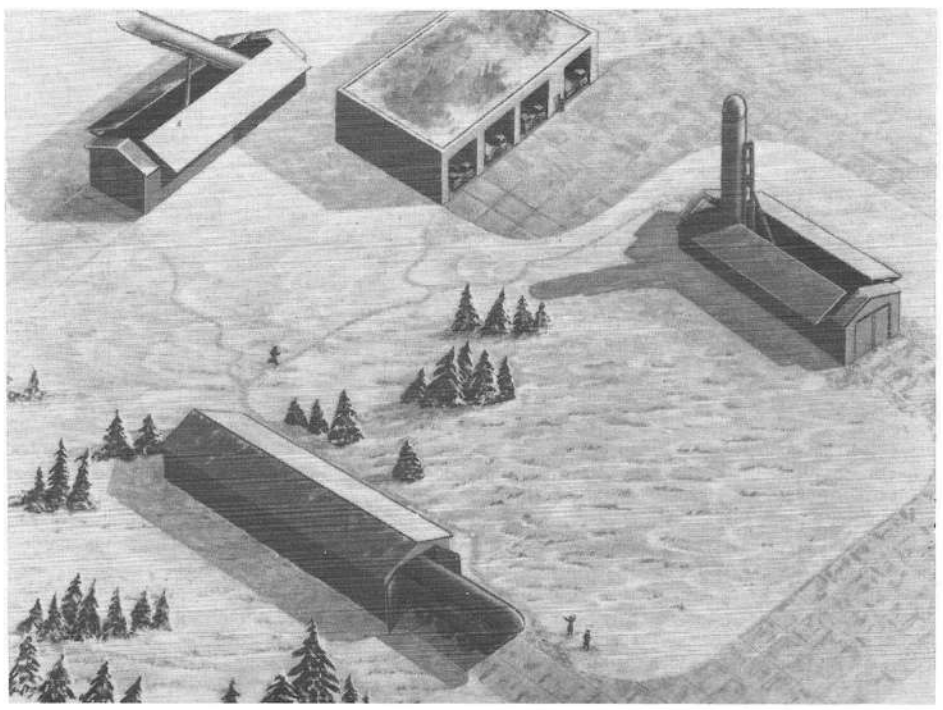
4779.111



SS-X-25 ICBM

The designation SS-X-25 has been assigned to what is believed to be a new, 'fifth generation' ICBM now being developed as a possible successor to the existing SS-19 ICBM (**2993.111**). US intelligence estimates, upon which most of what has been revealed to date is based, suggest that the SS-X-25 is of about the same size as the US Minuteman ICBM, with a length of between 18 and 19 metres.

Solid propulsion is used and the missile has three stages. A single re-entry vehicle is thought to be carried but there have been no published estimates of the possible yield of the warhead so far. Like its contemporary, the other new Soviet ICBM SS-X-24, the SS-X-25 is thought to be capable of either silo deployment or operation in a mobile form. The latter mode of deployment is officially considered the most likely to appear in the foreseeable future. US official drawings of possible SS-X-25 deployment (see illustration), which are presumably based on satellite intelligence photographs, reveal a noticeable similarity with the now widely deployed SS-20 mobile IRBM (**3219.111**) which prompts the suggestion that the SS-X-25 might be a development of the earlier weapon.

The Soviet Union is stated to have claimed that it is a development of the old SS-13 Savage ICBM (**2958.111**) and hence not an infringement of SALT agreements. Subsequent intelligence reports have yielded a link of a sort that could be held to support the Soviet contention (see below) but this is hardly conclusive.

US DoD opinion believes that in any case the SS-X-25 will possess a greater HTKP than predecessor systems, principally by virtue of better accuracy. Any assessments of this aspect of the SS-X-25 presumably must have been derived from monitoring telemetry data obtained during test flights carried out at the Plesetsk missile range. US reports (unofficial) have stated that some of these tests were notable for the fact that telemetry was sent in encrypted form, and the legality of this in respect of the SALT II terms has also been questioned.

This official US artist's impression of the new SS-X-25 ICBM system in operation suggests that the now abandoned 'race-track' MX basing mode idea may live on in Soviet minds

STATUS

Test flights of the SS-X-25 that have been reported in the West include: a failure on 27 October 1982; another from Plesetsk to the Kamchatka Peninsula (6436 km) on 8 February 1983; in the period February-May 1983 there was one failure, but one successful flight on 10 May 1983, and on 30 May there was an SS-X-25 launch with four RVs.

In early 1985, official US sources stated that two bases, thought to be for the SS-X-25, were nearing operational capability, these being of the type shown in the nearby illustration (issued by the US DoD). It has been estimated that initial operational capability (IOC) would occur in 1986, but unconfirmed Intelligence reports that have appeared in public claim that deployment had already started by the beginning of 1985.

US Press reports, claiming to quote the CIA's National Intelligence Daily publication, state that it is planned to deploy 460 SS-25s at two launch sites before the end of 1985. Deployments were claimed to have taken place in 1984 at Yoshkar Ola and Yurya. The former has silos containing SS-13s and the latter is said to be an SS-20 site. At Yoshkar Ola 60 SS-13s are thought to have been replaced with SS-25s with triple RVs, and the newspaper report added that 200 road-mobile SS-25s are to be deployed at each of the above sites. Later US press reports, also claimed to be based on leaked official Intelligence information, said that 24 concrete shelters for SS-25s had been completed at Yoshkar Ola and that the existing SS-13 silos there were being modified, possibly in preparation to receive SS-25 missiles. This report also stated that another 24 SS-25 shelters had been completed in the Yurya SS-20 launch area.

4894.111

SOVIET ICBM DEVELOPMENT

Both official and unofficial/leaked US sources claim to have evidence of development work on new Soviet ICBMs, additional to those specifically stated to be on the point of deployment such as the SS-X-24 and SS-X-25 weapons described in **4778.111** and **4779.111**, above. This entry summarises what has been gathered from these various sources regarding those Soviet ICBM programmes that appear to have adequate reference material to justify assigning provisional identities to them.

The fourth edition of *Soviet Military Power, 1985*, issued by the US Government, refers to "recent activity at Soviet ICBM test ranges [which] indicates that two additional new ICBMs are under development", and goes on to state, "A new ICBM to replace the SS-18 is nearing the flight test stage of development. Additionally, a solid-propellant missile that may be larger than the SS-X-24 will begin flight testing in the next few years. Both of these missiles are likely to have better accuracy and greater throw-weights than their predecessors."

Press reports in 1984, which were stated to be based on information from official US Intelligence sources, claimed that one of these new weapons had been identified as the replacement for the SS-18 (**2992.111**) and designated **SS-X-26**. This missile is reported as having been seen at the Plesetsk missile test range where flight testing was thought to be about to start in 1985. This has not been confirmed but could have taken place. Unlike the SS-18, the SS-X-26 uses solid-propellant rocket motors, and is said to be significantly larger than its predecessor. This observation is stated to be based on the size of SS-X-26 silos seen at Plesetsk.

The same report assigns the number **SS-X-27** to the other ICBM development identified by the Intelligence sources from new silos at the Tyuratam missile test centre and engine testing at a Soviet experimental facility at Dnepropetrovsk. This missile too will be much larger than the SS-18, and like it is powered by a liquid-propellant motor, these being the liquid-fuelled motors tested at Dnepropetrovsk. Where the SS-X-27 ICBM will fit into the overall Soviet strategic plan, what its basing arrangements will be and its final configuration remain, for the present, a matter for conjecture.

4819.001

SOVIET CRUISE MISSILE PROGRAMME

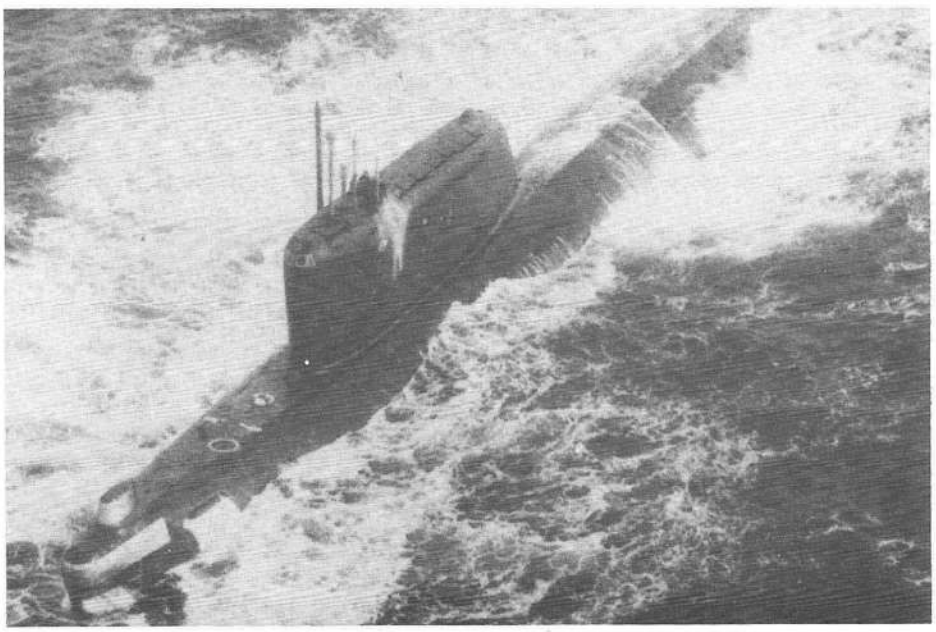
The Soviet Union has a long experience of cruise missile operation, admittedly mostly within a naval context, but signs have been detected that a programme to extend the areas of application of this category of weapon in Soviet service is now well advanced. Recent US analysis claims to have evidence of new air-, sea- and ground-launched cruise missiles of several types under development with one of them possibly reaching initial operational status by 1985.

The first category of cruise missile is believed to be very similar in design concept and physical parameters to the American Tomahawk (**3993.001**, **4197.221** and **4194.111**), and like that weapon, the Soviet cruise missile is expected to appear in a sea-launched version SS-NX-21 (**4796.411**), as an air-to-surface missile AS-X-15 (**3206.311**) and as a counterpart to the USAF GLCM in the SSC-X-4 ground-launched version. Insufficient data has been disclosed to make possible more than a general assessment of this class of Soviet cruise missiles, but it is thought that overall length is in the order of 7 metres and that a single warhead could be carried a distance of up to 3000 km. An air-breathing turbojet is the likely power plant, but the precise form of guidance is more open to doubt at this stage.

It has been suggested that SSC-X-4 missiles will be deployed with four-round mobile launcher vehicles, but this cannot be confirmed at present. US estimates suggest a possible operational deployment from 1985 onward, and it is thought that cruise missiles will be used in a similar fashion to Soviet Army rocket forces and SS-20 mobile ballistic missile units. The probable operational role will be in support of theatre operations. Flight tests of what is believed to be the SSC-X-4 cruise missile have been reported in 1984.

In addition to the Soviet 'Tomahawk-equivalent', the USSR is pursuing the development of a much larger class of cruise missiles, maybe about 12 or 13 metres long. These are expected to make an appearance in two or three years time, and there are likely to be both ground-launched and naval versions. No designation has been assigned to the ground-launched version, as yet, but the naval model is expected to undergo testing in a newly converted 'Yankee'-class submarine with the designation SS-NX-24. It is thought this weapon could be operational in about two years (ie in 1987) but a ground-launched version, if one is being developed would be several years later still.

Both the new categories ('Tomahawk'-class and 'large') Soviet cruise missiles are likely to be armed with nuclear warheads at first. The decision to provide alternative conventional payloads will depend on the type of guidance system employed, and the capability to attack hard targets that its accuracy provides.



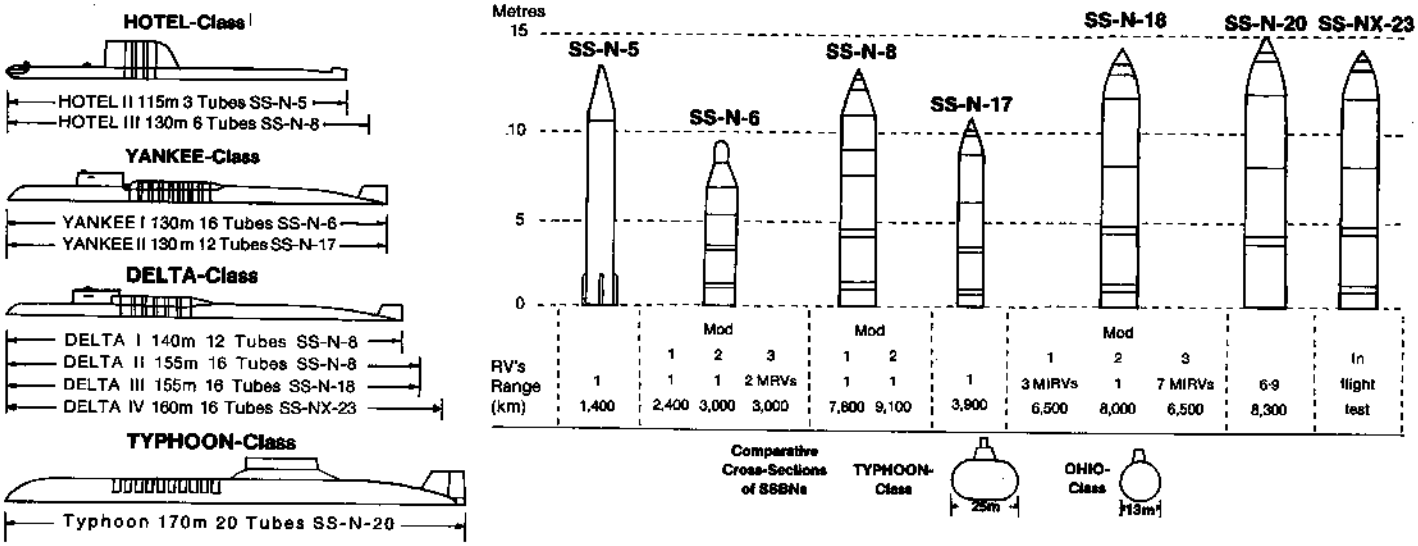
1153.411

SS-N-5 (SERB) SUBMARINE LAUNCHED BALLISTIC MISSILE

Serb is the code-name assigned by NATO to the successor to the Sark (**1152.411** in 1980-81 and earlier editions) Soviet submarine-launched ballistic missile. Serb has been described as representing the second generation in this class of missiles in the USSR.

Like its forerunner, Serb is similar in appearance to the Polaris A-2 missile in service with the USN, and it is understood to be a two-stage solid-fuel vehicle with inertial guidance. In size it conforms more closely with the dimensions of Polaris than does Sark, which is appreciably larger. According to official US information, the SS-N-5 is approximately 12·9 m in length and has a maximum diameter of 1·42 m. Launch weight has been estimated at around 18 tons. While there is fairly close agreement among the various authorities on these dimensions, there is no agreement on the missile's range capability. Estimates vary from about 1200 km to about 2400 km but the lower figure is more likely. A single re-entry vehicle with a warhead in the megaton range is carried.

When the Serb missile was displayed in the November 1967 parade, what is apparently a different ejection system to that employed in American submarine launcher tubes was revealed. At the base of the missile there is a cluster of 18 small, electrically fired cold-gas nozzles which are used to eject the missile from the sealed launcher tube. On passing clear of the submarine the section carrying these gas motors is jettisoned from the main missile body by explosive bolts fired when the first stage ignites.



Some 'Hotel' class submarines can carry three SS-N-5 SLBMs. Both boats and missiles are aged

STATUS

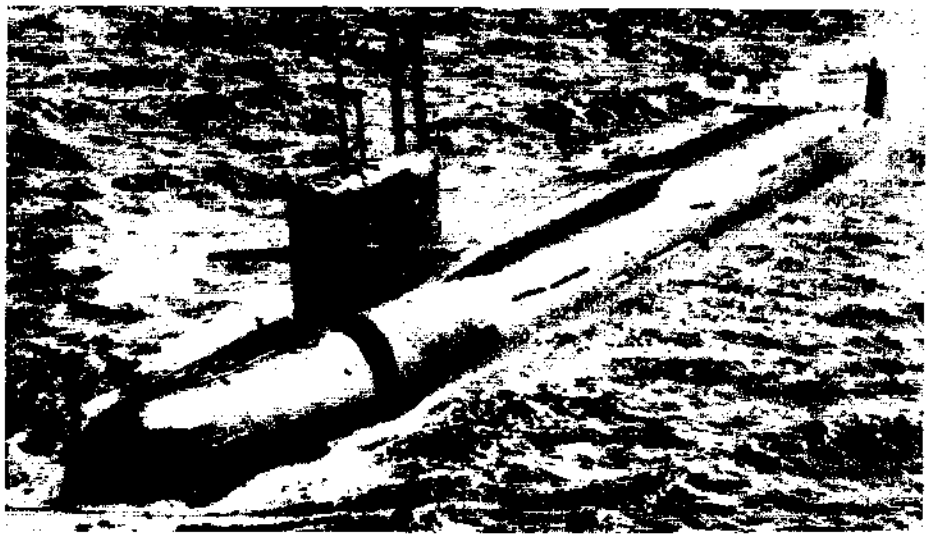
Operational (since 1963) in the later 'G' class (conventional) and the later 'H' class (nuclear) submarines on scales of two or three launchers per submarine. Estimates vary as to the number of SS-N-5s remaining operational. The Stockholm International Peace Research Institute (SIPRI) made an estimate of nine SS-N-5 missiles at the beginning of 1984, but the distribution of these among the much-modified 'Golf' class SSBs and 'Hotel' class SSBN submarines at this time is not certain. The SS-N-5 is regarded as obsolescent.

USSR Nuclear Ballistic Missile Submarines and Missiles

Soviet SLBM capability: Diagram showing composition of Soviet strategic submarine fleet and capabilities of SLBMs they carry. The first 'Typhoon' class submarine with SS-N-20 missiles has completed sea trials and is deployed at a base on the Kola Peninsula. Production of 'Delta III' class ships armed with SS-N-18 third generation SLBMs is believed to be nearing its end with 14 launched. Each has 16 tubes. Delta II boats have 16 SS-N-8 tubes, while earlier 'Delta I' class boats have 12 tubes. In 1984 there were four Delta II and 18 Delta Is. One 'Yankee III' class boat is fitted for SS-NX-17 tests, while 23 Yankee I & II class boats are deployed with SS-N-6 Mods 1 or 3. There is a declining number of 'Hotel II' ships which operate the ageing SS-N-5 SLBM, and one 'Hotel III' trials ship for the SS-N-8

1154.411
SS-N-6 (SAWFLY) SUBMARINE LAUNCHED BALLISTIC MISSILE

All three versions of the SS-N-6, Sawfly, submarine-launched ballistic missile are liquid-fuelled, and, based on US information, 9·65 m long and 1·65 m in diameter.



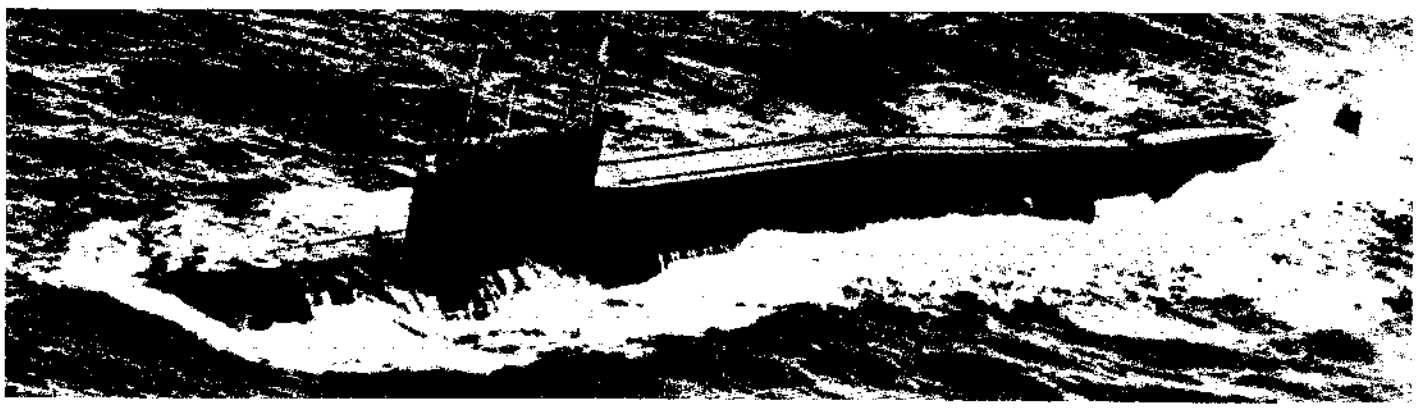
The Mod 1 is a single warhead version with a reputed range of 2400 km. In October 1972 flight tests began of a modified version which became known as the Mod 2 and this was given an increased range of about 3000 km, by virtue of an improved propulsion system. According to the American authorities the SS-N-6 Mod 2 is now capable of reaching any target in the USA from the 100 fathom contour off the coasts of the USA.

The SS-N-6 Mod 3 is the latest of the Sawfly development and has a range of some 3000 km, carrying a payload of two MRVs. These are not independently targeted.

An American DoD assessment claims that the combination of accuracy and yield of all three SS-N-6 versions is sufficient only for strikes against soft targets.

STATUS

The SS-N-6 entered service in 1968; the Mod 2 began operational service in 1973, closely followed by the Mod 3. Current deployments are all on 'Y' class nuclear submarines. It is likely that Mod 1 missiles are being replaced progressively by Mod 2 and 3 types.



'Yankee' class nuclear-powered SLBM submarines armed with SS-N-6 missiles

Production of 'Y' class submarines ended in 1975, when there were 34 boats of this class. Since 1978, to comply with the terms of SALT 1, the Soviet Union withdrew 12 'Yankee I' boats from SLBM duties to allow the overall Soviet ballistic missile submarine fleet to remain within the limit of 62 modern SSBNs established in 1972. Some of the laid-up 'Yankees' are thought to have been refitted as attack or cruise missile submarines. A US estimate of early 1985 stated that probably 336 SS-N-6 missiles remained in operational service.

3078.411
SS-N-8 SUBMARINE LAUNCHED BALLISTIC MISSILE

For some time past the SS-N-8 was thought to be a possible development of the SS-N-6 (Sawfly), but recently the US Defense authorities have claimed sufficient new evidence to justify regarding this weapon to be sufficiently different to warrant another designation. As yet, no NATO code-name has been issued or leaked in open sources.

According to official US data it is about the same length as the SS-N-5 at 12·95 m, but of increased diameter, approximately 1·65 m. It is the same diameter as SS-N-6 so that its greater length gives it an appreciably larger volume. It employs liquid-fuelled propulsion and can carry a single warhead to a range of almost 8000 km. The guidance system is said to incorporate stellar-inertial techniques, capable of

'Delta II' class submarines are armed with 16 SS-N-8 SLBMs compared with the 12 carried by 'Delta I' class boats

CEP values of 0·4 km. The American Chairman of the Joint Chiefs of Staff, General George S Brown, USAF, in 1980 said that the SS-N-8 is unique in having a range of 7800 km, exceeding by at least 3000 km the range of any other SLBM deployed in either the USA or USSR.

At one stage the possibility of three models of the SS-N-8 was reported but later information is that two versions entered service: Mod 1 with a single RV and a maximum range of 7800 km; and Mod 2 with 2 RVs and an increased range of 9100 km.

STATUS

The SS-N-8 was operational by 1973 and is now deployed in 'D' class Soviet submarines. In mid-1983 it was estimated that the Soviet Union had a total of 22 operational 'Delta' class submarines, with the 18 12-tube Delta Is and the 4 16-tube Delta IIs both armed with the SS-N-8 but an official US total of 292 SS-N-8s in service published in early 1985 implies a fleet of 19 Delta Is and four Delta IIs, ie one more Delta I. 'Delta III' class boats are armed with the later SS-N-18 (**3357.411**) and 'Delta IV' class boats with the SS-NX-23 SLBMs (**4795.411**).

3356.411
SS-NX-17 SUBMARINE LAUNCHED BALLISTIC MISSILE

The SS-NX-17 is one of two second-generation Soviet SLBMs (the other being the SS-N-18, **3357.411**, below) to appear in the mid-1970s and is the USSR's first SLBM to use a solid propellant and to be equipped with a post-boost vehicle (PBV). The latter feature strongly suggested an MRV or MIRV capability, although to date only single re-entry vehicle payloads have been reported.

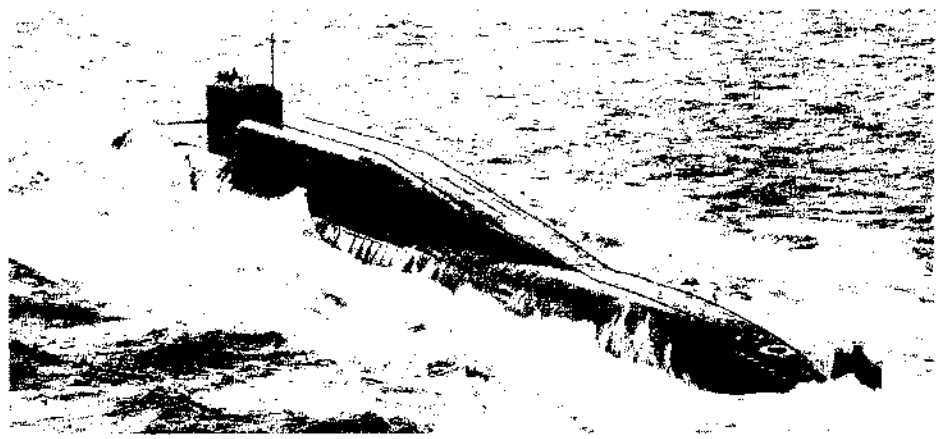
It began testing in 1975 and is believed to have been engaged in periodic sea trials since 1977 in a converted 'Yankee' class submarine with 12 missile tubes.

According to American official information, the SS-NX-17 is about 11·06 metres in length and 1·65 metres in diameter. Estimated range is 3900 km and inertial guidance is assumed.

The role of this weapon in the Soviet SLBM programme is far from clear from the available evidence to date. Evidence in open sources is mostly of the 'negative' sort, the most recent example being the dropping in official US sources of the 'X' (denoting experimental) from the SS-NX-17 designation. No reason has been given in support of this change and as there has apparently been no move to deploy this missile in any more submarines than the one 'Yankee' class boat that has been the sole platform for the SS-NX-17 since 1977, we see no justification for deleting the 'X' and thereby implying operational status for this system.

A single submarine of an ageing class seems an unlikely basis for a new strategic weapon system, and the seeming lack of urgency and/or progress in the programme could be indicative of an essentially R & D oriented effort that may have failed to live up to expectations thus far.

3357.411
SS-N-18 SUBMARINE LAUNCHED BALLISTIC MISSILE



The alternative Soviet designation RSM-50 has been suggested as applying to the SS-N-18 but as this has not yet been confirmed it is not proposed to use this designation for the present.

The SS-N-18 SLBM began flight tests shortly after the SS-NX-17 (**3356.411**) in 1975. It is similar in some respects to the SS-N-8 (**3078.411**) but somewhat larger, and is believed to be equipped with a more sophisticated guidance system. Liquid propellant is used and US estimates of maximum range give a figure of about 7500 km. Like the SS-NX-17, it is equipped with a large post-boost vehicle (PBV) and American sources claim to have identified three models. Mod 1 has a payload of three MIRVs and a range of 6500 km; Mod 2 has a single RV and 8000 km range; and the Mod 3 carries seven MIRVs with a maximum range of 6500 km.

Official US information suggests a missile length of about 14·1 m and a diameter of approximately 1·8 m, which places the SS-N-18 at the top of the list of SLBMs in terms of volume, but the American Trident II (D-5) SLBM will be of comparable size.

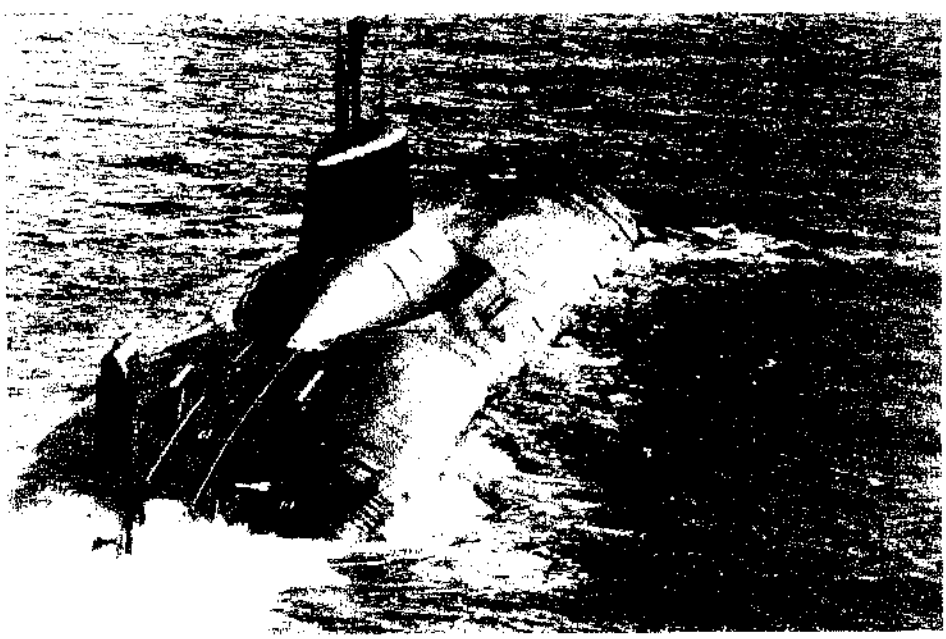
STATUS

Before November 1976, the SS-N-18 was tested from land-based launch sites in the USSR, but in early November the first submarine launch took place in the White Sea. There was another test in September 1978 when the SS-N-18 reached an impact area in the Pacific Ocean. In early 1979 the US DoD revealed deployment of the SS-N-18 aboard 'Delta III' class submarines. This had been confirmed by 1983 when it was estimated that there were 14 'Delta III' class submarines, with 16 tubes each, armed with the SS-N-18 SLBM. There was a total of 224 missiles operational in early 1985.

'Delta III' class nuclear-powered submarines are armed with 16 tubes each for SS-N-18s, most numerous of the Soviet Union's third generation of SLBMs

4208.411
SS-N-20 SLBM

This submarine launched ballistic missile was first mentioned in the 1981-82 edition of *Jane's Weapon Systems*, when the US designation included an 'X' for experimental or under development, i.e. SS-NX-20. In 1984 the US authorities deleted the 'X' and stated that with the entry into service of the first of the giant 'Typhoon' class of submarines, the SS-N-20 SLBM system that these ships fit is now considered operational.



According to US Intelligence estimates, the solid-propellant SS-N-20 is marginally larger than the SS-N-18 (**3357.411**), but probably carries a payload that offers more re-entry vehicles (up to nine compared with the seven of the SS-N-18 Mod 3) while having a greater range than the SS-N-18 Mod 2's 8000 km, at an estimated maximum of 8300 km.

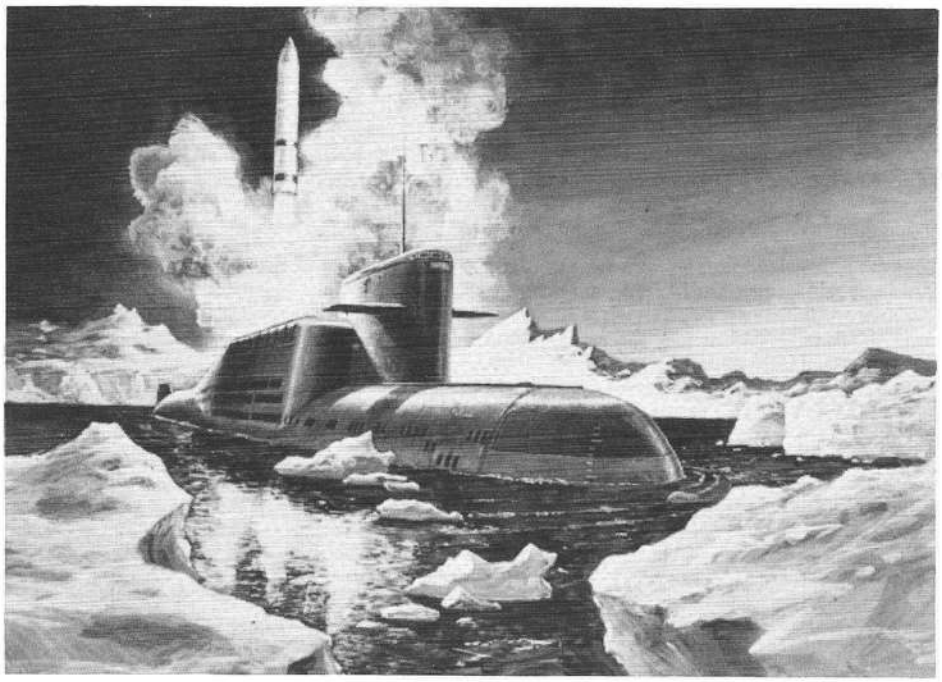
In the 'Typhoon' class submarines, which displace about 25 000 tons, 20 SS-N-20 missiles are stowed in two rows of launch tubes located forward of the boat's sail.

STATUS

Flight tests of the SS-N-20 were first detected in January 1980, reportedly with mostly unsuccessful results. Two more successful tests were reported in 1981, and in October 1982 a simultaneous submerged launch of four missiles took place. The first 'Typhoon' class submarine was launched in September 1980, and the second and third ships of the class by 1984. US authorities believe there may be three or four more of the class now under construction so that by the early 1990s there might be eight of these powerful boats operational.

In 1985 US authorities expected flight testing of a modified SS-N-20 to begin shortly.

Soviet 'Typhoon' class submarine is armed with 20 SS-N-20 SLBMs



4795.411
SS-NX-23 SLBM

Western intelligence authorities claim to have detected the existence of a new Soviet submarine launched ballistic missile under development to which the designation SS-NX-23 has been assigned. Few details have been divulged apart from the estimates that it has a larger throw-weight than the existing SS-N-18 SLBM that it is thought likely to succeed.

The SS-NX-23 is expected to be deployed in a new member of the 'Delta' class of submarines and to feature multiple re-entry vehicles and warheads with improved accuracy. Although flight tests of the new SLBM have been reported by the US DoD, no estimates of range or other performance characteristics have been released. The SS-NX-23 is thought to employ a liquid propellant rocket motor system but the number of stages is not known.

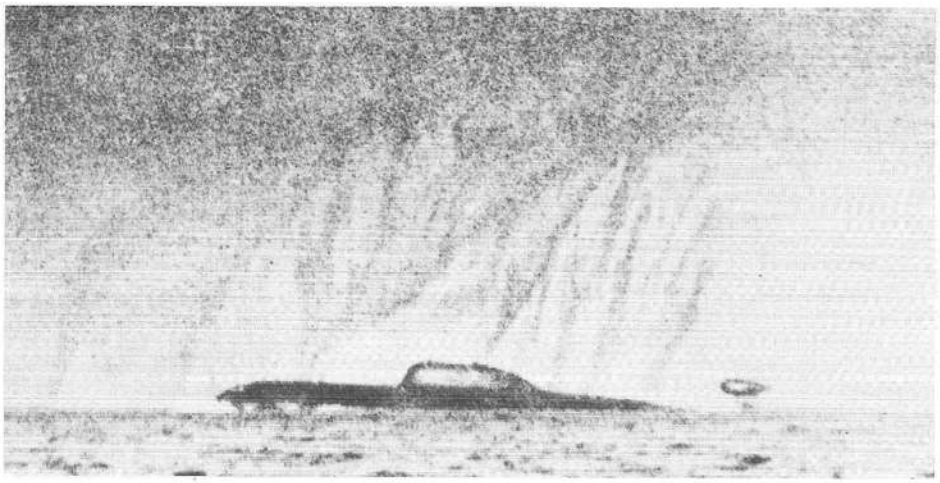
STATUS

Development. Flight testing is thought to have started in 1983. It has been suggested that the SS-NX-23 could enter operational service by 1985-86. Two ships of the new 'Delta IV' class had been launched by 1985, and as well as arming this class, SS-NX-23s may also replace SS-N-18s in 'Delta III' submarines.

An American vision of how SS-N-23 SLBMs could be launched by 'Delta IV' submarines from Arctic waters

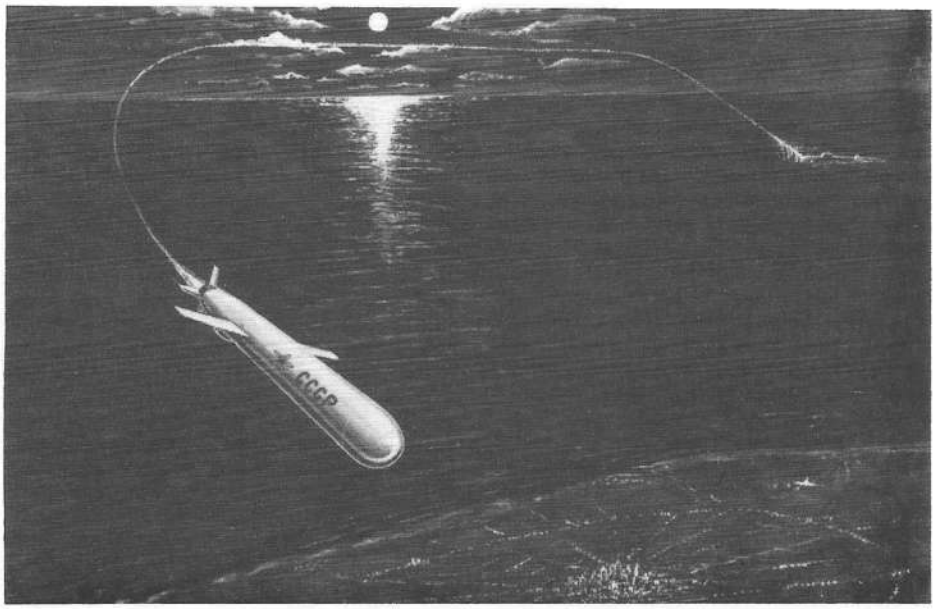
---

4796.411
SS-NX-21 CRUISE MISSILE



The Soviet authorities are believed by the US DoD to be developing a new long-range cruise missile similar to the American Tomahawk system (**4197.221**) that can, like the Tomahawk be launched from submerged submarines. The new Soviet weapon has been given the designation SS-NX-21, the letter 'X' denoting the fact that the system is still at the development stage.

Little is known about the appearance or detailed performance characteristics of the SS-NX-21, but it has been stated that this cruise missile can be launched from a standard torpedo tube so that a diameter of about 53 cm can be assumed. Folding flying surfaces are other likely features, and probably an air-breathing turbojet power plant, possibly coupled with a solid propellant rocket booster motor for broaching the surface of the sea and accelerating the missile to flying speed. These features are illustrated in the artist's impression issued by the DoD (see photo).



A maximum range of about 3000 km has been suggested, and a single warhead will probably be carried. Guidance techniques that could be employed include the use of programmed inertial guidance to the target area, based on target designation co-ordinates supplied by the parent submarine, followed by one or other of the various terminal homing options available, according to the nature of the target (eg radar homing, anti-radiation etc). Readers may find it helpful to consult the entries on the US Tomahawk cruise missile in its various roles to consider the guidance technique options available.

STATUS

Development programme. It has not been confirmed but flight tests are thought to have begun, and US authorities believe the SS-NX-21 could enter operational service in 1985, possibly in one or more classes of Soviet nuclear attack submarines if American expectations are realised. These launch platform possibilities include particularly the newer SSNs such as the 'Akula', 'Sierra' and 'Mike' classes as well as existing types such as the 'Victor III' class and some of the earlier 'Yankee' class.

New 'Akula' class nuclear attack submarines are seen as possible carriers of SS-NX-21 cruise missiles that could be used for land attack operations

DoD artist's impression of a Soviet SS-NX-21 submarine launched cruise missile attack

2932.131
ABM-1B (GALOSH) ANTI-BALLISTIC MISSILE MISSILE

Galosh is the NATO reporting name of the ballistic missile defence system deployed around Moscow by the Soviet authorities, based on the use of a missile thought to resemble the US Spartan anti-missile missile (**2811.131** in 1977 and earlier editions), and designated ABM-1B under the US system of codes. In the Mosow ABM complex Galosh is used in conjunction with various radars for target detection, engagement and tracking purposes, as described in the Land-Based Air Defence Systems section of this book (**3214.181**).

Apart from photographs taken of Galosh in its transporter container, which revealed four first stage rocket motor nozzles, in a Moscow parade in 1964, the world at large has seen little of this missile. However this enabled the length of the container to be estimated (about 20 metres), from which an idea of the missile size could be derived and this led to an estimate of about 2·75 metres for the diameter.

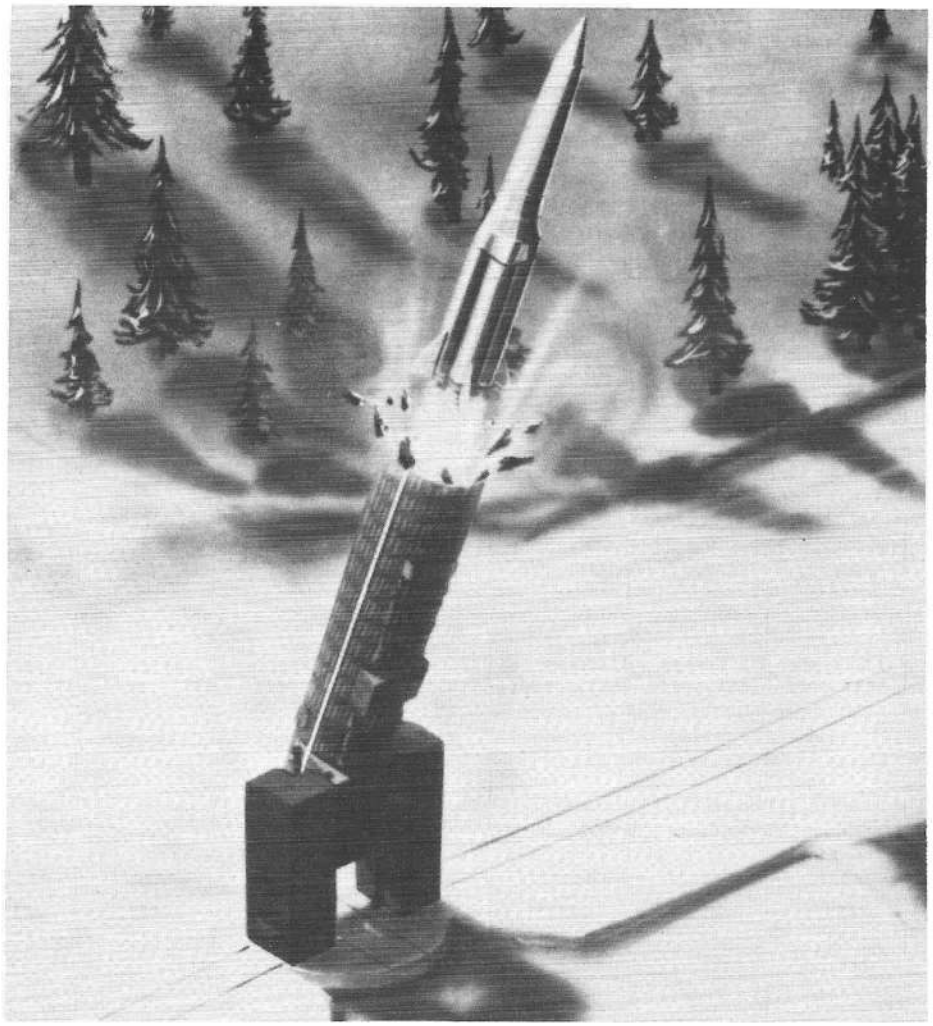
The original single-layer ABM system for Moscow was initially completed with 64 reloadable surface

launcher units for the ABM-1B located at four complexes surrounding the city, six Try Add (Triad?) guidance and engagement radars to each complex and the Dog House and Cat House target tracking radars to the south of Moscow. This is in the process of being upgraded to the total of 100 launchers permitted by the ABM Treaty of 1982.

According to official US assessments, when this upgrading is complete the new system will consist of a two-layer arrangement comprising: silo-housed modified long-range Galosh missiles designed for exo-atmospheric missile interception; silo-based high acceleration interceptors for endo-atmospheric interception; the associated engagement and guidance radars; and a large new radar at Pushkino that is designed to control ABM engagements. The silo-based launchers may be reloadable, and it is expected that the new Moscow system could be operational by the late 1980s.

An appreciable extension of the above facilities is thought to be in progress and this was summarised in the 1985 edition of *Soviet Military Power*. A rapidly deployable ABM system to protect important target areas in the USSR is believed to be under development, and it is claimed that radars, and ABM missiles that would be needed for widespread ABM defences beyond the 100 launcher limit set by the 1972 ABM Treaty has been initiated. It has been estimated that within ten years the Soviet Union would be in a position to deploy such a system at sites that could be built in a matter of months rather than years.

A typical site might consist of engagement radars, guidance radars, above-ground launchers, and the high acceleration interceptor. The new, large phased array radars under construction in the USSR, together with the Hen House, Dog House, Cat House, and perhaps the Pushkino radar appear to be designed to fit into a broader ABM system of this type. The overall impression gained by the US authorities from these activities is that the Soviet Union may be preparing a national ABM defence system for the whole country.

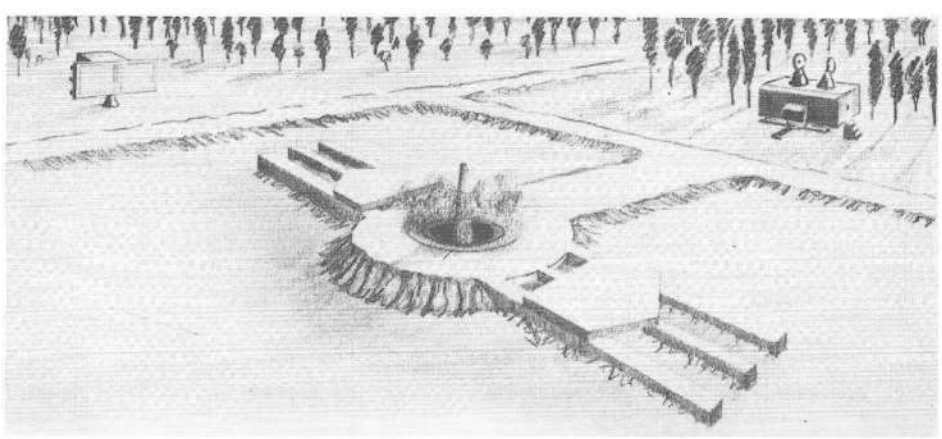


Additionally, the USSR is deploying the SA-10 surface-to-air missile system (**3620.131**), and flight testing the mobile SA-X-12 (**4774.131**) which is both a tactical SAM and anti-tactical ballistic missile weapon that may have the potential to engage NATO missiles such as Lance, Pershing I and II. It is thought possible that the SA-10 and SA-X-12 might also be able to intercept certain strategic ballistic missiles under some conditions.

CHARACTERISTICS

Type: Surface-to-air anti-ballistic missile
Guidance principle: Radar command
Propulsion: Probably 3-stage solid-propellant
Warhead: Multi-megaton nuclear
Missile length: About 20 m
Range: Estimated >300 km

STATUS



Operational at Moscow in four sites containing a total of 64 launchers. The Soviet Union is believed to have at least two new ABM development programmes in hand. One is reported to be a rapidly deployable system employing a phased array radar, missile tracking radar and a new missile. This system is described as a 'near-term' project. Far-term BMD weapon systems are also said to be in development.

Drawing of how the upgraded Moscow ABM system is expected to look when completed with silos for endo- and exo-atmospheric inteceptor missiles

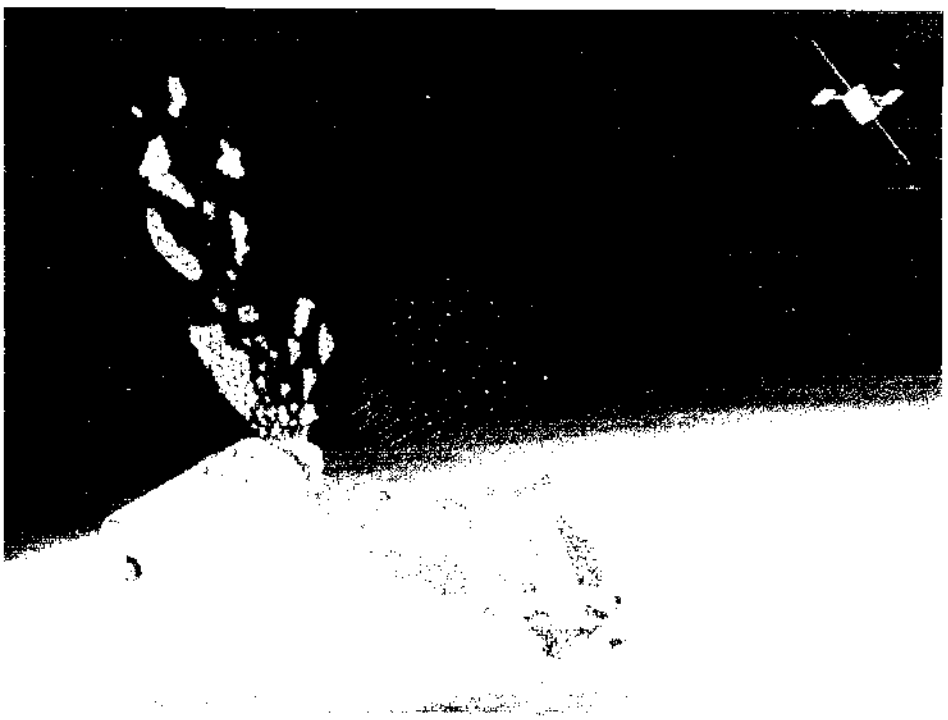
4895.131
SOVIET ADVANCED DEFENCE PROJECTS

Western analysis estimates that in 1984 the percentage of Soviet space launches for essentially military purposes rose to about 80 per cent from the 70 per cent which had been the norm in previous years, and from this it is presumed that military requirements exert a powerful influence on the direction of the Nation's scientific endeavours. It follows that the same attitude is credited to the Soviet Union's potential adversaries and consequently considerable effort is devoted in the USSR to defensive applications of space technology and the use of other advanced techniques to counter possible Western advances in military uses of space.

"Since the late 1960s, the Soviet Union also has been pursuing a substantial advanced defensive technologies programme – a programme that has been exploring many of the same technologies of interest to the United States in the SDI programme (**4896.131**). In addition to covering a wide range of advanced technologies, including various laser and neutral particle beams, the Soviet programme is much larger than the US effort in terms of the amount of resources invested – plant, capital and manpower. These efforts could lead to the testing of space-based ABM systems in the mid-1990s and to their deployment after the turn of the century. The President's initiative, therefore, is being pursued in part as a prudent response to Soviet R & D activities in this field and as an insurance against unilateral Soviet efforts to develop and deploy an advanced defensive system."

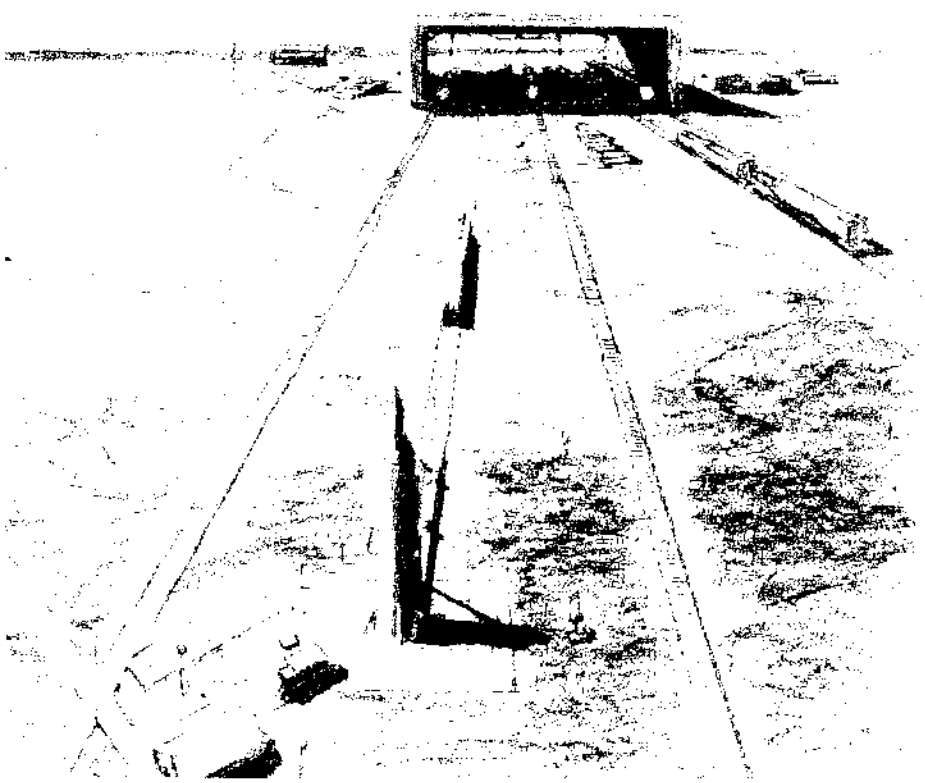
[Annual Report to Congress by Caspar Weinberger, US Secretary of Defense, Fiscal Year 1986, published February 1985.]

"Soviet directed-energy development programmes involve future ballistic missile defence (BMD) as well as anti-satellite (ASAT) and air defence weapons concepts." By the late 1980s, believe US authorities, the Soviet Union could have prototypes for ground-based lasers for BMD. Testing of the components for a large-scale deployment system could begin in the early 1990s. The many difficulties in fielding an operational system will require much development time, and initial operational deployment is not likely in this century. However, with high priority and some significant risk of failure, some test stages could be omitted to allow a ground-based laser BMD to be deployed by the early to mid-1990s.



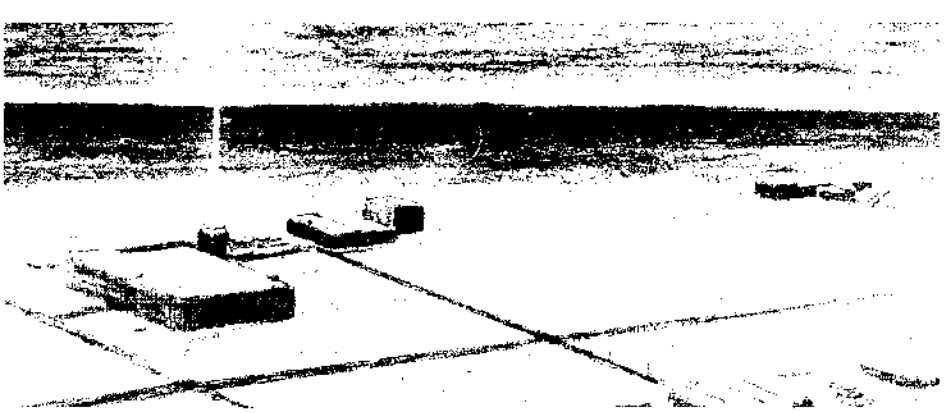
Ground- and space-based particle beam weapons for the same purpose are expected by the US authorities to be more difficult to achieve than laser systems, but it is claimed that the Soviet Union has a 'vigorous' programme under way for particle beam development and could have a prototype space-based system ready for testing in the late 1990s.

The USSR has begun development of at least three types of high-energy laser weapons for air defence. These include lasers intended for defence of high-value strategic targets in the USSR, for point defence of ships at sea, and for air defence of theatre forces. If past philosophies are pursued, air defence lasers are more likely to be deployed to complement rather than replace existing SAM and interceptor aircraft assets.



The strategic defence laser is probably in at least the prototype stage of development and could be operational by the late 1980s. It is thought most likely to be deployed in conjunction with SAMs in a point defence role. Since the SAM and laser systems would have somewhat different attributes and weaknesses, they would provide mutual support. The shipboard lasers probably will not be operational until after the end of the decade. The theatre force lasers may be operational somewhat earlier and are likely to be capable of structurally damaging aircraft at close ranges and producing electro-optical and eye damage at greater distances.

The Soviet Union is also developing an airborne laser, and assuming success in development, a limited initial deployment could begin in the early 1990s. Such a laser platform could have missions which include ASAT operations, protection of high value airborne assets, and cruise missile defences.



Work is also in progress on technologies that relate to other specific weapon projects, or that might lead to more advanced ASAT systems. These include space-based kinetic energy, ground- and space-based laser, particle beam, and radio frequency weapons. The Soviet Union is thought to believe that

An artist's impression of the satellite interceptor vehicle that the USSR has employed experimentally since the early 1970s

American drawing of the Tyuratam site where the USSR is said to have the capability of launching a series of ASAT spacecraft

Drawing by a US artist assumed to be working from satellite intelligence data of the Soviet directed-energy site at the Sary Shagan proving ground. This and lasers at the same site are thought capable of use in an ASAT role and possibly a BMD role

these techniques offer greater promise for future ASAT application than continued development of ground-based orbital interceptors equipped with conventional warheads. It is also thought that military applications of directed energy technologies hold promise of overcoming weaknesses in the Country's conventional air and missile defence.

The high-energy laser programme in the USSR, which dates from the mid-1960s is reported to be much larger than that of the USA, and more than half a dozen major R & D facilities and ranges have been built, employing some 10 000 scientists and engineers, for laser development. These teams are reported to be working on chemical lasers and to be continuing efforts on other high-energy lasers with potential weapons applications, such as the gas dynamic laser and the electric discharge laser. Related laser weapons technology work in progress is stated to include the means of producing electric power efficiently and high-quality optical component manufacture. A rocket-driven magnetohydrodynamic (MHD) generator that can produce 15 MW of short-term electric power has been developed, and this is a device which it is claimed does not have a counterpart in the West.

The Soviet Union has progressed beyond technology research, in some cases to the development of prototype laser weapons. There are already ground-based lasers that could be used to interfere with US satellites. In the late 1980s, there could be prototypes of space-based lasers capable of use as ASAT weapons. In addition, continuing Soviet programmes have reached the stage where they could include construction of ground-based laser ASAT facilities at operational sites. These could be available by the end of the 1980s, and would greatly increase the Soviet Union's laser ASAT capability beyond that provided by the existing test site at Sary Shagan. It is thought that operational systems for space-based laser ASAT purposes might be deployed in the 1990s, if the technology development proves successful, and if so a space-based laser system for ABM purposes can be expected for possible deployment after the year 2000.

The US report claims that since the 1970s the USSR has carried out a research programme to explore the feasibility of a particle beam weapon in space. A prototype space-based particle beam weapon intended only to disrupt satellite electronic equipment could be tested in the early 1990s, and one designed to destroy satellites could be tested in space in the mid-1990s.

A programme to conduct research into the use of strong radio frequency (RF) signals that have the potential to interfere with or destroy components of missiles, satellites, and re-entry vehicles has also been carried out for some time. It is estimated that by the 1990s the USSR could test a ground-based RF weapon capable of damaging satellites.

Soviet programmes for the development and application of directed energy technologies to strategic defence have been pursued very vigorously in the past, according to US sources, and will continue in the future.

In the area of kinetic energy weapons, using the high speed collision of low mass with the target as the kill mechanism, the USSR has a variety of research programmes in progress, which could result in a near-term, short-range, space-based weapon system useful for satellite or space station defence or for close-in attack by a manoeuvring satellite. Longer range, space-based systems probably could not be developed until the mid-1990s or later in the US view.

Soviet Space Programme

Soviet doctrine by no means overlooks the military potential of space and specific areas of military operations where space systems and assets are employed embrace such activities as ASAT operations and systems; intelligence collection; command, control and communications; meteorological support services; navigational facilities; reconnaissance and targeting; and survey and geodesy. Such military support systems are linked to ground, naval and air forces via Earth terminals, and reliance on them is reported to be growing. Also, according to the 1985 edition of *Soviet Military Power* published by the US DoD, space weapons play an important role in Soviet strategic operations, and this study claims that the Soviet co-orbital ASAT system, while launched from the ground, is a space weapon system, and goes on to state that the USSR has two ground-based lasers that are capable of attacking satellites in various orbits.

Since 1971 the USSR has had the ability to attack satellites in near-Earth orbit with a ground-based orbital interceptor. Using a radar sensor and a pellet-type warhead, the interceptor can attack a target in various orbits during the interceptor's first two orbits. (See **1506.351** *Jane's Weapon Systems, 1971-72*.) An intercept during the first orbit would minimise the time available for the target to take evasive action. The interceptor can reach targets orbiting at altitudes of more than 5000 km, but it is thought likely to be intended for high-priority satellites in lower orbits. The ASAT interceptor is launched from Tyuratam, where launching facilities include a number of launch pads, storage accommodation for interceptors and launch vehicles. Several interceptors per day could be despatched using the facilities that are said to exist at this site. In addition to the orbital interceptor, the Soviet Union has two ground-based, high energy lasers with ASAT capabilities. It is also believed that there is the technological capability to develop electronic warfare against space systems and/or to use ABM interceptors in a direct-ascent attack on low-orbit satellites.

Soviet Military Power, 1985 contains a useful summary of other Soviet space systems dedicated to military missions. These include satellites that perform reconnaissance, missile launch warning detection and attack warning, command and control, and ASAT operations, as noted above. Dual-purpose satellites that carry out some civil functions are used for communications, navigational support, and weather forecasting and monitoring, but the USA has no equivalent counterparts (as yet) to the satellites used by the Soviet Union for ocean surveillance, the electronic ocean reconnaissance satellite (EORSAT), or the nuclear-powered radar ocean reconnaissance satellite (RORSAT). Their function is to detect, locate, and target US and allied naval forces for Soviet anti-ship weapons. These systems are stated to track naval and merchant shipping, and four such satellites were launched in 1984, two of which were of the same type (RORSAT) that crashed in 1978 spreading debris (with some associated radioactivity) in northern Canada.

Recently the USSR has started using a new radar-equipped satellite system which is designed for mapping ice formations in the polar regions. These satellites are expected to appreciably enhance the Red Fleet's ability to operate in icebound waters. It has been noted that Soviet launches of spacecraft into geostationary orbits have increased in recent years. Most are assumed to be for communications purposes but they may not all be for this role, and some doubt remains as to the overall plan for this class of spacecraft. A Soviet equivalent to the American Navstar navigation satellite system for providing accurate position-finding facilities on a world-wide basis is reported to be in the early stages of development under the name of GLONASS. Other developments include improved routine reconnaissance satellites which are probably designed for longer duration sorties than earlier satellites which generally spent much less time in orbit than their US counterparts.

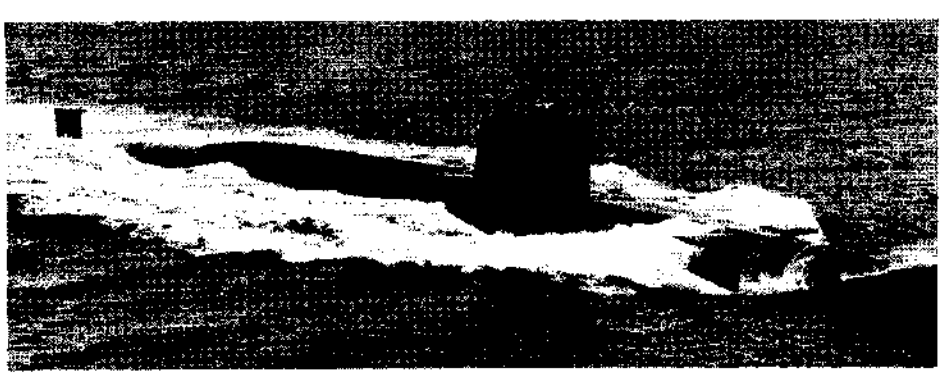
UK POLARIS MISSILES

The UK Polaris force of four submarines, each armed with 16 Polaris A-3 SLBMs have constituted the British nuclear deterrent since 1969. It is planned to continue this role until replaced by the UK Trident II system in the mid-1990s. Originally the standard US UGM-27C Polaris A-3 missile equipped with UK designed and built nuclear payload was used, but to maintain the system's effectiveness a programme to upgrade the payload was instituted under the code-name Chevaline. Missiles equipped with this system are designated Polaris A3TK and all four RN Polaris submarines are now equipped with this version.

Following retirement of Polaris from US Navy service, the Royal Navy remains the sole operator of this system.

CHARACTERISTICS

US designation: UGM-27C
RN designation: A3TK
Type: Submarine-launched ballistic missile (SLBM)
Guidance: Inertial
Propulsion: 2-stage, solid propellant
Warhead: 3 × 200 KT, or Chevaline (see text)
Re-entry vehicle: MRV or Chevaline (see text)
Length: 9·55 m
Diameter: 1·37 m
Launch weight: 13 600 kg
Range: 4630 km (approx)



Each standard missile is capable of a payload comprising three RVs with an estimated 200 KT yield each. Under the UK Polaris improvement programme code-named Chevaline, these are being replaced by manoeuvrable re-entry vehicles with new penetration aids. Other changes include fire control system modifications.

The Chevaline development was designed specifically to penetrate ABM defences (these surround Moscow, see **2932.131**), although it is not a MIRV system and does not involve any increase in the number of warheads associated with the Polaris force. Unofficially, Chevaline RVs are reported to have a yield of 40 KT and to be capable of separation between impact points of a maximum of 70 km.

It seems probable that not all of the 16 missiles that each Polaris submarine takes on patrol are fitted with the Chevaline payload. As this is specifically designed to penetrate ABM defences (which officially exist only around the Moscow region) missiles which might be targeted elsewhere would carry a normal Polaris payload.

STATUS

The Royal Navy has four nuclear-powered ballistic missile submarines, each carrying 16 Polaris missiles. They are (with launch year in brackets): HMS *Resolution* (1966), *Repulse* (1967), *Renown* (1967) and *Revenge* (1968). The UK Polaris force became fully operational in 1970.

HMS Resolution, *one of the Royal Navy's four Polaris submarines. 16 missiles are carried* (Royal Navy)

In 1982 it was reported that the Chevaline system had reached operational status. It was also stated that a programme costing about £300 million had been initiated for the replacement of Polaris rocket motors and some US stocks had been purchased to ensure continued availability of UK Polaris supplies.

In mid-1985 £32 million remained to be spent on the Chevaline programme and the re-engining of Polaris missiles, but this, it was claimed would bring the overall cost to over £1000 million. It was reported that some of the cost over-run was due to unexpected flight failures in US Navy and Royal Navy tests, which presumably led to a more extensive engine replacement plan than originally anticipated. New engines, after a series of proving firings, will be fitted into missiles stored at Coulport.

A three-year gap between the end of the commission of HMS *Resolution* and the first of the Royal Navy Trident submarines on-station date is expected to be compensated by extending the length of commission for the remaining Polaris boats, with longer periods between refits now possible due to the second-generation reactor cores now available.

The eventual replacement for the UK Polaris force will be the UK Trident SLBM system (**4209.411**), a version of the system entering service with the US Navy (**2840.411**).

CONTRACTORS

About 800 British firms were associated with the original UK Polaris programme. Some of the major contractors are listed below.

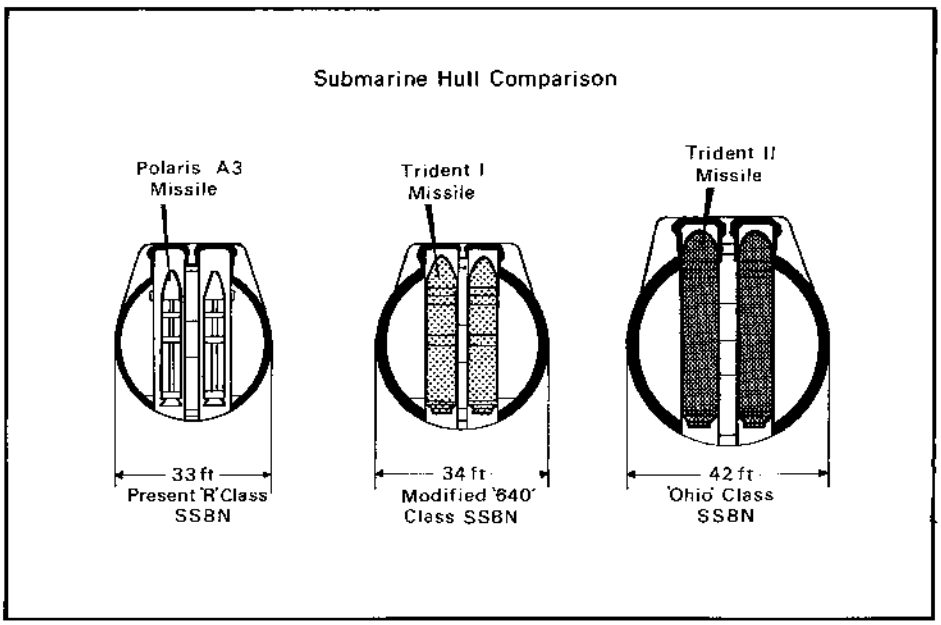
Submarines:
- Vickers
- Cammel Laird

Nuclear reactors:
- Rolls Royce

Royal Navy Polaris School:
- George Wimpey and Co
- Vickers
- GEC-Marconi
- British Aircraft Corporation
- Sperry
- EMI

4209.411

UK TRIDENT SLBM SYSTEM



A UK Government decision to procure the American Trident SLBM system (**2840.411**) as a replacement for the British nuclear deterrent based on the Polaris SLBM system (**2390.411**) was revealed in July 1980. At that time it was intended to acquire the Trident I (C-4) missile from the USA, fit British-built warheads, and deploy it in submarines of British design and construction. The resulting system would be entirely under British ownership and operational control, but the whole force would be committed to NATO in the same way as the current Polaris force. In the event, shortly after the UK decision was made public, the US administration opted to utilise the potential offered by the larger missile tubes fitted in the new 'Ohio' class of SSBNs (Trident I can be carried in the Poseidon SLBM tube, but the tubes for Trident II missiles are both longer and of greater diameter), and procure the more powerful Trident II (D-5) missile in the 1990s. This time-scale coincided with that envisaged for the British Polaris replacement programme and it appeared sensible to adopt the SLBM planned for US service at the same time.

Where the original UK Trident programme was based on building a new class of British SSBN which would use a missile compartment based on that of the USN 640-class SSBN, adoption of the Trident II made this impossible and the solution adopted is that of employing a centre section based on that used in the USN 'Ohio' class SSBN. The British version will have only 16 missile tubes, however, compared with the American ships' 24 tubes.

British-built warheads will be carried in a US-designed MIRV bus, and in early 1985 warhead design and development was reported to be progressing well. (A British nuclear test device with a yield of less than 20 KT was detonated in an underground test in the Nevada desert in mid-1983 and this was the 15th in a series of UK tests there since 1980. Though unconfirmed some, if not all, are thought to be linked with the UK Trident programme.)

The British Trident submarines will be powered by a new pressurised water reactor (PWR2) that will also be employed in a new class of British hunter-killer submarines. This reactor will have a longer core-life, so lengthening the period between submarine refits, and will also be appreciably quieter running, making the boat itself harder to detect as well as assisting detection of other submarines by its lower 'own-noise'.

The Trident II missile is expected to have an 'in-tube' life within the submarine of at least seven years, much longer than Polaris, thereby reducing the on-board maintenance considerably. If the planned fleet of four UK SSBNs is deployed, this should be adequate to provide an 'operational squadron' of three vessels continuously, so that with the fourth submarine undergoing refit there can be one armed Trident submarine on patrol at all times. Refits are planned to take place at intervals of about seven years for each submarine.

Comparison of submarine cross-sections for Polaris, Trident I and Trident II SSBNs illustrating how hull diameter increases with missile length

STATUS

Planned for entry into service in the mid-1990s to replace the UK Polaris force. A fleet of four SSBNs, to be built by Vickers at Barrow, is planned. The Trident II (D-5) missiles will be supplied from US sources under an inter-governmental agreement. Warheads will be a British responsibility. The estimated cost (June 1982) of the programme over a period of 15 years was in the region of £7928 million.

The UK Minister of Defence, in a statement in September 1982, announced a decision to use US facilities at Kings Bay, Georgia, USA for the initial preparation for service of UK Trident missiles and for their refurbishment at the end of each British submarine's 7 to 8 year commission period. On this basis it will not be necessary to go ahead with previous plans to build the full range of facilities needed for this purpose at Loch Long in Scotland, although some new facilities will need to be constructed.

The first of the four UK Trident submarines is expected to be ordered by the end of 1985 with the contract going to Vickers Shipbuilders. The boat will displace more than 15 000 tonnes, and will be 150 m long with a centre section diameter of over 12·8 m. The 1985 Defence White Paper stated that, since the decision to opt for the D-5 missile in March 1982, the only increase in the estimated cost of the Trident programme has been that attributable to inflation and exchange rate variations. Because of the decision to process UK Trident missiles in the US rather than the UK, substantial offsetting savings have been made (about £700 million) and at an exchange rate of $1·38 - £1, the estimated cost is just under £9·3 billion, of which it is expected that some 55 per cent will be spent in the UK.

UNITED STATES OF AMERICA

4560.111

US ICBM MODERNISATION PROGRAMME

In October 1981 President Reagan announced a comprehensive plan for modernising US strategic forces. A key part of that plan was his proposal to remedy growing deficiencies in the US land-based ICBM force. His plan called for deployment of the Peacekeeper (**4561.111**) missile with an initial operational capability in 1986. With this early deployment the President directed an aggressive research programme to identify a more survivable means of basing for the Peacekeeper missile. In November 1982, in response to a Congressional deadline, the Closely Spaced Basing plan was recommended by the Administration as the basing mode that provided the optimal survivability for Peacekeeper. Congress delayed voting on that recommendation pending a thorough review of alternatives, including a new small missile (unofficially dubbed 'Migdet man') in addition to the Peacekeeper.

The review of alternatives conducted by the President's Commission on Strategic Forces reaffirmed the necessity for a new ICBM and recommended that the Peacekeeper missile be deployed in existing silos with supporting R&D programmes to provide alternative forces for the 1990s.

The programme for ICBM modernisation, recommended by the President's Commission on Strategic Forces and accepted by the President, calls for deployment of 100 Peacekeeper missiles in existing silos and development of a small missile suitable for either fixed or mobile development. Initial operations of the Peacekeeper system would begin in 1986, and the full force would be operational by 1989. Supporting programmes include efforts to develop superhard structures, transporters for mobile deployments, and technology for deep basing of ICBMs.

Peacekeeper

The Peacekeeper is a four-stage ICBM that carries ten

independently targetable warheads which has many advantages over missile weapon systems currently in the US inventory (**4561.111,** below). It will be more accurate, able to carry more warheads, with greater range and can be targeted more flexibly than the Minuteman ICBMs. Its greater resistance to nuclear effects and better guidance system provide an improved ability to destroy very hard targets. Peacekeeper is to be deployed in existing Minuteman silos as shown in the photograph. The deployment will require a minimum of modifications to the silos to accommodate new support equipment, a shock isolation system, and a more sophisticated command and control system. The deployment will be near FE Warren AFB, Wyoming, as shown in the diagram.

Minuteman Modernisation and Peacekeeper Deployment

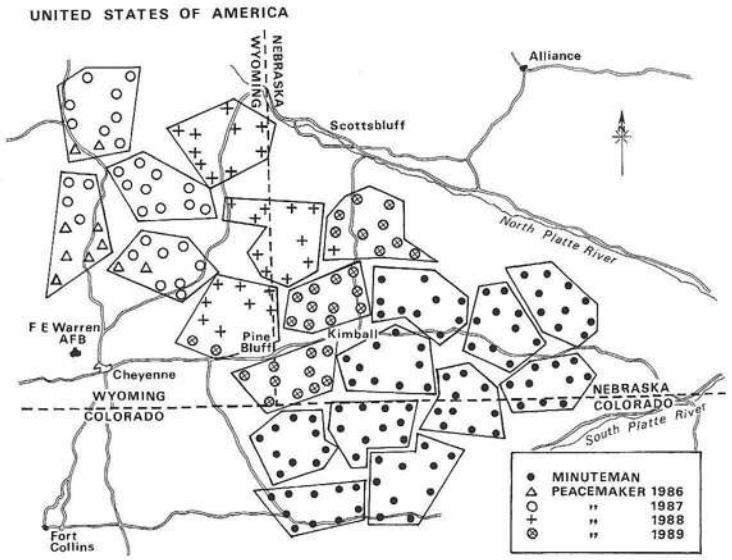
As noted elsewhere in this volume and earlier editions, the existing Minuteman ICBM system (**2716.111** and **2717.111**) and new Peacekeeper ICBM (**4561.111**) are involved in the US ICBM modernisation programme to the extent that silos of the former system are to have the Minuteman missiles they house replaced by newer Peacekeepers, while at the same time there is a general effort to improve US ICBM basing facilities. The most important of these efforts are summarised briefly in the following paragraphs.

A hardened intersite cable system (HICS) will provide a new pressure monitoring system for the cabling between sites at all Minuteman Wings. This is due to be completed in 1986. The integrated command, control and communications (C^3) programme is designed to improve security, reliability, and data handling capability for the National Military Command System. The improved Minuteman physical security system will replace the ageing radar network now used and will reduce the number of nuisance alarms now encountered. Deployment of this system at Wings I and VI, and Squadron 20 was planned to start in 1985, and the US Air Force plans to extend this security improvement to all six wings.

A Minuteman extended survival power system (MESP) will substantially extend the launch facility survival period by its greater resistance to the effects of nuclear radiation etc, at a time of conflict. It consists of high-energy lithium batteries, built by GTE, with controls provided for the application of power. Installation of these batteries at 200 Minuteman III launch facilities began in 1984 and this work will continue into 1986. The Minuteman transporter/erector fleet of vehicles is to be replaced in the near-term period by 35 new transporter/erectors, under a major upgrading programme. From April 1985, on-site depot teams will move into Minuteman Wings to carry out systematic integrated maintenance to the year 2000 under an Air Force programme called Rivet Mile.

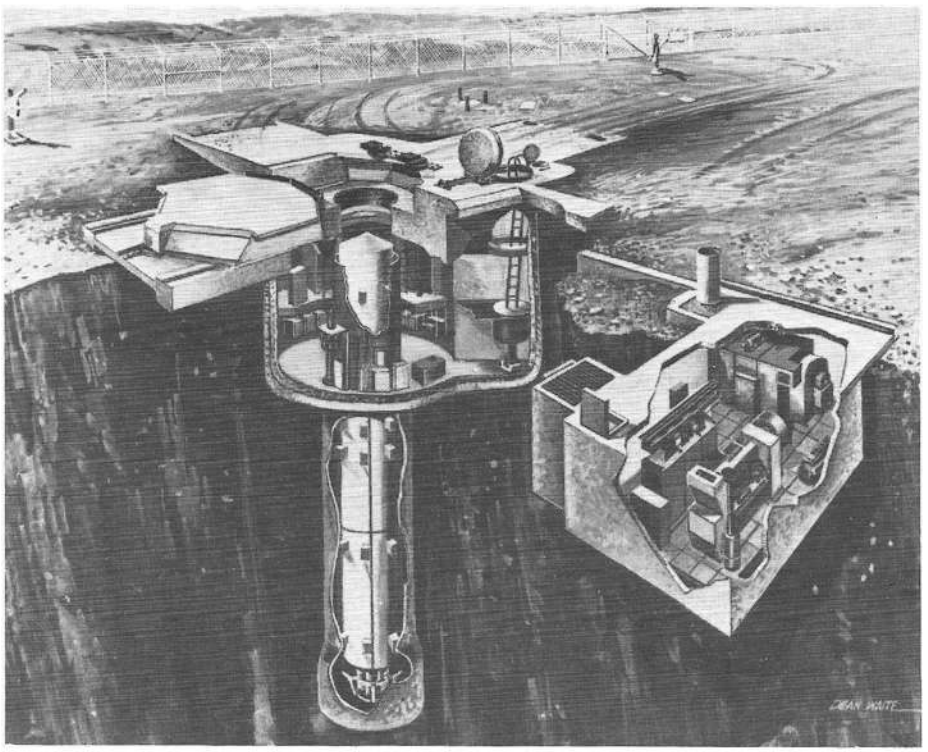
Most of the electrical equipment at Minuteman silos has been re-designed to support Peacekeeper. The existing Minuteman guidance and control cooler will be replaced with a new guidance and control conditioning unit; a new 96 V DC power supply will be added to power the advanced missile guidance system; a new programmer group and UHF transmitter for two-way communication with the Airborne Launch Control Centre (ALCC) will be added; and there will be modifications to the power supply systems and environmental control systems. Software changes for the guidance improvement program were completed in 1984. In 1986 development of a new stage III motor for Minuteman II is due to begin so that replacement of the ageing current motor can be carried out to allow Minuteman II to continue as a credible element of the US strategic ICBM force until the year 2000.

The major facility modification for Peacekeeper deployment involves removing the upper two metres of the launch tube liner to allow on-site assembly of the missile stages and re-entry system. The missile and canister will be suspended by a new shock isolation system that will provide protection from nuclear attack and induced ground shock. EMP protection will also be improved.



The Minuteman launch complex control centre facilities will be modified for C^3 integration. Computer-aided message processing programs will reduce the time from receipt of the launch authentication message to completion of the launch execution command. Hardware modifications will improve visual display and control functions in the launch control console and command message processing group. The HICS will be expanded, resulting in a single command and control system that interconnects ten launch control facilities and 100 launch facilities.

Deployment of Peacekeeper at Minuteman complexes will enhance the capability of the ALCCs by adding a demodulator/decoder and encrypting the existing UHF communications downlink. Remote re-targeting and launch of the Peacekeeper missile from the ALCC will be possible when command access has been permitted. The encrypted uplink at each launch facility allows the ALCC to monitor launch facility and missile status. Other electrical modifications will yield a configuration that supports both Peacekeeper and Minuteman. This entails a re-design of the ALCC power supply, code retaining power supply and other equipment to ensure EMP protection; these changes give the ALCC virtually the same command and monitoring capability as the launch control facility once ALCC access is established.



Funding for some of these efforts is included in the budget allocations for specific missile programmes, such as the Peacekeeper ICBM and the Small ICBM, and readers are directed to the appropriate entries (**4561.111** and **4897.111**) for further details. The funding tabulated below is from the 1985 DoD Budget for Minuteman modernisation and follow-on basing technology and relates to the actual, planned and projected funding (in $ millions):

Fiscal Year	**1984**	**1985**	**1986**	**1987**
Basing Technology	139	179·6	152·2	*
MM Development	4·9	4·7	31·2	95
Procurement	97·2	118·6	101·7	160·8

*To be determined.

Peacekeeper deployment in existing Minuteman silos near F E Warren AFB, Wyoming. New missile will replace 100 Minuteman ICBMs

Artist's impression of how Peacekeeper advanced ICBMs will be deployed in existing Minuteman missile silos. Modifications will be minimal and silo will not be hardened beyond existing level

4561.111

PEACEKEEPER (MGM-118) ICBM

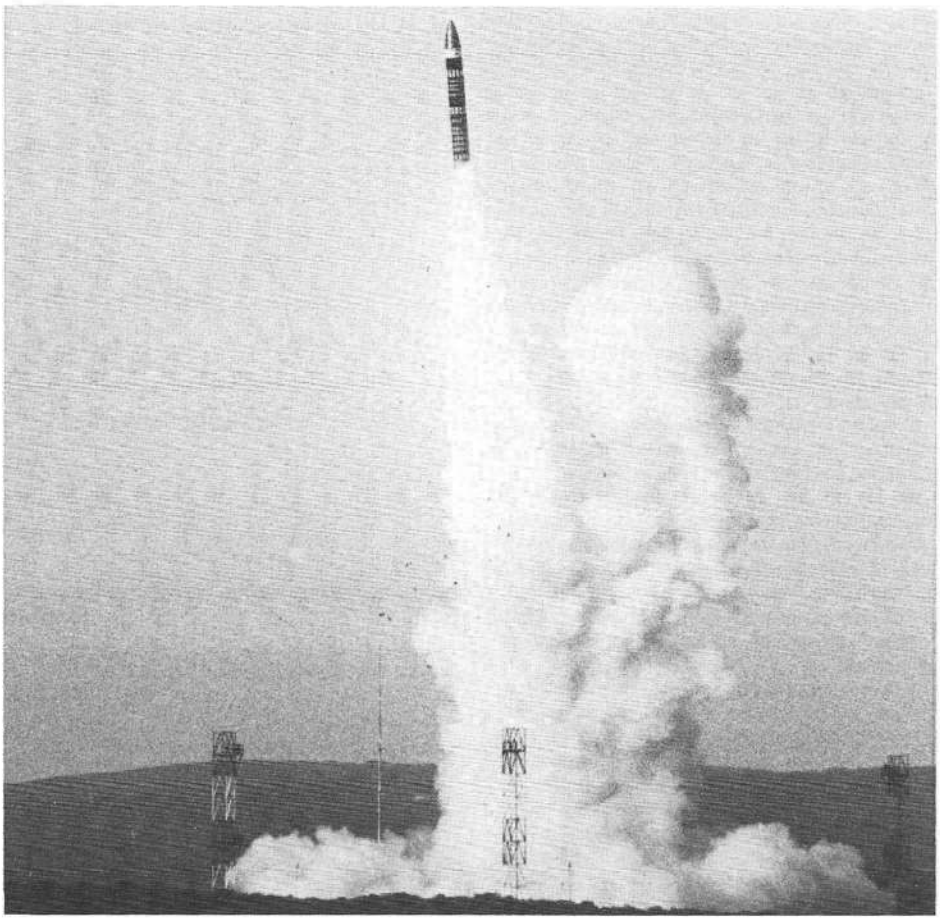
Peacekeeper is the name assigned to the weapon that was formerly known as the Advanced ICBM, or MX, and earlier work was described in **2718.111** in previous editions. It is a major element in the US ICBM modernisation programme (**4560.111**).

The MGM-118 Peacekeeper missile is a four-stage intercontinental ballistic missile (ICBM) which has been designed to deliver 10 Mk 21 re-entry vehicles to independent targets at ranges usually greater than 8000 km. The missile is about 21·6 m long, 234 cm in diameter and weighs about 88 450 kg. Three of the four stages use solid propellant materials exhausted through a single nozzle. Hydraulically operated thrust vector actuators move the nozzles to guide the missile along its flight path. The fourth stage, called the post-boost vehicle, uses a liquid propellant to power an axial thrust engine and eight small engines which are used for attitude control. The post-boost vehicle also includes a guidance and control system, a

deployment module and re-entry vehicles. The guidance function is performed by a completely self-contained inertial guidance and navigation system. During flight the missile is completely independent of ground references or commands.

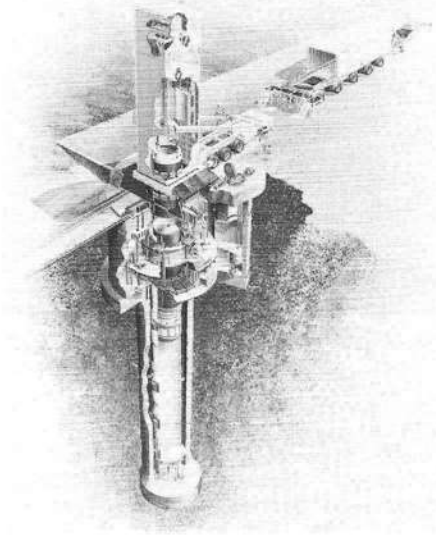
The first stage solid rocket motor weighs approximately 49 000 kg and is about 9·1 m long. It will boost the missile to about 23 000 m. Stage I is equipped with a single movable nozzle which is controlled by signals from the guidance and control system.

The second stage solid rocket motor weighs approximately 27 000 kg and is about 5·5 m long. Stage II ignites after the burn-out and release of Stage I and propels the missile to an altitude of about 88 000 m. Both stages use a synthetic rubber-based solid propellant with aluminium and oxidiser additives. Stage II has a single movable nozzle which incorporates an extensible exit cone. The exit cone is folded until Stage II is ignited; it then extends. This feature allows the exit cone to enlarge so that the performance of the stage is increased without making the diameter of the missile larger. The single nozzle is controlled by signals from the guidance and control system using power provided by hydraulic actuators which receive high pressure gas from a gas generator.



The third stage solid rocket motor weighing about 7·700 kg, is approximately 2·4 m long. Stage III provides thrust to boost the missile to about 213 000 m. Stage III ignites after burn-out and release of Stage II. Stage III uses a synthetic polymer plastic-based solid propellant with aluminium and oxidiser additives. Like Stage II, the Stage III single nozzle also has an extensible exit cone to obtain performance without increasing the diameter of the missile. The solid propellants in the first three stages are contained in motor cases made of a kevlar epoxy material. The Stage III nozzle is also controlled by the guidance and control system. The nozzle is movable and positioned by a hydraulic system powered by a solid-propellant gas generator.

The fourth stage weighs about 850 kg and is 1·2 m long. Stage IV uses a liquid bi-propellant rocket propulsion system which provides velocity and attitude corrections for this phase of the missile flight. Following the burn-out and separation of Stage III, the post-boost vehicle manoeuvres and each re-entry vehicle is released. The vehicle is then moved by its propulsion systems to new positions where the remaining re-entry vehicles are deployed in sequence. The propulsion system includes the liquid propellants and tanks, an axial engine and its thrust vector actuation system, and attitude control engines. The attitude control engines use the same bi-propellants as the axial engine.



The missile guidance and control (G&C) system is contained in the post-boost vehicle. The G&C system includes the inertial measurement unit (IMU), the missile electronics and computer assembly, ground and flight software, the in-flight cooling sub-system, airborne power supply, missile interconnection cables, the missile ordnance arm switch, the power distribution switch, the missile umbilical receptacle, the supporting structure, and shields. Inside the IMU is a floated sphere containing gyros, accelerometers and some associated electronics. The gyros generate a basic computer commanded frame of reference with which all missile movements are compared. The accelerometers measure all vehicle velocities with respect to that frame of reference. Utilising the position and velocity information generated by the gyros and accelerometers, the missile and electronics and computer assembly determines all guidance and control functions of the missile. The G&C system also determines the correct release point for vehicles near the termination of powered flight path.

The re-entry vehicles, which contain the weapons, are conically shaped and covered with materials to protect the weapons during the flight through the atmosphere to the target. The high speed re-entry will cause extreme heating requiring a surface material to ablate or erode in a controlled manner to protect the weapon throughout its flight.

In addition to the stages and re-entry vehicles, the missile also includes a shroud and the deployment module. The shroud, often called a nosecone, protects the re-entry vehicles during the ascent phases of flight. The shroud is topped with a nose cap made of a metal called Inconel, and contains a rocket motor to separate it from the missile.

Successful first flight of Peacekeeper (formerly the MX) ICBM in June 1983 from Vandenberg AFB, California. The unarmed missile covered a distance of approximately 4100 nm (7600 km) (USAF/DoD photo)

Martin Marietta is developing a Peacekeeper semi-trailer emplacer for inserting and removing missiles from their silos, and also a transporter/emplacer vehicle for the USAF

Peacekeeper (MGM-118) ICBM is ejected by gas generator at base of canister before first stage motor ignites. Note sabot-like packing falling away from missile as it emerges

The deployment module provides the structural support for the re-entry vehicles and carries the electronics to activate and deploy them. These vehicles are mechanically attached to the deployment module. The mechanical attachment is severed by explosive units which frees the re-entry vehicles allowing them to separate with minimum disturbances from the deployment module. Each re-entry vehicle is deployed at a position which will allow it to follow a ballistic path to its target.

The ten warheads will be modified versions of the Mk 12A re-entry vehicle which is used in the Minuteman ICBM, and in this role they are given the designation Mk 21.

The change from the Mk 12A to the Mk 21 re-entry vehicle (RV) reduced Peacekeeper range, and this caused an increase in throw-weight that further reduced RV range. The Mk 21 is heavier than the Mk 12A and not all of this increase in weight could be accommodated within the SALT II 3600 kg throw-weight limit for Peacekeeper, so that propellant had to be sacrificed, thereby further reducing range. According to the US Air Force the effects on range will be offset by the decision to site Peacekeepers in Nebraska and Wyoming rather than the original locations in Nevada and Utah further south. In this way, it is claimed, Peacekeeper with ten RVs will have the range to reach the most distant planned hard targets.

DEVELOPMENT

The US Air Force Strategic Air Command stated a requirement for a new ICBM in 1972. This weapon should be capable of destroying hardened targets and should itself be based in a survivable manner.

After the requirement had been validated, the programme was initiated as the MX (Advanced ICBM), renamed the Peacekeeper in November 1982.

The Peacekeeper programme, which includes a missile and a basing system, began full-scale development in September 1979 (about two years later than intended), but the basing plans then proposed to ensure survivability were not acceptable. On taking office in January 1981, President Reagan initiated a review of the American strategic forces and alternative options for modernising those forces. In October 1981 he proposed, as part of the US deterrent modernisation programme: continuation of Peacekeeper development, with the objective of near-term interim deployment of the missile in Titan or Minuteman silos that had been modified to increase their hardness; cancellation of the MPS (multiple protective shelter) basing system; and deactivation of the Titan II ICBM force.

However, Congress rejected the proposal for interim Peacekeeper deployment, and on 22 November 1982 the President then proposed stationing 100 of these missiles in an array of 100 closely spaced 'super-hard' silos near FE Warren AFB, Wyoming (the so-called 'Dense Pack' basing mode). Congress also rejected this, allowing funds for Peacekeeper missile development but not for procurement, while restricting funds for basing mode development. Flight testing of Peacekeeper was also forbidden until the basing mode had been approved.

Consequently the President set up a Commission on Strategic Forces in January 1983, to examine basing modes for Peacekeeper. The suggestions of the Commission comprised three main elements:

(1) siting 100 Peacekeeper missiles in existing Minuteman silos
(2) development of a new small ICBM (popularly known as 'Midget man')
(3) investigation of hardened silos, shelters, and mobile launcher systems.

The President endorsed these recommendations in April 1983 and Congress gave its approval the following month.

STATUS

After Congressional approval of the Peacekeeper basing mode in May 1983, production of Peacekeeper missiles began with a DoD request for funds for 27 missiles in the 1984 budget. This quantity was not approved however, instead Congress directed the USAF to deploy ten Peacekeepers in Minuteman silos by the end of 1986.

The Peacekeeper R & D flight-test programme, consisting of 20 planned launches, was initiated at Vandenberg AFB, California in June 1983. Phase I of the flight test programme, including the first five launches, was completed in June 1984 and was designed to test the missiles functional performance. The sixth flight test was completed in October 1984 and this marked the start of Phase II of the flight test programme. This phase is meant to test missile/RV capabilities and silo integration. Flight tests numbers seven to ten were scheduled for 1985.

The first phase of the Peacekeeper flight test programme had been completed by early 1985. The 41 RVs deployed on Peacekeeper flight test vehicles prior to then demonstrated excellent accuracy.

Peacekeeper missile deployment in SE Wyoming and SW Nebraska will be supported by the 90th Strategic Missile Wing at FE Warren AFB, near Cheyenne, Wyoming. 100 Peacekeepers will replace 100 Minuteman missiles in existing silos and initial operational capability (IOC) is planned for December 1986 with ten missiles deployed in Wyoming, and full operational capability with 100 missiles (69 in Wyoming and 31 in Nebraska, see map with entry **4560.111** - US ICBM Modernisation Programme) will take place by December 1989.

Full-scale development for basing began in June 1983, and a draft environmental statement was issued the following October. Public hearings followed and the final statement was issued in January 1984 and construction started on support facilities in mid-1984, above-ground silo modifications starting in 1985.

In 1984 the Peacekeeper programme moved from the engineering development stage to full-scale development and production. Primary and associate contracts were awarded for all four missile stages, and in January 1984 eight contracts were placed for G & C production facilities. Another 22 contracts were placed in April 1984 for production of the RV, RV system and fuze, and work was also carried out in support of the Peacekeeper G & C system housed in Stage IV.

In May 1984 it was reported that the USAF had amended its plan to employ composite structures in the Peacekeeper's Mk 21 RV, and a programme to qualify General Electric as a second source for production to the Mk 21 developer, Avco. GE provides the Mk 21's fuze.

Actual, planned and projected funding for the Peacekeeper programme contained in the fiscal year 1985 DoD Budget is as follows (in $ millions):

Fiscal Year	1984	1985	1986	1987
Development	1962·6	1699·7	804·1	360·6
Construction	31·2	95·7	55·8	60·5
Quantity	21	21*	48	48
Procurement	2153·6	1000*	3180·2	2798·3

*Dependent on Congress voting an additional $1·5 billion to produce the 21 missiles.

CONTRACTORS

Aerojet General: Second-stage.
Avco: Re-entry systems integration.
Boeing: Basing and deep basing support.
Charles Stark Draper Laboratory: Guidance and control technical support.
General Electric: Adaptation of Mk 12A warhead.
GTE Sylvania: Launch control system.
Hercules: Third-stage systems.
Honeywell: Specific force integrating receiver; gyro second source.
Martin Marietta: Missile assembly test and system support.
Northrop: Inertial measurement unit; target processor; third generation gyro.
Rockwell International: Fourth-stage system.
TRW: Targeting and analysis program.
Westinghouse: Launch canister.

4897.111

USAF SMALL ICBM

A small intercontinental ballistic missile (SICBM) is being developed by the US Air Force and the DoD as part of the US President's strategic modernisation programme (see **4560.111**). Following the recommendations of the Schriever commission, the USAF set up a SICBM Programme Office in July 1984 to direct development and acquisition policies for both missile and basing technologies.

Congress has established a 30 000 lb (13 600 kg) weight limit for the SICBM with sufficiently high accuracy to ensure a high probability of damage to hard targets. A single warhead is to be carried to maximum ranges of approximately 6000 nautical miles (11 000 km). The provisionally accepted characteristics appear in the table below. The re-entry vehicle will be the Mk 21 being developed for the Peacekeeper ICBM with a 500 KT warhead. The SICBM is under consideration for deployment on mobile radiation-hardened truck launchers to enhance system survivability. During peacetime the launchers will move about at random over large military reservations in a similar fashion to that planned for Peacekeeper when it was still known as the MX. At times of tension, the SICBM launchers would be permitted to travel more extensively to complicate an enemy's targeting task further still.

CHARACTERISTICS

Length: 40·2 m
Diameter: 3·65 m
Weight: 13 600 kg
Payload weight: 453 kg
Propulsion: Solid
Guidance: AIRS type or stellar-inertial
Re-entry vehicle: Mk 21 with 500 KT warhead.

Bell Aerospace, Boeing, General Dynamics and Martin Marietta have been selected to produce competitive designs for a launch vehicle capable of withstanding a minimum of 30 psi overpressure and at least 10 psi when moving. The vehicles are between 22·8 and 30·4 metres long with a height of about two metres, capable of a road speed of about 100 km/h, and are expected to have a gross weight of 54 000 to 68 000 kg. The basing mode for the SICBM has not been finally determined, but the missile will be designed to accommodate silo launching or the hardened mobile launcher. It is intended to award the contract for the full-scale development of the mobile launcher if it is required, after a basing mode has been chosen.

Northrop Corp is supplying guidance units for use in the SICBM programme under a contract awarded by the USAF in December 1984. The units will be Modified Advanced Inertial Reference Spheres (MOD AIRS), based on the guidance systems being produced for Peacekeeper. MOD AIRS has been designated as the base-line guidance unit for the SICBM programme.

STATUS

The recommended programme that is being followed by the USAF includes a competitive system definition phase; a competitive pre-full-scale development phase; and a full-scale development phase. The system definition phase was nearing completion by early 1985, and this built on Peacekeeper technology as well as assessing alternatives to ensure success in meeting the objectives set out for the SICBM. The pre-full-scale development phase began in late 1984 and was expected to continue with competitive contracting for weapon systems integration, propulsion, and the hard mobile launcher. The full-scale development phase for the basing mode(s) will begin in 1987, and this programme will lead to flight testing in 1988 with initial operational capability in 1992.

Eighteen development contracts had been awarded by early 1985 during the SICBM concept definition phase. These include work on the propulsion, hard mobile launcher, guidance and control, command and control, and weapon system concept definition efforts. Hardness validation tests of the mobile launcher began in October 1984 and continued into 1985.

Funding for SICBM development set out in the 1985 DoD Budget (in $ millions) was as follows:

Fiscal year	1984	1985	1986	1987
SICBM & Launcher	328·3	461·5	624·5	*

*To be determined.

2716.111

MINUTEMAN II INTERCONTINENTAL BALLISTIC MISSILE

Minuteman II was introduced as a considerably improved version of Minuteman I. The improvements, however, took the form of an upgrading of the missile's capabilities rather than a radically new departure as, in some respects, is Minuteman III (**2717.111**). Like Minuteman I it is a three-stage ICBM carrying a single thermonuclear warhead, but it has increased range and azimuth, providing greater targeting coverage, while carrying a larger payload. A more sophisticated guidance system is capable of pre-storing the locations of a larger number of alternative targets (see **2710.111**) and the over-all accuracy of the missile system is greater than for Minuteman I. The increased payload capability enables the missile to carry a larger thermonuclear warhead together with a number of penetration aids.

The first- and third-stage motors of Minuteman II are believed to be the same as those on Minuteman I but the second-stage motor is new.

CHARACTERISTICS

Service designation: LGM-30F
Type: 3-stage, solid-propellant, intercontinental ballistic missile
Guidance: Inertial, Rockwell International Autonetics

Propulsion: First stage, Thiokol TU-122 (M-55), approx 91 000 kg st; second stage, Aerojet SR19-AJ-1, approx 27 500 kg st; third stage, Hercules, thrust approx 16 000 kg. Thrust vector control on first- and third-stage motors by 4 movable nozzles. Second-stage motor has a single nozzle with secondary liquid injection for thrust vector control

Re-entry vehicle: Avco Type 11B and 11C with Mk 1 and 1A penetration aids, the latter supplied by Tracor Inc

Warhead: Thermonuclear single warhead of a yield unofficially reported as around 2 MT

Dimensions: Length 18·2 m; diameter approx 180 cm at first stage interstage

Launch weight: Approx 31 750 kg

Speed: >24 000 km/h at burn-out

Range: >11 250 km

STATUS

Operational. According to firm plans at the time of writing, 450 Minuteman II missiles will be kept on the active strength for some years to come. In 1982 it was stated that some Minuteman II missiles are allocated to the Emergency Rocket Communications System for SIOP communications.

The Minuteman ICBM completed 20 years in operational service in October 1982, and seems destined to serve for an appreciable time yet. Additional details of historical background, deployment and development over the years have appeared under entry number **2710.111** in previous editions of *Jane's Weapon Systems*. (See also US ICBM Modernisation Programme, **4560.111**).

CONTRACTORS

Assembly, test and installations: Boeing Aerospace Company, Seattle, Washington 98124, USA.

Systems engineering: TRW Systems Group, 1 Space Park CR, Redondo Beach, California 90278, USA.

Guidance: Rockwell International Corporation, Autonetics Strategic Systems Division, 3370 Miraloma Avenue, Anaheim, California 92803, USA.

Propulsion: Aerojet-General Corporation, 9100 E Flair Drive, El Monte, California 91734, USA; Hercules Inc, 910 Market Street, Wilmington, Delaware 19899, USA; Thiokol Corporation, Bristol, Pennsylvania 19007, USA.

Re-entry vehicles: Avco Systems Division, 201 Lovell Street, Wilmington, Massachusetts 01887, USA.

Penetration aids: Tracor Inc, 6500 Tracor Lane, Austin, Texas 78721, USA.

2717.111

MINUTEMAN III INTERCONTINENTAL BALLISTIC MISSILE

Minuteman III is the most potent weapon in the land-based armoury of the United States. Like Minuteman I and Minuteman II it is basically a three-stage ICBM powered by solid-propellant rocket motors, but it incorporates several features which make it more than a simple improvement on the two earlier members of the series.

Most of the special features relate to the final stage and re-entry system and the most significant, operationally, is the introduction of a MIRV system of three warheads. This MIRV head is essentially a fourth stage of the missile and is powered by a 135 kg thrust motor and manoeuvred by six small pitch and yaw motors and four smaller roll motors. These motors are controlled by the fourth-stage guidance package which also organises the release of the warheads, chaff, and decoys from the General Electric re-entry vehicle. The third stage of the missile has also been considerably improved by the introduction of a new motor using fluid-injection thrust-vector control, which gives a finer control of movement than the earlier arrangement of four movable nozzles and which, with improved guidance, enables the missile to carry its large payload over a greater range and at the same time reduce the missile's CEP to about 400 m.

CHARACTERISTICS

Service designation: LGM-30G

Type: 3-stage, solid-propellant, intercontinental ballistic missile

Guidance: Inertial, Rockwell International

Propulsion: First stage, Thiokol TV-122 (M-55), approx 91 000 kg st; second stage, Aerojet SR19-AJ-1, approx 27 500 kg st; third stage, SR73-AJ-1 Aerojet and Thiokol, approx 15 500 kg st; post-boost propulsion system, Bell Aerosystems package comprising 135 kg st bi-propellant (nitrogen tetroside/MMH) engine for fore-and-aft control, 6 10 kg st engines for pitch and yaw control and 4 skin-mounted 8 kg st motors for roll control. Propellant tanks are welded shut for long-term silo storage. All motors commanded by fourth-stage guidance package

Re-entry vehicle: General Electric Mk 12. Normal Minuteman III payload is 3 MIRV warheads plus chaff and decoys. 2 or 3 Mk 12 RVs can be carried with a yield of about 200 KT each. A Mk 12A RV with a yield of about 330 KT is being substituted for the Mk 12 on 300 Minuteman III missiles

Warheads: Thermonuclear, W-62 approx 200 KT each; or W-78, 330 KT each

Dimensions: Length 18·2 m; diameter 185 cm at first stage interstage

Launch weight: Approx 34 500 kg

Speed: >24 000 km/h at burn-out

Range: >13 000 km

CEP: <400 m

STATUS

Operational. Full planned force of 550 Minuteman III and 450 Minuteman II missiles are now operationally deployed. Considerable efforts are being sustained to maintain and enhance the operational potential of the Minuteman force, of which the Minuteman III is the principal element. These efforts embrace the Mk 12A, guidance accuracy improvements, silo upgrading and other programmes.

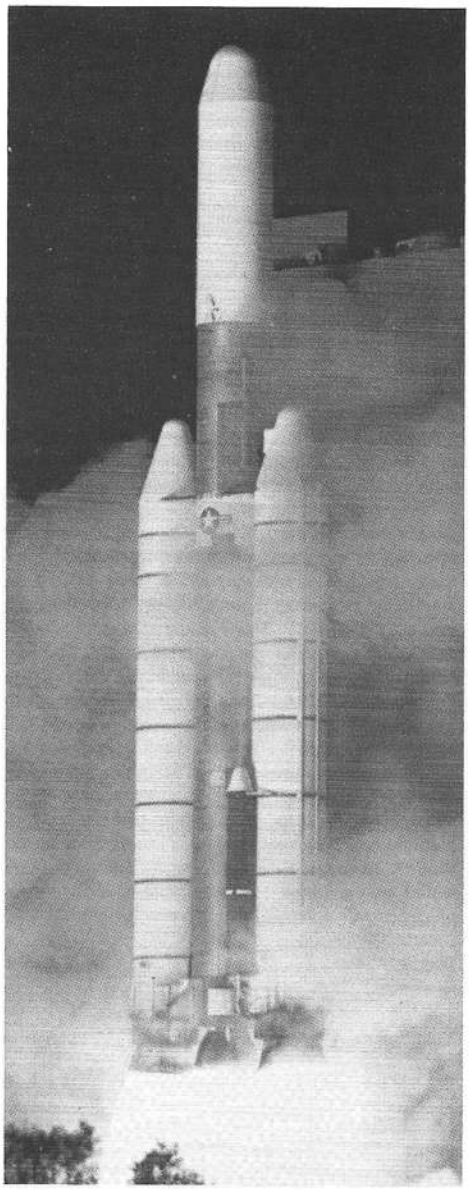
Replacement of Mk 12 warheads with Mk 12A RVs on some Minuteman III missiles is in progress and about 300 missiles are due to be fitted with the new RV which carries a W-78 warhead. This warhead is about 16 kg heavier than the Mk 12s and there is a consequent slight reduction in the Minuteman III range and MIRV footprint. Deployment of the Mk 12A began in December 1979. In the meantime the NS-20 guidance software improvements are scheduled for incorporation on all Minuteman IIIs.

As noted above, the Minuteman system had served as the main element of the American land-based strategic ICBM force since October 1982. Conversion of 100 Minuteman III silos in Nebraska and Wyoming to house MGM-118 Peacekeeper ICBMs will start in 1986. The first ten MGM-118s are due to be in position by December 1986.

(See also US ICBM Modernisation Programme, **4560.111**)

CONTRACTORS

Assembly, test, and installation: Boeing Aerospace Company, Seattle, Washington 98124, USA.



Systems engineering: TRW Systems Group, 1 Space Park CR, Redondo Beach, California 90278, USA.

Guidance: Rockwell International Corporation, Autonetics Strategic Systems Division, 3370 Miraloma Avenue, Anaheim, California 92803, USA.

As Titan II ICBMs are retired, redundant missiles may be reworked to the Titan III standard, shown here, for use as satellite launchers. This series of Titan III/34D operational launchers (over 120) has recorded a 97·6 per cent success rate

2826.111

TITAN II INTERCONTINENTAL BALLISTIC MISSILE

The LGM-25C Titan II is an improved version of the earlier HGM-25A Titan I intercontinental ballistic missile. It carries the largest of all US ICBM payloads and has a launch reaction time of one minute from its fully hardened underground silo.

Titan has been operational with the Strategic Air Command since 1963 and was originally deployed in three wings of 18 missiles each at Davis-Monthan AFB, Arizona; McConnell AFB, Kansas; and Little Rock AFB, Arkansas. Since entering service two missiles have been lost in silo accidents.

CHARACTERISTICS

Designation: LGM-25C

Type: Land-based intercontinental ballistic missile

Guidance: Inertial

Propulsion: 2-stage liquid propellant rocket motors. Stage 1: 195 000 kg st; stage 2: 45 000 kg st

Warhead: Nuclear. W-53, estimated 9 MT yield

Re-entry vehicle: General Electric Mk 6

Missile length: Stage 1: 21·3 m; stage 2: 6·1 m; re-entry vehicle: 4·3 m; total: 31·3 m

Missile diameter: 3 m

Launch weight: Stage 1: 117 000 kg; stage 2: 29 000 kg; re-entry vehicle: 3700 kg; total: 149 700 kg

Speed: >24 000 km/h

Ceiling: About 1500 km

Range: About 15 000 km

STATUS

Titan II is being phased out and it is planned to complete the retirement programme in 1987. Nevertheless it is arranged that those missiles on alert during the phase-out period will be in a position to contribute to the US deterrent posture. During 1982-84 the USAF made a number of improvements to enable the system to be operated safely until phase-out. Deactivated silos will be dismantled to comply with SALT terms, in step with Trident SLBM deployments. The 1985 budget requested $69·7 million for Titan system operation and winding down, and $10·3 million for silo dismantling. Deactivation of the first Titans took place in Arizona in November 1982 and this process is expected to continue gradually until 1987.

CONTRACTOR

Martin Marietta Aerospace, Denver, Colorado 80201, USA.

1133.411
POSEIDON C-3 (UGM-73A) FLEET BALLISTIC MISSILE

This is a two-stage, solid-propellant strategic missile designed for launching from submerged submarines of the USN. It was a successor to the Polaris A-2 and A-3 weapons. The range of Poseidon is the same as for the Polaris A-3, 2500 nm (4630 km), but weight is more than doubled at 29 480 kg. Dimensions are correspondingly greater with length 10·36 metres and diameter 188 cm, but the later missiles were capable of deployment in the launch tubes of Polaris submarines without major modifications to the ship.

A considerably increased nuclear payload of up to 14 MIRVs carrying W-76 warheads enables a single Poseidon to be used against a number of targets. An improved guidance system was also incorporated which provided double the accuracy, it is claimed, of earlier weapons.

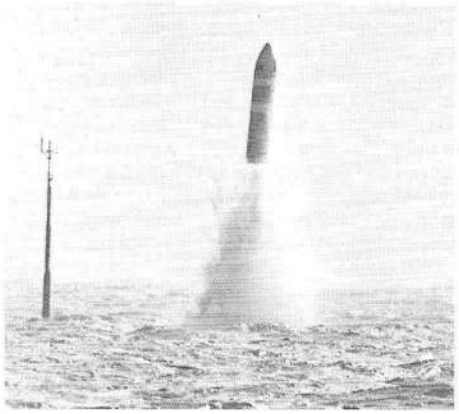
An improved fire control system, Mk 88, was produced for the Poseidon system by the General Electric Company. This interfaces with a later version of the Rockwell SINS (ships inertial navigation system), the missile and the launcher. Mk 88 performs target calculations, insertion of data into the guidance system, test and checkout launch order, and sequence control.

DEVELOPMENT

The first flight model of Poseidon was launched in August 1968 from Cape Kennedy, Florida. The 14th launch, in December 1969, was the first complete test of the weapons system, including the launcher, control, and missile sub-systems. Development flight testing was completed in June 1970.

STATUS

Poseidon became operational in March 1971. An undisclosed number of Poseidon warheads are assigned to NATO targets.



The fiscal year 1984 report by the US Secretary of Defense confirmed that 12 of the original fleet of 31 Poseidon submarines had been converted to operate the later Trident I (C-4) SLBM during the 1970s, and this programme has now been completed. Unless there are any later plans to modify more Poseidon boats to operate Trident I missiles, it is intended to progessively retire the remaining C-3 Poseidon submarines between 1993 and 1999. At 1 January 1985 there were 304 Poseidon SLBMs operational with the US Navy.

CONTRACTORS

Prime contractor: Lockheed Missiles and Space Company, PO Box 504, Sunnyvale, California 94088, USA.

Mk 88 fire control system: General Electric Company, Ordnance Systems Division, 100 Plastics Avenue, Pittsfield, Massachusetts 01201, USA.

Test launch of Poseidon

3993.001
CRUISE MISSILE PROGRAMME

The American cruise missile programme has been difficult to define satisfactorily for almost a decade, for reasons which have been discussed at some length under the above entry number in previous editions of this book. Summarised, US cruise missiles currently in, or planned for operation derive from two separate missile programmes each with their own developer and sponsoring service (USAF and USN), which subsequently were co-ordinated under DoD supervision. Since then models and applications have proliferated, thanks to a great extent to the inherent flexibility of the basic cruise missile concept and efforts of the weapons' producers and sponsoring agencies. Thus there have been air-launched versions derived from both the Boeing ALCM, AGM-86 (**1766.311**) and the General Dynamics BGM-109 Tomahawk. The latter has been developed in several versions: the MRASM (AGM-109H) medium-range air-to-surface missile (cancelled by Congress in fiscal year 1984); several ship- or submarine-launched models (**4197.221**); and the BGM-109G ground-launched cruise missile (**4194.111**). Additional details of the ALCM will be found in the Air-to-surface Missiles section of this volume, as will information on the GLCM in battlefield support context in the appropriate pages. Similarly naval applications of Tomahawk are discussed in the Shipborne Weapons section.

The extent to which any particular cruise missile model is 'tactical' or 'strategic' inevitably depends on the circumstances and the individual conventions that are adopted. However, judgements are frequently based on the parameters of range and payload capability, so that the three US cruise missiles listed in the following paragraphs normally qualify for consideration under the 'strategic' heading on this basis.

Reach of GLCMs with 2500 km range from various launch points (direct flight path)

TLAM-N: The nuclear armed version of the land attack Tomahawk (BGM-109A), tactical land attack missile – nuclear (TLAM-N) which will provide the USN with a long-range tactical weapon which can be used in support of world-wide objectives, including targets within reach of covert submarines operating in waters where America has neither sea nor air control. The nuclear SLCM is claimed to match a capability that has been deployed by the Soviet Union for a long time. Launches by both submarines and surface vessels are planned, and a vertical launch Tomahawk system is planned for certain ships.

ALCM: The AGM-86B air launched cruise missile (**1766.311**) is in production and will form a force of long-range nuclear-armed air-to-ground cruise missiles for use with Strategic Air Command B-52G bombers. This will provide the USAF with increased bomber routing flexibility and targeting options, and will reduce bomber exposure to enemy air defences. Initially, each bomber will have 12 ALCMs mounted externally on jettisonable pylons, with the current internal load of gravity bombs and SRAMs. In the mid-1980s, eight ALCMs will replace the internal load on each aircraft. By 1990 all B-52Gs will be loaded with 20 ALCMs each.

GLCM: BGM-109G, the ground launched cruise missile (**4194.111**) was intended as a response to Soviet deployment of long-range tactical weapons such as the SS-20 in the European theatre. The basic combat flight of the GLCM system consists of 16 Tomahawk missiles, four transporter-erector-launchers, and two launch control centres. One flight will maintain a quick reaction alert status on each main operating base during normal peacetime conditions, but during periods of increased alert status, the GLCM flights would disperse from the main base to satellite stations to ensure increased survivability if attacked. The initial operational capability (IOC) was achieved in December 1983, and

Launch of GLCM during USAF tests

construction of further GLCM basing facilities had already been started in the Federal Republic of Germany, Italy and the UK. Belgium was making basing preparations in 1983 and bilateral discussions between the Netherlands and USA were in progress. Present plans provide for 464 GLCMs to be based in Europe, deployed in 29 flights with 116 launchers; Britain and the Federal Republic of Germany have agreed to provide bases for about one third of this total each, and the remainder would be distributed between Italy, Belgium and the Netherlands.

The original submarine launching mode for the Tomahawk cruise missile employed the submarine's normal torpedo tubes, from which a stainless steel capsule containing the missile was ejected, but a new vertical launch system is under development by Westinghouse, under contract to the USN. Called the capsule launcher system (CLS) it is intended to add firepower to existing and future submarine fleets. Tomahawk missiles are loaded into the capsule at the factory and shipped as a unit ready for use, the capsule providing environmental protection, a means of control and communication, and facilities for a safe launch under all conditions of submarine manoeuvres. The vertical launch mode is claimed to offer an increase of up to 50 per cent in weapon loads compared with the present method which is constrained by the torpedo tubes installed. First installations will be in 'SSN 688' class submarines, within the bow section but external to the pressure hull, and a set of 12 Tomahawk missiles can be carried. These will be available for sequential launch, in addition to the weapons carried in the torpedo room.

STATUS

Tomahawk procurement, actual and planned (see following table), reflects the not unusual difficulties encountered in fielding a novel weapon system, and also the effects that resolution of such difficulties has on subsequent rates of procurement and deployment. The US Navy budgeted for 249 missiles in fiscal year 1986 and another 330 in the following year, for example. The anti-ship and nuclear land-attack versions of the system have already entered fleet service, and the conventionally armed land-attack model is undergoing extensive testing prior to general introduction. At present Tomahawks are fitted in battleships and a number of US submarines, and are to be installed in DDG-963 class destroyers. To maximise the number of weapons that can be carried on each ship, vertical launch systems (VLS) are being installed on the new SSN-688 attack submarines, CG-47 cruisers, and DDG-51 destroyers, and this system is being retrofitted in some DDG-963 ships. The VLS is essentially a cell of launch tubes in which different types of missile and rockets can be clustered.

The modernised cruiser USS New Jersey launches a BGM-109 sea launched cruise missile. USN plans to deploy nuclear tipped Tomahawk cruise missiles on surface ships and submarines for engagement of hard targets

Actual, planned and projected Tomahawk funding and procurement is as follows (in $ millions):

Fiscal Year	**1984**	**1985**	**1986**	**1987**
Quantity	124	180	249	330
Procurement	314·7	578·5	780	929·9

In accordance with NATO decisions, deployments of GLCMs to the UK and Italy began in late 1983, and follow on deployments to these countries, and new deployments to Belgium, West Germany and the Netherlands, are planned for the next few years. All 464 GLCMs are due to be in place in Europe by the end of 1988. GLCM procurement will be completed in fiscal year 1987.

By early 1985, 1080 ALCMs were deployed with about 90 B-52 strategic bombers, and more of these bombers were being prepared to carry this weapon. ALCM development and procurement (actual and planned) for the period 1984-87 (in $ millions) is as follows:

Fiscal Year	**1984**	**1985**	**1986**	**1987**
Development	35·6	25	14·2	15·1
Quantity	240	—	—	—
Procurement	421·3	79·4	34·4	21·9

Under an agreement signed in late 1982, McDonnell Douglas became a co-producer with General Dynamics of the Tomahawk cruise missile.

CONTRACTORS

AGM-86B ALCM: Boeing Aerospace Company, Seattle, Washington 98124, USA.

BGM-109 Tomahawk: General Dynamics Corporation, Convair Division, 5001 Kearny Villa Road, San Diego, California 92123, USA.

BGM-109 Tomahawk: McDonnell Douglas Astronautics Company, Titusville, Florida, USA.

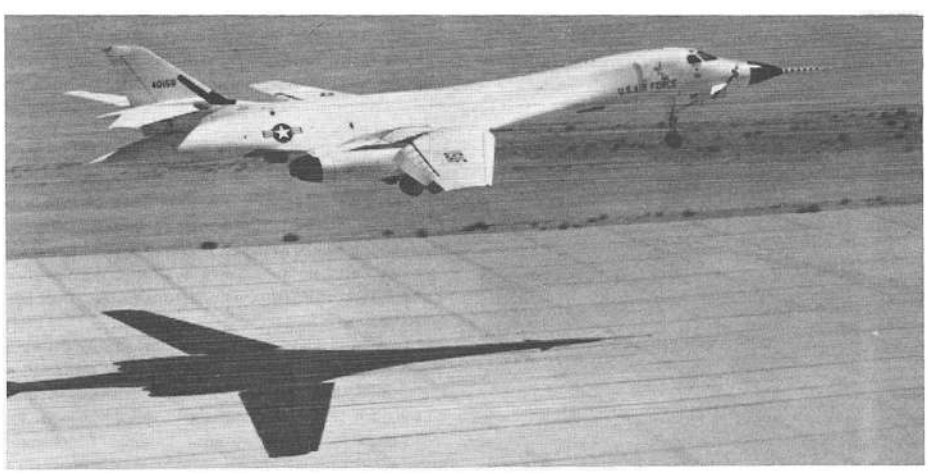
4562.311

US STRATEGIC BOMBER FORCE

The strategic bomber force operated by the USAF consists of B-52 and FB-111 aircraft capable of carrying nuclear or conventional free-fall bombs, the air-launched cruise missile (ALCM) (**1766.311**) or short range attack missile (SRAM) (**1107.311**) and the latest US figures on the composition of these aircraft assigned to strategic duties are as follows:

B-52G	167
B-52H	96
FB-111	61

By the end of the decade, an improving Soviet air defence system is expected to have seriously impaired the B-52's ability to penetrate Soviet airspace. The current Bomber modernisation programme is designed to ease this situation and to maintain the deterrent capabilities of the US bomber force in the 1990s and later.



The programme has three elements: the installation of ALCMs on B-52s; production of the B-1B bombers; the development of the Advanced Technology Bomber (ATB). A number of B-52s not equipped with ALCMs will be assigned to conventional missions. As the ATB bomber is deployed in the 1990s, it is planned to use the FB-111s as tactical aircraft rather than strategic bombers. A total of 1080 ALCMs were deployed on B-52Gs by 1985 when modification of B-52Hs to carry this weapon began. The adoption of the ALCM is expected to extend the operational life of the B-52 fleet by making it possible to operate against Soviet territory without having to penetrate Soviet airspace.

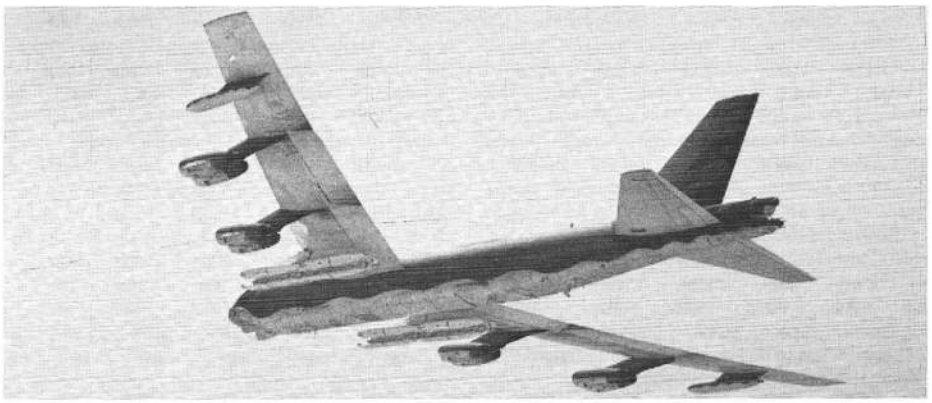
A follow-on cruise missile that is now under development, the Advanced Cruise Missile (ACM), which will have greater range than the ALCM and will incorporate 'stealth' technology is planned to provide further gains in the capability of the strategic bomber force. The increased missile range will add targeting flexibility, and the use of 'stealth' techniques will make the missile harder to detect and improve its penetration capabilities.

The future US strategic bomber force will be composed of cruise missile carriers and modern penetrating bombers. The B-1B will be the main penetrating bomber in the late 1980s and well into the 1990s. The first of 100 such bombers came off the assembly lines some months before the target date, and the B-1B will become operational in 1986. The ATB is intended to be produced in time to supplement the B-1B in the early 1990s, and design of the former aircraft will embody 'stealth' technology to ensure maximum ability to penetrate enemy defences.

STATUS

B-52 bombers were operational with a total of 1080 ALCMs in 1985 and a programme of conversion of B-52Hs to carry this weapon had been started. The first of 100 production B-1B bombers had been

B-1 bomber



completed by early 1985 and entry into operational service is expected in 1986. The ATB is planned for deployment in the 1990s.

Actual, planned and proposed funding for B-52 bomber development and procurement (in $ millions) is as follows:

Fiscal year	1984	1985	1986	1987
Development	68·7	22·2	16	10
Procurement	460·7	466·5	463·6	795·7

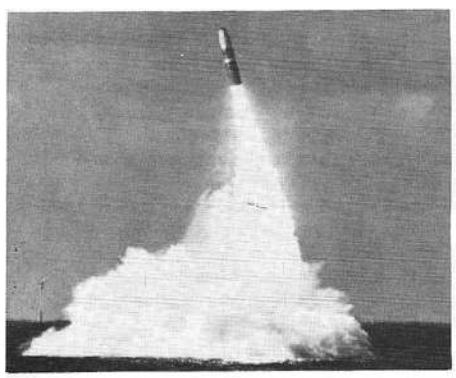
Actual, planned and proposed funding for B-1B bomber development and procurement (in $ millions, quantities in brackets) is as follows:

Fiscal year	1984	1985	1986	1987
Development	737·2	465	367·4	136·3
Procurement	(10)6124·5	(34)7630·7	(48)5624	—

B-52G with ALCMs loaded

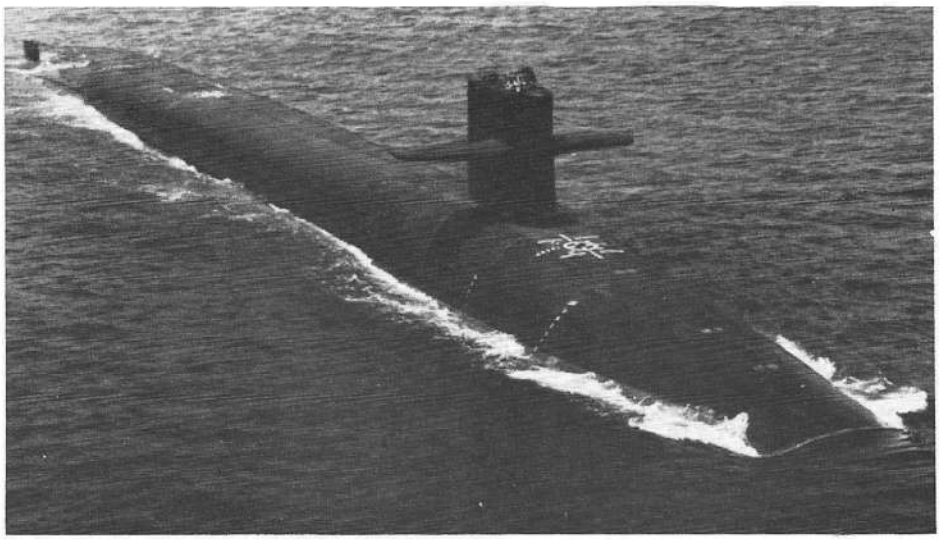
2840.411

TRIDENT C-4 (UGM-93A) STRATEGIC WEAPON SYSTEM



The UGM-93A Trident I (C-4) missile is a three-stage ballistic missile powered by solid-fuel rockets, and guided by a self-contained inertial guidance system, with a range approximately twice that of Poseidon (**1133.411**), or about 7000 km.

The guidance system for the C-4 missile, designated Mk 5, is smaller and lighter than that for Poseidon, thereby reducing inert weight and providing more space for missile propulsion. The Mk 5 guidance system is basically a functional equivalent to the all inertial Mk 3 Poseidon system. The most significant difference is the addition of a stellar sensor which takes a star sight during the post-boost phase of flight. The post-boost vehicle will correct its flight path based on data derived from the stellar sighting. This enables the Trident missile to meet Poseidon accuracy objectives at longer range. The function of the guidance system is to generate missile steering commands during powered flight that accurately direct the missile to the correct velocity, position, and altitude for re-entry body deployment to the assigned target. Control information is generated by inputs from the shipboard fire control sub-system and flight acceleration history.



The post-boost vehicle (PBV) is designed to permit corrections for errors in launch position data and manoeuvres to deploy re-entry bodies, following third stage separation.

A new Mk 4 re-entry body was developed for Trident I. In addition to the ballistic Mk 4 RV, the Mk 500 Evader manoeuvring RV was being developed as an option but the work is understood to have been discontinued. Instead, if it is decided to equip the Trident II (D-5) missile, development of a completely new Mk 5 re-entry system is more likely. Another possibility is the adoption of the Mk 12A warhead as used in some other US strategic missiles.

The launcher sub-system stows and protects the missiles aboard the submarine, pressurises the launch tube and missile before launch, and launches the missile from the submarine. The launch control group is of a new design to provide integrated control and monitoring of 24 missiles and tubes and will be collocated in the missile control centre to improve weapon system control and reduce manning to operate the equipment.

First launch of a US Navy C-4 Trident I SLBM from the submerged fleet ballistic missile submarine USS Ohio *off the coast of Florida* (US Navy)

USS Ohio *(SSBN-726) under way during sea trials. She later launched her first Trident SLBM* (USN)

The fire control sub-system prepares the missile guidance system with targeting and launch position data and co-ordinates the preparation of the launcher and missile test and readiness equipment for the missile launch. Two basic fire control configurations are being developed: the Mk 88 Mod 2 for retrofitting to Poseidon, and the Mk 98 Mod 0 for the new Trident submarine. A new fire control computer, the Trident Digital Control Computer (TDCC), will be required to handle the increased computational work involved in providing pre-settings for the C-4 missile. A digital read-in sub-system (DRISS) will provide a digital guidance interface under the control of the TDCC. The navigation data converter will convert analogue navigation and optical outputs to digital. These systems are common to both fire control configurations.

The Trident navigation sub-system is basically similar in design to that of the 640-class Poseidon SSBNs with the following improvements: (1) the major addition of an electrostatically supported gyro monitor (ESGM) to lengthen the time between navigation fixes and thereby reduce submarine exposure to potential detection; (2) provision for additional closed-loop air cooling to enhance maintenance and reliability; (3) selected modifications to reduce noise, harmonics, and susceptibility to stray electromagnetic interference; and (4) re-engineering of the navigation satellite receiver and the navigation sonar system to ensure economic manufacture.

It is planned to develop a Trident II missile. This will utilise the full volume of the Trident submarine missile tube, and will provide the USN FBM force with the ability to operate beyond the areas possible with the Trident I's 7000 km range. Trident II will be able to achieve this without any reduction in payload, whereas any increase in range of the Trident I is at the cost of a smaller payload.

Two options are being considered for Trident II. One is to increase the missile diameter, as well as its length to provide both greater range and increased payload. The second option would be to use more of the additional missile volume derived from the increased dimensions for still more payload at some sacrifice in missile range. Some of the enhanced payload capability will be devoted to obtaining increased accuracies. A variety of mid-course updating techniques and terminal sensor systems are under consideration as methods of improving accuracy. Updating by means of the GPS satellite navigation system is one example of the former, and there are a number of terminal guidance techniques which might be applied. Among the warheads contemplated for Trident II are existing units such as the W-76 used in the Mk 4 RV of the Trident I missile, and the W-78 which is used in the Mk 12A RV for the updated Minuteman.

CHARACTERISTICS

Length: 10·36 m
Diameter: 188 cm
Weight: 29 500 kg
Propulsion: 3-stage solid
Guidance: Stellar-inertial
Payload: Mk 4 RV with 8 × 100 KT MIRV; or Mk 5
Range: Approx 7400 km

OPERATION

Trident may be launched from submerged or surfaced FBM submarines and is ejected by the pressure of expanding gas within the missile launch tube. After the missile has attained sufficient acceleration and reached a specified distance from the submarine, the first-stage motor is ignited, the 'Aerospike' (an extensible spike at the nose of the missile to improve aerodynamic performance) is deployed, and the boost phase begins. When the first-stage motor burns out, it and interstage are separated from the missile, the second-stage motor is ignited, and the boost phase continues. As acceleration decreases because of second-stage motor burn-out, the second-stage motor is separated and the third-stage motor ignites to continue the boost phase. Third-stage burn-out completes the boost phase, after which the post-boost control system provides equipment section thrust and control until all the RVs have been deployed.

STATUS

In 1985 the major portion of the US sea-based

strategic deterrent consisted of 304 Poseidon (C-3) and 312 Trident I (C-4) missiles deployed in Poseidon submarines. Replacing C-3 missiles with C-4s yielded increased range and enlarged the submarine's operating areas, and thereby their survivability. But it is estimated that these submarines will reach the end of their useful lives in the 1990s. It is therefore planned to build a force of 12 Trident submarines ('Ohio' class), all of which eventually will be armed with 24 D-5 Trident II missiles.

The first eight Trident submarines will be armed initially with Trident I missiles, and Trident II missiles will be deployed on the ninth boat of the class and all subsequent ships, as well as being retrofitted in the first eight ships in due course. Initial deployment of Trident II missiles is expected in late 1989.

Trident II (D-5) is in full-scale development and the first submarine-launched flight test is expected to occur in spring/summer of 1989. Production of the missile is planned to begin in 1987, with 27 missiles; thereafter it is expected to produce 72 Trident II missiles per year from 1988 to 1992, inclusive.

Planned funding for Trident I procurement in fiscal year 1984 was $529 million for 52 missiles, and this will probably be the last batch to be built. As noted above, Trident II production is not expected to commence before 1987, but development funding in fiscal years 1984/85/86/87 was budgeted at $1473·2, $2049, $2 165·6 and $1719·8 million, respectively, and for the latter three years there were also planned preliminary expenditure on procurement of $162·9 $582 and $1865·5 million. In the last of these years (1987) 27 Trident II missiles are to be procured.

Several years ago it was announced that the British Government had decided to purchase the Trident system for Royal Navy submarines. Originally the Trident I version was to have been procured but after the US decision to discontinue Trident I production in favour of Trident II, the British elected to follow suit and adopt the later system. Details of the UK Trident programme appear in **4209.411**.

CONTRACTORS

FBM submarines: Electric Boat Division, General Dynamics Corporation, Groton, Connecticut, USA.

Trident missile system manager: Lockheed Missiles and Space Company, Sunnyvale, California, USA.

3216.131

US BALLISTIC MISSILE DEFENCE PROGRAMME

The US Army's ballistic missile defence (BMD) programme has been America's main activity in the area of defence against strategic weapons that would arrive from space, and R & D into many of the related areas of technology associated with the problems of this aspect of strategic warfare. Since the advent of the President's Strategic Defence Initiative (SDI, **4896.131**) the BMD programme has assumed a wider significance and this change is expected to be accompanied by some change in the future presentation of US Army and Defence Advanced Research Projects Agency (DARPA) activities which may make BMD less readily identifiable in budget and other government publications. Essentially this is because all US efforts that relate to strategic defence are being amalgamated into a single programme to minimise duplication and ensure maximum benefit from co-ordination of previously independently-sponsored projects.

The background and accomplishments of the Army BMD programme have been described under this entry number in earlier editions of this volume. The following paragraphs reflect the US Army's status report in early 1985.

BMD plays an important part in the pursuit of the SDI objective of identifying and developing the best technical options that could support decisions in the early 1990s on whether or not to proceed with development of a national BMD system. The BMD programme itself consists of a broadly based mixture of near- and far-term projects to support all five of the technical areas being followed by SDI (see **4896.131**). The final flight of the Homing Overlay Experiment (HOE) in June 1984 produced the first tangible results for the SDI programme by confirming technology for a non-nuclear capability to home onto and destroy ballistic missile warheads above the atmosphere.

Projects in progress at present include concept definition of a missile which would exploit the lessons learned in the HOE project and provide an option for non-nuclear engagement of attacking missiles above the atmosphere. Another project at the concept definition stage is a defence system that would use a missile which would operate in the upper atmosphere. Demonstration contracts for the appropriate sub-systems were being awarded in 1985 and will culminate in an integrated system demonstration in the late 1980s or early 1990s.

In addition to these and other near-term projects, the BMD organisation is continuing R & D for SDI on advanced technologies for far-term applications, such as a high energy free electron laser and a neutral particle beam device. This organisation is also contributing to realisation of the battle management/command, control and communications (C^3), and non-nuclear lethality aspects of SDI.

The HOE of June 1984 was referred to as a tactical prototype, and the interceptor vehicle employed a Honeywell long wavelength IR sensor, and a kinetic energy kill mechanism that consisted of a 15 ft diameter (4·6 m) net with weighted spokes which is wrapped around the interceptor vehicle body. Propulsion was by means of Rocketdyne bi-propellant rocket motor which could be throttled. The target was an ICBM with a dummy warhead launched from Vandenberg AFB toward an impact point north of the Kwajälein Atol in the Pacific Ocean. The interceptor was boosted from an island in the atol by Minuteman first and second stage motors, on a trajectory that was calculated to miss the target vehicle by over 30 km, so that the interceptor's homing system would have to locate the target, position itself to deploy the kill vehicle, acquire the target, intercept it and unfurl the kill mechanism and destroy the target by the kinetic energy of the resulting collision. This is stated to have been sufficient for the purpose without resorting to nuclear or conventional explosive devices.

In August 1984 a $289 million contract was awarded to Boeing Aerospace to demonstrate the use of airborne IR sensors and data processors in the anti-ballistic missile (ABM) context. A modified Boeing 767 aircraft will be used in the course of a five-year programme to develop what is known as the Airborne Optical Adjunct (AOA) that might be used in a layered ABM system to provide early warning of ICBMs, track RVs, discriminate between warheads and decoys, and give tracking information to ABM ground radars and interceptor vehicles. Long-wave IR sensors are being supplied by Aerojet ElectroSystems and Hughes Aircraft Co. and Honeywell is providing the data processing sub-system.

A $1·1 million contract placed with GTE in October 1984 provides for the company to carry out technical analyses of a C^3 system for the BMD system. The company will also provide the C^3 requirements for the AOA (above). The analysed data is to be delivered in January 1986.

CONTRACTORS

The US Army has listed the following as the major contractors engaged on BMD activities:

Boeing Aerospace Company, Seattle, Washington, 981124 USA.

Lockheed Missiles and Space Company, Sunnyvale, California, USA.

McDonnell Douglas Astronautics Company, Huntington Beach, California, USA.

Teledyne Brown Engineering, Huntsville, Alabama, USA.

LTV Aerospace Corporation, Dallas, Texas, USA.

4896.131

US STRATEGIC DEFENCE INITIATIVE (SDI)

American efforts to examine the feasibility of strategic defences against ballistic missiles were reorganised and gathered together under a new strategic defence initiative in response to a speech of March 1983 by President Reagan. The DoD initiated a Defensive Technologies Study to define a long-term research and technology development programme to explore the key technologies needed for an effective multi-layered ballistic missile defence (BMD) system.

To achieve this goal the R & D programmes of the US Army, Navy, Air Force, Defence Nuclear Agency, Department of Energy, and Defence Advanced Research Projects Agency (DARPA) that relate to missile defence were consolidated in 1984 into the Strategic Defence Initiative (SDI). The objective of the research programme is to develop a proven technology base that can lead to a defensive system that will destroy Soviet ballistic missiles during the various phases of flight (boost, post-boost, mid-course, and terminal). In the first of these (boost), the first and second-stage rocket motors are burning, and during this phase a unique and intense infra-red signature is produced; in the second phase, the bus (warhead carrier) separates from the main engines and the multiple warheads are deployed from the bus, together with such items as penetration aids, decoys, chaff etc. In the third (mid course) phase these travel on ballistic trajectories through space, and above the Earth's atmosphere. In the fourth (terminal) phase, warheads and penaids re-enter the atmosphere and become subject to its influences and effects. It is the aim of the SDI programme to find techniques that will permit engagement of attacking missiles in all four phases of flight.

There is an advantage in engaging the target missile in the boost phase because the warheads and penaids etc have not yet separated. There is also a military advantage in engaging the bus during the post-boost phase, since after deployment of the payload elements, it is necessary to discriminate between warheads and decoys so that only the real target(s) are destroyed. The technologies for the terminal defences are also likely to be applicable to defence against shorter range nuclear ballistic missiles that have brief flight times, eg. SLBMs and theatre-range ballistic missiles.

To manage research efforts, the SDI programme is divided into five major elements:

The first of these, surveillance, acquisition, tracking and kill assessment, is planned to explore the technologies needed to detect, identify, locate, and track ballistic missiles or their components during the boost, mid-course, and terminal phases of their trajectory.

The second element consolidates the third of the directed-energy weapons projects. Here, the research is conducted in the four general classes of directed energy weapons applicable to missile defence: space-based lasers, ground-based lasers, X-ray lasers, and particle beams.

The third research element is concentrated on kinetic energy weapons that are designed to destroy ballistic missiles or their components by direct impact. Research is focused on 'smart bullets' that could be fired from the ground or from space. An example of kinetic energy weapons research was the US Army's demonstration in July 1984 of the technologies necessary to intercept and destroy a ballistic missile warhead in space using non-nuclear kill mechanisms. (HOE see **3216.131**)

The fourth is the critical element and is related to the system architecture and battle management. In this area research is being conducted on how positive command and control might be set up for defensive purposes. Ten contracts were awarded in 1984 for the study of various strategic defence architecture options.

The final element is concerned with survivability, lethality, and key technologies, and research is concentrated on the problems of space electrical power sources, launch vehicle requirements, and the critical areas of ballistic missile lethality and defensive system survivability.

By following a co-ordinated programme it is hoped that by the early 1990s it will be possible to permit a decision whether or not to proceed with the development of a strategic defence system for the USA and its allies. In the event of a decision in favour

of proceeding with development and deployment, implementation would probably follow this pattern:

Research Phase: This embraces the current phase from the President's speech of 23 March 1983, to the early 1990s, when a decision on whether to go on into systems development would have to be taken.

Systems Development/Full-scale Development Phase: Assuming a decision to proceed in the early 1990s this stage would cover the design and construction of actual system prototypes and components, and their subsequent testing.

Transition Phase: This would be the period of incremental, sequential deployment of defensive systems, with the stated intention for each increment, in conjunction with effective and survivable offensive systems, to increase deterrence and reduce the risk of nuclear war. During this period, as the USA and USSR progressively reduce the value of such (strategic ballistic) missiles, significant reductions in their numbers could be negotiated and implemented.

Final Phase: This would be the period during which deployment of defensive systems would be completed and ballistic missile numbers would reach a minimum.

USAF SDI-related programmes

From 1985, several USAF programmes have been integrated into the SDI. The most noteworthy of these are the Advanced Warning System (now known as the Boost Surveillance and Tracking System), the Space-based Space Surveillance System (now called Space Surveillance and Tracking System), and the Strategic Laser Technology Programme (now a part of Directed Energy Weapons).

From that time these programmes are conducted under the SDI management to meet the broader range of requirements of BMD, while also meeting the present validated tactical warning/attack assessment and space defence requirements. The USAF is also heavily committed to the battle management and command, control and communications aspects, and the supporting technologies programme. During the 1980s experiments and demonstrations will be conducted to assess the feasibility of the applicable technologies and to support development decisions taken in the 1990s. This work is intended to assist in the decision-taking processes associated with the choice of whether or not to implement a national BMD system.

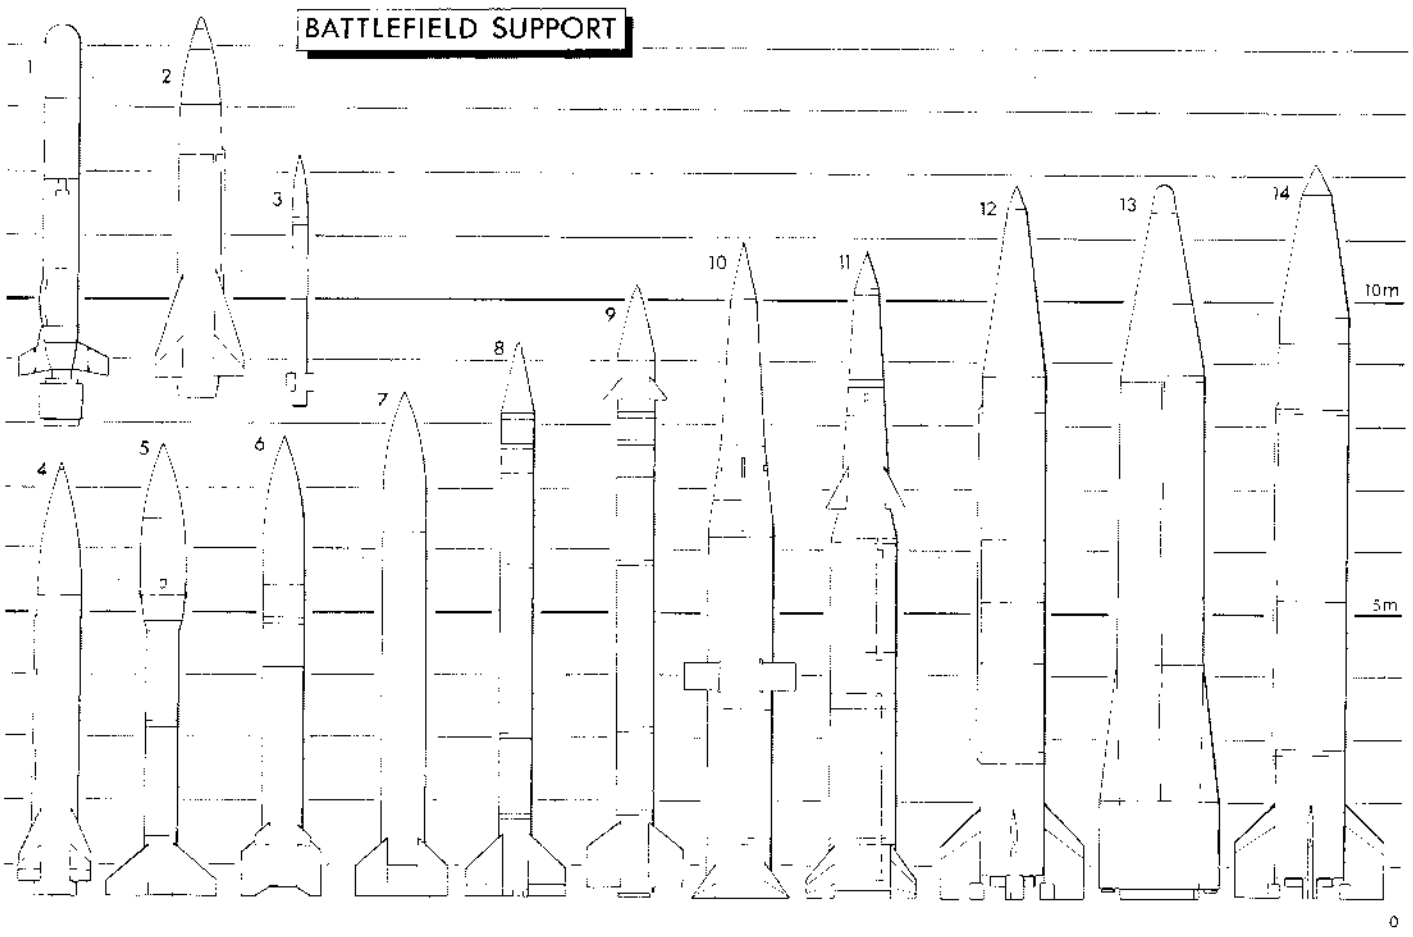
US Army SDI-related activity

The US Army's principal contribution to the SDI from its current activities in this area is the considerable experience that has been accumulated as a result of the BMD programme (**3216.131**). For example, the Homing Overlay Experiment (HOE) of June 1984 demonstrated the ability of a non-nuclear missile to intercept and destroy an incoming warhead beyond the Earth's atmosphere.

Directed energy research devices are already operating at several US laboratories, and these include a neutral particle beam device, and free-electron and chemical lasers at Los Alamos, Livermore, and at contractors' facilities. A 'low-cost' approach to a ground-based 'eximer' laser is also under study in the USA.

TACTICAL SURFACE WEAPONS

2283.111
INTRODUCTION



This section deals with land-based or shipborne tactical systems whose primary function is to attack surface targets. As such they inevitably include examples of several widely varying types of weapon, often differing considerably in the degrees of complexity involved in their design. Despite this, in general the entries that follow mostly fall within one or other of a few readily recognisable categories. For example anti-tank weapons are a common preoccupation and there are two broad approaches used in designing systems to counter individual tank targets or armoured formations: the small, often infantry-operated, guided missiles; and the more complex systems intended to engage multiple targets meant to combat tanks by indirect fire techniques. As far as practicable such generic divisions of the subject matter of this section are arranged in logical groups.

For the convenience of study and reference, weapons have been divided into four groups and are listed in alphabetical order of country of origin within these groups.

Battlefield Support Weapons
Anti-tank/Assault Weapons
Coastal Defence Weapons
Shipborne Weapons

Although the majority of the entries in this section are concerned with guided missile systems, a number of important weapons that do not come into that category strictly speaking, because their significance and operational potential makes it both sensible and convenient to treat both classes collectively. Typical of such blurring of distinctions which were once clear-cut but are now hard to distinguish categorically are modern multiple rocket systems and guided mortar rounds, and new types of sophisticated artillery shells with multiple sub-munition payloads. Weapons of this sort will be found among the first two of the above groups; readers whose interests lie more with the artillery pieces which may be employed to deliver such munitions, or for whom the means of transporting and deploying multiple rocket launchers are a primary concern are directed to our companion yearbook, *Jane's Armour and Artillery*, where full mechanical, constructional and other details will be found

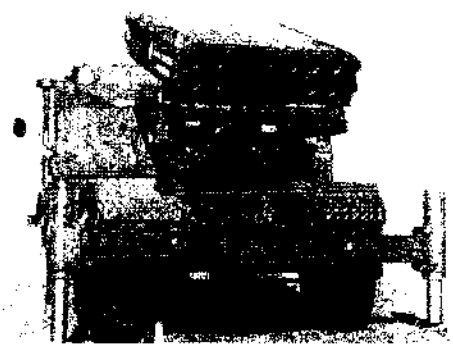
ARGENTINA

3674.111
SLAM-PAMPERO MULTIPLE ROCKET SYSTEM

The SLAM-Pampero is a multiple artillery rocket system developed in Argentina. A 16-tube launcher is employed for 105 mm calibre rockets which are stabilised by four 'wrap-round' fins at the rear of the missile. A single salvo of 16 rockets will fall within an area measuring 300 × 200 m, with maximum dispersion.

CHARACTERISTICS
Calibre: 105 mm
Launch weight: 90 kg
Warhead weight: 11 kg
Propellant: Solid
Max range: 12 km

DEVELOPMENT



Development for the Argentinian Army was undertaken under contract by CITEFA, the Research and Development Institute of the Argentinian Armed Forces.

STATUS

Pre-series production began in 1979.

CONTRACTOR

Instituto de Investigaciones Cientificas y Tecnicas de las Fuerzas Armadas (CITEFA), Zufriategui y Varela, 1603 Villa Martelli, Provincia de Buenos Aires, Argentina

Argentine mobile multiple rocket launcher SLAM-Pampero

3675.111
SAPBA-1 MULTIPLE ROCKET SYSTEM

SAPBA-1 is the designation of a new multiple rocket system under development for the Argentinian Army. Few details have been cleared for publication, but it is believed that this 127 mm rocket system is very similar in concept and certain engineering features to the Argentinian SLAM-Pampero 105 mm multiple rocket system (**3674.103**). In view of the probable all-up weight of the launcher unit with its 40 rockets (some 3000 kg), it seems likely that a self-propelled launcher vehicle is employed, and this may be either wheeled or tracked.

CHARACTERISTICS
Calibre: 127 mm
Launch weight: 56 kg
Propellant: Solid
Launcher capacity: 40 tubes
Max dispersion for multiple launch: 500 × 400 m

STATUS
Development programme.

CONTRACTOR
Instituto de Investigaciones Cientificas y Tecnicas de la Fuerzas Armadas (CITEFA), Zufrategui y Varela, 1603 Villa Martelli, Provincia de Buenos Aires, Argentina.

BRAZIL

4146.111
ARTILLERY ROCKETS

For a number of years, Brazil has been developing unguided rockets. Pioneer work was carried out in the 1960s by the Army Departmento de Estudos e Pesquisas Tecnológicas (Department of Studies and Technological Research). At present, there is very close co-operation between the Army Instituto de Pesquisa e Desenvolvimento (Research and Development Institute) and private industry, which has resulted in a number of systems that have reached operational status with the Brazilian Army and a number of unnamed foreign forces.

Astros

The artillery Saturation Rocket System (Astros) is a mobile multi-calibre rocket system composed of launchers, fire control unit and resupply vehicles, mounted on identical 6 × 6 trucks. The rockets employed are of 127, 180 and 300 mm calibre and provide ranges of nine to 60 km, although maximum ranges of up 70 km have been reported. High explosive and cluster type warheads are available. The fire control system used is the Swiss Contraves Fieldguard system (**3314.181** in the Army Fire Control Systems section of this volume). The Astros system has been sold to a number of countries, among which, it is claimed, is Iraq.

108R (SS-06)

Designated 108-R by the Brazilian Army, this system consists of a 16-tube launcher for 108 mm, spin-stabilised rockets produced by Avibrás. These carry an HE warhead of about three kg and have a range of about 9·2 km. The launcher may be mounted on a two-wheeled trailer for towing by virtually any military vehicle, or may be vehicle-mounted. The launcher crew is said to consist of five men, and the system is fully operational.

SS-07

This system, which has also reached operational status, comprises a 36-tube launcher for Avibrás 70 mm rockets, which are virtually standard FFARs with a four kg warhead and a range of 7·5 km. The launcher may be either trailer- or vehicle-mounted.

SBAT 127

This is an adaptation of the Avibrás SBAT-127 HVAR, with a 20 kg warhead and a range of 15 km. The launcher is a 12-round unit for trailer or vehicle mounting, and the system is operational.

X-20

This is the designation of a 180 mm artillery rocket system, known as the X-20 in the Brazilian Army. The rocket carries a 35 kg warhead and has a maximum range of 35 km, being spin-stabilised by cruciform fins. A three-rail launcher assembly is suitable for either mounting on a tracked chassis, or towing by a 6 × 6 vehicle.

X-40

Already operational in the Brazilian Army, this system consists of a 300 mm calibre rocket capable of carrying a 146 kg warhead to ranges of 68 km. The launcher is a three-rail assembly mounted on a Bernadini X1A1 light tank known as the XLF-40.

CHINA (PEOPLE'S REPUBLIC)

5154.111
107 mm TYPE 63 MULTIPLE ROCKET LAUNCHER

The Type 63 MRL is in service in three models: mounted on a two-wheeled carriage and towed behind a light truck, mounted on the rear of a 4 × 4 or 6 × 6 truck and finally in the mountain role. In the latter it is broken down into man-pack sizes and weighs only 281 kg, assembled, when it rests on four trails, ie two to the front and two to the rear. Incendiary and HE warhead rockets are produced for the Type 63 system.

CHARACTERISTICS
Calibre: 106·7 mm
Number of barrels: 12
Elevation: +57°
Depression: -3°
Weight travelling: 602 kg
Weight of rockets: 18·8 kg (HE); 18·74 kg (incendiary)
Length: 841 mm (HE); 915 mm (incendiary)
Warhead weight: 8·33 kg (HE); 7·54 kg (incendiary)
Max velocity: 372 m/s (HE); 383 m/s (incendiary)
Max range: 8500 m (HE); 7885 m (incendiary)
Fuze: Jian-1
STATUS
In service in Albania, China, and Viet-Nam.
CONTRACTOR
NORINCO, China North Industries Corporation.

4872.111
130 mm TYPE 70 MULTIPLE ROCKET LAUNCHER

The Type 70 self-propelled rocket launcher is used to fire 130 mm artillery rockets. The 19-tube launcher is mounted on top of a Type 531 tracked APC type vehicle, which gives the system good cross-country capabilities and a certain degree of armour protection.

The spin stabilised HE rocket has an HE warhead (other types are possible but have not been confirmed) and all 19 rounds can be fired in less than 12 seconds. The time to prepare for rocket launch, after coming to a halt, is about two minutes, and half that time to move off again after firing.

CHARACTERISTICS
Calibre: 130·65 mm
Number of tubes: 19
Elevation: 0° - 50°
Traverse: 180°
Weight of rocket: 32·8 kg
Weight of warhead: 14·74 kg
Fuze: Jian-1
Max velocity: 437 m/s
Max range: 10 370 m
STATUS
Production.
CONTRACTOR
NORINCO, China North Industries Corporation.

4873.111
107 mm TYPE 81 MULTIPLE ROCKET LAUNCHER

The Type 81 multiple rocket launcher is designed for operation either directly from the rear of a light 4 × 4 cross country truck, or dismounted by means of a pair of detatchable lightweight wheels that permit the launcher to be man-handled or towed some distance from the parent vehicle for firing from the ground. It consists of a single 12-tube 107 mm calibre elevating and traversing firing unit.

The launcher is fitted with magazines so that a group of rockets can be reloaded on the vehicle. There are two firing mechanisms permitting the launch procedure to be carried out either from the vehicle or on the ground. A radio set is provided for crew communications.

The Type 81 can be used with either the HE or the incendiary 107 mm rockets of the Type 63 rocket system, and maximum range is about eight km.

CHARACTERISTICS
Calibre: 107 mm
Number of tubes: 12
Elevation: 0° - 60°
Traverse: 105°
Rate of fire: 10 - 12 s (12 rounds on vehicle); 6 - 9 s (12 rounds on ground)
Total weight in combat: 3615 kg (with 2 sets of rockets)
Rockets: Type 63 HE or incendiary
STATUS
Production.
CONTRACTOR
NORINCO, North China Industries Corporation.

3672.111
140 mm MULTIPLE ROCKET LAUNCHER

A 19-tube 140 mm calibre rocket launcher, mounted on the rear platform of a standard military truck, is deployed in some numbers by the Chinese People's Liberation Army. The weapon is probably of Chinese origin, although in view of the 140 mm calibre which is shared by such Soviet equipments as the BM-16-16, BM-14-17 and PRU-14, Soviet practice could well have influenced the design. The most obvious indication of originality in the Chinese equipment is the use of 19 launch tubes, arranged in two rows: one of ten over another of nine tubes. There are likely to be other, more subtle, differences between the Chinese and Soviet hardware, but it is also likely that the performance of individual rounds of the same calibre will be very similar. This suggests a muzzle velocity of about 400 m/s and a typical range of some ten km.

The launcher is likely to be adjustable in both elevation and traverse, and the operational arrangements probably provide for rapid re-supply and reloading. All-up weight of the loaded vehicle and launcher must be in the region of 8500 kg.

STATUS
In service.
CONTRACTOR
Chinese State Arsenals.

CZECHOSLOVAKIA

5137.111
122 mm ROCKET LAUNCHER M-1972 (RM-70)

The M-1972 rocket launcher was first seen during a military parade held in Czechoslovakia in 1972. The designation RM-70 has also been associated with this weapon. It basically consists of a modified Czechoslovak Tatra 813 (8 × 8) truck chassis, on the very rear of which has been mounted the Soviet BM-21 rocket launcher (**5555.103**). The cab is of the forward control type and is fully armoured. Immediately behind the cab is a rack of 40 rockets, which enable the launcher to be reloaded in five minutes, compared with ten minutes for the Soviet BM-21 launcher. The Czechoslovak vehicle has greater cross-country capability than its Soviet counterpart and is provided with a central tyre pressure regulation system, which enables the driver to adjust the tyre pressures to suit the type of ground encountered.

122 mm rocket launcher (40 round) M-1972

CHARACTERISTICS

	Long Rocket	Short Rocket
Calibre	122 mm	122 mm
Length	3·226 m	1·905 m
Weight	77·5 kg	45·8 kg
Max velocity	not available	450 m/s
Max range	20 500 m	11 000 m

Launcher
Capacity: 40 rounds, plus 40 in reserve
Weight: 14 000 kg (loaded)
Length: 7·76 m
Width: 2·5 m
Height: 2·7 m
Elevation: 0 to +50°
Traverse: 240°
STATUS
In service with Czechoslovakia, East Germany and Soviet Union. Yugoslavia produces its own version of this weapon, mounted on a 12-ton FAP-2220 BS truck. The general arrangement is similar to that of the Czechoslovak system, but with a 32-tube launcher and a slightly different reloading device.
CONTRACTORS
Chassis - Tatra (Czechoslovakia). Launcher - Soviet State Arsenals.

VAP 80 mm MULTIPLE ROCKET LAUNCHER

The VAP 80 mm 12-tube multiple rocket launcher has been developed by the Egyptian Sakr Factory to provide rapid fire support for light infantry units and similar formations. The system consists of a 12-round launcher mounted at the rear of an Egyptian-built jeep type vehicle, but it is possible to mount it on any similar vehicle of this class. Two stabilisers are employed to give support when firing.

Elevation and traverse of the launch unit are effected manually, and there is provision for remote control of the firing operation at a distance from the vehicle. The 80 mm calibre rockets employed are spin stabilised with four folding fins at the rear end. Two types of warhead are available, illumination and HE fragmentation, and both types use a mechanical impact fuze.

CHARACTERISTICS
Calibre: 80 mm
Length: 1500 mm
Weight: 12 kg
Max range: 8000 km
Rocket burn time: 1 s

STATUS
In production.

Sakr Factory for Developed Industries, PO Box 33, Heliopolis, Cairo, Arab Republic of Egypt.

4875.111
122 mm MULTIPLE ROCKET LAUNCHER

The 122 mm rocket launcher consists of two banks of three rows of five 122 mm launcher tubes located side-by-side in a single assembly that is mounted on a turntable carried on the rear of a 6 × 6 military chassis. This vehicle is apparently an Egyptian version of the Soviet ZIL-131 2·3 t truck as used in the BM-21 40-round multiple rocket system. The launcher assembly can be elevated and traversed manually.

The system is designed for use against enemy targets spread over areas up to 20 km distant, and the rate of fire enables up to 40 projectiles to be fired in 20 seconds. HE fragmentation warheads, initiated by a mechanical impact fuze with three settings for action against troop concentrations and infantry support weapons, are provided. Two different brake rings are used to control the rocket range and ensure optimum arrival angles.

CHARACTERISTICS
Calibre: 122 mm
Rocket length: 2·87 m
Weight: 66·6 kg
Fin span: 244 mm
Propellant: Double base, 20·5 kg
Max velocity: 690 m/s
Max range: 20 km (approx)
Dispersion at max range: 110 × 230 m

STATUS
Production.

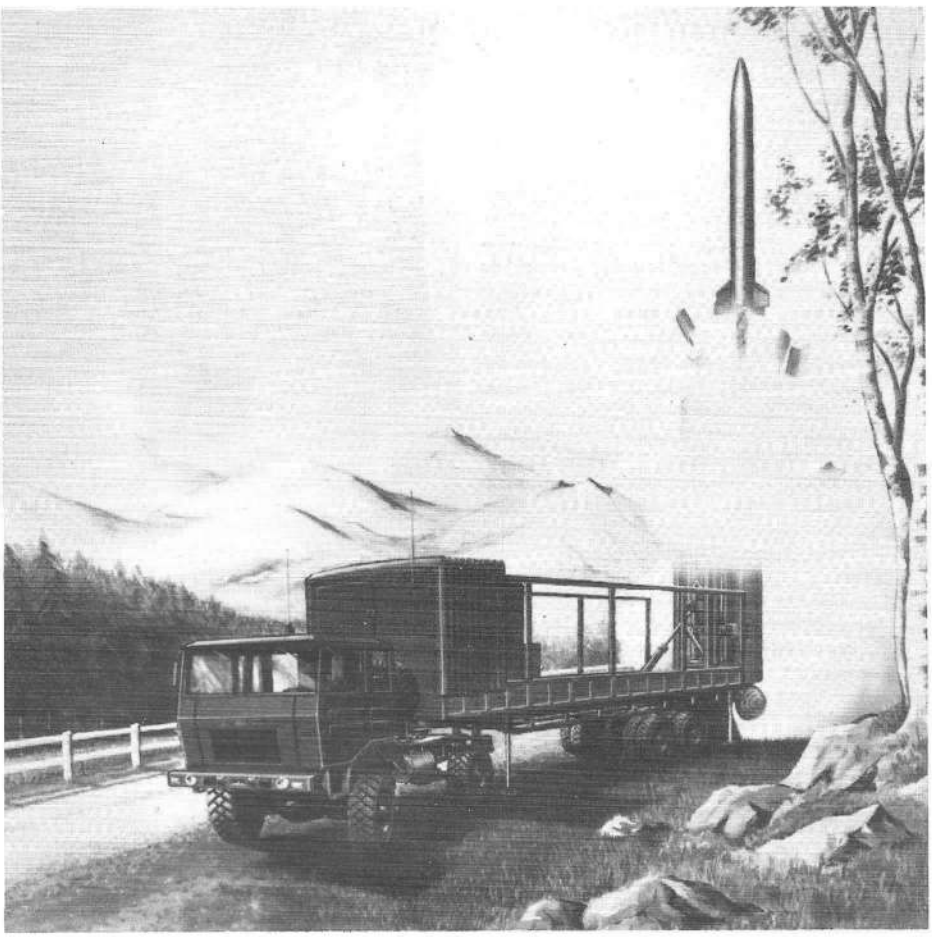
HADES TACTICAL SURFACE-TO-SURFACE MISSILE



In mid-1983 the French Ministry of Defence decided to go ahead with a new tactical surface-to-surface missile system to replace the existing Pluto weapon system (**2130.111**) and definition studies and other preliminary work was entrusted to Aérospatiale.

Definition studies were continuing in 1984 under the management of Aérospatiale, under the guidance of the Direction des Engins (DGA) and in collaboration with the Commissariat à l'Energie Atomique (CEA) for the nuclear payload. Like the Pluton system it will replace, Hades will be a mobile system, and a likely configuration is shown in the nearby drawing issued by the contractor based upon the results of their definition studies. As can be seen, the missile is transported on a semi-trailer and housed in a canister which can be elevated into the firing position on arrival at the launch site. The front part of the trailer carries a shelter which is assumed to house fire control equipment and positions for the operating crew.

Range of the Hades missile is expected to be in the region of 350 km, carrying a nuclear warhead of between 10 and 25 KT. No other details are available at this early stage.

According to the 1983 French Defence Budget, the cost of developing Hades is estimated at between FFr7000 million and FFr10 000 million, and current plans envisage production of a total of 180 missiles. Hades is expected to succeed Pluto in French Army service in 1992.

CONTRACTOR
Aérospatiale, Division Systemes Balistiques et Spatiaux, BP 96 - 78133 Les Mureaux, Cedex, France.

Contractor's impression of Hades tactical surface-to-surface missile system deployed and in operation. Nuclear payload will be carried to a maximum range of about 350 km

---

2130.111
PLUTON BATTLEFIELD SUPPORT MISSILE

Developed to meet a French Army requirement, Pluton is a surface-to-surface tactical nuclear missile. The weapon, which has a range capability from 20 to 120 km, is installed on and fired from the AMX-30 tank chassis, the missile container being used as a launching ramp. Missile and warhead are supplied separately to operational units.

In addition to the AMX-30 launching vehicle the system includes command vehicles containing data processing equipment organised round the IRIS 35M computer of the Plan Calcul Militaire. This is a third-generation general purpose computer capable of operation under severe environmental conditions. If operational circumstances require it, target data can be obtained in real-time from an R.20 drone (**2127.351**) equipped with a Cyclope passive IR reconnaissance system (**1070.353**). Missile guidance is by means of a simplified inertial system based on a SFENA semi-strap-down system. Alternative warheads are available: the 25 kiloton yield AN-51 which contains the same MR50 nuclear charge as the AN-52 free-fall bomb carried by French Air Force Mirage III and Jaguar aircraft, or a 15 kiloton nuclear payload. The former is intended for important targets in an enemy's rear, while the smaller yield device would be employed for use nearer to the main battle area.

CHARACTERISTICS
Type: Land-mobile, vehicle-launched, tactical nuclear weapon system
Guidance: Inertial
Propulsion: Dual-thrust solid-propellant rocket motor. Propellant weight 1200 kg
Warhead: Nuclear 25 and 15 KT
Missile length: 7.64 m
Body diameter: 65 cm
Span: 141 cm
Launch weight: 2423 kg
Range: 10-120 km
CEP: Believed to be 150 - 300 m depending on range
Crew (launch vehicle): 4

STATUS
Initial production contracts were awarded in 1972, and deliveries to the French Armed Forces began early in 1974. It is now operational with four French regiments (3, 25, 60 and 74) and a fifth (32nd) is in the process of being equipped with Pluton. Each

regiment has six launchers plus the appropriate support and re-supply units.

In mid-1977 General Jacques Ménard, second-in-command of the French Army planning and study department, said that consideration of a 'Super Pluton' for the period after the 1960s was already in hand. This weapon would have an appreciably higher performance with improved warhead, greater range and higher accuracy.

A later possibility to emerge (partially) was the Aérospatiale Hades project disclosed in 1980, an air-breathing missile, possibly of the integral rocket ramjet type, which was proposed as the basis of a successor to Pluton. Various trajectories were considered including terrain following but no decisions have been announced.

RAFALE ARTILLERY ROCKETS

Rafale is the name given to an artillery rocket concept which in general outline is similar to that of many other multiple rocket-launching systems but differs from some of them in the design of the rockets and the nature and purpose of the warheads.

Rockets are tube-launched and fin-stabilised, the fins being folded when in the launch tube. Also within the folded fin assembly are small flaps which can be set to erect when the fins open and thus act as air brakes when the missiles are required to operate at shorter ranges. Three sets of air brakes, with different surface areas, provide for three minimum ranges with an elevation angle limited to 15°.

Alternative warhead arrangements have been developed for anti-personnel and anti-armour operations. In each the main warhead contains a number of secondary charges - 35 ball grenades in the anti-personnel warhead and 63 shaped-charge grenades in the anti-armour warhead. The grenades in each are designed to detonate on impact, each ball grenade releasing 360 balls, which are said to be effective against troops at a distance of 20 m from the point of impact. Each anti-personnel grenade weighs 350 grams and ejection of grenades from the rocket warhead is accomplished at a height of about 700 m above the target area, with a timing precision of about one millisecond, by means of a series of detonating cords. By these means a total of 12 600 fragments are distributed over an area of 20 hectares. Each shaped-charge grenade has an armour-plate penetration capacity of 80 mm. Under development is a warhead which will contain five anti-tank mines.

These secondary charges are ejected from the main rocket at altitude – the ejection being timed by a fuze – so as to produce a shower of projectiles over a substantial area. Premature explosion of the main warhead is prevented by a fuze-timed safe-arm device.

CHARACTERISTICS

Rocket calibre: 147 mm

Rafale rocket system mock-up on Berliet 6 × 6 truck chassis (ECPA)

Length: 350 cm
Launch weight: 82 kg
Propulsion: Dual-thrust solid propellant motor
Tube exit velocity: 100 m/s with 5 m launch tube
Max velocity: 1050 m/s
Range: 9 - 32 km
Time of flight: 110 s max
Warhead: Anti-personnel or anti-armour, 22 kg

The launcher comprises a 30-tube unit which can be truck- or trailer-mounted and can be trained and elevated. For each launcher carriage there is a control unit which in addition to distributing firing commands and air-brake actuation commands to the rockets contains also a drift computer and a pre-launch tester. Round-by-round or small-salvo firing are possible; the rate of fire is about two rounds/second. A crew of five is needed.

LARS—110 mm ARTILLERY ROCKET LAUNCHER

The Light Artillery Rocket System (LARS) launcher comprises two groups of 18 launch tubes (4-5-5-4), which can be mechanically trained and elevated, and from which are launched 110 mm calibre rockets. These rockets can be equipped with a variety of warheads and can be launched singly, in partial salvoes, or salvoes. The rockets are flight stabilised by fins which are folded and protected by a cover for storage and handling. A warhead has been developed which will carry either eight AT-1 anti-vehicle mines or five AT-2 anti-tank mines.

The complete system was originally mounted on the rear of a Magirus Jupiter (6 × 6) truck chassis which was fitted with an armoured cab, but subsequently the system was removed from these chassis and fitted onto the MAN (6 × 6) truck chassis.

CHARACTERISTICS

Calibre: 110 mm
Propulsion: Single-stage, solid-propellant rocket motor
Warhead: Choice of high explosive, incendiary, or smoke
Range: 15 km. Minimum 6·5 km
Fire control: Contraves Fieldguard

Launcher
Capacity: 36 rockets in 2 groups of 18 launch tubes mounted on a 6 × 6 wheeled prime mover
Laying: Mechanical
Traverse limits: +130°
Elevation limits: 0 - 55°
Rate of fire: 36 rockets in 18 s
Weights: Rocket 25 kg. Truck and launcher 13 t. System weight in battle order 15 t

STATUS
209 supplied to Federal German Army.

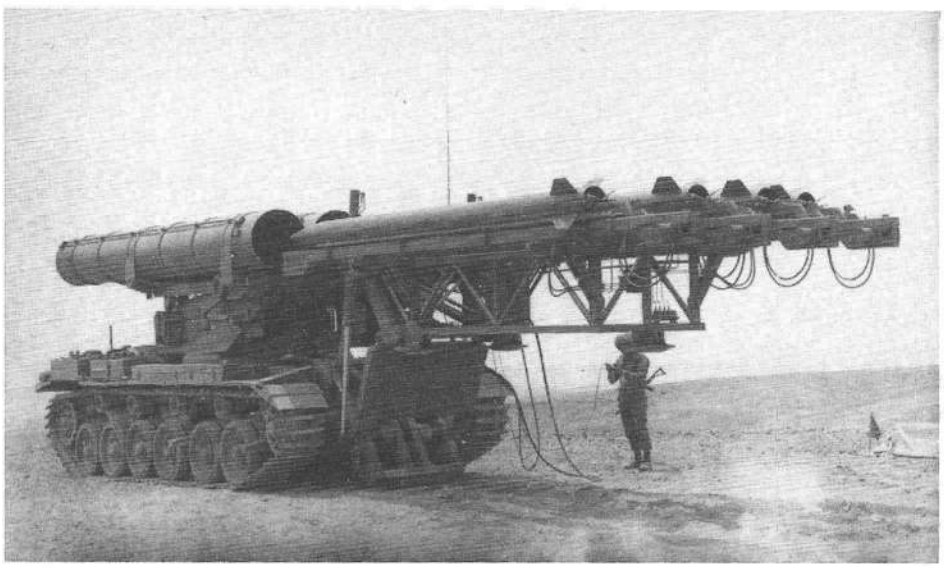
LARS 2 110mm artillery rocket system on MAN 6 × 6 vehicle

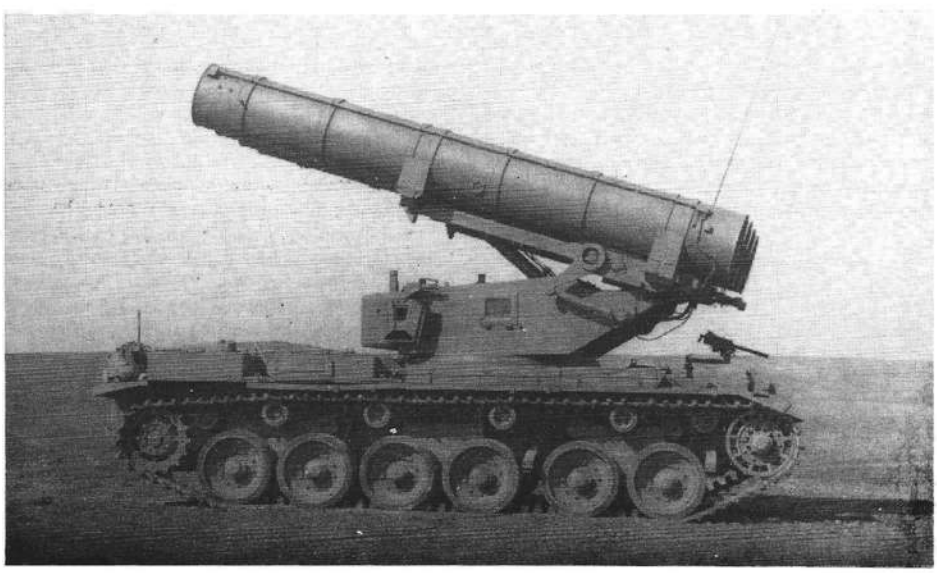
ISRAEL

4098.111
ISRAELI MEDIUM RANGE ROCKET (MAR 290)



The basic 290 mm MAR 290 artillery rocket is 5·45 metres long, with a launch weight of 600 kg of which 320 kg is the warhead. Range is approximately 25 km. These rockets were originally launched from a lattice constructed four-round launcher mounted on the top of a Sherman tank chassis, the vehicle itself being manoeuvred to adjust firing azimuth, with elevation being hydraulically actuated. This model is still in use with the Israel Defence Force (IDF) but recently a new launch system has been developed based on the use of a Chieftain tank hull equipped with a new four-tube elevating and traversing launcher on a superstructure carried on the original turret ring.

Each launcher tube has an internal diameter of 700 mm to accommodate the rocket tail fin span of 570 mm. The overall height of the Chieftain with the rocket tubes in the lowered position is 3·6 metres and the vehicle weight is about 50 tons. A crew of four is carried: commander, driver, and two fire control operators. Details of the fire control system employed have not been disclosed. Rockets are launched with all four crew members inside the vehicle. Once all four rockets have been fired, the launch vehicle moves to a fresh position where reload rounds are already emplaced.



The fresh rounds are taken to this location by a truck which lowers them to the ground for the packaging to be removed. For this the truck uses its own handling crane, which is also used to lift the prepared rounds onto a special reloading frame. When the launcher vehicle approaches, it employs a system of two lugs and a bracket on the hull front to engage corresponding items on the loading frame. The frame is then connected to the vehicle's hydraulic system and a ram on the frame lifts the entire frame off the ground into a raised horizontal position until the rockets are in line with the launching tubes. The launch tubes have previously been rotated to point to the launch vehicle's rear. Using hydraulic power the rockets are then pushed into the launch tubes, and the whole sequence is carried out by one man in about ten minutes using a remote control unit. After loading, the frame is lowered to the ground, the hydraulics and mechanical systems are disconnected, and the frame may then be used for more rockets to be loaded by the supply truck.

CHARACTERISTICS
Type: Unguided, fin stabilised
Rocket diameter: 290 mm
Length: 5·45 m
Fin span: 570 mm
Weight: 600 kg (launch)
Warhead: 320 kg
Propulsion: Solid rocket motor
Range: 25 km (provisional)
Launcher
Tube diameter: 700 mm
Traverse: 360°
Elevation: 0 - 60°

DEVELOPMENT
Israel Military Industries (IMI) was instructed by the IDF to produce a version of the Soviet 240 mm BM-24 artillery rocket, using examples captured in the 1967

Reloading operation of MAR 290 artillery rocket system (T.J. Gander)

New tubed launcher for MAR 290 artillery rocket system mounted on Chieftain chassis (T.J. Gander)

Earlier lattice construction four-round MAR 290 launcher vehicle based on Sherman tank

war as the pattern. The resulting equipment has a range of more than 10 km and is understood to be in service still with the IDF, using launchers mounted on ZIL-157 trucks. The larger 290 mm rocket which became the MAR 290 originated in 1965 and later utilised some of the experience gathered in the course of the 240 mm artillery rocket development programme.

STATUS
The original MAR 290 with the four-round lattice launcher is still operational with the IDF and the new tube-launch version is thought to be about to enter service.

CONTRACTOR

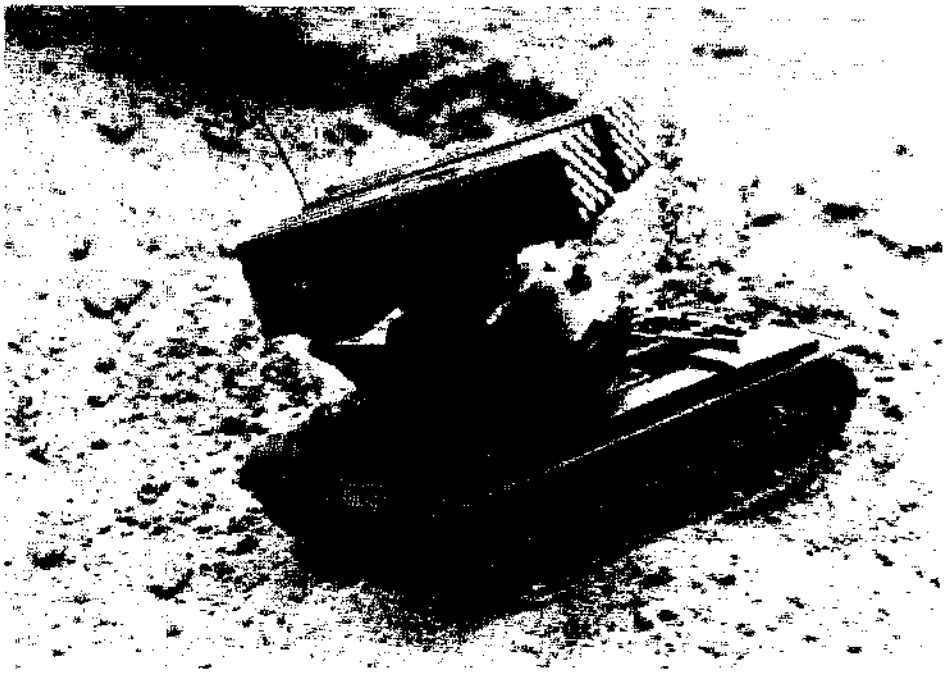
4759.111
LAR 160 LIGHT ARTILLERY ROCKET SYSTEM

The LAR 160 is a multiple launch rocket system designed to direct unguided artillery rockets at battlefield targets at ranges of up to 30 km from tubed launchers mounted on vehicles such as the M-548, M-809, AMX 15T or M-47. These are typical examples and any vehicle from a standard 6 × 6 military truck to virtually any tank chassis may be used.



The first carrier used during trails was an M548 tracked vehicle carrying 32 rounds, but the later production version used a turretless AMX 13 light tank with two 18-tube LPCs. These vehicles have a three-man crew: drive, commander and signaller/gunner operating the fire control system.

A 30 km maximum range and a warhead payload capability of 50 kg enables a wide range of warheads to be employed, including HE, illuminating, AP, and special purpose payloads such as scatterable mines, and dual-purpose submunitions. The rocket calibre of 160 mm allows virtually any payload that can be accommodated in a conventional 155 mm artillery round to be carried by the LAR 160 rocket. A radar-based fire control system is normally employed to ensure optimum accuracy, and if the Fieldguard pilot round technique is also used, maximum surprise in the target area can be achieved.

The system consists of the tracked or wheeled carrier vehicle on which is mounted an expendable multiple launcher containing fuzed, sealed-in 160 mm rockets. A typical LAR 160 battery comprises six launchers with up to 50 tubes (M-47 medium tank chassis) so that a large quantity of warheads or submunitions can be delivered to the target within about 30 seconds of opening fire. The rockets are fired from launch pod containers (LPCs) made up of varying numbers of tubes, depending on the size and type of carrier vehicle used. The tubes are filament wound in glass fibre and have integral guide rails. There is a polyurethane foam filler between the launch tube and the hexagonal aluminium outer envelope. The hexagonal section permits simple construction of LPCs of different capacities.

The LAR 160 rocket is a free flight, fin stabilised, solid propellant, surface-to-surface round comprising: a low drag aerodynamic nose section, payload section, a short burn-time solid rocket motor, and folding wrap-around stabilising fins that deploy when the rocket leaves the launch tube. The number of rockets in each LPC bundle is adjusted to suit the carrying capacity of the vehicle used, and a suitable turntable with elevating mechanism is normally provided. Reloading is rapidly accomplished by replacing an empty LPC with a freshly loaded one.

Fire control systems suggested for the LAR 160 system are the Contraves Fieldguard (**3314.181**), or the Westinghouse Quickfire system based on the arrangement used in the Sgt York mobile AA gun system (**3618.131**) using a version of the F-16 AN/APG-66 nose radar (**3303.353**). In both cases, precision radar tracks pilot rockets fired to 60 – 75 per cent of their full trajectory before being detonated in mid-air to avoid alerting the target area. The computer then calculates aiming data from the trajectory information derived from the pilot shot(s) and the projected impact point(s).

Model of LAR 160 on M47 tank chassis, with two 25-round LPCs

CHARACTERISTICS
Rocket
Calibre: 160 mm
Length: 3·311 m
Rocket motor length: 2·032 m
Warhead length: 1·279 m
Fin span: 350 mm
Launch weight: 110 kg
Weight at burn-out: 77 kg
Propellant weight: 36 kg
Warhead weight: 50 kg
Launch pod container (18-tubes)
Length: 3·46 m
Width: 1·0 m
Height: 820 mm
Weight: 2522 kg (complete); 540 kg (empty)

STATUS
In production and operational with IDF. The system has been exported to an unspecified country (AMX 13 vehicle version) and arrangements have been initiated with a number of US companies with a view to adoption by American Forces.

ITALY

3764.111
FIROS 6 FIELD ROCKET SYSTEM

FIROS 6 is a field weapon system based on the SNIA BPD two inch (51 mm) rocket, capable of performing an anti-guerrilla and infantry support role within a distance of six km. The launcher of the modular type has 48 launching tubes and is installed on a light vehicle with high manoeuvrability and velocity characteristics, allowing the system to perform missions on difficult terrains (jungle, forest, desert). Each firing unit can carry the number of rockets required for firing at least two ripples. The fire control unit offers the possibility of firing partial or complete ripples of rockets with pre-selected warheads.

The rocket has high accuracy due to a special folding fin assembly unit and can carry the following types of warhead: HEI (high explosive incendiary), PFF (pre-formed fragmentation), AT-AP (anti-tank anti-personnel) SM (smoke), SP (spotting), illuminating, practice (smoke, flash and inert).

The FIROS 6 system is supplied either in the 'package' version, inclusive of the vehicle, or in a 'kit' version which can be easily installed on vehicles already in service with armed forces. SNIA BPD has developed an installation of the system with a 48-tube launcher on the Land-Rover Mod 109. The system has also been successfully installed and demonstrated on the FIAT Campagnola 1107AD and 6614 APC.

Fiat 6614 APC vehicle equipped with FIROS 6 rocket launcher system

CHARACTERISTICS
(Typical example installed on Land-Rover 109)
Time to bring the system into action: 3 minutes
Ripple time: 5 s (48 rockets)
Disengagement time: 1 minute
Vehicle: Land-Rover Mod 109
Max speed on road: Over 90 km/h (fully loaded)
Loading capability per mission: 2 ripples (96 rockets)
Overall length: 4·46 m
Overall width: 1·65 m
Overall height: 1·95 m
Rocket launcher
Number of tubes: 48
Elevation: -5 to +45°
Azimuth: ±105°
Length: 2·00 m
Width: 0·60 m
Height: 0·91 m
Weights
Empty launcher: (including sighting and firing units) 250 kg
Payload: (96 rockets) 460 kg; empty vehicle 1850 kg; crew (3 men) 240 kg; overall weight of launch unit in combat conditions 2800 kg

STATUS
In production.

CONTRACTOR

5230.111
FIROS 25 FIELD ROCKET SYSTEM

The FIROS 25 field rocket system has been developed as a private venture by SNIA BPD. It is an area saturation weapon system and is based on the 122 mm SNIA BPD unguided rocket. The system is intended for employment either in battery missions or isolated missions and can cover large areas in the 8 to 25 km zone.

A typical battery would consist of a command post equipped with a fire direction system, six firing units and six or more escort units. The firing unit is a modular rocket launcher installed on a heavy truck (6 × 6) vehicle or a tracked vehicle. The launcher consists of two removable modules with 20 launching tubes each. The escort unit can carry four launching modules. The loading operations are carried out removing the empty module by a jib crane fitted on the support vehicle and installing the filled one ready to fire.

The firing unit has a fire control system and a link with the command post to acquire the necessary firing data in real time. The fire control system has been designed to enable selection of the number (from 1 to 40) and type (see below) of rockets to be fired.

In isolated missions only firing units would be employed, each consisting of the launching vehicle fitted with the launcher and with fire control and fire directions systems enabling direct or indirect fire.

The rocket can carry a variety of different warheads, from the conventional types (HE, PFF, WP) to the sub-ammunition types dispensing anti-tank or anti-personnel mines and bomblets.

CHARACTERISTICS

Time to bring the system into action: 5 minutes
Ripple time: 20 s (40 rockets)
Disengagement time: 1 minute
Reloading time: 5 minutes
Launcher Unit
Number of tubes: 40 (20 per module)
Elevation: 0 to +55°
Azimuth: ±105°
Crew: 3
Landing Module
Length: 3·7 m
Width: 0·82 m
Height: 0·69 m
Empty weight: 400 kg
Loaded weights: 1470 kg (conventional W/H); 1690 kg (submunition W/H)

STATUS

Rockets and complete system are in production.

SOUTH AFRICA

4527.111
VALKIRI 127 mm ARTILLERY ROCKET SYSTEM

Valkiri is a highly mobile artillery rocket system capable of producing high rate saturation fire on area targets at ranges of between 8 and 22 km. It can be deployed on its own or in support of more conventional artillery weapons against area targets such as camps, troop concentrations and convoys of soft skinned vehicles. Due to its high mobility, it is ideally suited to the 'shoot-and-scoot' principle of deployment, ie, to bombard the enemy and move to safety as soon as possible before he can retaliate.

The system has been designed with simplicity of operation and mobility as prime requisites, the latter being achieved by the choice of a suitable launch vehicle consisting of a 24 tube pack mounted on a light 4 ton 4 × 4 petrol driven vehicle. The elevation and traversing of the tube pack is hydraulically assisted; power for the hydraulic system being derived from the power take-off of the launcher or from the vehicle battery. During firing the launcher is stabilised by means of a pair of hydraulic supports mounted at the rear of the launcher.

Standard artillery techniques are applied to sight the launcher; the sight being mounted in the side of the launcher and stored in a special container on the vehicle when not in use. The rockets can be fired singly or in ripples of between two and 24 from within the cab of the vehicle by means of an electronic firing unit mounted inside the cab or remotely via a remote firing unit which can be connected to the launcher via a 50 metre plug-in cable.

A test circuit is incorporated in the firing unit to check the status of the rockets and associated firing circuits as regards possible open or short circuits prior to firing.

At the heart of the Valkiri system is the 127 mm calibre rocket, which consists of a missile comprised of three main sections: the nose housing warhead and fuze; the double base propellant motor; and a tail section consisting of the rocket exhaust nozzle and a folding fin assembly. Total length is 2·68 metres and the weight of each round has been estimated as being in the region of 60 kg. Both contact and proximity fuzes have been developed for the Valkiri, the latter being the most commonplace in South African service because of the nature of the particular operational needs which tend to emphasise the system's anti-personnel applications. For similar reasons the standard warhead is an anti-personnel prefragmentation type consisting of a matrix of about 8500 steel balls which are cast in epoxy resin within a thin walled cylinder surrounding the explosive. The fuze is screwed to the front of the warhead and the proximity fuze now employed represents an important operational advantage over the Soviet BM-21 according to South African sources.

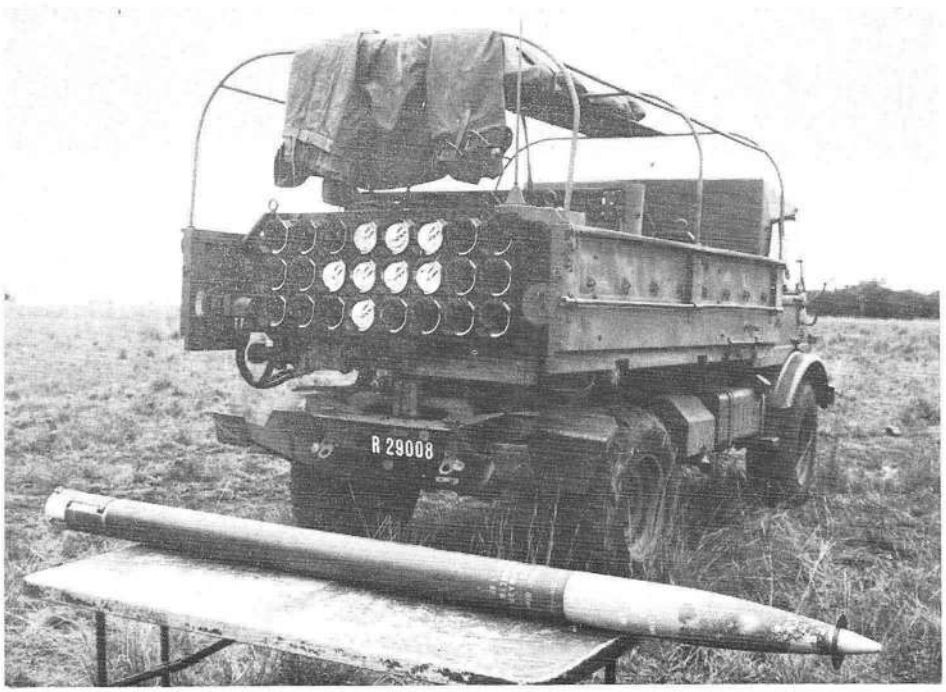
The Valkiri radio proximity fuze incorporates a contact back-up fuze facility and employs a system of frequency agility that is claimed to make it almost impervious to enemy jamming. It is also unaffected by smoke, dust, clouds or rain and capable of operating over a temperature range of -15° to +65° C. Arming is automatic as a result of an acceleration of 40 *g* for a minimum of one second, together with high airspeed; the operating airspeed range is 150 - 1000 m/s and there is a minimum impact angle of 20°. The new Valkiri fuze is powered by an internal wind turbine generator and the device is being developed by the Fuchs electronics concern for Armscor.

Only one size of propulsion rocket motor is required, this giving a maximum range of 22 km, which can be adjusted downward to 15 km by means of the launch elevation angle selected and reduced still further by use of steel drag rings affixed to the rocket body to a minimum of 7·5 km. In addition to the wrap-around aerodynamic fins at the rear of the rocket, spin stabilisation contributes to accuracy and spin is imparted to the round at launch by means of lugs and guides in the launch tubes. Ignition of the propulsion motor is effected electrically, and there is a test circuit to check the status of rockets prior to firing. The warhead lethal area is on average 1500 metres² and the missile accuracy at maximum range is quoted as 290 metres (standard deviation) in azimuth and 200 metres in range (standard deviation).

The Valkiri launcher has a total of 24 tubes arranged in three horizontal rows of eight, carried on a traversing and elevating mount which is operated hydraulically. This mount is integrated with a standard light four-ton Unimog 4 × 4 petrol driven chassis, the only other modification to which is the provision of two hydraulically actuated stabiliser spades which are used when deployed for firing. A canvas top cover is provided for the launcher tube assembly and apart from the inconspicuous retracted support spades there is no external evidence of the vehicle's function so that to a casual observer it appears as an ordinary truck carrying troops or supplies whilst on the move. Hydraulic power for the stabilisers and traverse and elevation of the tube assembly is derived from either the vehicle's power take-off or from the battery. Each launcher vehicle carries the firing crew of two, radio, sight and on-vehicle or remote fire control equipment.

The fundamental unit of the Valkiri system as operated by the SADF is one of the launcher vehicles described above, and this is known as a multiple artillery rocket launcher (MARL). The SADF organisational structure provides for one first line ammunition carrier vehicle to each MARL, the former being a standard SAMIL 5 ton truck fitted with a collapsible cargo stowage assembly which is also capable of fitting other vehicles. Each of these ammunition carriers transports 48 Valkiri rockets in containers, together with fuzes, tools and other ancillary equipment. Folding steps at the rear of the vehicle facilitate loading and unloading of ammunition by hand. Four MARLS and their resupply ammunition carriers comprise one artillery troop under a fire control team, which is under the direction of battery HQ. Two troops constitute one battery, batteries coming under the control of regimental headquarters. Associated with each troop fire control is a survey team and a meteorological team, the latter having a Unimog-based support vehicle that is fitted with an anemometer and wind vane mounted on a telescopic mast for surface wind measurement to be used in ballistic computation.

In addition to the mast-mounted sensors, at the MARL sites a wind gun which fires a small calibre projectile is used to estimate the prevailing local ground wind conditions. These local meteorological data complement upper atmosphere conditions obtained by the divisional met data system based on the S700 meteorological ground station which operates in conjunction with balloon-borne radio sondes. Operationally high first-round hit capability is achieved by compensating for the prevailing upper air and surface wind conditions by means of range table correction computed from the data obtained as described above. Meteorological and upper air wind data obtained by the divisional S700 system (**4494.161**) is transmitted direct to individual troop fire control units of each battery within a division.



A MARL can be ready to fire within five minutes of arriving at a pre-surveyed site so that theoretically in under six minutes a battery can launch a total of 192 rockets carrying high explosive anti-personnel warheads to a target up to 22 km away. In accordance with the 'shoot-and-scoot' principle embraced by the system designers, each MARL can be ready to move again in a maximum of two minutes. Alternatively, in ten minutes each could be reloaded with another 24 rockets and ready to fire again. These performance factors (see also tabulated characteristics, nearby) allied to vehicles capable of road speeds up to 90 km/h, road, rail and air (C130 or C160) transportability, modest initial cost and low manning requirements add up to a remarkably cost-effective weapon system that reveals an outstanding ability to rapidly assess and define an operational requirement and react quickly and economically to meet it.

CHARACTERISTICS

Launcher
Number of launch tubes: 24
Firing rate: 1 per second
Firing mode: Singly or any ripple between 2 and 24
Elevation: 888 mils (max)
Traverse: 1851 mils

Valkiri 127 mm rocket system launcher preparing for operation (T. J. Gander)

Valkiri MARL vehicle ready to move with 127 mm rocket on table (T. J. Gander)

Vehicle: 4-ton 4 × 4
Max speed on open roads(loaded): 90 km/h
Crew: 2
Time to load 24 rockets: 10 minutes (max)
Time for deployment of launcher on a surveyed site: 5 minutes
Rocket
Calibre: 127 mm
Length: 2680 mm
Propulsion: Double base solid fuel rocket motor
Warhead
Type: Prefragmentation
Lethal area: 1500 m² average
Fuze: Proximity or contact
Performance
System effectivity (battery of 8 launchers) kill effectiveness on a standard 400 × 500 m
NATO target: 30%
Range: 8 to 22 km (with drag rings)
Precision at maximum range
Standard deviation in azimuth: 270 m
Standard deviation in range: 190 m
Accuracy at maximum range
Standard deviation in azimuth: 290 m
Standard deviation in range: 200 m
STATUS
Operational since 1981 with South African Defence Forces. Development began in 1977 and was completed in March 1981. In production.

TERUEL 140 mm MULTIPLE ROCKET SYSTEM

The 140 mm multiple artillery rocket system used by the Spanish Army is based on mobile launcher vehicles mounted on Pegaso 3050 6 × 6 track chassis on the rear of which is carried an elevating assembly consisting of two 20-round blocks of launch tubes for the 140 mm calibre rockets. The driving cab of the vehicle can be provided with a roof mounted machine gun for self defence against aircraft or other lightly armoured threats.

The rockets are equipped with a 1·57 second solid fuel propulsion motor, and by the selection of one of three types of aerodynamic air brake three different trajectories can be flown for the same tube elevation angle. Rockets also have flip out stabilising fins. Either an 18·6 kg HE warhead containing 6·6 kg of composition B explosive, or a 21 kg sub-munition warhead can be employed. The latter payload is available in three versions: (a) with 42 anti-personnel grenades, 400 steel pellets and percussion fuzes, (b) 28 hollow charge grenades with contact fuzes and capable of penetrating 100 mm of armour, or (c) six pressure activated anti-tank mines fitted with anti-disturbance devices. The rocket fuzes may be either the PDM-34A1 contact type, proximity or timed. Mixed loads of all three types of rocket can be contained in each of the 20-round blocks carried on the launcher vehicle, and may be selected for firing according to the target(s) to be engaged. Reloading is effected manually.

A re-supply vehicle with four 20-round blocks is allocated to each firing vehicle, as part of the battery, and the system is normally deployed in battalions of three batteries each with six firing vehicles.

CHARACTERISTICS
Calibre: 140 mm
Number of tubes: 40
Length of rocket: 2·044 m (HE); 2·14 m (sub-munition)
Weight: 26 kg (HE); 59 kg (sub-munition)
Max range: 18 200 m
Max velocity: 687 m/s
Reload time: 5 minutes
Max elevation: +55°
Traverse: 240°
Crew: 2 or 3
STATUS
In service. The exact extent to which the Teruel 140 mm system has replaced earlier Spanish artillery rockets (**2033.11** in earlier editions) is not known.

OERLIKON 81 mm TYPE RWKO14 ROCKET LAUNCHER

The Type RWKO14 multi-tube rocket launcher is designed for firing Oerlikon 81 mm SNORA unguided solid fuel rockets. This rocket has folding fins and a pure internal burning propulsive element. The RWKO14 comprises two groups of 15 launch tubes mounted symmetrically on a one-man armoured turret, carried on an APC (see illustration). Loading is simple and a typical reloading time is about six minutes. Aiming in traverse and elevation is by manual operated mechanism and laying is accomplished by means of a computer-assisted aiming periscope, Type RLK252. The firing control arrangements provide for single round firing of rockets in pairs and for salvoes, and used for ground-to-ground engagements, ranges of 4 to 10 km are attainable.

CHARACTERISTICS
Calibre: 81 mm
Rate of fire: 2 × 300 rounds/minute (max)
Length of tubes: 2000 mm
Ammunition: 81 mm SNORA rockets, with different shell types
Length: 1548-1784 mm (depending on type of shell)
Mass of shell: 15·7 - 19·7 kg (depending on type of shell)
Max rocket speed: 520 - 670 m/s (depending on type of shell)
Aiming periscope: Type RLK 252
Magnification: ×7
Field of view: 9°
Slant error correction: 10°
Aiming range
Traverse: Unlimited
Elevation: -10 to +50°
Turret weight: 820 kg (empty)

STATUS
In production.
CONTRACTOR
Machine Tool Works, Oerlikon Bührle Ltd, CH 8050 Zurich, Switzerland.

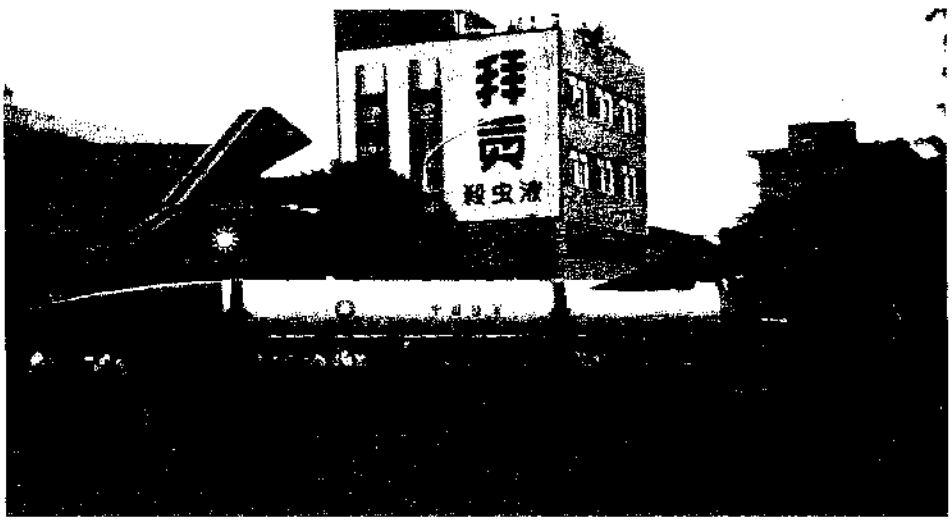
CHING FENG (GREEN BEE) SURFACE-TO-SURFACE MISSILE



This weapon made its first public appearance at a National Day parade in Taipei in October 1981 when it appeared preceded by what were reported as associated fire control and radar facilities. Little firm information from sources in Taiwan has been made available but the Ching Feng was described as a medium range surface-to-surface or surface-to-air missile with a maximum range of more than 100 km. From the photograph the weapon would seem to be carried by a transporter trailer rather than a launcher vehicle, which to some extent leaves the method of deployment and launching procedure details unknown. The size and general arrangement of Ching Feng suggest that the nearest likely relative is the American Lance battlefield support weapon (**2682.111**) and there is a considerable degree of superficial similarity which could well be backed by internal and less visible points of similarity, or even identical features. There has been no official confirmation that Lance was ever among the items of military hardware supplied to Taiwan by the USA before the change of policy introduced during President Carter's term of office, but co-operation between Israel and Taiwan has been noted in other instances (eg. the Hsiung Feng coastal defence missile, **4442.121**, and its obvious relationship with the Israeli Gabriel, **6019.221**) and Israel is known to operate the Lance SSM.

Lance exists in versions with either conventional HE or nuclear warheads but it seems unlikely at present that either Israeli Lance or the Ching Feng has other than a conventional payload. Therefore the latter probably most closely resembles an earlier version of Lance, with very similar performance and operating characteristics. Significant Lance characteristics in this context include: simplified inertial guidance, range of about 120 km, storable liquid-propulsion, and a launch weight of approximately 1400 kg.

STATUS
Operational with the Republic of China's Army. The Chung Shan Institute of Science and Technology is reported to have been responsible for development of Ching Feng, but the precise extent of indigenous expertise in the design of this weapon cannot be determined from available evidence at present.

WORKING BEE-4 127 mm ARTILLERY ROCKET

The Working Bee-4 multiple artillery rocket system is believed to be related to the Working Bee-6 artillery rocket system (**4345.103**) to the extent that both systems share a common calibre of rocket, namely 127 mm. However it can be seen from photographs showing both these systems side by side that the Working Bee-4 round is much shorter than the Working Bee-6, thus indicating a shorter range. Other differences that are readily apparent are the non-training mounting for the launch tubes of the Working Bee-4 on a tracked and armoured vehicle, and their number (40, compared with the Working Bee-6's 45). It is not known if the Working Bee-4 launcher vehicle is equipped to carry reload rockets or has any facilities for this.

STATUS
In production and operational with Taiwanese forces.
CONTRACTOR

4345.111
WORKING BEE-6 127 mm ARTILLERY ROCKET

Under the designation 'Working Bee-6' the Taiwan State Arsenal has developed and produced a 127 mm multiple artillery rocket system which was first revealed in the National Day Parade in October 1981. The weapon consists of a group of launch tubes comprising five rows of nine tubes carried on a trainable platform mounted on a heavy duty military truck. The block of launchers can also be elevated, apparently by means of screw jacks, and it is estimated that the rockets are about three metres long. They are probably fin-stabilised although spin-stabilisation cannot be ruled out. No details of performance have been disclosed, nor any particulars of the firing or reloading arrangements. There is no sign of any reload facilities on the launcher vehicles themselves.

There are a number of close resemblances between this weapon and the recently revealed South African Valkiri 127 mm multiple rocket system (**4527.111**) and they may in fact share some aspects of their origin although both are claimed as indigenous developments. Evidence of close collaboration with Israeli defence developments has been noted in the past (eg the Israeli Gabriel and Taiwan Hsiung-Feng naval missiles) and it is possible that the Working Bee-6 is a further example of this co-operation.

STATUS

In production and operational with Taiwanese forces.

UNION OF SOVIET SOCIALIST REPUBLICS

3327.111
SS-1 (SCUD) BATTLEFIELD SUPPORT MISSILE

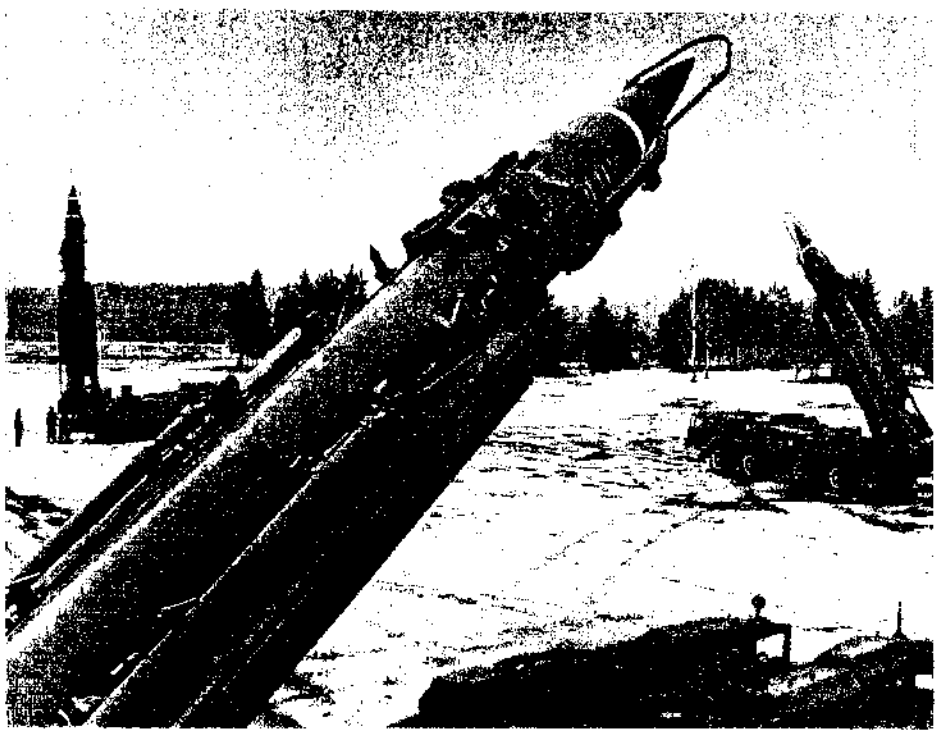
The SS-1 family of heavy artillery rockets code-named Scud by NATO has been operated by Soviet forces and some client states for a number of years. Over the years it has seen a series of steady improvements and modifications (as recorded under this entry number in earlier editions of this volume). The latest model to have been identified by western sources is the SS-1C, which is now, in turn, being progressively replaced by the later SS-23 weapon (**4550.111**). The longer range Scud C was confirmed in a US Armed Services Committee reference in hearings of April 1978 to the KY-3 Scud, when it was stated that this version was first deployed in 1965. It was added that the later version has a longer range than Scud B, but a lower CEP accuracy.

Scud is a land-mobile system, single missiles being carried on a vehicle that combines the functions of transporter and erector by means of hydraulically actuated rams which raise the missile to the upright position for launching. Scud A and Scud B have both been deployed on the tracked JS-III chassis, but from 1965 onwards Scud B only has been reported on the MAZ-543 eight-wheeled transporter vehicle.

Liquid propulsion is employed, and the launch preparation time is quoted by Soviet sources as about one hour. Associated with Scud batteries, in addition to the re-supply and loading vehicles already noted, are a meteorological mobile unit which includes an End Tray weather radar, a ZIL-157V tanker vehicle with a trailerised pump unit, and command and control vehicles. The End Tray is assumed to be for radio-sonde tracking and data collection for use in obtaining upper-air information for ballistics computation prior to launch. A fairly lengthy survey procedure is also entailed on arrival at the firing position, and both tripod-mounted theodolites and optical devices attached to the missile/launcher by special brackets are employed for this. At least two types of theodolite have been noted.

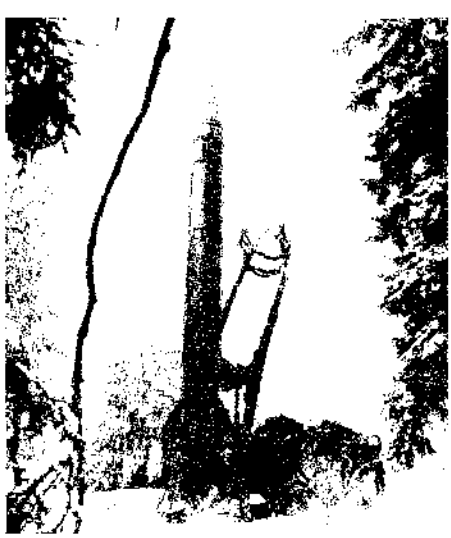
The data below refers to the standard Scud B; Scud A is roughly 0·5 m shorter and has reported range capability of some 130 km. The reputed range of the Scud C model is in the region of 450 km.

CHARACTERISTICS



Type: Surface-to-surface, artillery missile
Configuration: Cylindrical body with conical nose and cruciform cropped delta tail surfaces
Length: 11·25 m
Diameter: 85 cm
Weight: 6300 kg (estimated)
Propulsion: Storable, liquid
Range: 180 - 300 km
Guidance: Simplified inertial
Warhead: Nuclear, optional non-nuclear warhead

STATUS



Operational in Warsaw Pact forces. In addition to the Soviet Forces, Bulgaria, Czechoslovakia, East Germany, Hungary, Poland and Romania have been reported as operating Scud. Non-Warsaw Pact countries to have received this weapon include Egypt, Iraq, Libya and Syria. All but the Soviet missiles are likely to be fitted with non-nuclear warheads.

Latest official US estimates state that more than 400 Scud launchers confront NATO in Europe, with about 100 more deployed near the Sino/Soviet border and 75 facing the SW Asian and Turkish area. Scud missiles in Soviet service are deployed on a scale of missile brigades assigned to armies and fronts, each brigade having 12 to 18 launchers. There is one brigade in the strategic reserve.

From the numbers deployed, their length of service and the successive stages of development and improvement they have undergone, the Scud series of weapons is well regarded with in the Warsaw Pact and beyond. A successor system, designated the SS-23, is expected to replace Scud units deployed in brigades at army and front level. This will probably have improved accuracy and a range of 500 km compared with the Scud's 300 km. It is expected that first deployments of the SS-23 will replace Scud missiles facing NATO and China.

2959.111
SS-12 (SCALEBOARD) BATTLEFIELD SUPPORT MISSILE

Scaleboard is the NATO name for a short/medium-range ballistic missile which is identified by some sources with the SS-12 in the US series. It is a mobile missile and is normally transported on a MAZ-543 eight-wheeled vehicle similar to that sometimes used for Scud B (**3327.111**). Its warhead has been reported to be in the megaton range. This suggests that it has rather greater destructive power than its approximate equivalent in NATO, the American Pershing missile (**2965.111**).

Unlike the Scud missiles, which in transit are exposed to view as they rest in their elevating cradles, the Scaleboard missile is enclosed in a ribbed split metal casing which is elevated with the missile into the firing position.

Scaleboard appears to be approximately the same length as Scud B – rather more than 11 m – but larger in diameter. Its range has been estimated in the region of 700 – 800 km. Nothing is known about its guidance system but it is presumed to be some form of inertial guidance suitable for use with a missile that is elevated from the horizontal to the vertical shortly before firing.

SS-12 Scaleboard missile on the move

CHARACTERISTICS
Type: Surface-to-surface tactical
Configuration: Scaleboard has not been publicly revealed outside the launcher/erector casing which completely envelopes the missile. The following dimensions are based on studies of the container and transporter vehicle (MAZ-543)
Length: 11·25 m
Diameter: 100 cm
Weight: 6800+ kg
Propulsion: Presumed storable liquid
Range: 700 – 800 km (estimated)
Guidance: Presumed inertial
Warhead: Nuclear

STATUS
Believed to be fully operational in the USSR, but there remains a marked scarcity of reliable information regarding the precise role of this weapon and the scale of its deployment. However it was noted in 1984 that for the first time the Soviet authorities deployed Scaleboard forward to Eastern Europe. These missiles are now reported to be deployed normally with Soviet combined arms formations, and current estimates of numbers suggest 60 or more facing European NATO forces, 40 in the Soviet Far East, one battalion in strategic reserve and a similar number facing Turkey. Steady replacement of the SS-12 Scaleboard by a more recent design, the SS-22, is presumed to be continuing.

4548.111
SS-21 BATTLEFIELD SUPPORT MISSILE

SS-21 is the designation assigned by the US to a replacement for the FROG-7 battlefield support missile (**2926.11**) and which was believed to have been under development from the early 1970s. Unofficial reports state that it is a single-stage weapon 9·44 m long and about 46 cm in diameter with a range of some 60 km, although later official US reports now quote a longer range for the FROG-7 (70 km) and as much as 120 km for the SS-21 replacement.

As with the first reports on the SS-21, the closeness of the figures then suggested for the new missile to those for its forerunner prompted questions concerning their origin and the manner in which they were derived. Were they obtained indirectly from photographs or other visual evidence, for example, or were they arrived at by deduced reckoning? The SS-21 is claimed to be a guided missile, but no indications are given of the technique employed and neither is there reliable information on the kind(s) of payload carried. The latter are thought likely to include nuclear, conventional HE, and chemical warheads although the possibility of some kind of sub-munition warhead designed for use against specific types of target such as airfields, vehicle parks, troop concentrations etc. ought not to be ruled out.

SS-21 short-range tactical nuclear missile revealed publicly in Red Square on its transporter/erector/launcher vehicle (A. P. Laser photo)

STATUS
Official US sources claimed in 1981 that a few SS-21s had been deployed operationally, but that it had been capable of deployment since 1976. No reason (or confirmation) of this apparent inconsistency has emerged so far. In 1984 US officials stated that SS-21 was a division-level weapon to replace the FROG-7. This assessment is still maintained and in 1985 the US DoD reported that there were about 375 FROG and SS-21 launchers confronting NATO in Europe, with another 200 in the Soviet Far East and 100 more in the SW Asia/Turkey region. An estimated total of 75 were held in the strategic reserve depots. It was considered that in addition to an increased range of some 120 km, other operational benefits include better reliability and increased accuracy. The evidence for these conclusions was not divulged.

4549.111
SS-22 BATTLEFIELD SUPPORT MISSILE

A replacement for the large, long-range battlefield support SS-12 (Scaleboard) missile (**2959.111**) has been reported in official US circles for several years under the designation SS-22. There are no confirmed illustrations of this weapon nor any published performance data or technical details. The 1985 edition of the US Government publication *Soviet Military Power* says of the SS-22 it is expected to replace Scaleboard missiles on a similar scale of deployment, although details of this are sketchy. Reported range for the SS-22 suggests a figure of between 800 – 900 km.

Further speculation about the characteristics and performance of the SS-22 must await more adequate evidence.

4550.111
SS-23 BATTLEFIELD SUPPORT MISSILE

The SS-23 is the battlefield support missile thought by official US sources to be the successor system for the long-serving and widely deployed SS-1 Scud weapon system (**3327.111**). Scud is normally deployed in brigades at army and 'front' levels, and in Soviet service it is believed to be in the process of progressive replacement by the SS-23. The latter is reported to have an increased range of up to 500 km compared with the Scud's approximate 300 km, coupled with increased accuracy. As noted in earlier entries on the Scud system, it is considered likely that any replacement for this system would probably incorporate improvements leading to reduced reaction and re-firing times, but as yet this cannot be confirmed. Official US DoD estimates anticipate first operational deployments of the SS-23 to be replacements for some of the 400+ Scud missiles facing NATO in Europe, and/or the 100 Scuds in the Sino/Soviet border region.

2926.111
FROG-7 BATTLEFIELD SUPPORT MISSILE

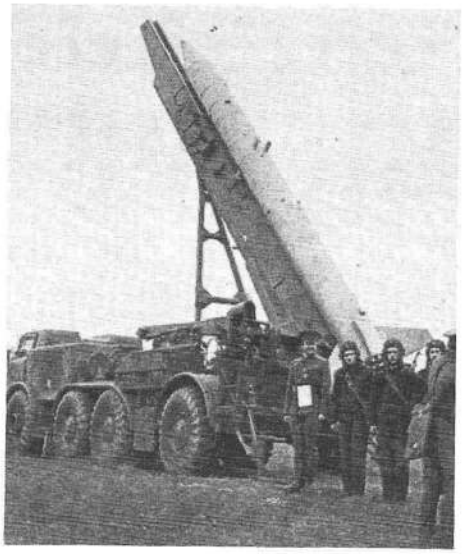
The introduction of FROG-7, first shown to the public in 1967, marked a new departure in carrying vehicles – the vehicle used being a modern, wheeled, erector launcher (ZIL-135). The missile too, had a more modern look about it, reverting to the original single-stage design and having a cylindrical warhead of the same diameter as the missile. It has a much cleaner appearance than its predecessors. This missile is probably the last of the unguided ballistic free rocket over ground (FROG) series (see **2890.111, 2922.111, 2923.111** and **2924.111** in 1980-81 and earlier editions), some of which were supplied to Warsaw Pact states and other client states by the USSR. Mostly FROG-3s and FROG-5s, have been replaced by the FROG-7.

The main nozzle of the single-stage rocket motor is surrounded by a ring of much smaller nozzles.

CHARACTERISTICS
Type: Surface-to-surface, spin-stabilised unguided tactical missile
Propulsion: Single solid-propellant motor
Warhead: Nuclear or HE
Length: About 9 m
Diameter: About 55 cm
Launch weight: About 2 t
Range: 60 – 70 km

STATUS

Operational in the armies of several Warsaw Pact countries. Also supplied in quantity to Egypt, Iraq, Libya, North Korea, and Syria. Some missiles, supplied by the Soviet Union to Syria, were actually fired against the Israelis in the 1973 Arab-Israeli war.



They were equipped with high-explosive warheads. It was at one time suggested that these particular missiles may have been a guided version (see **2927.111**) but this has not been confirmed or repeated recently; in any case they appear not to have been very effective as HE weapons.

An official US estimate of 1985 claimed that there were a total of 375 FROG and SS-21 launchers facing NATO forces, with more than 200 FROGs in the Soviet Far East, about 100 in the SW Asia-Turkey region, and 75 in a strategic reserve. In Soviet service, FROG is normally deployed in battalions of four missiles at divisional level.

Progressive replacement of Soviet Army FROGs by the newer SS-21 is reported to be continuing.

Crew prepare FROG-7 for launch

Positioning elevated FROG-7 missile

5555.111

ARTILLERY ROCKETS

The Soviet Union has been using multiple rocket launchers since before the Second World War, and since then has continued to develop new systems. Multiple rocket systems are used by all members of the Warsaw Pact and some members have either developed their own systems or modified Soviet equipment to meet their own requirements. Details of other Warsaw Pact multiple rocket launchers will be found under the following entries:

Czechoslovakia	BM-21/M-1972 SP (**5137.103**)
Czechoslovakia	RM-130 SP (**2024.103**)
Poland	WP-8 Towed (**2611.103**)
Romania	M-51 SP (**2612.103**)

The BM-21 is the most widely used of all of these multiple rocket launchers, and each tank and motor rifle division has a battalion of these, each battalion having three batteries of six launchers. The rockets can be fitted with a variety of warheads including high explosive, chemical, smoke, and biological.

STATUS

122 mm BM-21: Entered service in 1964 and is used by most members of the Warsaw Pact; it has also been exported to many countries, including Angola, Cuba, Egypt, Iran, Syria, and Viet-Nam.

122 mm M-1972: Entered service in 1971/72 and consists of a Czechoslovak Tatra-813 8 × 8 truck with a Soviet BM-21 launcher mounted on the rear; a special rack is carried behind the cab which contains a further 40 rockets. This enables the launcher to be quickly reloaded. It is known to be used by Czechoslovakia, East Germany, and the Soviet Union.

132 mm BM-13-16: This is the oldest of all of the Soviet multiple rocket launchers as it entered service in the Second World War. It is no longer in front line service but is still used for training. The rockets are launched from rails rather than from a frame or tube.

140 mm BM-14-16: Entered service in the early 1950s and has been used by Poland and the Soviet Union. It is no longer in front line service.

140 mm BM-14-17: Entered service in 1959 and is a development of the earlier BM-14-16; it is still used by Poland and the Soviet Union.

140 mm RPU-14: This towed multiple rocket launcher is used only by the Soviet airborne divisions and is issued on the scale of 18 per division.

BM-21 122 mm multiple rocket systems ready for action

BMD-25 240 mm rockets in foreground. BM-14/17 rockets on right

200 mm BMD-20: Entered service in the 1950s but is no longer used in large numbers. Some are used by North Korea.

240 mm BM-24: Although developed in the 1950s this still remains in service with a number of countries including Algeria, East Germany, Egypt, and Syria. A number were captured by Israel and these are now used by the Israeli Army.

240 mm BM-24T: This has only been used by the Soviet Army and is the same launcher as the above but mounted on the AT-S medium tracked tractor.

BM-25: Entered service in the 1950s. Its rockets are believed to have a liquid, rather than a solid-propellant. The rockets are the heaviest and have the longest range of all the Soviet multiple rocket launchers.

Early in 1978 it was reported that the Soviet Union had developed a new large calibre multiple rocket system which also incorporated a rapid reload capability similar to that employed on the 122 mm M-1972 multiple rocket system.

Notes:

There are also three short rockets:

(1) length 1·905 m; weight 45·8 kg; maximum range 11 000 m

(2) with booster; range 19 000 m

(3) length 1·225 m; weight 112 kg; maximum range 6575 m.

BM-27: Thought to have entered Soviet Army service in 1977, this system's 220 mm rockets can be fitted with a variety of warheads, including: HE, bomblets, minelets and probably chemical. Deployed in artillery brigades of Soviet tank army (three battalions with 18 launchers each) and the Combined Arms Army (one battalion with 18 launchers).

4194.111

GLCM GROUND LAUNCHED CRUISE MISSILE

The GLCM system consists of the Tomahawk missile (BGM-109) integrated on an air-transportable, ground mobile-launcher unit. Together with its launch control van, it will be protected in its peacetime location within a hardened shelter. The ground mobility will lessen the risk of destruction by an enemy pre-emptive strike in the event of war. The USAF is implementing plans to deploy GLCMs and Pershing II surface-to-surface missiles (**2767.111**) in various parts of Europe as the major element of the NATO Theatre Nuclear Forces modernisation programme, initiated principally as a response to Soviet deployment of SS-20 IRBMs in Europe.

The GLCM can be used for both selective or general nuclear release options against fixed targets such as lines of communications, logistic facilities, airfields, command posts and stationary tactical targets such as staging and assembly areas.

The basic GLCM combat unit consists of 16 missiles loaded on four TELs (transporter/erector/launcher vehicle) with two mobile launch control centres. As noted above, the missile is the BGM-109 Tomahawk air-breathing cruise missile with a 2500 km range, flying at low altitude to avoid radar detection and AA defences, and carrying a nuclear warhead. An inertial navigation guidance system updated by terrain contour matching (TERCOM) information directs the missile in flight. More details of this system have been published in earlier editions of *Jane's Weapon Systems*. Each TEL provides transport, protection, elevation and launch support for four cruise missiles, and enables rapid movement from main operating bases to remote launch locations. In combat-alert conditions, GLCMs may be moved from protective hardened shelters to areas where natural terrain offers concealment for movement and firing operations. Until launch, each missile rests in an aluminium canister which is loaded within the TEL, the wings, control fins and engine inlet being retracted during storage. To launch the GLCM, a solid-propellant rocket motor boosts the missile to cruising speed. During the boost phase fins unfold, the engine inlet and wings deploy. The turbofan engine then ignites to sustain flight; after approximately 13s the booster motor burns out and is then jettisoned.

The TEL vehicle, produced by General Dynamics also, weighs about 33 055 kg and is 16·5 m long. It is capable of off-road driving and can be carried in C-130, C-141 and C-5 transport aircraft. The design incorporates provisions for nuclear safety and protection against small arms fire.

Two launch control centre vehicles (LCCs) accompany each GLCM combat unit. The launch control sub-system consists of two launch consoles with displays and a computer and software for system control, status monitoring, mission data storage and transfer, and missile re-targeting. The launch control sub-system is integrated with the communications sub-system within a shelter carried on the LCCs, and primary and reserve power supplies are incorporated on these vehicles. There will be redundant communications links and a lightweight fibre-optic data link between each TEL and LCC vehicle. Environmental control and protection for the crew from CBR hazards are also included. Each LCC vehicle weighs about 36 000 kg and is approximately 17·3 m long.

Within the secure main operating bases, protected buildings will provide weapon storage, maintenance and inspection. It is planned that the crews will install warheads, load TELs and undertake periodic inspection and maintenance of all GLCM combat unit parts. The missiles will be fuelled in advance and can be stored for months in their aluminium canisters without requiring scheduled maintenance or handling. Hardened concrete shelters designed to house two LCCs and four TELs protect each GLCM combat flight group from conventional attack during storage, including precision air attacks. The GLCM shelter concept divides each structure into three cells which each hold two TELs or LCCs.

GLCM will be deployed in 'flights', each consisting of a total of 26 vehicles (2 LCCs and 4 TELs carrying 16 missiles, and 20 support vehicles) manned by a total complement of 70 personnel. In transit from the main operating base (MOB) to remote launch sites it is planned to move GLCM flights in two parts called the first and second critical elements, respectively.

CHARACTERISTICS

Type: BGM-109G GLCM

Length: 6·4 m (with booster)

Max diameter: 53 cm

Wing span: 2·5 m

Weight: 1773 kg (with booster)

Speed: High subsonic

Range: 2500 km

Warhead: Nuclear W84

Propulsion: Williams International Corp turbofan; Atlantic Research Corp solid booster

Guidance: Inertial navigaton plus TERCOM

STATUS

The GLCM system is in production, with initial operating capability achieved in December 1983 and with a total of 560 production missiles planned by 1988. By then 132 TELs should have been delivered, and 74 LCCs.

Under the NATO Theatre Nuclear Force modernisation programme it is planned to deploy 464 GLCMs in Western Europe and the UK. The anticipated programme development and production costs exceed $3000 million and the USA will pay the full cost of development and production of the GLCMs, but NATO will share the funding of the European-based storage and operating facilities. The USAF in Europe will operate the GLCM system. Two main bases for GLCM units in the UK have been designated: Greenham Common, Berkshire, which was the first with six flights and 96 missiles, and Molesworth, Cambridgeshire with a total of 64 missiles.

Under a contract signed in September 1982, McDonnell Douglas began building complete Tomahawk (GLCM) cruise missiles, joining General Dynamics Corporation as a producer. The first McDonnell Douglas-built missiles are expected to leave the production line in 1984.

GLCM base construction continues in Britain and Italy, and preparations are in progress for deployment elsewhere in European NATO countries, with sites

planned for Belgium, West Germany and the Netherlands in the next few years. All 464 GLCMs are scheduled to be installed in Europe by the end of 1988. GLCM procurement will be completed in FY 1987.

2682.111

LANCE BATTLEFIELD SUPPORT MISSILE

Lance is a surface-to-surface guided missile designed to provide general battlefield fire support for an Army corps. It is replacing both Honest John and Sergeant missiles. It can carry either a nuclear or conventional high-explosive warhead and its range has been estimated at approximately 130 km. It requires an eight-man crew, half the number required for Honest John (**2652.111**) and Sergeant (**2804.111** in 1980-81 and earlier editions).

This highly mobile missile can be delivered by aircraft or helicopter, has good mobility over ground and can swim inland waterways. Lance uses simplified inertial guidance, and is the first US Army missile to use ready-packaged and storable liquid propellants. Major ground support equipment includes a self-propelled launcher, a fully mobile lightweight launcher, and a transporter/loader.

In the field, Lance complements conventional divisional tube artillery and extends the resources for nuclear or non-nuclear supporting fire available to the divisional commander.

The Lance missile comprises a warhead section, a guidance package, fuel tankage, and an engine. The guidance package is a rugged low-cost device conceived and developed in the US Army Missile Command's Guidance and Control Laboratory. Over the operational range of the missile it is claimed to have a high degree of accuracy and reliability.

Spin-stabilisation in flight is achieved initially by venting some of the propellant gases through canted vents in the body of the missile. After initial spin has been imparted in this way it is maintained by aerodynamic pressure on the canted fins at the base of the missile.

Propulsion is by a Rocketdyne storable liquid-propellant engine comprising two concentrically-mounted sections. The outer section provides thrust during the boost phase of the missile's flight, and during this phase, which corresponds to a flight of about a mile (1600 m), the missile is under tight control by the control and guidance electronics. When the on-board inertial system detects that the predetermined velocity has been achieved, the boost motor is extinguished and the missile continues on a zero-*g* flight powered by the (inner) sustainer motor. At a predetermined point in the flight this motor too, cuts out, and the missile finishes its journey in free flight.

For land-mobile operations the weapon system is transported on two tracked vehicles (US Army's M113 family) one of which (M752) functions as an erector/launcher while the other (M688) carries two extra missiles and a loading hoist. Both vehicles are on the M667 chassis, with a road speed/range capability of 68 km/h/450 km. For air mobile operations the lightweight launcher will be more appropriate and this and the missile can be taken into the battle zone by helicopter or parachuted from a fixed-wing aircraft.

CHARACTERISTICS

Designation: MGM-52C

Type: Mobile surface-to-surface tactical guided missile

Guidance: Simplified inertial

Propulsion: 2-part, concentric pre-packed storable liquid-propellant motor

Warhead: Nuclear (W70-1/2/3) or HE

Length: 6·14 m

Diameter: 56 cm

Launch weight: 1285 - 1527 kg

Speed: Mach 3

Range: 130 km

DEVELOPMENT

The Lance prime contractor was selected in 1962. The research and development contract was awarded in January 1963. The first test firing was made at White Sands Missile Range in March 1965. The first firing from the engineering model lightweight launcher was in July 1965 and first firing from the self-propelled launch vehicle came the following month. Lance development was delayed for approximately one year when problems were encountered with the propulsion system and the rocket engine, but these difficulties were subsequently overcome. The first production model was delivered to the US Army for service testing in April 1971; the first Army launch took place that August and service testing was completed in March 1972.

During development a total of 156 flight tests were conducted - including 37 Army launches, all but one of which were successful.

Nuclear armed Lance missiles were initially equipped with the W70-1 and later the W70-2 warhead, subsequent development led to initial operational capability for an enhanced radiation/reduced blast (ER/RB) warhead for Lance, the W70-3, which was available from 1982 onward. Other alternative payloads that have been studied in conjunction with the Lance missile include a variety of multiple sub-munitions for use in the Assault Breaker programme (**3989.111** in 1983-84 and earlier editions), and some of this technology is now being applied to other programmes such as the Joint Tactical Missile programme.

STATUS

Lance was type-classified 'standard' early in 1972 and the first training battalion was activated in April. The weapon was subsequently deployed with six US battalions in Europe and two in the USA as a training base. The first operational launch took place in November 1972. Lance has been purchased by Belgium, West Germany, Italy, Israel, Netherlands and the UK. Lance is regarded as possibly being the basis of a recently revealed missile known as Ching Feng (Green Bee) (**4547.111**) in the Republic of China (Taiwan) Army by whom it is operated.

Lance missile prepared for launch

To extend the range of tactical applications of the weapons the US Army has a non-nuclear warhead which employs cluster bomblets and would be used against different targets from those for which the nuclear warhead is required. Lance production was completed in 1980, but an advanced, solid-propellant flight vehicle plays an important part in the Assault Breaker anti-armour programme as the T-22. It is

possible that the T-22 might be used as a basis for a new weapon which may become a candidate for a new stand off tactical missile programme.

2765.111

PERSHING Ia BATTLEFIELD SUPPORT MISSILE

Pershing Ia is an improved version of the Pershing ground-to-ground guided weapon system (**2764.111** in 1973-74 and earlier editions) that is now deployed with the US Army and the Federal German Republic in Europe.

The most obvious change that has taken place is the replacement of the XM474 tracked vehicles on which system components were mounted by a set of wheeled vehicles based on the M656 five-ton truck. The system now has an improved erector/launcher, an articulated truck and trailer combination that carries both the missile and its warhead (previously carried on separate vehicles) and capable of both paved road and cross-country travel. The other vehicles are a transporter for the programmer-test and power stations, the firing battery control central truck, and the radio terminal set vehicle with an inflatable antenna. All the equipment is transportable by the CS-130, C-141, and C-5A cargo aircraft.

System reaction time of the Pershing Ia has been reduced by improvements in the erector/launcher and by the introduction of automatic countdown. The radio communications system has also been expanded. There is no change in the missile itself.

Most recent of the improvements is an automatic reference system (ARS) which employs gyro compass techniques similar to those used in navigation and which enables the missile to be fired from a previously unsurveyed site. Associated with ARS is a sequential launch adapter (SLA) which permits the Pershing commander to count down and launch up to three missiles from a single control station without uncabling and recabling after each missile is launched. European-based Pershing units received ARS/SLA ground equipment in 1976/77.

DEVELOPMENT

A $66 million development contract was awarded to Martin Marietta in 1966. This was followed by two production contracts, one for $52 million in 1967 and one for $32 million in 1968. Production started in November 1967 and was completed in 1971.

Pershing Ia equipment began deployment with US and West German forces in Germany in the summer of 1969 and was completed in 1971.

CHARACTERISTICS

Military designation: MGM-31A

Type: Land-mobile air transportable surface-to-surface tactical ballistic missile system

Guidance: Inertial

Propulsion: 2-stage solid-propellant rocket motor

Warhead: Nuclear W50: these are believed to be 400KT warheads

Missile length: 10·5 m (approx)

Missile diameter: 1 m (approx)

Launch weight: About 4600 kg

Speed: Mach 8

Range: 160 - 740 km

STATUS

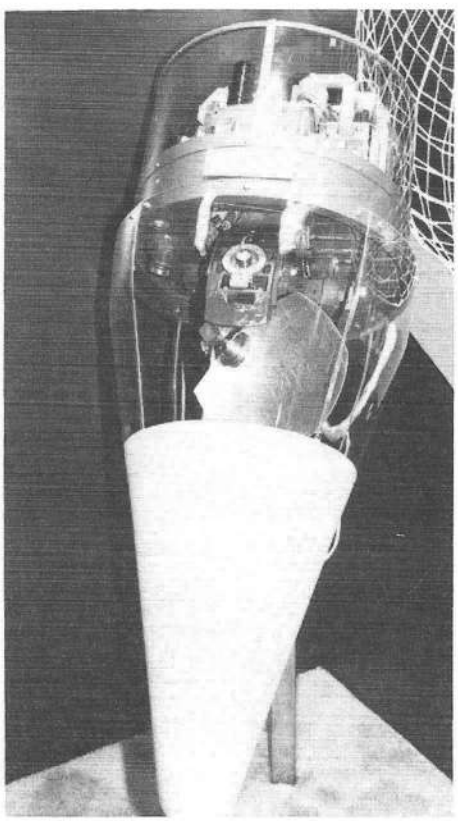
Operational with German and US forces in West Germany. Progressively being replaced by Pershing II. (Expected completion date: end of 1988.)

CONTRACTORS

Complete system: Martin Marietta Orlando, Orlando, Florida, USA.

Propulsion: Thiokol Chemical Corporation.

Communications: Collins Radio Company.



Inertial navigation: Bendix Corporation, Eclipse-Pioneer Division.

2767.111

PERSHING II BATTLEFIELD SUPPORT MISSILE

The Pershing II system is a modular modernisation of the currently deployed Pershing Ia (**2765.111**).

A new inertial navigation system developed by Singer-Kearfott, and a new re-entry vehicle (RV) which incorporates a high-accuracy, terminal guidance system developed by Goodyear Aerospace are used in the later version of Pershing. Range is increased to approximately 1800 km. The enhanced accuracy combined with terminal guidance and control facilities enables warheads of appreciably reduced yields to be employed to engage small hardened targets. Earlier Pershing missiles carry W50 warheads, which are thought to be 400 KT, and these have been criticised for being excessively large and destructive for battlefield use. Pershing II will carry a single W85 warhead, with a relatively low yield.

Close-up of Goodyear radar area guidance (RADAG) system in nose of Pershing II showing gimbal-mounted scanner (T.J. Gander)

The Pershing II terminal guidance system incorporates an all-weather radar correlation unit that compares the live radar returns with a pre-recorded and stored radar image of the target area. Continual automatic comparisons of the two provides control signals to actuate the control vanes which are a distinguishing feature of the Pershing II RV. The RADAG (from radar area guidance) system relies upon inertial navigation system information from the second stage booster for position data prior to separation. Soon after re-entry, the Goodyear RADAG system is activated to sweep the target area below the rapidly descending RV, and provide accurate position updating to the inertial system. The scanner of the RADAG guidance package rotates at 120 rpm, and corrective commands are computed continuously to bring the RV back on course to its designated impact point.

Under a contract awarded by Goodyear, Norden Systems is delivering computerised systems to be used for the preparation of reference scenes that will be used to guide Pershing II missiles to their targets. Norden will supply six systems: five are miniaturised PDP-11/70Ms (also known as AN/UYK-42(V)), and one a commercial PDP-11/70 for use by Goodyear for software development. The Norden equipment is used in conjunction with digitised computer discs of possible target areas, which are supplied by the US Defence Mapping Agency (DMA). These discs, called the data base, cover such land features as terrain, elevation, rivers and buildings, and the data base is fed into the Norden computer system which predicts what the missile will see on its radar during flight.

The Norden systems are being delivered to Goodyear, apart from the two for the DMA headquarters in Washington and another for the US Army Engineer Topographic Laboratories at Fort Belvoir, Virginia. Those going to Goodyear are for mounting on government-furnished five-ton trucks.

STATUS

The Pershing II advanced development programme was completed in May 1978. Five flights of the missile were conducted successfully to test and evaluate the terminal guidance system. Full-scale development began in February 1979 with the award of a $360 million contract to Martin Marietta. Sub-contractors for Pershing II include Bendix for airborne and ground computers. Goodyear for the radar guidance sub-system, Hercules for propulsion motors, and Singer-Kearfott for the inertial measurement system.

In May 1978 it was stated that the US Army had plans to deploy a Pershing II brigade in the Federal Republic of Germany, consisting of three missile battalions of 36 missile launchers each. The brigade will require approximately 3800 men.

Pershing II missile erected from its erector/launcher vehicle and ready to fire

Pershing II will be deployed in Europe in a similar fashion to Pershing Ia. This entails three American battalions of four firing batteries each with three firing platoons of three erector/launchers with missiles. The US Army now has 108 Pershing Ia launchers, but the number of missiles is classified, however replacement by Pershing IIs will be on a one-for-one basis. The initial production contract for Pershing II was signed in June 1982 and the first of 18 planned flight tests took place in July. This was a failure due to faulty production techniques in the rocket motor, but the second test was successful and the programme continued on schedule.

By September 1984 21 test launches had been made, the latest (August 1984) achieving a range of almost 1600 km after launching from Cape Canaveral, Florida. Production deliveries to the US Army began in May 1983, and at 1 January 1984 production contracts awarded to Martin Marietta amounted to $725 million. That month the first Pershing II entered service in West Germany.

Production was authorised of batches of 72 missiles costing $404 million in FY 1984, and 70 more in the following year at a cost of $370 million. Sums allocated for completion of the programme in FYs 1986 and 1987 were $334.7 million and $7.3 million, respectively. It is expected that by the end of 1988 deployment of all 108 Pershing IIs in Germany will be complete.

CONTRACTOR

Martin Marietta Orlando, Orlando, Florida, USA.

4440.111

GEMSS

The ground-emplaced mine scattering system (GEMSS) is a passive, primary anti-armour system. The trailer-mounted mine dispensing system, M128, provides a commander with a flexible means for placing large quantities of anti-tank and anti-personnel mines over appreciable areas in a short time. GEMSS is the principal ground-based system of the FASCAM family of scatterable mines designed to provide lay down minefields at short notice to present obstacles to the advance or other movement of enemy armour. The other FASCAM systems include mines sown by airborne dispensing systems and artillery delivered mines.

The M128 GEMSS dispenser can be towed by tracked or wheeled vehicles, and it holds up to 800 mines weighing about 1·8 kg each which are ejected sideways at selectable intervals of 30 or 60 metres, with their density being determined by the rate of launch and the speed of the towing vehicle.

The M75 anti-tank mine has a magnetic influence fuze giving it the ability to attack the full width of the target vehicle and the M74 anti-personnel mine is a ground blast fragmentation mine which is activated by an automatically deployed tripline sensor. Both types of mine have a built-in self-destruction mechanism, set by the dispenser operator, to provide the choice of a long- or short-time interval. Once the SD time has elapsed, the minefield is neutralised, permitting unhindered movement of friendly forces. Using GEMSS, up to 800 mines can be emplaced in 15 minutes.

STATUS

The FYs 1984 and 1985 budgeted for a total of 87 XM128 GEMSS mine dispensers at a cost of $15·8 million. No funds were sought for 1986, but procurement of a further 74 XM128s costing $13·8 million is planned for 1987. In the FY 1986 funding there is provision for procurement of 237 XM138 auxiliary mine dispensers (Flipper) at a cost of $2 million, to be followed in 1987 by a further 225 units costing $1·5 million. The latter allocations (1986-87) may actually relate to the Volcano (**4876.011**) multiple delivery mine programme which is due for implementation in that period.

CONTRACTORS

Engineered Systems Development Corporation.

Aerojet-General Corporation.

Honeywell Incorporated.

4876.011

VOLCANO MULTIPLE DELIVERY MINE SYSTEM

Volcano is a rapid mine dispensing system. GATOR anti-tank (BLU-91/8) and anti-personnel (BLU-92/8) mines, now being procured by the US Air Force and Navy, will be loaded into canisters (XM88 canister mine and XM87 practice canister mine) which can be placed in standard dispenser racks for army helicopter or ground vehicle use.

The system is composed of mounted launcher racks with mounting hardware, and electrical dispenser control unit, and the mine canister. Volcano provides a rapid and flexible means of placing tactical minefields to delay, confine to specific channels, and interdict attacking enemy forces. The helicopter version, which will replace the M56 helicopter delivered mine system, will permit low-altitude, reduced vulnerability, delivery of about 800 mines by a single UH-60A Black Hawk helicopter. Ground vehicles will be able to deliver varying quantities of mines.

It is planned to issue air systems to equip four helicopters per Combat Support Aviation Company; ground systems will be issued, three to each Divisional Engineer Company and one per Corps Engineer Combat Company. Mine canisters will be supplied within the army class V supply system.

CHARACTERISTICS

Vehicle	No. of Systems	No. of Canisters	No. Mines
UH-60A Black Hawk	One-4 racks	160	828
M548 Cargo Carrier	One-4 racks	160	960
M817 5-ton Truck	One-4 racks	160	960
M113 APC	One-2 racks	80	480

STATUS

Honeywell was awarded a $10·5 million contract in 1983 for advanced development of Volcano. It is planned to start procurement of Volcano in FY 1986, in which year apparently no funds are being sought for procurement of the ground-emplaced mine scattering system, GEMSS, (**4440.111**), to enable funds to be used to meet an urgent requirement for scatter mine systems in the US Army light infantry divisions.

CONTRACTOR

To be nominated.

3987.111

US ROCKET ASSISTED PROJECTILES (RAP)

In common with many European countries, the United States is devoting much effort to the development of rocket assisted projectiles for tube artillery. In general these developments relate to unguided projectiles, although some attention has been given to laser guidance systems for such rounds.

As ranges increase, even if precision remains the same, absolute dispersion increases and therefore a laser guidance technique would obviously assist in overcoming this. On the other hand the greatly increased cost of the guided over the unguided round makes it desirable to explore the possibilities of unguided rounds thoroughly before abandoning them in favour of guided missiles. Results so far appear to be encouraging.

A further difficulty is the loss of payload resulting from the incorporation of a rocket motor in the projectile. In parallel with the development of the RAP rounds, therefore, there is also a programme aimed at increasing the effectiveness of the reduced payload by the use of new materials and processes in the construction of the warheads.

The rocket motors in the projectiles must be designed to withstand very large stresses. Mean accelerations in guns currently in service are typically about 5000 *g* for a 105 mm howitzer and about 20 000 *g* for a high-velocity tank gun, with 30 000 to 40 000 *g* in sight for the next generation of the latter. RAP rounds for field artillery may thus have to withstand chamber pressures in the order of 3000 kg/cm², acceleration in the order of 18 000 *g* and rotation rates up to 17 000 rpm.

To achieve increased ranges for the US Army's 155 mm and 8-inch howitzers, an RAP has been developed for each and is being procured. The 155 mm high explosive RAP round (M549) is a separately loaded projectile composed of two distinct components: the warhead, and the rocket motor. This round can be fired from existing gun systems. The 8-inch round (M650) is used with the M110A1/A2 self-propelled howitzers and the M198 155 mm towed howitzer.

DEVELOPMENT

RAP projects are controlled by (and much of the research and development work is done at) the US Army Armament Research and Development Command (ARRADCOM), Dover, New Jersey (formerly Picatinny Arsenal). The 155 mm projects are managed by the US Army Material Development and Readiness Command's Office of the Project Manager for Cannon Artillery Weapon Systems (PMCAWS) at Dover, where that work is centred. Other projects are centred in ARRADCOM's Large Calibre Weapon Systems Laboratory.

STATUS

The fiscal year 1984 report to Congress by the US Secretary of Defense stated that in that year the USA will continue to build up its inventory of improved conventional munitions and RAPs and a total of $878 million was requested for this purpose. The budget showed a total of 98 457 155 mm RAP rounds and 33 904 8-inch RAPs. These figures incorporate production for both the US Army and Marine Corps.

CONTRACTOR

Various manufacturers will be involved, and these will be named as production contracts are awarded.

2652.111

HONEST JOHN BATTLEFIELD SUPPORT MISSILE

Honest John is a simple surface-to-surface free-flight rocket that has the accuracy of standard artillery and considerably better battlefield mobility. The unguided rocket is driven by a single-stage solid-propellant motor and can carry either a nuclear or a high-explosive warhead.

Designed to fire like conventional artillery in battlefield areas, Honest John is now the oldest US-developed missile system still fielded. Studies were begun by US Army Ordnance in 1950, and shortly after that Douglas Aircraft (now McDonnell Douglas) submitted proposals based on the Ordnance specifications and became prime contractor for the system. Firing tests were successfully completed in 1951 at White Sands, New Mexico.

The resultant system comprises a simple rocket and a highly mobile self-propelled launcher. Operation is simple – there are no electrical controls – and normal crew training and standard fire control techniques are employed.

CHARACTERISTICS

Military designation: MGR-1B

Type: Mobile surface-to-surface unguided tactical missile.

Propulsion: Single-stage solid-propellant rocket motor

Warhead: Nuclear (W31) or high explosive

Length: 7·5 m

Diameter: 76 cm

Launch weight: 2040 kg

Range: 7·5 – 37 km

STATUS

Honest John has seen service with the armed forces of Belgium, Denmark, the Federal German Republic, France, Greece, Netherlands, South Korea, Turkey, the United Kingdom, and the USA. Production ceased some time ago and the missile has been replaced in US Army service by Lance (**2682.111**). Honest John remains in service with Greece, South Korea and Turkey.

4060.111

MULTIPLE LAUNCH ROCKET SYSTEM (MLRS)

The multiple launch rocket system (MLRS) is a highly mobile automatic rocket system developed to enable a firing crew with a minimum amount of training to shoot a complete 12-rocket load, reload rapidly and fire again. Its purpose is to complement cannon artillery in engaging massed attack by enemy formations on an area basis rather than by engaging individual targets in succession. This artillery rocket programme was initially known as the general support rocket system (GSRS), which designation applied from 1972 to December 1979 when the name was changed in the interests of uniformity and acknowledgement of the system's adoption as a NATO standard rocket. A memorandum of understanding covering the intended adoption of MLRS by Britain, France and Germany has been concluded by these states and the USA (Italy joined the group in 1982). Two teams, headed by Boeing and LTV Aerospace and Defence Company (formerly Vought Corporation) respectively, produced competing designs for MLRS, with LTV being selected as the prime contractor in April 1980.

The MLRS configuration can be seen from the illustrations. It is designed to be operational day and night in all types of weather and to engage and defeat the following targets: tube artillery and rocket counter-batteries, air defence concentrations, trucks, light armour and personnel carriers as well as supportive troop and supply concentrations. Each LTV MLRS launcher has the capacity to neutralise one artillery battery or an equivalent target with a full 12-rocket launcher load.

Its tracked mobile launcher uses the same chassis and running gear as does the US Army's infantry fighting vehicle (IFV) and gives MLRS cross-country capability comparable to the M1 Abrams tank; thus, MLRS can be part of a combined arms, tank-led combat team.

The self-propelled launcher loader (SPLL) is able to fire a single rocket or to ripple fire two to twelve rockets. During ripple fire operations each rocket is quickly and automatically fired by the fire control system which re-positions and re-aims the remaining rockets after each shot. The system can ripple fire its entire rocket load in less than one minute.

SPLL is self-laying and designed so that its three-man crew can safely stop at a firing site, conduct an entire fire mission, including rocket launches, and quickly depart the firing site without ever leaving the cab. The same crew can rapidly reload the SPLL with 12 more rockets. The two six-pack launch pod containers can be loaded or unloaded singly or simultaneously.

The SPLL carries two launch-pod containers, each containing six rockets. The rockets are preloaded and sealed into the launch tubes of the container. The loaded container has a ten-year storage life without requiring any special environmental protection or field maintenance. The SPLL vehicle is a complete system containing its own fire control system, stabilised reference package/position determining system, launcher drive system and self-loading and self-unloading devices. It uses its own internal system to aim the rockets and monitor system characteristics during rocket firings.

MLRS self-propelled launcher/loader deployed for action

A large 25-ton tracked vehicle, the SPLL is 6·9 metres long, 2·6 metres high and 2·9 metres wide. It can get in and out of firing positions very quickly, enhancing crew survivability.

The SPLL can travel overland at 64 km/h and can accelerate from 0 to 48 km/h in 19 seconds. It can traverse a 60 per cent slope, a 40 per cent side slope, a 91 cm vertical wall and a 229 cm trench. It can also ford 102 cm of water.

It accommodates a crew of three soldiers: a driver, gunner and commander. The cab is equipped with an over-pressure ventilation system to prevent rocket exhaust fumes from entering the cab during launches. Armour protection, heating, ventilation and noise attenuation are also provided for crew safety and effectiveness.

Each finalist in the MLRS competition designed its own SPLL, but the basic carrier is the same – the fighting vehicle system carrier, manufactured by FMC Corporation, San Jose, California. It is powered by a Cummins 500 horsepower, four-cycle diesel engine. Because it is constructed from suspension and powertrain components common to the Army's new M2 IFV and the M3 cavalry fighting vehicle (CFV), logistics and maintenance in the field are simplified.

The MLRS surface-to-surface, highly accurate free-flight rockets have a range in excess of 30 km and provides an important complement to conventional artillery systems.

Each launcher load of 12 MLRS rockets can place almost 8000 M77 sub-munitions in an area (typically) 23 hectares at mid range against a single target. At maximum range this area is approximately doubled. Each M77, a derivative of the original M42, has about the same destructive power as a hand grenade and contains a shaped charge that allows it to penetrate light armour.

The low-cost solid-propellant rocket motor for the LTV Aerospace and Defence MLRS is produced by the Atlantic Research Corporation in Camden, Arkansas.

Innovative concepts were included which make the design particularly adaptable to economical high-rate production, such as use of low-cost commercially available hydroxy terminated polybutadiene (HTPB) propellant ingredients, low-cost insulation and igniter designs, use of quick-cure chemical processes to minimise tooling costs and manufacturing cycle times, an economical deep drawn 4130 steel motor case, and a moulded phenolic nozzle. An important feature incorporated into the MLRS propulsion system design is the employment of technology which is readily adaptable to high-volume production both in the United States and in NATO countries.

MLRS includes the development of three warhead types: dual-purpose anti-material and anti-personnel munitions, scatterable anti-tank mines and guided anti-tank sub-missiles. The dual-purpose warhead was the first developed for the system and dispenses M77 sub-munitions.

Rockets fired by MLRS are launched using a fire control system provided by Norden Systems who developed the fire control system using elements from the US Army battery computer system (BCS), an automated command and control system for up to 12 guns at the artillery battery level. The fire control system has four elements: the electronics unit which directs all system activities; the fire control unit which interfaces with the rockets; the fire control panel for the operator; and a small hand-held unit for loading and unloading launch pods.

Primary functions of the fire control system include digital communications with the BCS or TACFIRE, semi-automatic processing of fire missions, re-aiming between rockets during ripple fire, ballistic computations and load/unload operations. During a fire mission these functions can be entered

MLRS rocket launch

automatically or manually, but always under the control of the crew. The on-board system has a 504-character alpha-numeric fire control display panel that communicates to the operator in plain language rather than a code. It can communicate in any native language. The system does the firing computations and prompts the crewman to perform the next function. The system provides automatic re-targeting, thereby allowing a rapid, accurate volume of fire on many individual targets.

To eliminate the need to fire from surveyed sites (and for fresh survey after repositioning) MLRS features a new position determining system (PDS), giving greater combat mobility to the MLRS. The crew knows the position of the SPLL at all times as the PDS continuously computes the launcher position by measuring the distance and direction travelled by the vehicle. The PDS is supplied by Bendix, who provide the stabilisation reference package, part of the original MLRS aiming system. By minor adaptations to the SRP, Bendix was able to add the positioning facility to the north-seeking gyro-compass of the SRP. The first production version of the SPLL was delivered to the US Army in August 1982.

CHARACTERISTICS

Type: Artillery, surface-to-surface
Guidance: None (free rocket)
Length: 4 m
Diameter: 227 mm
Range: 30 km+
Propulsion: Solid rocket
Warhead: M77 sub-munition, dispensing
Rockets carried: 12 per launcher
Max launch rate: Rapid ripple, 12 rounds in less than 1 minute

DEVELOPMENT

US Army MLRS concept definition study contracts were let in March 1976, and these were completed later that year. Competitive development by the Boeing and Vought teams began in 1977 and Vought fired its first MLRS demonstration rocket at White Sands Missile Range in December 1977. In April 1978 Vought began firing rockets from a prototype launch-pod container, and in December 1978 the first NATO-sized MLRS rocket was launched. The first launch from a complete SPLL was in March 1979. Firing under US Army supervision started in September 1979, this series of 24 firings being completed in December 1979. Thirty-six more rockets were launched by the Army between then and February 1980. In the period 1977-80 a total of 127 rockets was fired by Vought.

The overall MLRS programme embraces several planned system enhancements and modifications, and there are also a number of other projects relating to it that have varying degrees of official backing. The most significant of all these planned or potential variants are summarised in the following paragraphs.

Lightweight MLRS: As its title suggests, this manufacturer's project is an attempt to provide the fire power of a heavy division combined with the mobility of a light division, by mounting a six-round launcher assembly on a modified M113 tracked vehicle. Lightweight MLRS has more than 80 per cent of its parts which are common to the standard MLRS and M113 equipments. The same launch pod/containers are employed for both MLRS versions, the fire control is the same, as are the communications and stabilisation reference platform/position determining system, and the crew arrangements of three or one in an emergency are identical. The loaded weight of a Lightweight MLRS vehicle is 10 437 kg compared with the 24 276 kg of the basic MLRS. No details of the status of this proposal of the early 1980s have been received.

MLRS-TGW: The MLRS Terminal Guidance Warhead programme is the result of an agreement between the USA, United Kingdom, Federal Republic of Germany, France and Italy to provide the MLRS with an active anti-armour capability by the development of terminally guided warheads. The basic concept is as follows:

The MLRS-TGW rocket flies a ballistic trajectory to a predetermined point in space. The TGW dispersal system is then initiated by the rocket fuze to dispense the six sub-missiles near the target area. Each is preprogrammed to a preset trajectory. The sub-missile seeker is activated automatically to search the terrain below for an appropriate target. When this is accomplished, the seeker will guide the warhead to engagement of the target. The TGW is being designed and developed by an international contractor team that includes: Martin Marietta Aerospace (US), Diehl GmbH (FRG), Thomson Brandt Armements (France), and Thorn EMI Electronics (UK), these four national prime contractors jointly owning MDTT Inc, a company which received a $90 million US Army Missile Command contract in late 1984 for TGW development.

Basic MLRS prime contractor, Vought Missiles has associate agreements with the various TGW contractors and expects to play an important part in the integration of TGW with the MLRS system. The fire control system will be updated for MLRS-TGW operation, and a new electrical unit will be incorporated to support MLRS growth over the next 15 years. The latter involves digital data interfaces, software, enlarged computer memory, and multiple processors.

The TGW will consist of six sub-missiles which have external dimensions and ballistic characteristics identical to the AT2 warhead section used for dispensing German scatterable mines in the MLRS Phase II programme. The warhead section will also contain a sub-missile dispersal system activated by the warhead fuze at a designated point in space near the target(s). It is anticipated that millimetric wavelength radar will be used by the TGW seeker.

Laser-guided MLRS: Texas Instruments and Vought have combined efforts to create a new concept which has been proposed to the US Army for use of the MLRS against armour and known as the Laser-guided MLRS. The idea is to use the standard MLRS production propulsion motor rear section with the seeker and guidance nose of the Paveway III laser-guided bomb system, coupled with the Hellfire shaped charge anti-tank missile warhead. Growth potential claimed for this approach includes the option of substituting a SADARM multiple target payload for the single Hellfire warhead. Targets would be designated by lasers operated by ground forces (infantry or vehicle-mounted), or by RPVs in the same way as planned for the Copperhead laser-guided artillery shell.

ABRS: The Assault Ballistic Rocket System is a Vought proposal to employ the MLRS system as a shore bombardment weapon deployed aboard US Navy amphibious assault forces such as LST 1179 class vessels. In this role, it is claimed, ABRS would be 12 times more effective than the 155 mm vertically loaded naval gun and 25 times more effective than the 5-inch/54 gun. A typical fitting would involve standard MLRS launcher units mounted on the after deck with reload supplies of MLRS rockets stowed below. No information of the Navy response to this proposal has been received.

Laser Doppler Velocimeter: This is a proposal by Vought in co-operation with Raytheon that is intended to offer improvements to all versions of MLRS operation, particularly in terms of accuracy and simpler fire control. The idea is to employ a coppler laser based velocity measuring system to obtain rapid wind data for use in MLRS fire control computations. The operating principle is based on the fact that transmitted laser energy is reflected by airborne aerosols, and the backscattered energy exhibits a doppler shift in frequency which is proportional to the aerosol velocity along the laser beam. By arranging for the laser beams to perform a conical scan about a vertical axis, it is possible to determine the total velocity components. This can be accomplished in 30 seconds with a claimed accuracy of better than 0·5 m/s velocity and ±20 mils in azimuth. Wind profiles from five to 300 metres altitude can be obtained in this way, using a two-unit equipment that can be mounted externally on the MLRS launcher vehicle. Total weight is less than 100 kg, and most components of the system are standard production military approved hardware.

STATUS

In April 1980 the US Army selected LTV as prime contractor for MLRS. Subsequent funding awarded under four separate contracts (maturation research and development, initial production facilities, low-rate production and multi-year procurement) amounts to a total of approximately $2 billion, calling for delivery of 333 SPLLs and almost 400 000 rockets in launch-pod containers. Initial production began in early 1982. Ultimately the production rate is expected to reach 6000 rockets per month. It is planned to employ MLRS in the NATO forces of Britain, France, West Germany, and Italy as well as those of the USA.

In January 1983, Britain became the first foreign country to order MLRS when a $5·2 million contract for four launchers and 108 practice rockets plus training equipment was signed. Delivery is due in 1985. The Federal Republic of Germany followed suit in March 1983 with a $2·3 million contract for two launchers plus training hardware.

MLRS was fielded by the US Army in early 1983 and is now deployed with Army units in the USA, Europe and South Korea.

CONTRACTORS

LTV Aerospace and Defence has assembled a team of experienced Army sub-contractors to develop and produce the MLRS.

Self-Propelled Loader Launcher
Sperry-Vickers: Launcher drive system
Norden Systems Inc: Fire control system
Bendix Guidance Systems: Stabilised reference package/position determining system
LTV: Launcher/loader module
Launch Pod Container
Brunswick: Launch tubes
LTV: Launch/pod container integration
Rocket
Atlantic Research Corporation: Propulsion system
LTV: M77 munition warhead
LTV: Rocket integration
Government Furnished Equipment
FMC Corporation: MLRS carrier
US Army: M77 sub-munitions

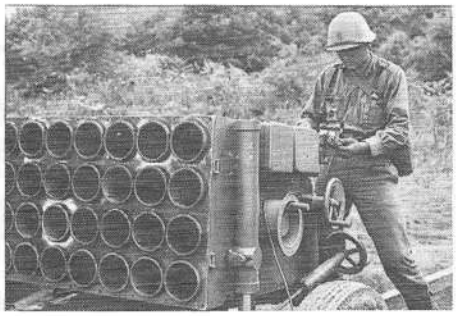
YUGOSLAVIA

2266.111
128 mm ROCKET LAUNCHER M-63

Based on the Czechoslovak RM-130 rocket launcher (**2024.103** in 1982-83 and earlier editions) this artillery rocket system is made in Yugoslavia. It comprises a 32-tube launcher for 128 mm spin-stabilised rockets. The launcher is mounted on a two-wheel trailer and the road wheels, together with the spread trails form the platform for the launcher when in operation. The launcher assembly can be elevated or depressed by handwheel; there is also a traverse hand-wheel, but the available traverse is limited to a few degrees for correction of aim - otherwise the launcher box would foul the road wheels. Firing is electrical.

CHARACTERISTICS



Rocket
Calibre: 128 mm
Length: 814 mm
Weight: 23 kg
Warhead weight: 7·55 kg
Launcher
Capacity: 32 rockets
Weight: 2·5 t approx
Elevation: 0 - 48°
Traverse: 30°
Max rocket velocity: 420 m/s
System range: 8·6 km
Rate of fire: 160 rounds/minute
Time to reload: 3 minutes
Crew: 3 - 5

STATUS

Service.

CONTRACTOR

M-63 rocket launcher

5153.111
YMRL 32 128 mm MULTIPLE ROCKET LAUNCHER M77

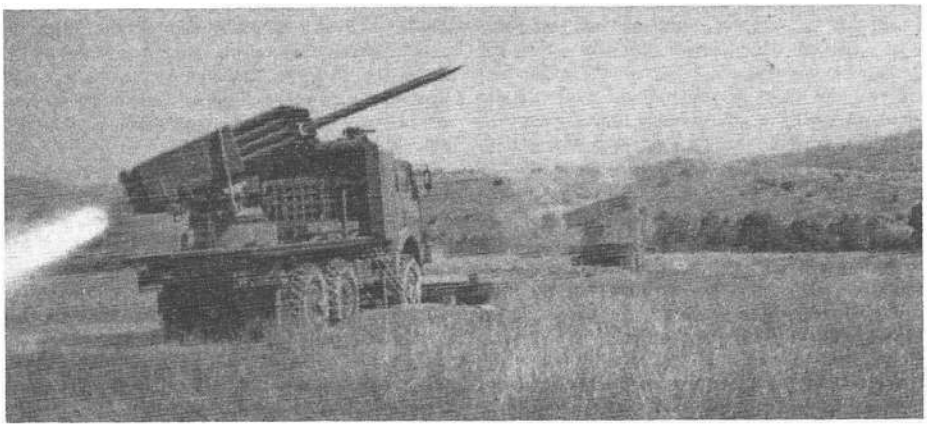
The YMRL 32 (M77) was first seen in 1975 and is a modified civilian FAP 2220 BDS 6 × 4 truck chassis with a 32-round rocket launcher mounted on the rear of the body. Behind the cab is a reloading system with a further 32 rockets. In concept the YMRL 32 128 mm system is similar to the Czechoslovak BM-21/M-1972 rocket launcher (**5137.111**).

The launcher has an electric/hydraulic control system and the rockets can be fired from the cab of the truck, or away from the vehicle with the aid of a remote control system. When the 32 rockets have been fired, the launcher is swung into the horizontal position and the reloading system is raised until it lines up with the launcher. It takes about two minutes to reload the complete launcher.

CHARACTERISTICS

Calibre: 128 mm
Length: 2·6 m
Weight: 65 kg
Warhead weight: 20 kg (inc 5 kg explosive)
Number of tubes: 32
Range: 20 km
Rate of fire: 18s for 32 rockets (single or ripple)
Elevation: 0 - 50° (auto or manual)
Traverse: 360° (auto or manual)
Time to fire and move (64 rounds): 4 - 5 mins
Dispersion: 0·6% of range (approx)

STATUS



In service with the Yugoslav Army.

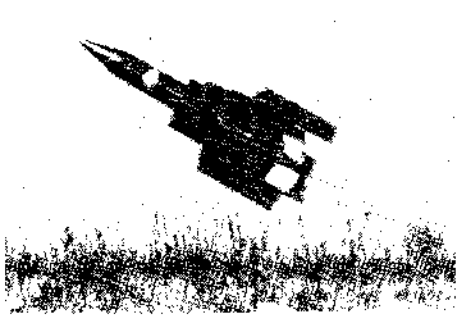
MATHOGO ANTI-TANK MISSILE



The Argentinian Mathogo anti-tank missile is a first-generation weapon relying upon wire guidance. It is designed to be carried and operated by an infantry soldier, but can also be launched from vehicles, helicopters or light aircraft. It is fitted with a hollow charge warhead and is reported to be able to disable the most modern tanks. In general appearance Mathogo is similar to the Swedish Bantam (**2363.111**), in particular the wing planform, but although there may be some connection between the Swedish and the Argentinian designed missiles, the weights and dimensions are not the same.

The complete system comprises: a water-tight container and launcher and 50 metres of cable; the control unit and binocular sight. Each control unit can be connected to four missiles and can be augmented by a distributor unit.

CHARACTERISTICS

Type: Surface-to-surface anti-tank guided missile with air-to-surface capability

Guidance principle: Wire-guided command to line of sight

CITEFA Mathogo anti-tank missile shortly after launch. Note absence of smoke and flame plume

Guidance method: By control of spoilers in trailing edge of wings

Gyro: Powered by solid propellant pellet

Propulsion: Booster and solid sustainer

Internal power: Thermal battery

Missile length: 998 mm

Diameter: 102 mm

Weight: 11·3 kg (missile); 19·5 kg (missile and launcher)

Effective range: 350 - 2100 m

Cruising speed: 90 m/s

A special simulator for training purposes, using moving or fixed targets, can be connected to the standard control unit. There is also a battery charger that is connected to the control unit.

DEVELOPMENT

Mathogo was designed and developed by CITEFA (the Argentinian Scientific and Technical Research Institute of the Armed Forces) under contract from the Argentinian Army.

STATUS

Development was completed in 1978 after a test programme involving more than 100 launches. It is in production.

CONTRACTOR

CITEFA (Instituto de Investigaciones Cientificas y Tecnicas de las Fuerzas Armadas), Zufriategui y Varela, 1603 Villa Martelli, Provincia de Buenos Aires, Argentina.

BRAZIL

4193.111

BRAZILIAN COBRA 2000 ANTI-TANK MISSILE

The West German designed Cobra 2000 anti-tank missile (**2181.111**) was first supplied to Brazil some years ago, and was subsequently the subject of a licence agreement between the two countries. The co-ordinating activities of the Brazilian Cobra missile programme are the responsibility of the Army's Instituto de Pesquisa e Desenvolviment (Institute of Research and Development) in Rio de Janeiro. Following the delivery of a batch of Cobra missiles produced by MBB in Germany for evaluation and general familiarisation, IPD began a programme aimed at obtaining completely national Cobra production and support capabilities in Brazil. In 1980 this programme was reported to be almost complete, and several batches of pre-production missiles manufactured by IPD at a pilot factory have been delivered to the Brazilian Army for troop familiarisation.

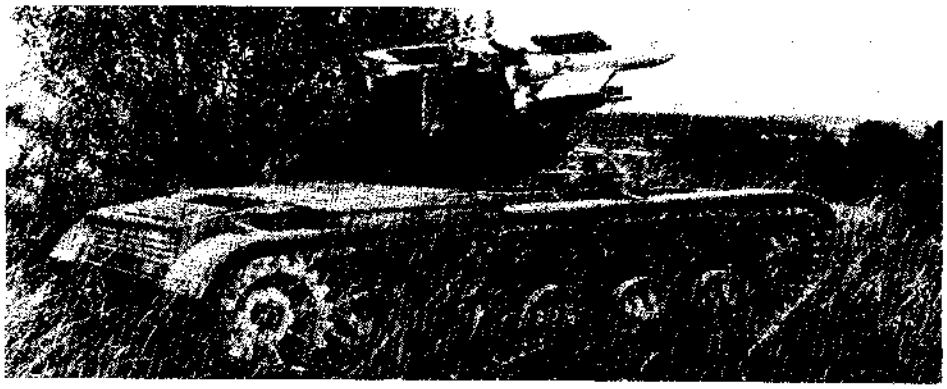
No details have been obtained, but it is thought probable that in view of the age of the original design, the more recently developed Brazilian version is likely to incorporate a number of component, manufacturing, and detail changes that embody the benefits of advances made in the interim.

FRANCE

2139.111

SS 11 BATTLEFIELD MISSILE

SS 11 is a line-of-sight wire-guided battlefield missile intended for firing from land vehicles, naval vessels, and slow-moving aircraft. Normally fired from a launching ramp it may also be used with a simplified ground launcher. The designation SS 11 is applied to the surface-to-surface version; the similar air-to-surface version is known as the AS 11 (**1173.311**).



OPERATION

The operator acquires the target by means of a magnifying optical device. As soon as the missile enters his field of vision after launch, the operator commands it to his line of sight by means of a joy-stick. The signals are transmitted over wires trailed from the missile. Tracker flares are installed on the rear of the missile for visual reference.

When installed in a helicopter or ship the simple sighting device used for land vehicles is replaced by a special stabilised sight.

CHARACTERISTICS

Type: Surface-to-surface tactical guided missile
Guidance principle: Command to line-of-sight
Guidance method: Optical tracking and manual wire-guided remote control of missile by vectoring the thrust of sustainer efflux (TVC)
Propulsion: 2-stage solid-propellant rocket motor
Warhead: Various (see text)
Missile length: 120 cm
Missile diameter: 16·4 cm
Span: 50 cm
Launch weight: 29·9 kg
Average cruising speed: 115 – 190 m/s
Minimum turning radius: 1 km
Range: 500 – 3000 m
Armour penetration (140AC warhead): 600 mm minimum

SS 11 missile

SS 11 B1

Since 1962, the SS 11 B1 version, using transistorised firing equipment, has been in production. It is available with a variety of different warheads, including an inert type for practice: the Type 140AC anti-tank warhead capable of perforating 60 cm of armour plate, the Type 140 AP02 explosive semi-perforating anti-personnel warhead (2·6 kg of explosive) which will penetrate an armoured steel plate 1 cm thick at a range of 3000 metres and explode about 2·1 metres behind the point of impact, and the Type 140 AP59 high-fragmentation anti-personnel type with contact fuze.

HARPON

A variant of the SS 11 was produced and supplied to French, West German and Saudi Arabian forces under the name Harpon. It was an SS 11 with a modified guidance system and was described in some detail in **2095.111** in 1981-82 and earlier editions of this book.

STATUS

By mid-1980 some 174 000 of the SS 11 series of missiles had been delivered, including both ground and airborne versions and including also the Harpon (**2095.111**) version, to more than 20 customer countries. Production has now ceased.

CONTRACTOR

Aérospatiale, Division Engins Tactiques, 2-18 rue Béranger, 92322 Châtillon Cedex, France.

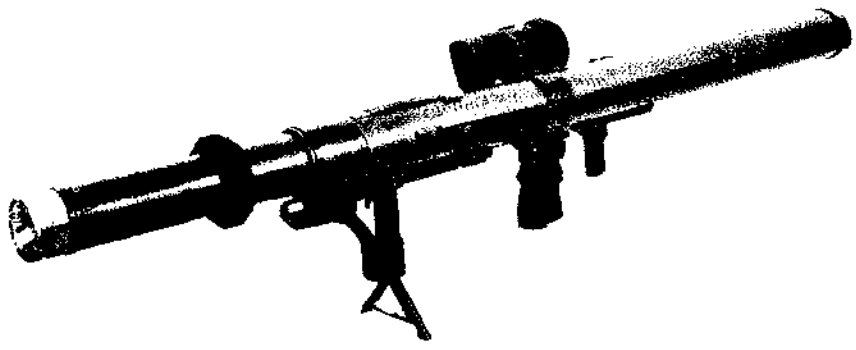
2055.111

ACL-STRIM ANTI-TANK ROCKET LAUNCHER

This is a man-portable anti-tank weapon that has been adopted by the French Army where it is known as the 89 mm LRAC Model F.I.

Designed primarily for infantry use, the ACL-STRIM is a lightweight rocket launcher that fires an 89 mm rocket with an effective range of 400 metres. In the firing position the weight of the launcher and rocket is 8·6 kg; for transport, the launcher units weigh 5·4 kg and each round of ammunition in its container weighs 3·2 kg. The system is thus readily carried into action by combat troops.

The launching tube is made of glass and resin laminate and its shoulder piece and foregrip can be adjusted to suit the user. An APX M-309 sighting telescope, which is detached for transport, is clipped to the side of the launching tube.



The rocket comprises a warhead and a propulsion system. The warhead has a streamlined plastic cap in which is mounted a piezo-electric generator that detonates the charge on impact with the target. The shaped charge is contained in an aluminium alloy casing streamlined by a plastic fairing. To the rear of this is the base fuze which is at safe in the transport position and is armed in flight by gases tapped off from the propulsion system.

For transport the rocket is carried in a sealed container which in operation forms part of the launching tube and contains the electrical circuits that mate with the firing circuits in the launcher.

At normal incidence the rocket will penetrate 400 mm of armour and the weapon is effective at incidence angles up to 75° from normal.

DEVELOPMENT

Development of the ACL-STRIM was initiated by Luchaire SA and the first design study was made in 1964. The system is now in production and went into service with the French Army in 1969.

ACL-STRIM loaded and ready to fire

CHARACTERISTICS

Weapon
Calibre: 88·9 mm
Length: During transport, 1·168 m; in firing position, 1600 mm
Mass: During transport, with 0·5 kg sighting telescope, 5·4 kg; in firing position, 8·6 kg
Rocket
Diameter: 88·9 mm
Diameter of shaped charge: 80 mm
Total length: 0·600 m
Container length: 0·626 m
Total mass: Without container, 2·2 kg; with container, 3·2 kg
Mass of explosive of the shaped charge: 0·565 kg
Ballistic characteristics
Muzzle velocity: At +20°C, 291 m/s; at +51·5°C, 295 m/s; at -31·5°C, 287·2 m/s
Combat range: For a 1·21 s flight time (max ordinate: 1·8 m): 315 m
For a 2·3 m max ordinate (1·36 s): 360 m
Effective range: 400 – 500 m
Time of flight at 400 m range: 1·56 s
Ammunition: Anti-tank, anti-personnel/light armoured vehicles; smoke; incendiary; practice. For training, a sub-calibre barrel for firing 7·5 mm cartridges at combat ranges is available
Effectiveness of the shaped charge
Thickness of armour plating steel perforated at 0° incidence with T3 warhead: 480 mm
NATO targets 100% perforated: Single target, heavy tank, 120 mm/65°; dual target, heavy tank, 40 + 110 mm/60°
Operating limit incidence: 74 – 75°

STATUS

In production. In service with French and other armies. This weapon has been sold to 21 foreign states.

CONTRACTOR

The system is being produced jointly by Luchaire SA, 180 Boulevard Haussmann, 75 Paris 8e, France, and by the Manufacture Nationale d'Armes de St Etienne.

4552.111
ACCP ANTI-TANK MISSILE

The ACCP (antichar courte portée) is a short range anti-tank missile for use by foot soldiers in the battlefield at ranges of up to 600 metres, but principally with fighting at close quarters in urban districts in mind. Now under development, the Aérospatiale concept calls for a very high penetration missile in preference to the alternative of rockets, the accuracy of which can be adversely affected with increasing range. The ACCP has an effective range of 25 to 600 metres, and a very short flight time enables the use of simple, inexpensive components. The propulsion system also is low-powered so that the weapon can be fired within a confined space.

A simple guidance system is employed that uses an IR marker on the missile which is tracked throughout its flight by a CCD camera in the firing unit so that corrections can be signalled to it to command the missile to the line-of-sight to the target via guidance wires.

CHARACTERISTICS

Weight: 10 kg (round in tube, ready to fire): 11 kg in tactical container
Length: 930 mm
Diameter: 152 mm
Guidance: CLOS
Propulsion: Solid
Range: 25-600 m

Aérospatiale ACCP short-range anti-tank missile system

Max speed: 300 m/s (terminal)
Penetration: 900 mm steel
Sight: CCD camera
Optical field: 200 mrad
Magnification: ×4

STATUS

Development. Initial tests carried out in 1982.

CONTRACTOR

Aérospatiale, Division Engins Tactiques, 2-18 rue Béranger, 92322 Châtillon Cedex, France.

GERMANY (FEDERAL REPUBLIC)

2181.111
COBRA 2000 ANTI-TANK MISSILE

This weapon system – full designation BO 810 Cobra 2000 – comprises a small wire-guided anti-tank missile, a control box, and cable links. It is a lightweight low-cost weapon suitable for operation by one man, who can readily carry, set up, and fire two missiles.

OPERATION

Unlike many other wire-guided missiles, Cobra is not launched from a container; the missile is simply set down on the ground and, when it is fired, a booster mounted on the underside gives it a jump start that lifts it clear of even rough ground before the sustainer develops full power.

Before launching, the missile is connected to the control box by a cable. This control box contains a battery that supplies the power required to launch and control the missile and, once connected, the missile can be launched simply by pressing the launch button. By means of a junction box up to eight missiles can be connected simultaneously to the control box on which is mounted a selector switch that enables the operator to fire and control these missiles one at a time.

A target coincidence guidance technique is used. The operator has a joystick control which enables him to give lateral and vertical commands to the missile through the guidance wire trailed out behind it. Immediately after launch the missile has to be gathered rapidly into the operator's line-of-sight to the target and quite substantial movements of the joystick may be necessary to achieve this; thereafter relatively small movements should suffice to keep the missile framed in the target. Tail-mounted flares make it easy for the operator to see the missile in flight.

An electrical testing device built into the control unit enables the controller to carry out a pre-launch check.

The cable attached to the missile is 20 metres long and that attached to the junction box is 50 metres long. The operator can thus position himself conveniently up to either 20 or 70 metres from any one missile.

CHARACTERISTICS

Type: Surface-to-surface anti-tank weapon system
Guidance principle: Command to line-of-sight wire-guidance; optical gathering and tracking
Guidance method: By control of spoilers in wings
Propulsion: Solid-propellant sustainer with separate non-jettisonable booster mounted below the missile
Warhead
(A) hollow charge type, total mass 2·7 kg: penetration 500 mm armour
(B) ATS (anti-tank/shrapnel) 2·7 kg, penetration 350 mm armour prefabricated fragmentation with destructive effect within 10 m radius
Missile length: 95 cm
Body diameter: 10 cm
Wing span: 48 cm
Launch weight: 10·3 kg
Weight at burn-out: 8 kg
Max speed: About 85 m/s
Range: 400 – 2000 m

DEVELOPMENT

Cobra was designed and developed by Bölkow GmbH, the first design study being carried out in 1957. The system first went into service in 1960, since when more than 170,000 (including those manufactured under licence) have been supplied to the armed forces of 18 countries. A first generation missile, Cobra has been produced in two versions, the Cobra 2000 described here being slightly the heavier of the two and having a maximum range of 2000 metres whereas the earlier Cobra had a maximum range of only 1600 metres. It is still in production but its improved successor, Mamba (**2188.111**), has been so designed as to make it easy for countries using Cobra to change to the new system at whatever rate suits them best.

STATUS

In service with the forces of Argentina, Brazil, Denmark, Greece, Israel, Italy, Pakistan, Spain, and Turkey. West German production has ceased.

In 1980 it was expected that series production in Brazil of Cobra 2000 would be handed over to private industry, after several batches of missiles manufactured at a state-owned pilot factory had been handed over to the Brazilian Army for troop familiarisation.

CONTRACTORS

Originally manufactured by Messerschmitt-Bölkow-Blohm GmbH, in the Federal Republic of Germany. The warhead and sustainer motor are made by Oerlikon-Bührle, Switzerland. Manufacturing licences have been granted in Brazil, Italy, Pakistan and Turkey.

2188.111
MAMBA PORTABLE ANTI-TANK WEAPON SYSTEM

Mamba is an anti-tank missile first announced by MBB late in 1972. Of the same general type as Cobra (**2181.111**), it incorporates two major improvements in the missile, in addition to numerous other changes, and MBB have developed a completely new controller for the system. The new missile, however, will accept Cobra warheads and can be used with existing Cobra controllers by users wishing to change to the new weapon, and existing Cobra vehicle launchers can readily be modified to accept Mamba.

One of the major differences between Mamba and Cobra is that, whereas the latter used an oblique-thrust booster (to give a jump start) and an axial sustainer, Mamba has a one-cell dual-purpose oblique-thrust engine which not only retains the jump-start facility but also provides a weight compensation during the cruising phase. This saves the operator from continually having to counteract gravitational droop during the cruising phase. The other major change is the increase in maximum speed from 85 to 140 m/s.

The new controller incorporates an extremely powerful monocular with an oblique (×7) eyepiece. This permits direct transition from observation with the naked eye to telescope magnification without head movement, thus avoiding the main difficulty of this transition. This control unit is completely independent of any power sources, batteries etc; it performs all the functions which are performed for Cobra by the test and control units, and it is operable from –40 to +60° C.

Four output sockets from the controller can be connected to single missiles and a fifth can be connected either to a fifth missile or an eight-outlet junction box, giving a total control capability of 12 missiles selected by a switch on the controller. Missile launching is by push-button and guidance by joystick, power for the ignition impulse and the joystick signals being provided by a clockwork motor operating a generator. One winding of the motor suffices for eight launches.

The Mamba system thus comprises only the missile and the control unit. It is conveniently packaged in a water-, dust-, and tropic-proof pack which is of a convenient size for carrying and stacking. Like Cobra, Mamba can be fitted with alternative shaped-charge, or training warheads and these are easily interchangeable.

Mamba is primarily designed to be launched from the ground, and since it can be laterally diverted up to 45° from its launching direction its envelope of action is very wide. If required, however, it can also be launched from a vehicle and a standard five-missile launching frame has been designed for this purpose. Any kind of vehicle can be fitted with this frame, on which the missiles are mounted in a ready-to-fire position but from which they are easily removed. The

controller can be either mounted on the vehicle or removed for remote operation.

CHARACTERISTICS

Type: Surface-to-surface anti-tank weapon system

Guidance principle: Command to line-of-sight with optical tracking

Guidance method: Wire-guidance control of wing mounted spoilers

Propulsion: Single cell, dual purpose solid propellant, oblique-thrust rocket motor

Warhead: Hollow charge type total mass 2·7 kg, 500 mm armour penetration. Dummy for training. All warheads interchangeable

Missile length: 955 mm

Body diameter: 120 mm

Wing span: 400 mm

Launch weight: 11·2 kg

Max speed: 140 m/s

Effective range: 300 - 2000 m

Flight times

500 m: 6 s

1000 m: 10 s

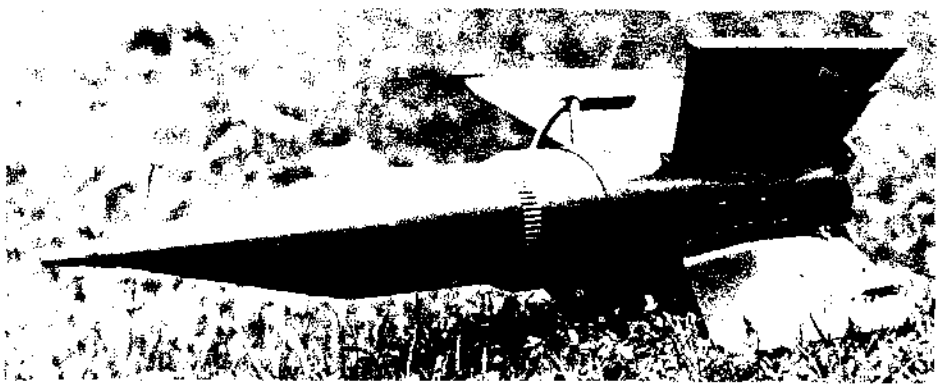
2000 m: 17·5 s

Controller dimensions: 300 × 250 × 100 mm, 9·55 kg

Packed missile (with accessory bag): 365 × 402 × 605 mm, 18 kg

Cable system (including junction box, reel etc): 393 × 408 × 416 mm, 26 kg

TRAINING



A special training aid, Type 1212/1 SU, has been designed. This is a simulator using a combat area presentation on a TV screen with superimposed symbols - which move appropriately - to represent target and missile. The trainee operates a standard controller in conjunction with this display.

STATUS

The weapon is in production and supplied to a number of other countries.

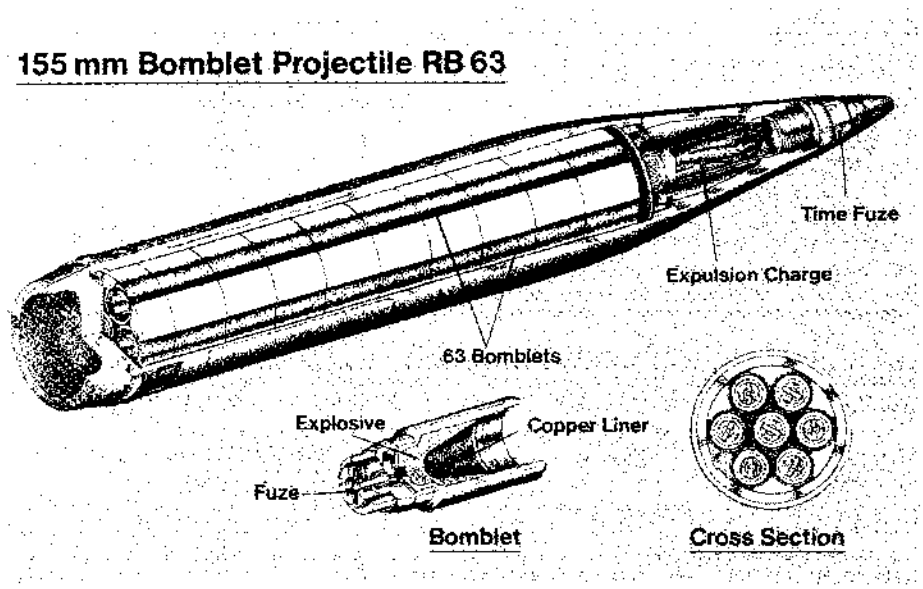
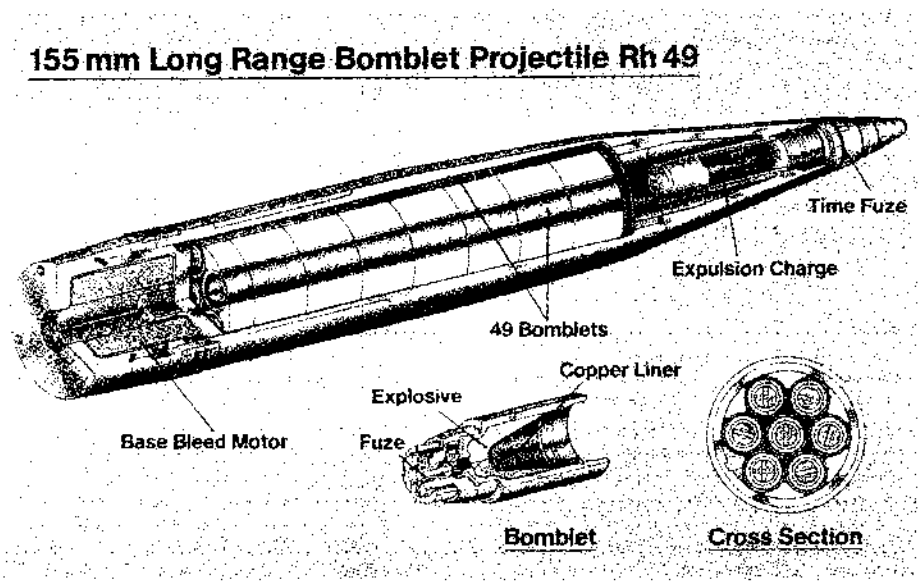
RHEINMETALL ANTI-ARMOUR AMMUNITION DEVELOPMENTS

Rheinmetall is developing a range of both 'smart' munitions and so-called 'brilliant' artillery ammunition for use against existing and anticipated armoured formation threats. Known details of some of these projects are summarised below.



The underlying philosophy rests on the view that long range artillery systems firing smart munitions can effectively engage multiple light- and heavy-armoured targets at greater range than main battle tanks using kinetic energy penetrators. However, these new rounds will not replace conventional artillery ammunition used in close support of manoeuvring units. Instead, such ammunition enables approaching armoured units to be engaged before they join first echelon formations, so that the defender has an ammunition mix to meet any tactical situation.



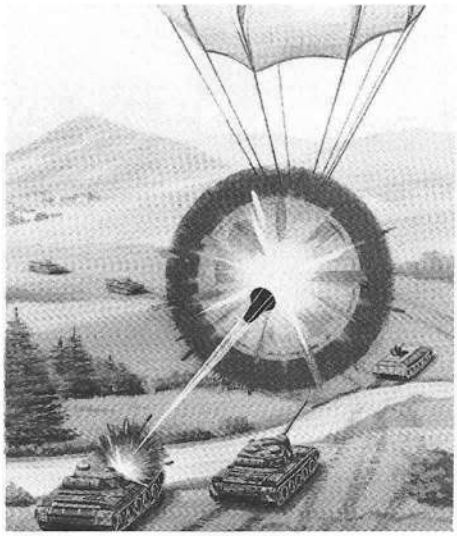
MLRS-TGW: This programme is covered in greater detail earlier in this section dealing with longer range theatre missile systems. The multiple launch rocket system (MLRS) Phase III terminal guidance warhead operating system, in which the warhead contains six terminal guided submunitions, is described in entry **4060.111**. Rheinmetall is participating in the international consortium developing this version of the MLRS and is responsible for the warhead, fuze and the safe-and-arm unit of the TGSM. These are dispensed over the target area and each glides in search of separate targets. A millimetre wavelength sensor provides target location which is used to guide the vehicle. A high performance shaped charge warhead will be used to achieve the target kill.

ZEPL Target Locating Self-forging Projectiles: Rheinmetall is developing the ZEPL 'smart' submunition for 155 and 203 mm artillery. ZEPL is a German acronym for a target locating, self-forging projectile submunition. In concept, a spin-stabilised carrier shell ballistically transports three ZEPL submunitions to the target area where they are ejected from the carrier by a time fuze. A specially shaped parachute stabilises the ZEPL causing the sensor to search in a tight spiral pattern over the target area. On achieving a target 'lock-on', a charge is ignited so that the submunition forms a projectile which penetrates the target almost vertically and at high velocity. Both the 155 and 203 mm ZEPL shells can be fired at the highest artillery zone charge.

EPHRAM: EPHRAM is the German acronym for a terminal guided, tube launched projectile, a 155 mm artillery round that Rheinmetall calls 'brilliant', and which is designed to engage light- and heavy-armour at extended ranges. The method of operation is as follows. A spin brake slows down the projectile rotation over the target area to reduce the vertical speed. At an altitude of about 800 metres, the sensor head starts scanning the target area. After identifying and locking on to a target, lateral thrusters are fired which direct the projectile onto the target. A shaped charge warhead then detonates, penetrating the target on impact.

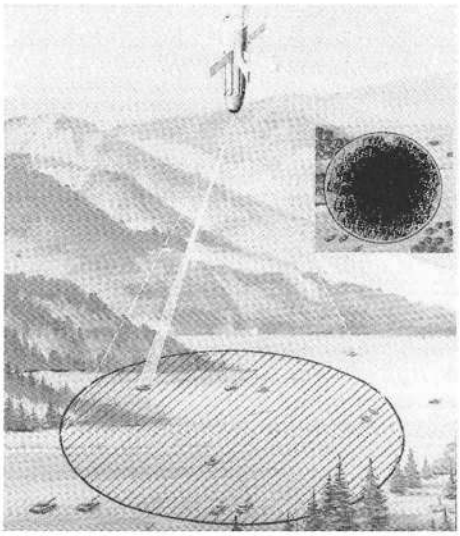
155 mm Carrier Shells: The US 155 mm M483 carrier shell with its M42 and M46 bomblets (see **4880.111** in the US pages of this section) represents the first generation of improved conventional munitions (ICM). Rheinmetall is producing its own models of 155 mm carrier shell and bomblet 'cargo', designated RB 63 and Rh 49.

Rheinmetall 155 mm improved conventional munitions (ICM)



The new improved bomblet used in the Rheinmetall round has the same modes of operation as the US munitions, but is somewhat larger and heavier so fewer can be carried. Each bomblet also contains a new fuze to replace the M223, and this is claimed to have a lower failure rate. Numbers following the 'RB' and 'Rh' designation denote the number of bomblets carried, and the reduced number in the Rh 49 provides the space needed for the base bleed feature of the longer range shell. The basic RB carrier shell has a length of 899 mm. When fired with a zone 8 charge, the RB 63 has a maximum range of 22 km and the Rh 49 a range of about 30 km.

STATUS



Development programmes.

INTERNATIONAL

4159.111

ADATS (AIR DEFENCE ANTI-TANK SYSTEM)

ADATS is the title of an international project to develop a battlefield weapon system to acquire, track and engage low-altitude high performance aircraft, helicopters, armoured vehicles and RPVs. The programme is led by Oerlikon with Martin Marietta collaborating under contract.

A modular design concept has been adopted for the fully integrated, self-contained missile system, which can be mounted on a variety of wheeled and tracked armoured vehicles. ADATS comprises an X-band search radar, forward-looking infra-red (FLIR) and TV trackers, a laser rangefinder and a carbon dioxide laser which provides a guidance beam for the beam-riding ADATS missile, a fire control computer and control consoles, and eight ready-to-fire missiles in their containers.

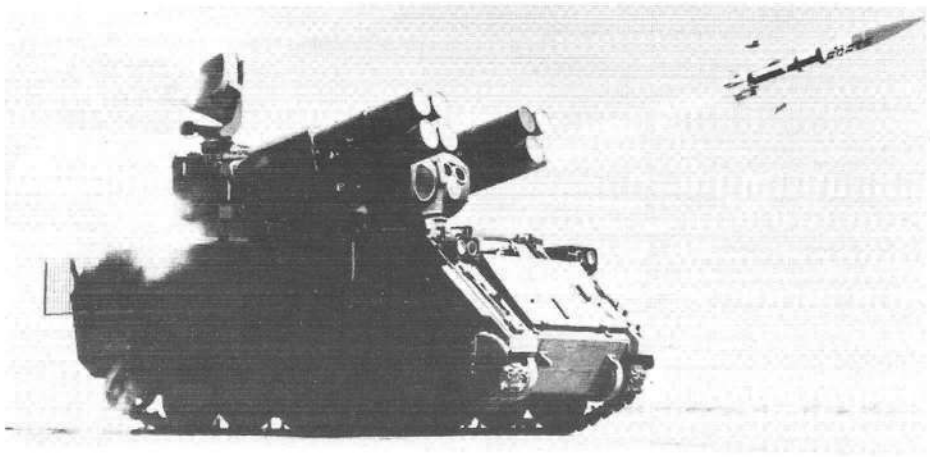
The ADATS missile has a heavy dual-purpose warhead equipped with a proximity fuze for air targets and impact fuze for use against ground targets. Smokeless propulsion accelerates the missile to speeds of over Mach 3. The complete system will provide high lethality against both air and surface targets, with availability to operate effectively in a dense ECM environment and under adverse weather conditions. Additional details of ADATS operation will be found in **4158.131** in the Mobile Surface-to-Air Guided Missile System section.

CHARACTERISTICS

Length: 2·05 m (2·2 m in canister)
Diameter: 152 mm
Weight: 51 kg (approx)
Propulsion: Solid
Range: 8 km
Ceiling: 5000 m
Speed: Mach 3 plus
Warhead: Dual-purpose 12 kg plus
Fuze: E/O proximity and impact
Penetration: 900 mm plus armour steel
Search radar: 20 km range, dual beam, search on the move capability, 360° cover.

Swiss soldiers operating ADATS during Swiss Army European tests of the system in 1985

STATUS



Unguided test launches of ADATS missiles were carried out in the USA in 1981, and all-up guided launches began in 1982. The development test phase was completed in June 1984 after 39 missile firings.

A pre-production programme is in progress under the leadership of Oerlikon-Bührle with Litton Systems Canada, Martin Marietta and Contraves Italiana. Litton has been involved in a major technology transfer of the electronic sub-system of ADATS since August 1984. As a result of sole manufacturing rights assigned to them by Oerlikon-Bührle, Litton will employ this technology to build the electronic systems and in addition supply the C^3 systems in all ADATS sold world-wide.

The Swiss Army awarded a contract for tactical evaluation in specific European environments. The system was a major element of a submission for the Canadian LLADS project.

2212.111
HOT ANTI-TANK MISSILE

HOT (Haut subsonique Optiquement téléguidé tiré d'un Tube) is a heavy anti-tank weapon being developed by Aérospatiale and Messerschmitt-Bölkow-Blohm. With low-speed spin-stabilisation like Milan (**2215.111**), it is a tube-launched, wire-guided missile of larger size and higher performance than Milan but with the same general principles of operation. HOT was planned as a replacement for the SS 11 (**2139.111**) missile and its mission profile corresponds to a NATO requirement for a missile to operate primarily from armoured or unarmoured vehicles and helicopters.

Like Milan, the missile has tail fins which fold down against the body in its launch tube and open out in flight. Guidance is automatic command to line-of-sight (CLOS) with an IR tracking system. The latter was developed by SAT and is produced in collaboration with Eltro in West Germany. Several versions are produced: for rotating tank turrets, for vehicles without turrets and for helicopters.

With the TCA system of guidance, all the operator has to do is to aim carefully at the target with an optical sighting device. When the missile is launched, IR radiation from its tracer flares is detected by a precision goniometer that is associated with the optical sight and that has its reference axis accurately parallel to the optical axis. Departure of the missile from the optical axis gives rise to an angular error signal which can be combined with an estimate of range (based on the known flight characteristics of the missile) to give a measure of the linear departure of the missile from the line of sight. This measurement is then used to generate command correction signals for the missile whose flight is controlled by means of a jet vane system.

OPERATION

Once the target has been visually acquired, all that the operator has to do is aim carefully at the target, launch the missile, and maintain his aim steadily during the missile's flight. An advantage of this guidance system is that, because the departure of the missile from the line of sight is measured by the system, the amount of flight correction required can be determined to a similar degree of accuracy and, as a result, the initial gathering of the missile on to the line of sight can be accomplished quickly. This has the important effect of giving the system a good short-range performance.

HOT can be fired from armoured or other vehicles, from helicopters or from dug-out positions and in all conditions of visibility that permit the operator to aim at the target.

German Tank Destroyer with HOT Casemate vehicle launcher

The list of vehicle types (land and airborne) to which the HOT system has been fitted is extensive and includes the following:

AFVs and Land Vehicles:

M113 series APC - 2 tubes: 11 rounds inside

AMX 10P APC (**5009.102** in 1979-80 and earlier editions) - 4 tubes

Panhard M3B APC (**5022.102** in 1979-80 and earlier editions) - 4 tubes; 14 rounds inside

Saviem VAB armoured car - 4 tubes; 8 rounds inside

Raketenjagdpanzer 3 (**5014.102** in 1979-80 and earlier editions) - 1 tube; 8 rounds inside

Helicopters:

B0105M PAH 1 - 6 tubes

Gazelle SA 341/SA 342L - 4 or 6 tubes

Alouette III (trials only)

Dauphin SA 361H - 8 tubes

Lynx - 8 tubes

A selection of the launch equipment employed in these various installations is described in the following paragraphs.

Mephisto

This system was specially designed to permit HOT to be installed on the Saviem VAB armoured car, but is capable of use in other vehicles of the same class. Firing is possible in all directions, and reloading is accomplished from within the vehicle as the four launchers retract while the vehicle is in the 'on-road' configuration.

The Mephisto system consists of an electrically actuated lifting module which elevates four launchers (with their HOT rounds) into either of two positions:

(1) a high position which provides sufficient clearance to allow the module to rotate 360° in azimuth, and
(2) a low position, wherein the system is retracted within the vehicle to enable the ramps to be reloaded from inside.

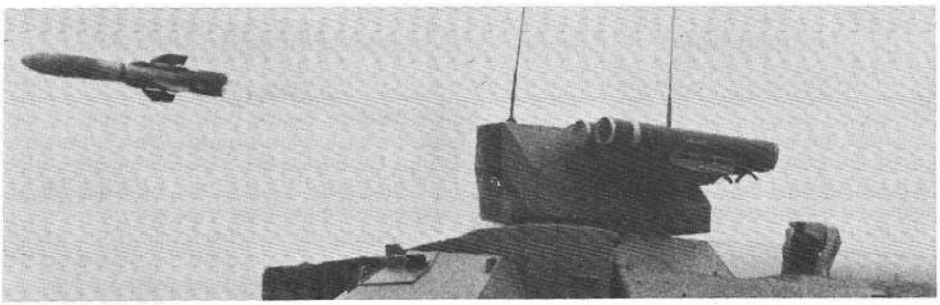
Four-round HOT/Mephisto installation

Other items are the sighting system and the missile guidance electronics. The former comprises a swivelling head periscopic sight with stabilised optics, located on the axis of the launch module and partially retractable for the 'on-road' configuration. There is internal stowage for eight reload rounds. This version is in development for the French Army and claimed to be under consideration by the British and West German forces.

Launching Gear UTM 800 (Electric)

Here operation of the gear is undertaken by only one man, sitting. The movement in azimuth and elevation direction is achieved electrically. The guidance system in separated elements version is installed within the turret itself. Four missile ramps can be loaded manually. The turret has a relatively low weight and small installation volume. It can be installed on several types of vehicle. Production for the Panhard M3 vehicle is under way.

Launching Gear Lancelot (Electric)



The AMX 10 HOT vehicle is equipped with the TL HOT turret, which is served by two men. Azimuth and elevation movement is performed electrically by direct command. The guidance system is divided into small boxes and installed in the turret using a special sight for the gunner. Four launching ramps are manually loaded from the rear.

Launching Gear for Casemate Vehicle (K3S)

This consists of a retractable clamp system and a periscope guidance unit. Empty launch tubes are automatically thrown clear after launching. The reloading of up to eight missiles is automatic on retraction of the clamp system in the vehicle. Operation is entirely under NBC protection.

HCT Launching Gear (Electro-Hydraulic)

Due to the absence of a turret basket assembly, the HCT (formerly HAKO) installation exhibits reduced weight and dimensions. The standard-design guidance equipment is located at various points in the vehicle body and linked to the turret assembly by flexible cable. The operator can direct the turret through ±180° in relation to the vehicle axis for rapid target acquisition; he has the use of a stick control to rotate the turret electro-hydraulically through ±30° in relation to its initial position. This enables precision pointing and target tracking. The stick also controls the angle of elevation of the sighting optics. A stabiliser system may be added for installation on

HOT missile leaves UTM 800 turret launcher on M3 APC

wheeled vehicles. The turret can hold two or four ready-to-fire munitions; reloading is manual.

The HCT turret is a simple and light assembly enabling installation of the HOT anti-tank system on armoured vehicles, even of small dimensions.

CHARACTERISTICS

Type: Long-range, vehicle mounted, wire-guided, anti-tank weapon with airborne applications

Guidance principle: Command to line-of-sight. Optical aiming with automatic IR tracking.

Guidance method: Wire-guidance control of jet vane system

Propulsion: Solid-propellant booster and sustainer

Warhead: Hollow charge

Missile length: 1·275 m

Missile diameter: Warhead: 136 mm (HOT 1); 150 mm (HOT 2)

Span: 310 mm

Launch tube length: 1·3 mm

Launch tube diameter: 175 mm

HCT twin-tube HOT launcher turret

Weight: Missile and container 32 kg. Missile at launch 23·5 kg

Max speed: 250 m/s

Flight duration

2000 m : 9 s

3000 m : 13 s

4000 m : 17 s

Range: 75 m – >4 km

Penetration: >800 mm of solid armour (HOT 1); >1200 mm (HOT 2). NATO triple-armour target at 65° incidence. Effective against composite armour

Operating conditions: -40 to +52° C at up to 95% rh

DEVELOPMENT

The first design study for the system was made in 1964. Development is now complete and the new HOT 2 missile with improved warhead will enter service during 1985.

STATUS

The system has been ordered by the French and West German forces following user trials which included the helicopter version. Several other countries have also placed contracts for HOT vehicle and/or helicopter installations, to make a total of 12 user countries in all.

CONTRACTOR

Responsibility for management, sales, and production is vested in Euromissile, 12 rue de la Redoute, 92260 Fontenay-aux-Roses, France.

2215.111

MILAN ANTI-TANK MISSILE

Milan (Missile d'Infanterie Lèger Antichar) is a wire-guided, spin-stabilised, anti-tank missile system.

The current second-generation system, Milan 2, incorporates a semi-automatic guidance technique that requires the gunner to do no more than maintain the cross wires of his guidance unit on the target during the missile's flight. The system comprises a missile in a container and a launch and control unit. Before the launch, the container - which also serves as a launch tube - is mounted on the launch and control unit. This in turn can be either mounted on a tripod to be fired from a ground position or, mounted on a pivot, from a vehicle.

Although heavier than some of the small first-generation anti-tank missiles, Milan 2 is readily portable. It is also suitable for operation from armoured or unarmoured vehicles. In its simplest form operation is effective in daylight, at dawn and dusk and, by means of battlefield flares, at night. It can be fired over fresh or salt water.

MILAN now has a night-firing capability through addition of the MIRA thermal imaging device manufactured by TRT, Siemens and Marconi, and adopted by the French, German and British armies. This consists of a case weighing approximately seven kilograms which can be mounted on the standard firing post. Target detection is possible at a range of over three kilometres, and firing the extreme range of the system.

To contend with improved tank armour making its appearance in certain theatres, the three nations collaborating in Milan and MIRA production and development (France, West Germany and the UK) evolved an improved warhead (K 115) which was introduced in 1984. This has an increased diameter of 115 mm compared with 103 mm of the standard item. It also has a different configuration as can be seen from the photograph and the extended nose is arranged to ensure a greater effective stand off distance for the hollow charge payload. The launcher tube is modified to accomodate the larger diameter warhead, and the increased stand off results in appreciably enhanced armour penetration characteristics.

Milan 2 with K115 warhead in-flight configuration

OPERATION

At launch the missile is ejected from its container by a piston which in turn is propelled by a gas generator located at the rear of the launch tube and working on the recoilless principle. The ends of the tube are protected for storage and transit by caps which must be removed before firing.

As the missile emerges from the tube, the tube is disconnected from the launch unit, and the forces in the system are sufficient to throw it backwards from the launcher to a distance of about three metres, leaving the launcher ready for reloading.

When the missile is ejected from the tube its wings, which impart a slow spin to the missile, flick open. The missile then coasts forward until, at a sufficient distance from the launcher to avoid harm to the gunner, the warhead is armed.

Built into the launcher/sight unit is an IR TCA guidance system similar in operation to that described above for HOT (**2212.111**). After launching, the missile is gathered to the gunner's line of sight using wide-angle detection. Detection sensitivity in this phase is presumably relatively low but at close range the signal strength from the IR flares in the missile's tail will be high. For subsequent guidance narrow-angle detection is used. MBB in Germany with SAT in France and Eltro in West Germany are jointly responsible for production of the IR guidance system, and SNIAS for missiles. BAe and MCCS are responsible for the major portions of the appreciable quantity on order for UK forces' use.

CHARACTERISTICS

Type: Surface-to-surface, man-portable, anti-tank weapon system

Guidance principle: Automatic command wire-guidance

Guidance method: Optical tracking of target only. Automatic IR tracking of missile and control by vectoring thrust of sustainer efflux

Propulsion: Ejector in tube (gas generator). Solid-propellant boost/sustainer motor

Warhead: Hollow charge. 115 mm

Penetration: Against a solid target (at 90° incidence) at maximum lethality range between 850 and 1000 mm

Missile length: 0·77 m

Body diameter: 0·09 m

Fin span: 0·27 m

Weights: Missile and container: 12 kg; launcher and control unit with tripod: 16·5 kg

Max speed: 200 m/s

Range: 25 - 2000 m

Time of flight: 7·3 s to 1000 m, 12·5 s to 2000 m

Milan firing post equipped with the MIRA night firing device

DEVELOPMENT

Following the Franco-German agreement, discussion started between Nord-Aviation and Messerschmitt-Bölkow in 1962, and a design study was completed in 1963. Technical evaluation and firing demonstrations by and for the French and West German forces were completed in 1971. User trials in France, Germany, and other countries followed. In June 1972, a successful series of demonstrations was given to representatives of some 30 countries. During the official Franco-German trials, which were designed to test the weapon's efficiency in a wide range of environmental conditions, a hit probability of 88·6% was established in 665 firings.

In the period to December 1984, 46 579 missiles were fired by various customers. The percentage of satisfactory technological performance of the firings overall was 94%, and among the latter ones, the direct hits scored amounted to more than 92%.

STATUS

183 000 missiles and 3500 firing points have been ordered by the forces of 35 countries. More than 201 000 missiles have been put into production. Current production is running at a rate of 950 missiles and about 20 firing posts per month.

Series production of the Milan 2 improved K115 warhead began in late 1984.

Milan is in licence production for Great Britain, Italy and India.

CONTRACTORS

Messerschmitt-Bölkow-Blohm GmbH, Munich, and Aérospatiale, Paris, are main contractors. BAe, TRT, Siemens, MCCS Eltro, Luchaire-STRIM and SAT are also involved.

Management, sales, and responsibility for production: Euromissile, 12 rue de la Redoute, 92260 Fontenay-aux-Roses, France.

4545.111

EMDG PROGRAMME

Stemming from the ATEM project (**3611.111** in 1982-83 and earlier editions) of the late 1970s for the joint development of a new European anti-tank missile, a new programme to embrace that concept and also to widen its scope evolved in 1980 with the formation in Paris of the Euromissile Dynamics Group by Aérospatiale, British Aerospace and MBB. The three companies represent the participating nations, but provision exists for the later inclusion of additional countries if desired.

Memoranda of understanding (MOU) were drawn up between the British, French and German authorities to cover the collaborative development of two new anti-tank missiles to meet the individual requirements of all three states. These envisage the replacement in the 1990s of such weapons as Milan, HOT, Swingfire and TOW, and to do this two new missile systems are considered necessary: a short to medium range missile, and a long range weapon. Aérospatiale is to play the leading role in the development of the former, which will be a lightweight, man-portable weapon, with a range of 2000 metres using laser beam-riding guidance for all-weather day/night operation. The long range missile will be developed in both air and land launched versions. It will be a fire-and-forget weapon employing passive IR homing to permit a high rate of fire and extensive manoeuvre capability for the

launch vehicle in the interests of evasive action after launch. BAe will assume a leading role for the land launched version and MBB will take a similar role in the case of the air launched long range missile. Planned range of the long range weapon is in the region of 4500 metres.

STATUS

An MOU between France, the German Republic and the UK calling on the three to agree their operational requirements for a new anti-tank missile was signed in 1976. Studies were initiated which led to new staff requirements and the formation of EMDG and the programme to develop a family of 'third generation' anti-tank missiles to meet European needs. Project definition is expected to be completed in the mid-1980s and development contracts have been awarded amounting to £25 million to complete the definition phase of both weapons.

ISRAEL

4859.111

MAPATS ANTI-TANK WEAPON

The Systems Division of Israel Military Industries (IMI), faced with a requirement for a new anti-tank missile capable of challenging existing and anticipated new generation armour, has developed a weapon system designated MAPATS, that was revealed in 1984. It was initially described in the TOW entry (**2830.111**) in the 1984-85 edition of *Jane's Weapon Systems*, and the Israeli weapon does in fact share many features of the US-designed TOW missile, which is produced under licence in many parts of the world.

IMI MAPATS laser beam-rider version of TOW anti-tank missile (T. J. Gander)

However, although MAPATS employs similar missile body and control surface arrangements to TOW, it uses an entirely different guidance technique and is more than merely an improved version of TOW. The MAPATS system consists of an infra-red beam-riding missile and a launcher/sight unit. The maximum range is 4500 metres and a hollow-charge armour-piercing warhead capable of penetrating 800 mm of brinel 300 steel is carried. It is launched from a crew-transportable launcher, and the missile's glass-fibre container forms part of the launching system. When fired the missile follows a laser-generated beam which is pointed at the target by the gunner.

The IR beam projector is mounted on the traversing unit of the launcher system and can be steered in azimuth and elevation, thus permitting precise target tracking. Built into the beam projector is a high-power optical sight which is used for target acquisition and tracking. The sight has a crosshair optically aligned with the centre of the beam. In flight the MAPATS missile senses the IR beam via a rear-mounted sensor, and measures its deviation from the beam centre, using this information to correct its trajectory to regain the line-of-sight (LOS). This system is claimed to be immune to jamming and completely automatic. The gunner has only to maintain the sight crosshair on the target until the missile hits.

For protection and storage the missile is packed in an expendable glass-fibre tube, which is loaded into the launcher complete. After firing the empty tube is discarded. The missile is powered by two motors, an ejector and a flight motor. The former burns out and separates from the round within the launch tube. The moment this occurs, the IR detector in the tail and the guidance loop are activated. At a safe distance from the gunner, the flight motor ignites, accelerating the missile to peak velocity. From this point the round coasts until it hits the target. It is stabilised in flight by four wings which flip out and lock into position on leaving the launch tube. Aerodynamic control is by four surfaces that individually respond to the commands of a digital autopilot. There is an on-board gyro for attitude control, and both this and the control surface actuators are cold gas powered.

To maximise the effects of the hollow-charge warhead, it is detonated at the optimum stand-off distance by means of an extending nose that operates immediately after launch. This essentially mechanical method of ensuring stand-off detonation is preferred to electronic proximity fuzes, some of which can be jammed.

The main components of the launcher unit are: the beam, generator, tripod, traversing unit, launch tube and electronics unit including batteries etc. The combined weight is less than 70 kg and the launching system can be installed on a jeep, M113 APC and a variety of armoured vehicles including tanks.

CHARACTERISTICS

Length: 1.45 m
Diameter: 148 mm
Weights: 29 kg (in container); 18.5 kg (out of tube); 14.7 kg (after motor burn-out)
Hollow charge weight: 3.6 kg
Hollow charge diameter: 144.4 mm
Range: 4500 m
Ejection velocity: 70m/s
Peak velocity: 315 m/s
Velocity at 4000 m: 19.5 s
Time to target at 4000 m: 19.5 s
Penetration: 800 mm
Traverse unit
Max tracking rates: 140 mrad/s, azimuth and elevation
Azimuth range: 360°
Elevation range: –20° to +30°
Beam generator/sight
Optical sight magnification: × 13
Optical sight viewing angle: 5.5°
Laser peak pulsed power: Over 20 W
IR beam modulator: Reticle system
IR beam zoom ratio: 1:60

STATUS

Believed to be in early production.

3991.11

PICKET ANTI-TANK MISSILE

Picket is a shoulder-launched anti-tank weapon suitable for use by infantry against armoured fighting vehicles or fortified positions. It is inertially controlled along a line-of-sight to the target. In operation, the operator acquires the target through an optical sight, and within one half-second of pressing the trigger the missile is launched and the operator may then discard the launcher and take cover.

This missile consists of an armour piercing warhead, a guidance section, a single-stage sustainer rocket motor, a control section and an ejection rocket motor. The last named accelerates the missile to the initial ejection velocity and imparts spin to the round within the launcher tube. Three folding fins spring open as the missile emerges from the tube, and simultaneously a spring device separates the ejection motor from the missile which then coasts until it has reached a safe distance from the operator and before the main motor is ignited. The latter provides a constant thrust throughout the entire trajectory.

The guidance and control system includes a gyroscope, an electronics package and a thrust vectoring system consisting of four jet tabs in the motor efflux. The gyro is uncaged about 100 milliseconds after the weapon is fired, and from then on the missile is locked to its inertial heading. The gyro senses and corrects angular velocities imparted to the round at launch, due either to the gunner's movements or to tip-off and crosswinds. The round travels at supersonic speed for virtually all of its flight.

Each round consists of a missile packed in a disposable launcher tube sealed by end caps; clip-on trigger and sight units are carried separately until the Picket is prepared for action.

CHARACTERISTICS

Length: 76 cm
Diameter: 81 mm.
Weight: 4·2 kg

Israel Aircraft Industries Picket anti-tank missile

Launcher weight: 1·8 kg
Range: 500+ m
Guidance: Gyro-stabilised to line-of-sight at launch
Warhead: HE

STATUS

Production.

FOLGORE ANTI-TANK WEAPON

Folgore is the name given to a light, recoilless, anti-tank rocket projector currently under advanced development in Italy by Breda Meccanica Bresciana with the collaboration of Snia Viscosa. It is a two-man system classified by its designers as a short-range system, having a maximum range of 1000 metres.

Folgore can be fired from the shoulder or from a tripod. In the tripod version two men perform the function of aimer and loader and the aimer is aided in his task by a telescopic sight fixed to the launcher which enables him to estimate target range, target speed and elevation angle in a few seconds. In the shoulder version the weapon is provided with a lighter optical device and a bipod, and if necessary, can be carried, loaded and fired by one man. The ammunition, which is the same for both versions, is composed of a rocket and a launching charge; the rocket is fin-stabilised and has a hollow-charge warhead.

In addition to the tripod-mounted and man-portable versions of Folgore, a number of designs for turret installations of this weapon for fitting in various armoured vehicles were revealed in 1982. One such, for the new OTO R3 light armoured vehicle introduced by OTO-Melara also mounts a 7·62 mm machine gun and the sighting system. Other Folgore turret designs exist for use on different APCs, light tanks or other AFVs including: a power-operated turret with two Folgore tubes and a 12·7 mm machine gun; a power-operated turret with a single 7·62 mm machine gun; and a manually-operated turret with one Folgore tube and a single 7·62 or 12·7 mm machine gun.

Folgore anti-tank missile system deployed for action

CHARACTERISTICS

Weapon off tripod
Launcher length: 1·85 m
Launcher calibre: 80 mm
Max range: 1000 m
Minimum range: 50 m
Weapon at shoulder
Data as above except that omission of tripod and electro-optical sighting system gives a light, one-man version, intended for ranges up to 700 m.

Ammunition
Length: 74 cm
Weight: 5·2 kg
Rocket weight: 3 kg
Muzzle velocity: 380 m/s
Max speed: 500 m/s
Max trajectory height: 2·2 m at 500 m range; <3 m at 700 m range

STATUS

Development and field trails complete. Preparation for mass production in progress.

KAM-3D ANTI-TANK MISSILE (TYPE 64)

KAM-3D is a command-controlled wire-guided anti-tank missile system which is standard equipment for the Japan Ground Self-Defence Force (JGSDF) where it is also known as the Type 64 MAT (Missile Anti-Tank).

The KAM-3D missile has an orthodox configuration, with a cylindrical metal body and cruciform metal wings incorporating full-span trailing-edge spoilers for control. Propulsion is by a two-stage Daicel Co solid-propellant rocket motor, the booster stage of which accelerates the missile to its cruising speed in 0·8 s, after which the sustainer stage maintains this speed.

The missile can be fired singly or in multiple units by infantry and is carried by jeeps and helicopters. It is launched at an elevation of 15° and the operator controls it via an optical tracking system, using a flare by day and the sustainer rocket exhaust by night as a visual reference. A gyro-stabilisation system is embodied in the missile. A three-man firing team is required to operate the system. Control is achieved by using a thumb-button control box.

Group of JGSDF jeep-type vehicles are armed with Type 64 anti-tank missiles (left) and later Type 79 Jyu-MAT heavy missile anti-tank (right)

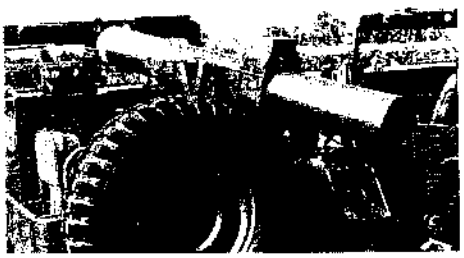
CHARACTERISTICS

Type: Man-portable wire-guided anti-tank missile
Guidance principle: Command to line-of-sight with optical tracking
Guidance method: Wire-guidance control of vibrating spoilers on wing trailing edges
Propulsion: 2-stage solid-propellant rocket motor
Missile length: 100 cm
Missile diameter: Body: 12 cm. Span: 60 cm
Launch weight: 15·7 kg
Cruising speed: 85 m/s
Turning radius: 250 m
Range: 350 - 1800 m

DEVELOPMENT

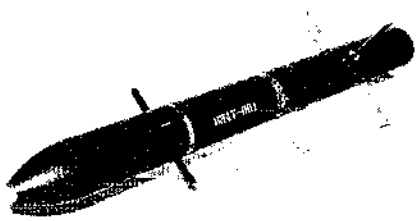
Following a design study carried out in 1956, development of this missile was started in 1957, under a contract awarded by the Technical Research and Development Institute of the Japan Defence Agency. The KAM-3 weapon system was adopted as standard equipment of the JGSDF in 1964 after several hundred test rounds had been fired, and has the official designation, Type 64 ATM. Trials showed that the missile's velocity control system enabled three out of four unskilled operators to hit a target with their first round after completion of a two week training course with the ATM simulator. Skilled operators could score 19 hits in 20 firings.

A field test set (KAM-3TE) and a simulator (KAM-3TP) are made by the main contractor.



STATUS
Operational with the Japanese Self Defence Forces. No details of exports have been given
CONTRACTORS
Manufacturers of the complete system are Kawasaki Heavy Industries Ltd, Aircraft Group, 4-1 Hamamatsu-cho 2-chome Minato-ku, Tokyo. Other manufacturers known to have been associated with the system are:
Warhead - Daikin Kogyo Co.
Rocket motor - Daicel Co; Nippon Oil & Fats Co.
Missile guidance - Nippon Electric Co.
Guidance wire - Fujikura Cable Works.

2263.111
KAM-9 (TYPE 79) BATTLEFIELD MISSILE



This is known also as the Type 79, Jyu-MAT, (Jyu heavy Missile Anti-Tank), and is an extended range SACLOS anti-tank weapon having a higher performance than the KAM-3, which can be used against armoured vehicles on both land and water. The missile is launched from a tubular container, which is used also for transport and storage. A solid-propellant launch motor ejects the missile from the container to a safe distance from the operator; the flight motor then ignites and accelerates the missile to its cruising speed of 200 m/s in a few seconds.

The Type 79 has been designed to meet a requirement for a defensive weapon to engage the landing craft of an amphibious assault force, as well as tank targets. A special warhead was developed to cater for this dual role. It is basically a HEAT round but incorporates an enhanced fragmentation effect, and two types of fuze are employed: for the purely anti-tank role the contact fuze which has a piezo-electric element is used and the other is a variable delay fuze.

The missile is placed in its transport and storage container at the factory, and fired from the container.

Type 79 Heavy-MAT anti-tank weapon system on its Type 73 carrier vehicle

KAM-9 missile

Prior to firing, the container is placed on the launcher which comprises the firing control device, missile checkout, tracking mechanism, and built-in sight unit. The optical sighting device is designed to be operated by one man. During the missile's flight, the operator simply keeps the optical sight trained on the target, and sensors translate the course deviation to electrical signals which are fed into a computer. The computer then feeds course corrections into the missile through the guidance cable.

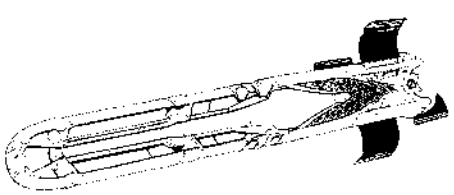
Instead of a flare for IR missile tracking, an xenon lamp is used as the IR source, this being powered by a thermal battery which also provides electrical power for the missile guidance system.

The launching system has two operational modes: direct, and separate firing.

CHARACTERISTICS
Missile
Length: 1565 mm
Diameter: 152 mm
Span: 33 cm
Container: 170 × 20 cm
Weight: 42 kg (in container)
Propulsion: Solid propellant booster and sustainer
Guidance: SACLOS. Optical sighting, IR tracking; wire command link
Warhead: Hollow charge with piezoelectric fuze or SAP HE with contact/electromagnetic fuze
Range: 4000 m (max)
Speed: 200 m/s

A complete Type 79 firing unit consists of two launcher units, a sight unit, control/guidance electronics unit, and a connecting cable reel. Each launcher is normally mounted on a tripod, and one of them also carries the sight. The other launcher may be sited up to 50 metres away from the sight and is remotely operated via connecting cable. The remote facility coupled with the smokeless rocket motors used offers the operating crew good protection from enemy counter fire and enhanced operational flexibility. The complete system weighs 278 kg and requires a crew of five; it is carried on two Type 73 jeep-type small trucks.

STATUS
Operational with the Japanese Ground Self Defence Force. Reports received in 1980 indicated that work started in 1978 on a medium anti-tank missile, KAM-40 (medium-MAT) to follow existing Japanese weapons in this category. The guidance technique will probably be a semi-active laser homing system, and research and trial manufacture of the homing head and laser designator has been carried out with three competitive designs.



In late 1983 it was reported that a prototype batch of eight missiles had been completed, and delivery of a laser designator, launcher and test equipment was expected in March 1984. It was also anticipated that a second batch of 60 rounds with two designators and launchers will be ready by the end of May 1985.

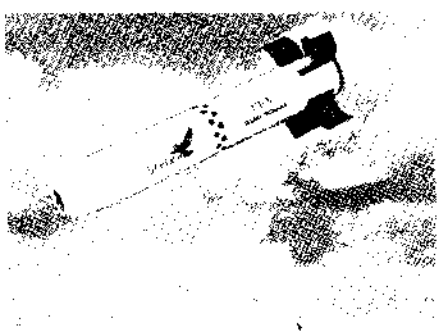
STRIX ANTI-TANK GRENADE



Strix is the name given to a joint FFV-Saab development project aimed at producing an IR homing anti-tank grenade which can be launched from 120 mm calibre mortars. As may be expected from the chosen delivery method, the Strix missile will attack targets from above, thereby engaging a less heavily armoured part of the tank or other AFV. The nearby illustration gives an indication of the configuration of the weapon and shows it to have a set of four wrap-around tail fins for projectile stabilisation, and a set of multiple side-thruster rockets arranged peripherally midway along the body length for manoeuvring in the course of terminal guidance to its target. An IR sensor located in the nose of the projectile will detect targets by their heat signature and provide correction signals which selectively actuate the side-thruster jets to ensure a hit on the target.

Cutaway diagram of Strix anti-tank weapon

The developers estimate that three projectiles fired at a typical armoured formation would disable one or two targets.

CHARACTERISTICS
Calibre: 120 mm
Weight: 20 kg (including sustainer)
Length: 800 mm
Range: 600 m - 8 km
Guidance: IR homing, side-thrusters for manoeuvring
STATUS
Development project.

84 mm RCL CARL-GUSTAV

Two versions of this weapon are described - the 84 mm RCL Carl-Gustav M2 and the more recently developed M2-550.

M2 Weapon

This is a recoilless gun intended primarily for use as an anti-tank weapon but suitable also for other assault roles. It can fire HEAT, HE, smoke, or flare ammunition and has a practical range, with HEAT rounds against moving or stationary targets, of 400 or 500 metres, and with HE rounds of 1000 metres. Smoke can be fired up to 1300 metres and flare shells up to 2300 metres. A rate of about 6 rounds/minute is easily achieved.

The weapon can be carried, loaded and fired by one man but a two-man team is standard - one carrying and firing the gun and the other carrying ammunition and assisting in the loading operation.

The gun is breech loaded and cannot be fired until the venturi has been rotated back into position and locked after the round has been inserted. The round is fired by a percussion-operated side primer, the firing mechanism being contained in a tube on the right-hand side of the barrel. This mechanism is hand-cocked, is operated by a two pressure trigger and has a safety-catch.

Open or telescopic sights can be used: the telescopic sight has a ×2 magnification and a 17° field of view and is fitted with a temperature correction

M3 lightweight Carl-Gustav

device. The weapon is fired from the shoulder, and when fired in the prone position, or over a trench or parapet, a sprung bipod mount provides support just forward of the shoulder pad.

Cartridge cases of ammunition are made of light metal alloy with a plastic blow-out disc at the rear. HE, smoke, and flare shells are spin-stabilised; the HEAT shell is aerodynamically stabilised and fitted with a slipping ring to ensure that the hollow charge performance is not reduced by excessive speed of rotation.

M2-550 Weapon

The 84 mm RCL Carl-Gustaf M2-550, also described as the Anti-Tank System FFV 550, is a later development of the M2 weapon and features a new rocket-assisted HEAT round.

The FFV 556 telescopic sight is used with the new HEAT round. One scale is used when firing the HEAT ammunition and the other scale, in use when the range knob is pulled out, is used when firing HE and smoke ammunition.

The 84 mm FFV 551 HEAT round is stabilised by fins which unfold as the round leaves the barrel and has a rocket motor which increases the shell speed from its muzzle velocity of 260 to 350 m/s maximum. The rocket motor comes into operation when the shell is about 18 metres from the muzzle and burns for 1·5 s. The shell will penetrate 400 mm of armour, and the piezoelectric fuze system enables the weapon to function up to 80° incidence.

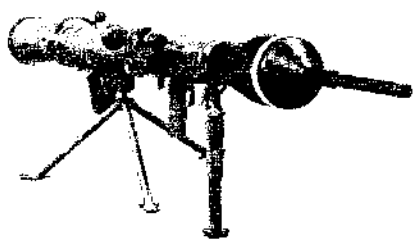
Like the HEAT round for the M2 weapon the FFV 551 round is fitted with a Teflon slipping ring to reduce the spin imparted by the rifling of the Carl-Gustav barrel. Practical engagement range with this ammunition is 700 metres.

The family of ammunition for the earlier M2 version is compatible with the 550 system.

CHARACTERISTICS

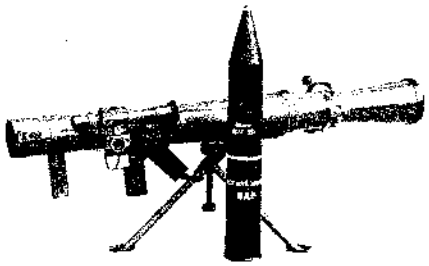
M2 (M2-550)

Calibre: 84 mm (84 mm)
Weapon length: 1130 mm (1130 mm)
Weight of gun and mount: 15 kg (15 kg)
Weight of sight: 1 kg (1·1 kg)
Weight of HEAT round: 2·5 kg (3·2 kg)
Anti-tank range: 400 - 500 m (700 m)
Training equipment: Sub-calibre adapters are available for both weapons to enable them to be used with small-arms ammunition for training purposes



STATUS

In production and in service in several countries.



HEAT FFV 597

The current Carl-Gustav system is designed to defeat present-day combat vehicles, but to enable it to engage the more sophisticated MBTs in the 1990s the system will be upgraded with oversize HEAT round FFV 597. This is rocket assisted and fin stabilised. The warhead is designed to penetrate the front of compound-armour main battle tanks.

The round will be carried in two parts: warhead, and propulsion system (including rocket-motor). Loading will be carried out by inserting the propulsion system as normal Carl-Gustaf ammunition and the warhead from the front. The two parts will be joined inside the barrel by a connecting device.

Carl-Gustav with FFV 597 HEAT round loaded

84 mm RCL Carl-Gustav with HEAT 551 round

CHARACTERISTICS

Calibre (outer dimension): 125 mm
Weight (complete round): 7 kg
Weight (propulsion system): 3 kg
Weight (in flight): 5·8 kg
Length (in weapon): 1·5 m
Length (warhead): 0·75 m
Muzzle velocity: 140 m/s
Maximum velocity: 375 m/s
Range (effective): > 300 m
Armour penetration: 900 mm

M3 Weapon

Carl-Gustav M3 is a lightweight version (8 kg complete) of this weapon. It is built up on a steel liner with the rifling, and covered with carbon-fibre winding. The venturi is made of glass-fibre. All external parts are made of aluminium and plastic. All existing types of Carl-Gustav ammunition can be used with the M3 with unchanged performance.

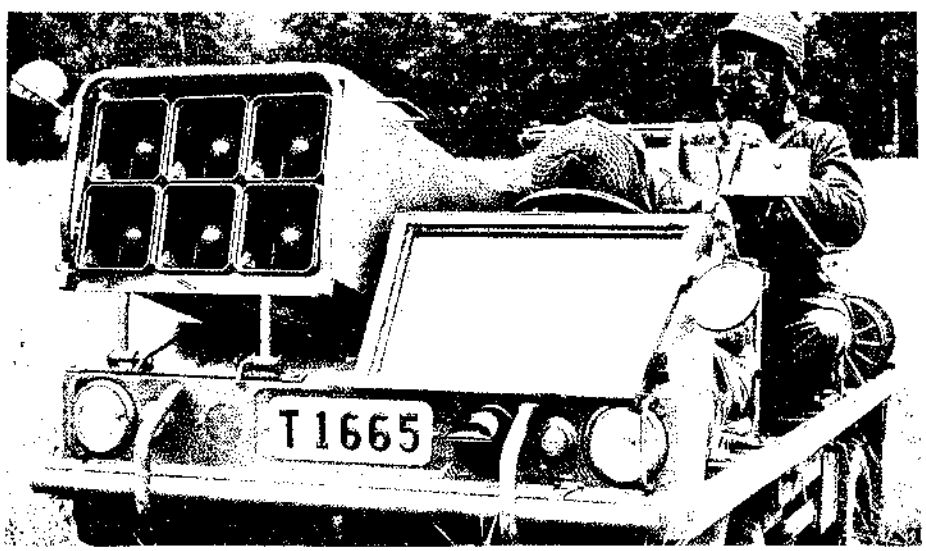
STATUS

Development. Series production began in 1984.

CONTRACTOR

FFV Ordnance Division, S-631 87, Eskilstuna, Sweden.

2353.111



BANTAM ANTI-TANK MISSILE (BS 53)

Bantam is a small wire-guided anti-tank missile, designed for operation by a single infantry soldier, but suitable also for use when mounted in land vehicles or small military aircraft. The missile has a hollow-charge warhead and is said to be able to 'kill' the most modern heavy tank.

The complete system in its simplest configuration comprises the missile in its combined transport and launching container with carrying harness, a control unit, and 20 metres of cable. All this weighs only 20 kg, of which the launching weight of the missile is 7·5 kg.

CHARACTERISTICS

Type: Surface-to-surface anti-tank guided missile with air-to-surface capability
Guidance principle: Wire guidance
Guidance method: By control of vibrating spoilers on trailing edges of wings
Propulsion: 2-stage (booster/sustainer) solid-propellant motor
Warhead: Hollow charge; electrical fuze; weight 1·9 kg; armour penetration better than 500 mm
Missile length: 0·85 m
Missile diameter: Body: 0·11 m. Span: 0·4 m
Weights: Container with missile: 11·5 kg; minimum system with 1 missile: 20 kg
Range: <300 m - 2000 m
Hit probability: 95 - 98% at 800 - 2000 m
Cruising speed: 85 m/s

The six Bantam missiles pointing forwards on the Puch-Haflinger jeep can be fired in two to three seconds after the vehicle has stopped. Six more missiles are carried at the rear of the jeep

STATUS

In service with Swedish and Swiss forces but no longer in production.

CONTRACTOR

AB Bofors, Ordnance division, Box 500, S-691 80 Bofors, Sweden.

4544.111

RBS 56 BILL ANTI-TANK MISSILE

Bofors, under a contract awarded in mid-1979 by the Swedish Defence Materiel Administration (FMV) is developing a light anti-tank missile called 'Bill' for the Swedish Army, whose designation for it is RBS 56. Development was carried out in close co-operation with the Swedish Army.

The RBS 56 is a wire-guided command to line of sight weapon with an effective range capability extending from 150 to 2000 metres, and which is fired from a container/launcher tube that can be either tripod or vehicle mounted. A sight that provides for both day and night operation is carried separately and is attached to the container tube for launching. Setting up for use can be completed in 20 s according to the manufacturer. Propulsion is by a solid-propellant rocket motor which exhausts through nozzles disposed around the circumference of the missile body to the rear of the sustainer motor which is housed in the nose section. Cruciform wings and control surfaces flip out after launch and these are located in the tail section of the missile, where there is also a tracking signal transmitter.

A shaped charge HE warhead is carried which is normally detonated by a delayed proximity fuze. An unusual feature of the warhead is that it is angled to direct its energy at 30° downward from the missile's longitudinal datum. This, and a missile trajectory which is automatically maintained at a height of approximately one metre above the aimer's line of sight to the target, are claimed to yield a higher kill probability. The chances of striking the less heavily armoured upper surfaces of a tank are increased, and the angled warhead means that it is less likely to strike a sloping surface at a shallow, glancing angle, thereby enhancing the penetration characteristics. The angled attack also ensures that when sloping surfaces are encountered, the thickness of armour to be penetrated is effectively lessened.

CHARACTERISTICS
Type: RBS 56. Top attack, wire-guided command to line-of-sight
Length: 900 mm
Diameter: 150 mm
Max span: 410 mm
Weights: 16 kg (missile in container); 27 kg (firing unit); 11 kg (sight and stand)
Warhead: HE shaped charge
Combat range: 150 – 2000 m (stationary targets); 300 – 2000 m (moving targets, 10 m/s crossing speed)
Time of flight: 6 s (to 1200 m); 10 s (to 2000 m)
Setting up time: 20 s
Reloading time: 7 s
STATUS
Initial test firing completed. Planned for entry into service with the Swedish Army in 1986-87. A Kr 47·5 million Swedish Army contract was disclosed in May 1985.
CONTRACTOR
AB Bofors, Ordnance Division, Box 500, S-691 80 Bofors, Sweden.

RBS 56 Bill anti-tank missile demonstrates its 'top attack' capability

TAIWAN

4438.111
KUN WU ANTI-TANK MISSILE

Kun Wu is the name given to a wire guided anti-tank missile produced by the Chung Shan Institute of Science and Technology. It was first seen publicly in the 20th Republic of China National Day Parade in Taiwan during October 1981.

The Kun Wu is evidently based upon the Soviet designed Sagger AT-3 (**2950.111**). Reports from Taiwan state that the Chung Shan Institute, which was responsible for Kun Wu development, is known to have studied captured examples of the Sagger said to have been acquired in Viet-Nam.

The photographs support such a contention although it is not known if the optical guidance and control system used with the Sagger is retained for the Chinese version of the system or if a different method is used for the direction of the four rounds that are usually deployed on each vehicle. It can be expected that Kun Wu performance will at least equal that of Sagger, including a maximum range of up to 3000 metres with a launch weight of over 11 kg. Other parameters are likely to be similar to those of the Soviet missile, which is described on a later page. Sighting arrangements are not known and it is quite possible that the missiles are fired remotely by the operator some distance from the vehicle. Launch vehicles so far noted all have a prominent radio antenna fixed to one corner of the body. Whether or not this has some special purpose is not known.

Kun Wu anti-tank missiles mounted on Jeep. Four rounds are carried on each vehicle in this configuration (L. J. Lamb)

STATUS
Production and in service.

2985.111
AT-2 (SWATTER) ANTI-TANK MISSILE

Swatter is the NATO code-name for the anti-tank missile which is known as the AT-2 in the US code and is carried on the BRDM armoured amphibious vehicle.

Of similar size to the AT-1, but heavier (29·4 kg), it is believed to be a more advanced missile – probably in the class of the French SS 11 – and certainly has a different configuraton. Control is by elevons mounted on the trailing edges of the rear-mounted cruciform wings.

The standard mount on the BRDM vehicle carries four missiles mounted on guides, with four reload rounds in the BRDM-2 vehicle installation. Radio command to line-of-sight guidance is employed, the command link having three frequencies as protection against electronic countermeasures. There is also the possibility of separate terminal homing (probably IR) being provided, and this with radio guidance suits the Swatter for airborne roles such as part of the armament of the Mi-24 Hind attack helicopter.

As deployed on the ground Swatter does not arm until it has flown 500 metres from the launch site. The Swatter launcher on the BRDM has a lateral traverse of 45°, as originally deployed. A later version, sometimes called Swatter 2, has a different launcher on the BRDM-2 which may well be capable of training over a much larger arc.

Close-up of AT-2 Swatter anti-tank missile four-round launcher on BRDM reconnaissance vehicle

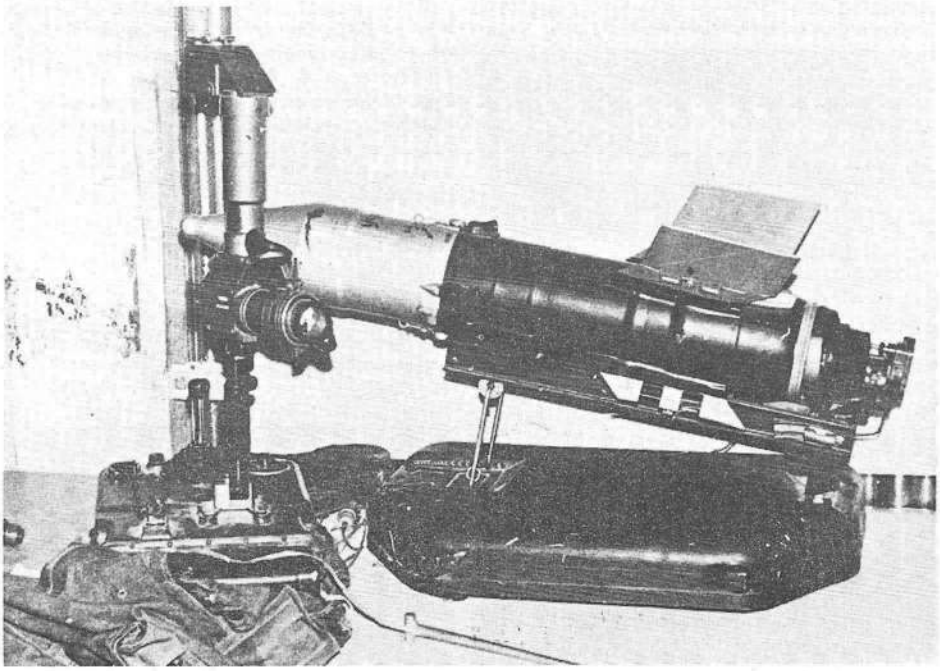
Swatter 2 is thought to be slightly larger than the original Swatter, with an estimated length of 1·56 metres and 16 cm diameter.

CHARACTERISTICS
Type: Anti-tank, surface-to-surface and air-to-surface
Configuration: Cylindrical body with rounded nose. Rear set cruciform wings. Two small foreplanes. Ramp launched
Length: 1·16 m
Diameter: 13·2 cm
Span (max): 66 cm
Weight: 29·4 kg
Propulsion: Solid
Range: 500 – 3500 m
Guidance: Radio command to line-of-sight, possible with terminal homing
Warhead: HEAP
Penetration: 500 mm
Average velocity: 150 m/s
STATUS
In service only with Warsaw Pact forces and those of Egypt and Syria.

2950.111
AT-3 (SAGGER) ANTI-TANK MISSILE

Sagger is the NATO code-name for the small wire-guided anti-tank missile, known by the US code AT-3. More compact than either the AT-1 (Snapper) or AT-2 (Swatter) missiles (**2983.111** in 1984-85 and earlier editions and **2985.111**), but apparently carrying an equally powerful warhead, it is deployed in various vehicle mountings including a 2 × 3 mounting on the BRDM-1 amphibious reconnaissance car and a single mount on the BMP-1 armoured personnel carrier. A more recent installation is on the BMD light tank and it can also be deployed on the Hind helicopter. Other vehicle mountings are on the BRDM-2/BTR40PB and the Czechoslovak SKOT OT-64 Model 5 armoured personnel carrier. There is also a single manpack mounting that enables it to be fired from the ground.

In the BRDM vehicle the two clusters of three missiles are mounted retractably and are shielded when in the firing position by the cover plate that protects them when in the retracted position.



The manpack version is also known as the 'suitcase' Sagger, because the missile is carried in a glass fibre case, with the warhead separated from the rest of the missile. The lid of the case has a rail that enables it to be used as a launcher for the weapon after assembly of the missile. A control unit which incorporates a periscopic sight, a control stick, switches for missile selection, and batteries is carried in a separate container. Sagger is fired from a remote position which enables the operator to be located up to 15 metres from the missile launcher. The periscopic sight has a magnification of ×10. A three-man firing team is normally employed, with a total of four missiles per team. Either one or two men may serve as Sagger controllers, each with a sight and control unit and two missiles, while the third man deploys ahead armed with an RPG-7 for closer range protection if need be. Used in this way the effective engagement range of Sagger is considered to be between 1000 and 3000 metres, and such a team could be deployed with four missiles checked and ready to fire in about 12 to 15 minutes.

As deployed with the BRDM vehicle, the Sagger gunner can operate either within the vehicle itself or move to a position outside up to 80 metres distant. Six missiles can be rapidly fired by use of the selector switch on the control/sight unit which has a ×8 magnification. The BRDM can carry a total of 14 missiles. The larger, tracked, BMP vehicle, on which the Sagger launch rail is carried on the barrel of the 73 mm smooth bore gun, has a total capacity of four or five Saggers.

Client states of the Soviet Union on occasion evolve their own methods of mounting and deploying weapons of Soviet origin, that differ from the system(s) used by the USSR. A recent example of this is the 4×4 vehicle mounted version of the Sagger anti-tank missile introduced by Yugoslavia. The armoured vehicle is known as the BOV-1 and it is surmounted by a rotating turret on which are carried six Saggers housed in two rectangular container/launchers with three rounds in each. Sufficient rounds for at least one manual reloading (ie six missiles) are reported to be carried inside the vehicle hull. Yugoslavian forces also employ Saggers in an airborne role, some Gazelle helicopters being fitted with launch facilities for four missiles.

CHARACTERISTICS
Type: Surface-to-surface guided anti-tank missile
Guidance: Wire-guided command to line-of-sight, optical tracking
Propulsion: Solid-propellant motor, 2-stage
Warhead: Hollow charge
Missile length: 86 cm
Missile diameter: 11·9 cm
Launch weight: 11·3 kg
Range: 500-3000 m
Penetration: 400 mm
Average velocity: 120 m/s
STATUS
Extensively deployed by USSR and Warsaw Pact forces and by other nations, particularly in the Middle East and elsewhere. The Chinese-built version of the Sagger is believed to be essentially identical to the original Soviet model.

In the early 1980s Taiwan introduced an indigenous anti-tank missile called the Kun Wu which bears some obvious resemblances to Sagger and it has been reported from Taiwan sources that development of Kun Wu (**4438.111**) was based on examples of Sagger, although the warhead could be different.

Complete AT-3 Sagger man-portable anti-tank weapon with sight on left and missile on carrying case

---

3638.111
AT-4 (SPIGOT) ANTI-TANK MISSILE

The designation AT-4, Spigot, was at first provisionally assigned to a man-portable, tripod-mounted version of the AT-5, Spandrel, anti-tank missile (**3608.111**). As employed by infantry, a crew of three men normally constitutes a Spigot section, between them carrying a total of four rounds plus the sight and mount.

Later information however (including an East German photograph showing a BRDM launcher for three AT-4s and two AT-5s) while confirming the similarities between these two missile types makes obvious the larger dimensions of the AT-5 Spandrel. It would therefore appear that while the basic engineering and guidance techniques may be the same for both types, the larger size of the Spandrel is mostly due to the larger propulsion motor needed for the increased range.

The sight appears to use separate optical paths which are presumed to be employed for tracking of the target (under control of the gunner) and the Spigot missile, corrections to the latter's trajectory being automatic subsequently in response to the gunner following the target.

Spigot is expected to become a replacement for the

Preparing AT-4 anti-tank weapon for firing

AT-4 Spigot anti-tank missile deployed

AT-3, Sagger, in the course of the next few years, although the older missile is unlikely to disappear from the scene entirely for a long time.

CHARACTERISTICS

Type: Man-portable surface-to-surface wire-guided anti-tank missile

Guidance: Semi-automatic command to line of sight; optical tracking

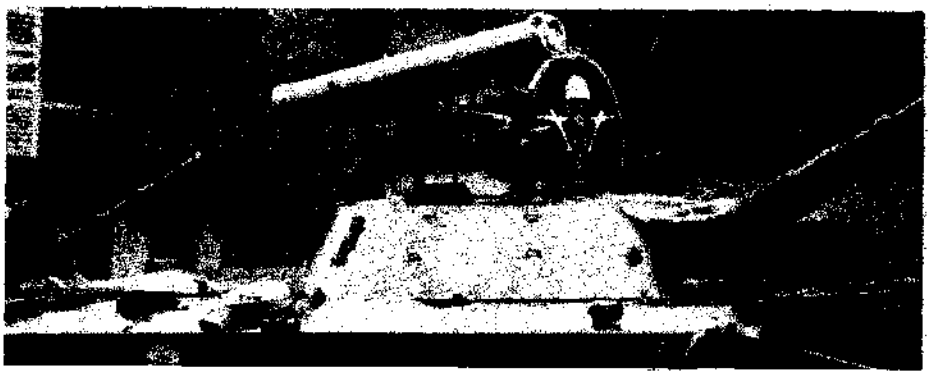
Propulsion: Solid

Warhead: HEAT

Launcher length: 1·2 m

Launcher diameter: 13·5 cm

Launch weight: 10-12 kg (estimated)



Range: 2000 m (approx)

Speed: 150-250 m/s (approx)

Penetration: 500 mm

STATUS

In service and observed with Soviet, Polish, East German and Czechoslovak units.

AT-4 Spigot infantry mounting modified for use on top of BMD-1 airborne fighting vehicle. Spigot anti-tank missile replaces AT-3 Sagger sometimes used in this fashion. This Spigot application first seen on parade in Moscow, October 1983

3608.111

AT-5 (SPANDREL) ANTI-TANK MISSILE

AT-5, Spandrel, is the designation of a recent anti-tank weapon deployed on Soviet BRDM-2 AFVs. So far, only the launchers on these vehicles have been seen by Western observers. As can be seen from the adjacent illustration, five tubular launchers mounted on a presumably trainable turret are carried on each vehicle. These resemble those of the HOT and Milan anti-tank missiles (**2212.111** and **2215.111**), and while no official dimensions are available, the AT-5 is probably nearer to the latter in size.

The BRDM-2 has a hatch in the roof immediately behind the AT-5 which is probably for reloading purposes, and, according to official US estimates, the total vehicle load is 10 rounds.

A rotatable optical sighting/tracking head is incorporated in the BRDM-2, mounted in the vehicle roof above the right-hand front seat. The shape of the launch tubes has led some observers to conjecture that some form of gas generator is used to eject the missile before the propulsion motor is ignited, and, also giving cause for speculation, these tubes have always appeared to be unpainted metal of bright or light colour. The reason for this has been conjectured as being related to a need to minimise the internal temperature of the tube, possibly to protect the propellant. An East German photograph showed a BRDM-2 vehicle turret on which were mounted a mixed armament of three AT-4 Spigot anti-tank missiles flanked on each side by an AT-5 Spandrel missile. From this photograph is was clear that the Spandrel has a larger diameter launch tube.

As the missile itself has not been displayed in public, all published estimates of performance must be regarded as speculative and the following table of characteristics are only provisional.

CHARACTERISTICS

Type: Surface-to-surface guided anti-tank missile

Guidance: Command to line-of-sight, optical tracking

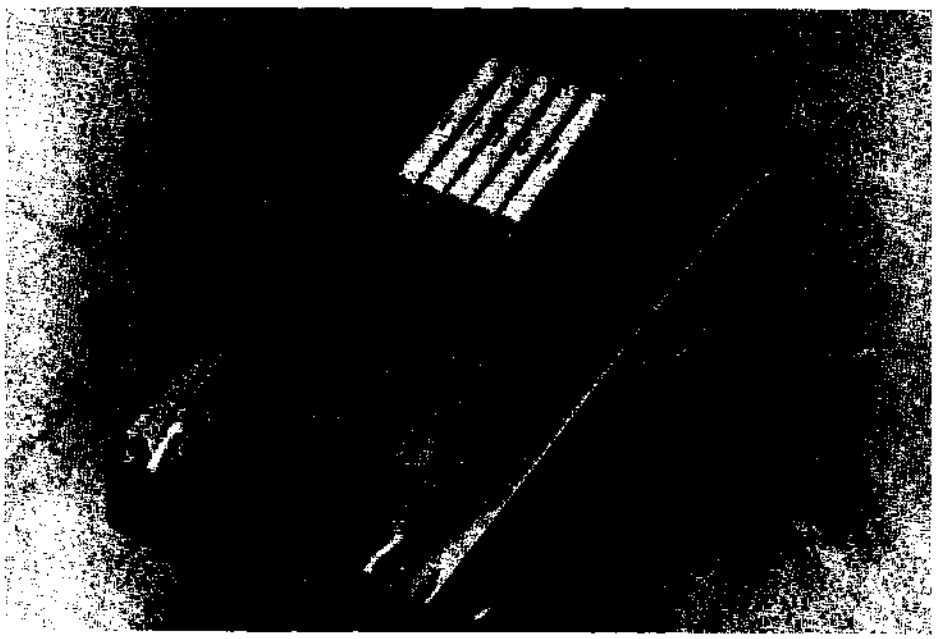
Propulsion: Solid

Warhead: HEAT

Launcher length: 1·4 m

Launcher diameter: 18 cm

Launch weight: 12-18 kg (estimated)



Range: Approx 4000 m (estimated)

Speed: Approx 150-250 m/s

Penetration: 500 mm

STATUS

3639.111

AT-6 (SPIRAL) ANTI-TANK MISSILE

AT-6, Spiral, is the designation of a new anti-tank missile about which, at this stage, little is known. It is reported to have been deployed on Soviet Mi-24 Hind D attack helicopters, and it is possible that this is the missile to which some sources have applied the designation AS-8. Resolution of this confusion must await the arrival of more evidence.

The AT-6 is thought to employ a semi-active homing system which could be either IR based or of laser target-marking technique which has been suggested by some observers.

STATUS

Early operational deployment.

SWINGFIRE ANTI-TANK MISSILE

Swingfire is a long-range command-controlled anti-tank weapon system capable of engaging and destroying the heaviest armour. Armoured and soft-skinned vehicle variants are available. The missile is wire-commanded, signals being generated by an operator's joystick control, and the commands are interpreted by the missile as demands for a change of heading; thrust vector control is employed.

An important feature of the system is its indirect fire capability with the launcher concealed behind cover in such a way that there is no direct optical sight-line from launcher to target. The operator can be stationed a considerable distance (up to 100 metres) from the launcher by means of a separation cable between sight and launcher, and the missile will be gathered into his field of view by the automatic programming of the initial flight of the missile.

The system can be installed in almost any kind of military vehicle and installations have been devised for a wide range of tanks, armoured personnel carriers, armoured cars, and scout cars. In some instances provision can be made for reloading within the vehicle in which case a rate of fire can be obtained that is comparable with that of a gun system. Vehicle launcher installations do not require traversing or elevating gear, and the missiles are fired from launcher boxes stowed in specially prepared bins or attached externally to the vehicle at the correct launch attitude. Vehicle tilt compensation is provided by the tilt unit. In all cases emphasis has been laid on protecting the equipment and the crew so that the system has a high degree of survivability on the battlefield.

In the case of the armoured vehicle variant, two basic methods of operation are possible. In one, the missile is controlled from the launching vehicle, the operator using a periscopic sight that forms part of the main vehicle installation to engage targets in his field of view over a 90° arc – that is, 45° on either side of the direction in which the missile launcher is pointing. In the other method the operator uses a portable separation sight and stations himself in a suitable vantage point anywhere within 100 metres radius of the launcher. This latter method is used with a pallet-mounted system. A four-missile launcher pallet is mounted on a Land Rover type vehicle. The

missiles can be fired with the launcher either on the vehicle or dismounted and deployed on the ground.

The system's missile control equipment can be installed either in a vehicle (AFV variant) or on the launcher pallet.

CHARACTERISTICS

Type: Mobile anti-tank guided missile system. Panclimatic. Missiles prepacked in sealed launcher boxes

Guidance principle: Wire-commanded. Heading demand signals referenced to autopilot. Optical sighting with automatic initial gathering. Manual steering (direct or separated). ×1 or ×10 magnification sights

Guidance method: Thrust deflection of main motor efflux by jetavator

Propulsion: 2-stage boost and sustainer solid-propellant motor

Warhead: Hollow charge powerful enough to defeat all known combinations of armour

Range: Minimum – from less than 150 m at direct fire to 300 m with max separation. Max – 4000 m

Fire arcs: Azimuth ±45° without launcher traverse. Elevation +20°, –10° relative to mounting plane

Special features: Ease of concealment. Immunity to ECM

DEVELOPMENT

British Aerospace Dynamics Group based their design, development, and production programmes on experimental work originally done by Fairey Engineering Ltd. The first design study was made in 1958 and the first public announcement concerning the system was made in 1962. The system went into service with the British Army in 1969.

A new combined sight has been developed which will permit current variants of Swingfire to be used operationally at night and in poor visibility.

Current Swingfire applications are as follows:

(1) **FV 438** – the British Army guided weapon vehicle for Armoured Regiments based on the FV 432 armoured personnel carrier

(2) **Striker** – the guided weapon vehicle in the new CVR(T) series. Striker is also in service with the Belgian Army

(3) **Swingfire Pallet** – a crew-portable version which can be transported on and fired from any vehicle or trailer from a long wheel base Land Rover upwards, or fired from the ground. It can be carried over short distances (of the order of 400 metres) and deployed by its three-man crew. For this purpose it is broken down into two or three-man loads. When in action it is always used in the 'separated fire' mode and covers an arc of fire of 90° without traversing the launcher. It can be air-transported, parachuted into action, and air-dropped as a complete system. Swingfire Pallet is fully established in service with the Egyptian Army and is in production in Egypt

(4) **Micro-miniaturised (MM) Swingfire** – Development has been completed on an MM standard of programmer and control equipment to replace the existing black boxes, ie the programmer, selector unit etc. The new standard of equipment is compatible with the existing sighting systems including the combined sight. MM electronics will save significant space and weight and will enable Swingfire to be fitted to an ever greater range of vehicles. There is also a lightweight alternative to the Combined Sight developed by Thorn EMI and BAe, which will fit on the separation sight base in place of the present telescope.

CONTRACTOR

British Aerospace Dynamics Group, Six Hills Way, Stevenage, Hertfordshire SG1 2DA, England.

Swingfire Combined Sight enables this long-range anti-tank missile to be used at night or in low visibility. This is accomplished by combining thermal imaging with the optical sight using passive IR sensing to detect the target

In its pallet configuration Swingfire anti-tank missiles can be carried and launched from soft-skinned vehicles such as the Egyptian CJ6 jeep

3986.111

LAW 80 LIGHT ANTI-ARMOUR WEAPON

LAW 80 is a one-shot low cost disposable short range anti-tank weapon developed to replace existing weapons which are either light and ineffective or of a size which demands crew operation to achieve lethality. It provides a capability for the individual soldier to engage current and future MBTs over short ranges and achieve a high probability of hitting the target. The unique performance of the HEAT warhead (armour penetration well in excess of 600 mm) ensures that MBTs both current and future can be defeated from any aspect, including frontal attack.

LAW 80 anti-tank weapon sectioned

Much attention has been placed on the need for the firer to obtain a good hit on the target, since the firing of almost all types of LAW projectile is likely to reveal the firing position. It is dangerous and time consuming to engage with a second weapon. To achieve this accuracy, a built in 9 mm spotting rifle is used. This spotting rifle contains five pre-loaded rounds, any number of which may be fired, without revealing the position of the firer. The ammunition is ballistically matched to the main projectile marked by a tracer and by a flash head to record a hit on a hard target. At any time the operator can select and fire the main projectile.

Shock absorbent end caps protect the weapon for carriage and storage. The sight has its own sliding protective cover. The end caps provide sealing for the tubes to protect the projectile against the effects of water immersion, even though the projectile itself is sealed. The end caps also support the projectile against the effects of mishandling such as end drops. After removal of the end caps, the tube containing the HEAT projectile is extended rearwards from the outer tube. The launch tube is automatically locked into position. This moves the centre of gravity of the weapon from the carrying handle to the shoulder rest to provide an ideal balance suitable for any firing position.

The sight is separately bonded to the front tube and a forward sliding cover allows the sighting prism to erect. The sight is of unit magnification with the graticule projected through the sighting prism into the firer's line of sight, like a head up display. The sight can be used with one or both eyes open and for low light use the graticule can be illuminated with a tritium light source selected by the firer, making the weapon effective down to starlight levels of illumination.

LAW 80 anti-tank weapon ready to fire

The projectile is initiated with a totally non-electric (and therefore totally EMC proof) system comprising a percussion cap in the launcher connected by a flash tube to the rocket igniter. The rapid burn of the rocket motor ensures that the efflux is contained and directed rearwards by the launch and blast tubes, leaving the projectile to coast from the muzzle to the target. No debris of afterburn is projected at the firer,

the recoil is not discernible, and the noise level at the firer's ear is significantly less than 180 dB.

The forward part of the projectile consists of the HEAT warhead and its fuzing unit, and a double ogive nose switch which also provides the optimum stand-off distance. The fuzing unit generates electrical energy to fire the warhead by means of piezo crystals and contains various safety devices to ensure that the warhead does not arm until safe separation from the firer is achieved. At the rear of the projectile the composite aluminium and filament wound motor case has an extruded vane propellant. Four wrap-around fins are mounted on the rear of the motor. These are spring loaded to erect at muzzle exit to provide stability and to spin the projectile as it coasts to the target.

CHARACTERISTICS

Launcher length: 1·5 m(ready to fire); 1 m (on move)
Shoulder weight: 8·8 kg
Projectile weight: 4 kg (in launcher)
Projectile diameter: 94 mm
Armour penetration: >600 mm
Dispersion: 1 mil approx
Maximum effective range: 500 m
Rear danger area:< 20 m approx
Warhead arms at 10 to 20 m
Protected against NBC effects
Inert to RF hazards in battlefield conditions

DEVELOPMENT

It has been developed principally by the prime contractor, Hunting Engineering Ltd, and by the UK Royal Ordnance Factories on behalf of the UK Ministry of Defence who intend to make large production purchases. It is now available for approved export from Hunting Engineering Limited.

4757.111
LAWMINE ANTI-TANK WEAPON

In a collaborative venture, the Bracknell Division of British Aerospace and Hunting Engineering are developing a new unattended anti-tank weapon called Lawmine, which is designed to engage targets automatically at ranges from under 10 metres to 100 metres or more. This weapon combines the LAW 80 anti-tank projectile (**3986.111**) with an advanced automatic target detection system that is mounted on the LAW 80 launch tube.

Any heavy tracked or wheeled AFVs crossing the line of fire are automatically sensed and the round is fired to hit the target at a point optimised to cause maximum damage. The system is unaffected by adverse weather and operates by day or night. The mine requires a very narrow field of view which enables it to be sited within buildings or similar urban surroundings.

The Lawmine system was defined in response to a UK MoD requirement and is designed to be deployed in conditions where for logistic reasons, or because of time constraints, tactics or terrain, use of conventional anti-tank mines is precluded.

4756.111
MERLIN ANTI-TANK MORTAR BOMB

Merlin is an 81 mm mortar bomb which, after firing, automatically selects its target and homes on to it. This system provides an effective fire and forget capability for infantry confronted by tanks and armoured personnel carriers. The bomb is compatible with many existing types of 81 mm mortars. Therefore the introduction of Merlin into service requires no changes to the mortar or unit organisation. Additionally no test equipment or spares are required. The bomb's terminal guidance, steep angle of attack and hollow charge warhead ensure top armour penetration. Merlin's attack footprint allows engagement over a ground area of 300 by 300 metres against moving targets. Cost per kill figures are low.

The seeker in the nose of the bomb is an active millimetric radar and guidance is provided by four fins behind the seeker which are deployed in the latter stages of the bomb's trajectory.

DEVELOPMENT

British Aerospace funded development for the Merlin system from September 1981, leading to official interest culminating in the GST for MORAT of April 1983. Agreement has been reached on a contract shared equally between BAe and the UK MoD and covering project definition and the pre-development phase. The British Government has placed a contract worth £11 million for this joint work.

STATUS

The preparatory work by BAe has covered feasibility of the project and the first stage of the project definition by early 1984. Development continuing.

Test firing of Merlin 81 mm terminally-guided anti-armour bomb

2475.111
VIGILANT ANTI-TANK MISSILE

Vigilant is a man-portable wire-guided anti-tank missile system. In its simplest configuration the system comprises a launcher box containing one missile, a sight controller, a pocket battery, and a length of interconnecting cable. The launcher box is set down on the ground with the missile inserted, pointing in the direction from which a threat is anticipated, and the operator, who carries the sight controller and its associated battery, takes up a suitably unobtrusive position where he has a good field of view. This position may be up to 63 metres from the launcher box. Thus positioned the operator can engage targets over arcs of fire of +10° in elevation and +35° in azimuth, and at ranges of from 200 to 1375 m.

CHARACTERISTICS

Type: 1-man portable anti-tank missile system. Pan-climatic
Guidance principle: Wire-guided. Heading demand signals referenced to missile autopilot. Optical sighting. Manual or semi-automatic control
Guidance method: Servo-controlled surfaces in pairs
Propulsion: 2-stage solid-propellant motor
Warhead: Hollow-charge. Weight in excess of 5 kg with fuze
Range: 200-1375 m
Special features: Ease of concealment. Immunity to ECM

STATUS

Although now regarded as obsolescent, Vigilant remains in limited use. The system has been widely sold and went into service with the British Army and the Defence Forces of Finland and Kuwait in 1963, of Saudi Arabia in 1964, and of Libya in 1968 and to the Abu Dhabi Defence Forces in 1971. No longer produced.

UNITED STATES OF AMERICA

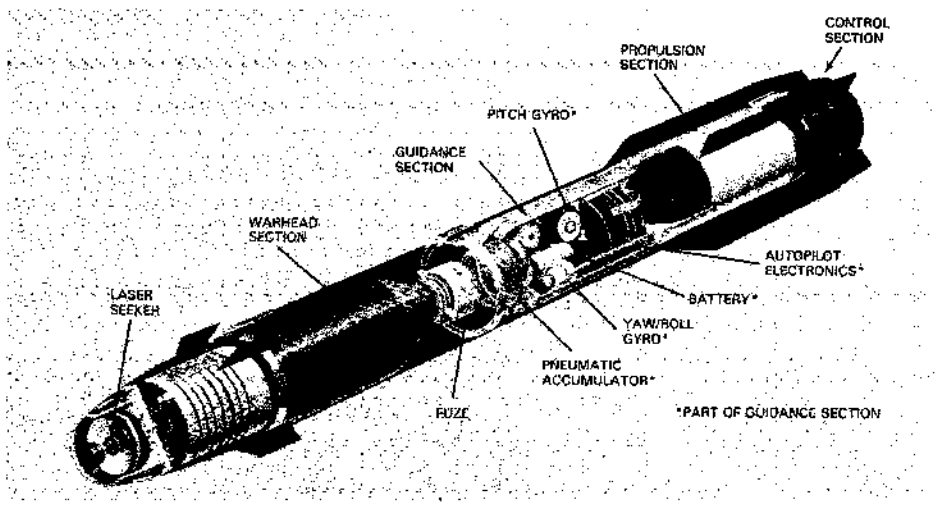
4877.111
HELLFIRE MODULAR MISSILE

The Hellfire modular anti-armour weapon, originally developed for use from ground attack helicopters in the anti-tank role **(1391.311)**, has been fired in the ground-launched mode from a ground vehicle during US Army tests. Rockwell International is under contract to the Swedish Government to adapt the weapon to a new shore defence application **(4878.121)**.

The ground vehicle used in the tests carried out by the US Army's 9th Infantry, High Technology Light Division in late 1982 was a one-ton pickup truck on which twin Hellfire launcher rails were pedestal mounted, together with the fire control equipment. Modifications to the vehicle were minimal and consisted of installing the launcher pedestal and its azimuth and elevation controls, missile storage racks for six missiles, and a special firing panel.

As initially operated (in the air-launched mode) Hellfire uses a laser seeker to home onto reflected energy from either an airborne or a ground laser target designator, but combined IR/RF and imaging IR seekers are being developed for the system and this will give the missile a wide range of delivery modes, including engagement from defilade.

CHARACTERISTICS



US Army designation: AGM-114A
Length: 1625 mm (laser); 1727 mm (IR/RF); 1778 mm (IRIS)
Diameter: 178 mm
Fin Span: 326 mm
Weight: 45.7 kg (laser); 47.8 kg (IR/RF and IRIS)
Range: 7 000 m
Warhead: Tandem twin shaped charges

2573.111
DRAGON ANTI-TANK/ASSAULT WEAPON (FGM-77A/FTM-77A)

Formerly known as MAW (medium anti-tank assault weapon system), Dragon was developed for the US Army and Marine Corps. It employs a command to line-of-sight guidance system and consists of three main items: a tracker, a recoilless launcher, and a missile. The tracker includes a telescope for the gunner to sight the target, a sensor device, and an electronics package. The tracker is reusable and is attached to the launcher; the missile is never seen by the gunner and after firing the launcher is discarded.

The Kollsman-produced Type SU-36/P IR tracker **(3089.183** in 1979-80 and earlier editions) is the guidance element of the system, and consists of a six-power optical sight aligned with an IR sensor, an electronics package, the trigger, and safety catch. The IR sensor acquires a flare in the tail of the missile as it leaves the launcher. The relative angular positions of the missile and the line of sight to the target are continuously compared with the sight electronics and used to derive correction signals which are transmitted to the missile via the guidance wires.

The missile is ejected from the tube by a gas generator using a recoilless technique. When it emerges folding fins flip open and the missile starts to roll. Thereafter propulsion and control forces are provided by the 60 small sustainers which fire in pairs on demand from the tracker. In operation, the gunner sights the target through the telescopic sight then launches the missile. While he holds his sight on the target, the tracker senses the missile position relative to the gunner's line of sight and sends command signals over wire to the missile.

As commands are sent continually to the missile, the side thrusters apply corrective control forces. The thrusters are fired at appropriate roll angles so that the missile is automatically guided throughout its flight.

Dragon deployed and ready to fire

CHARACTERISTICS

Designation: M47 (FGM-77A/FTM-77A)
Type: Anti-tank guided missile
Guidance: Wire-guided, command to line-of-sight
Propulsion: Recoilless launched, solid-propellant rocket motor
Warhead: Shaped charge
Launch weight: 13·8 kg (ready to fire)
Range: 1 km

STATUS

Dragon is deployed in US Army units but production for this service is now complete. A number of other countries are stated to have had procurement of this system under consideration. American users of the system also include the US Marine Corps. Some of the US Dragon inventory was suffering from a short shelf-life of the rocket thrusters, according to a recent Army statement and it has been stated that rocket thrusters are being upgraded.

CONTRACTORS

McDonnell Douglas Astronautics Company, Titusville, Florida, USA - developer, initial production, engineering support, and night tracker.

Kollsman Instrument Company, Syosset, New York, USA - tracker production.

Raytheon Company, Bristol, Tennessee, USA - round production.

4551.111
GUIDED ANTI-ARMOUR MORTAR PROJECTILE (GAMP)

The US Army has a requirement for a guided projectile to be fired from existing M30 4·2-inch/107 mm mortars deployed by the new light divisions and the Rapid Deployment Force (RDF) and capable of use against armoured targets. The original expected in-service date was 1986-87, but this was subsequently deferred and the latest figure mentioned was 1989.

GAMP (GD)

The guided anti-armour mortar projectile (GAMP) submission by General Dynamics relies to an appreciable extent on experience gained with the company's Assault Breaker terminal guided sub-munition (TGSM) programme, during the course of which tests demonstrated techniques applicable to the GAMP munition.

GAMP is fired towards the target area where it autonomously searches for and acquires targets while rejecting natural and man-made background noise. This is accomplished using a two-colour infra-red wide-search-area seeker in the nose of the projectile. After target acquisition, four flip-out fins in the tail section control flight to result in impact with the top of the tank.

The projectile is loaded and fired in the normal manner from a standard M30 4·2 inch mortar, and after launch the tail guidance fins and cruciform fabric wings deploy to stabilise flight and steer to the target.

CHARACTERISTICS

Airframe length: 737 mm
Overall length: 846 mm
Diameter: 107 mm
Weight: 13.1 kg

Raytheon GAMP

The Raytheon Company has also produced a solution to the GAMP requirement. The projectile is approximately 750 mm long and has folding wings set about two thirds of the way back along the body. Set in the nose behind an ejectable cover is a two-colour IR homing sensor derived from that used on the Sidewinder air-to-air missile (**3068.331** in 1983-84 and earlier editions). Behind this is a Garret fluidic jet reaction control system, the gas generation system and the digital electronics package. Much of the rear third of the projectile body is occupied by the HEAT warhead. The nose-mounted seeker is understood to have a 500 metre elliptical footprint with a slant detection range of between 1000 and 2000 metres. It is designed to be effective within a 400 metre weather overcast ceiling. Range of the GAMP is expected to be between 6000-8000 metres and a top attack profile will be used.

STATUS

Development.

2830.111
TOW ANTI-TANK MISSILE (BGM-71)

TOW is an acronym for tube-launched, optically-tracked, wire-guided, and describes a heavy assault ground-to-ground (or air-to-ground) anti-tank guided weapon system.

The TOW launcher system, for infantry use, is made up of five elements, none of which weighs more than 24 kg, although the complete launcher weighs 78 kg when assembled and ready to fire. Two of these elements are a tripod and a traversing unit, mounted upon the tripod, to which the tripod launch tube and optical sight are attached. The gunner's optical sight is of high magnification and equipped with aiming cross-hairs which when combined with the smooth, stable motion of the traversing unit permit very accurate tracking of moving targets after very little operator training. The fifth individual element is the electronic guidance computer which sends steering commands automatically to the missile in flight.

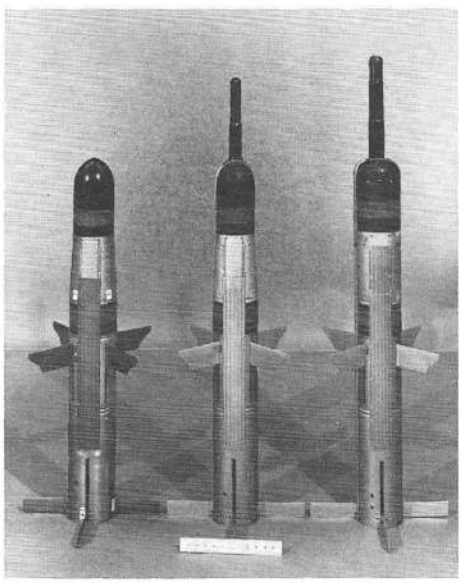
The missile itself is contained in a sealed storage and transport container which becomes a launch tube extension when placed in the launcher breech. After the breech locks, all electronic contacts to the missile are automatically closed, and TOW is ready to fire.

The missile contains two solid-propellant motors. The launch motor ejects the missile from the launch tube and is burned out by the time the missile has left the tube. Only after the missile has flown several metres does the flight motor ignite, so that no protection is necessary for the gunner against hot exhaust gas and propellant particles. The flight motor is mounted in the centre of the missile with its two exhaust nozzles mounted on either side. This arrangement prevents interference with the guidance wires which are placed at the tail of the fuselage. Steering commands are transmitted by the two wires which uncoil from two separate spools. Short cruciform wings in the centre of the missile and the cruciform rudder surfaces all unfold after leaving the launch tube. Missile manoeuvring is done entirely aerodynamically (without jet vanes) so that TOW maintains good manoeuvrability throughout missile flight. The electronics unit is mounted between the flight motor and the armour-piercing warhead.

US Marines firing TOW missile from a Jeep-mounted launcher (US Navy)

After the missile leaves the launch tube, a light source in the tail comes on so that the optical sensor on the launcher, which is bore-sighted with the gunner's telescope, can track the missile along its flight path. The light source is sufficiently strong to allow automatic guidance to the maximum range of the missile under all conditions in which the target is visible to the gunner.

MOBILE INSTALLATIONS



TOW can also be installed in most of the available wheeled or tracked vehicles capable of cross-country travel. The US Army is using it on armoured personnel carriers, jeeps, and AH-1S Cobra helicopters: the US Marine Corps has tested it on the 'mechanical mule'. Moreover, the American Army is equipping with a vehicle which affords greater protection to the crew whilst firing TOW. Called the Improved TOW Vehicle (ITV) (M901), it consists basically of an M113A1 armoured personnel carrier that has been modified to carry an armoured cupola or weapon station. A large pod, containing two TOW launchers, a day sight, AN/TAS-4 night sight and target acquisition sight, is attached to the base of the cupola by lifting arms. When not in use, this pod rests on the rear deck of the vehicle. The gunner operates the TOW from inside the cupola, which is designed to provide protection equal to that of the M113A1. The cupola is equipped with hand-operated power controls that allow the gunner to raise and lower the pod and rotate the cupola a full 360°. Also provided is an optical system of lenses and prisms which enables him to look into the pod-mounted TOW sights.

To operate the system, the gunner raises the pod about 1·2 metres above the deck of the vehicle by extending the lifting arms. He then simply looks into the TOW sights, aims at a target, launches a missile and guides it to the target.

Two other US Army vehicles have been equipped with TOW firing systems: the M2 Infantry Fighting

TOW 2 anti-tank missile leaving launch tube of US Army M2/M3 Bradley fighting vehicle system

TOW missile family with (l to r): basic model; improved TOW (ITOW); and TOW 2 with larger warhead, extensible probe and higher impulse flight motor

Vehicle, and the M3 Cavalry Fighting Vehicle. Both these vehicles evolved from the US MICV (mechanised infantry combat vehicle) programme and the TOW installation is virtually identical in each case with a two-tube launcher assembly carried on the left side of the vehicle's main armament (25 mm cannon) turret. When travelling, this launcher is retracted and lies alongside the turret; reloading can be performed from inside the vehicle, manually, and the M2 version can carry five reload rounds while the M3 has provision for 10 reloads.

Overseas countries have also adopted armoured TOW systems. The Netherlands have their own version of the M901 ITV, which is known to the Dutch as the Armoured Infantry Fighting Vehicle (AIFV), and this consists of a considerably modified M113 chassis equipped with the Emerson ITV turret. The Netherlands designation of the AIFV is YPR 765 PRAT.

In 1978 Thyssen Henschel built two prototypes of the Jagdpanzer Rakete armed with a single-tube TOW launcher, and known as the Jaguar 2. It is used with an AN/TAS-4 night sight and the launcher has a traverse of 30° left or right and an elevation of +15 to -10°. It was expected that over 150 of these vehicles might be procured for the Federal Republic German Army following evaluation.

The adaptability of TOW for the armament of fighting helicopters has been thoroughly demonstrated. For details of helicopter applications of TOW see **2831.311**.

CHARACTERISTICS

Military designation: BGM-71

Type: Heavy anti-tank guided weapon system

Guidance principle: Automatic missile tracking and command guidance from optical target tracker

Guidance method: Wire guidance control of gas-operated aerodynamic tail surfaces

Propulsion: 2-stage solid-propellant motor. First stage quadruple; second stage single. Recoilless launch

Warhead: HEAP shaped charge

Missile length: 117 cm*

Missile diameter: 15·2 cm

Launch weight: 18 kg*

System weight: 102 kg including 1 missile

Speed: Believed to be at least 1000 km/h

Range: Minimum: 65 m; Max: 3750 m

Rate of fire: 3 launches in 90 s

Crew: 4

*TOW 2 is 140 cm with probe extended, and weight 21·5 kg at launch

DEVELOPMENT

In 1980 the US Army embarked on a programme to improve the performance of the TOW system against advanced enemy armour. The first phase of the programme involves an improved five-inch diameter warhead to increase the armour penetration characteristics; it is of the same size and weight as the standard TOW warhead but of improved design. This version became known as ITOW or Improved Tow and can be recognised by the 127 mm long extensible nose probe which provides ITOW with an optimum stand-off detonation distance to ensure maximum effect from the hollow charge warhead. The second phase of the programme, known as TOW 2, incorporates a heavier six-inch diameter warhead of still greater penetration performance and this occupies the full diameter of the missile body. Also the missile guidance system is improved by the use of a microprocessor based sub-system which gives greater flexibility in guidance programming and higher accuracy. To compensate for the added weight, the missile motor has an improved propellant to provide a higher impulse.

Laser TOW

In mid-1984 Israel revealed a version of TOW that employs a form of laser beam-riding guidance to replace the normal wire guidance link. This version was developed over a period of about four years by the Israel Military Industries organisation, and is described in **4859.111** in the Israeli pages of this section

STATUS

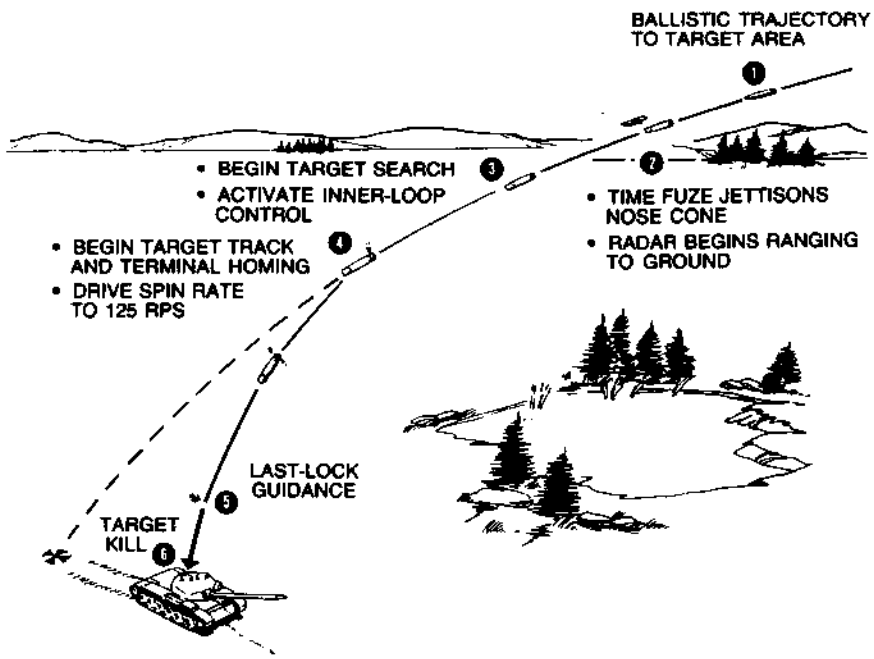
Basic TOW has been in the US inventory for several years, and the system has been adopted by between 30 and 40 countries. By early 1985 more than 350 000 missiles had been produced. A TOW thermal night sight and an improved warhead have been introduced into US service with the ITOW. Production of TOW 2 missiles and modification kits to convert basic launchers to the TOW 2 configuration have been delivered to the US Army since early 1983. The fiscal year 1984 report to Congress by the US Secretary of Defense, Casper W Weinberger stated that the US Army and Marine Corps will continue procurement of TOW with the improved warhead and guidance system. At the same time existing missiles will be fitted retrospectively with these improvements and initial deliveries of new TOW 2 production missiles have begun. Funded and planned TOW procurement for the fiscal years, 1985-87 is as follows: 1985 - 14 355 ($252.8); 1986 - 24 882 ($299·2); 1987 - 21 333 ($288·7), all funding in millions.

CONTRACTORS

Hughes Aircraft Company, Canoga Park, California 91304, USA, is the prime contractor for the system, having developed it for the US Army Missile Command.

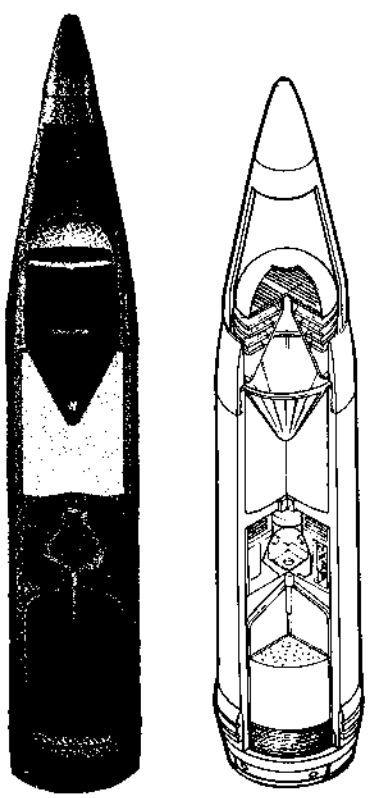
Emerson Electric Co, Electronics and Space Division, 8100 Florissant Avenue, St Louis, Missouri 63136, USA, are prime suppliers of the launcher, missile guidance set, optical sight, and traversing unit.

Texas Instruments Incorporated, PO Box 226015, Dallas, Texas 75266, USA, is the major contractor for the infantry ground launcher TOW 2 retrofit kits which include a digital missile guidance set and the AN/TAS-4A night sight.



4880.111

US ICM

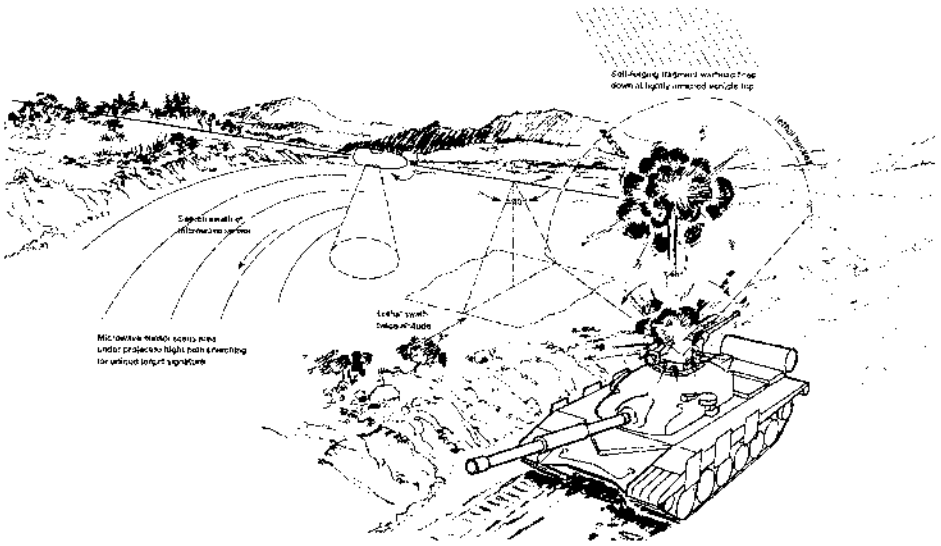


Under the heading of Improved Conventional Munitions the US Army is implementing a programme to develop a variety of technologies to enhance the capabilities of tubed artillery in battlefield support roles. Ammunition for use against both troops, armoured formations and other important theatre targets are within the scope of this programme which embraces technologies for terminal guidance of projectiles, 'smart' sub-munitions, cargo carrying shells and related technical problems. One such project is the SADARM (sense and destroy armour) programme which is described separately (**3988.111**) below. Some of the less advanced current programmes being pursued by the US Army are outlined below.

Projectiles: Currently ICM programmes centre on either or both of two standard artillery calibres, 155 mm and 8-inch (203 mm), and as noted below the SADARM programme involves the use of cargo-carrying shells of both these calibres. The two standard US cargo-carrying shells are the 155 mm M483A1 and the 8-inch M509A1. The latter dispenses 180 M42 dual-purpose sub-munitions which are effective against both personnel and vehicles. The 155 mm M483A1 carries 88 dual-purpose sub-munitions that offer both light armour penetration and anti-personnel capabilities by including shaped hollow charges and fragmentation payloads.

RAAMS: Also using the 155 mm projectile is the remote anti-armour mine system (RAAMS) where the projectile is used to carry nine M718 or M741 anti-tank mines. The M718 is the 'long life' model, which can remain emplaced for a period of more than 24 hours (reportedly) before self-destruction is automatically initiated, and the M741 has a shorter emplaced life. These shells can be fired to a range of up to 17 km to lay down an anti-tank minefield in the face of an advancing enemy. After the pre-determined active life of the minefield has elapsed it should be safe for friendly forces to advance over the ground. The M781 mines weigh approximately 2·26 kg. A proportion of the mines carried can be equipped with disturbance fuzes to discourage enemy mine clearance activities.

Operating sequence of Honeywell proposed 155 mm CGSP



Cutaway drawing of 155 mm CGSP

Area Denial Mines: There are long- and short-life versions of area denial artillery munition (ADAM) rounds, M692 and M731, respectively. In both cases each 155 mm shell carries 36 anti-personnel mines which are actuated by a self-deploying trip wire or disturbance fuze. Tests have started on a system whereby a 155 mm shell is used to deploy six expendable communications jammers (EXJAM). These units are ejected from the rear of the shell in flight by a timer/sequencer and then slowed and stabilised in flight by fins and a streamer, to bury themselves on contact with the ground to a depth of a few cm. They then start transmitting to disrupt enemy communications.

XM864 155 mm Projectiles: A base bleed cargo-carrying 155 mm projectile (XM864) has reached the advanced development stage, and this will provide improved range without the impaired accuracy that rocket assisted projectiles sometimes encounter as the price of greater range performance. Ranges of up to 23 km when fired from the M109A2/A3 howitzers, and 26 km from the towed M198 are hoped for.

CGSP: Honeywell has proposed, in answer to the US Army's requirement for a cannon-launched, 155 mm fire-and-forget, anti-armour projectile, the conventional geometry smart projectile (CGSP). This would consist of a 155 mm shell equipped with a ring laser rate sensor providing reference signals to a guidance system that includes a millimetric wavelength seeker which uses the projectile's spin to aid scanning, and fluidic reaction jet control for missile guidance. The CGSP will follow a ballistic trajectory to the target area after firing, a timer will initiate jettison of the nose cone and the radar begins ranging measurements to the ground. Target search follows shortly after and the target tracking and terminal homing phases are commenced at the appropriate times with corrections to the trajectory by means of the fluidic reaction jets near the rear end of the projectile.

Operating principle of Aerojet STAFF ammunition

STAFF: The smart top attack, fire-and-forget (STAFF) concept is a novel approach by Aerojet Electro Systems to the engagement of armoured targets by indirect gun fire. Like the Honeywell CGSP (above) the projectile's spin plays an important part in the detection and location of the target, but in the STAFF technique a microwave sensor is used to scan a swath beneath the projectile during its relatively horizontal trajectory over the target area. This is accomplished by pointing the sensor at the right-angles to the projectile's spin axis, which ensures that a belt of terrain parallel to the trajectory is continuously scanned as the projectile spins and passes overhead. Calculations indicate that a swath width equivalent to twice the projectile's height can be scanned. The sensor is programmed to detect specific target signatures, and on encountering one that is within range a self-forming fragment warhead is fired downward to penetrate the top armour of the tank or other target.

3212.111

COPPERHEAD CLGP (M712)

Copperhead is the name assigned to the M712 cannon launched guided projectile (CLGP), a 155 mm round equipped with a terminal guidance system and launched from conventional howitzers into an essentially ballistic trajectory, although by means of a technique known as trajectory shaping, it is possible to use shallow flight path angles which allow Copperhead to be used with cloud ceilings below the specified 3000 feet (914 metres). This provides more guidance time below the clouds and increases projectile acquisition range. During flight the target is illuminated by a laser designator operated by a forward observer. The seeker in the nose of the CLGP acquires the reflected laser signature and uses this signal to operate control surfaces on the projectile to cause it to follow a collision course to the target.

The origin of the system rests in the US Army requirement for a means of bringing indirect fire to bear on tanks and distant armoured targets with a high kill (preferably first round) probability using a shaped charge warhead. Indirect fire demands the use of a forward observer or a forward air controller who calls for fire in the conventional manner and designates the target during the last seconds of the projectile's flight. Several options are provided for this requirement.

Target designator systems which can be used with Copperhead include the AN/TVQ-2 ground laser locator designator (**3051.193**), the hand-held AN/PAQ-1 laser target designator (LTD) (**3157.193**), modular universal laser equipment (MULE) (**3816.193**), the Type 306 Laser Target Marker Ranger (UK), various RPV designator systems, and the AAH advanced attack helicopter target and designation system (TADS) (**3609.353**). A designator mounted on an armoured vehicle, such as the M113 is under consideration.

The Copperhead round is fired in an inactive state, thus simplifying the precautions needed to protect the guidance system from acceleration shocks. An acceleration-sensitive battery, initiated by firing the projectile, supplies power for guidance and control, as well as initiating and operating a timer which controls the internal operating sequence. Timer adjustment is dependent upon the required range, and therefore is similar to setting a timed fuze.

Associated with a setting of the timing switches is the selection of the trajectory mode for a ballistic trajectory or a fly under/fly out (FUFO) trajectory. The latter is intended for ranges of over 8 km and for bad weather where the projectiles travel at a lower altitude to provide a longer time beneath cloud ceiling for acquisition and guidance. The ballistic trajectory is used for shorter range shots and/or good weather conditions.

Coding of the laser signature which will be accepted by the seeker is also set in at the same time as the above selections are made. This coding will match that being used by the forward operator of the laser designator.

The Copperhead CLGP is made up of three sections; guidance, payload, and stabilisation and control. The configuration is aerodynamically controlled by cruciform in-line wings and tail fins that provide roll stabilisation and lateral manoeuvrability sufficient to provide an impact 'footprint' adequate for successfully engaging manoeuvring armoured targets.

The guidance section consists of the seeker and electronic assemblies which are housed within the nose cone and steel housing. The seeker uses folded body-mounted optics with a spin stabilised gimballed mirror (seeker gyro). The seeker gyro is spun-up mechanically by a steel spring and sustained and torqued electrically.

The payload section includes an HESH warhead in a steel structure and a fuze module. The latter incorporates six grazing sensors to detonate the warhead if the nose sensor does not directly hit the target.

The stabilisation and control section includes the flip-out aerodynamic surfaces and associated actuator mechanisms. Deployment of the fins is delayed until after the muzzle exit by the effects of launch acceleration. When deployed at their 20° sweep angle, the tail fins are canted to maintain a six to eighteen revolutions per second projectile roll rate, which aids stability and also allows liberal tolerances in vane manufacture.

CHARACTERISTICS

Type: M712

Weight: 63·5 kg

Length: 137·2 cm

Warhead weight: 22·5 kg

Explosive weight: 6·4 kg

Max range: 16 km

Minimum range: 3 km

A typical impact 'footprint' has been reported as about one kilometre radius from the nominal aim point.

STATUS

Production of Copperhead was authorised in March 1980 with the award of a $62 million contract to Martin Marietta. The fiscal years 1981 and 1982 allowed for procurement of 3125 and 4550 rounds respectively, at a cost of $117·6 million and $141·1 million, with projected procurement of 7629 rounds in fiscal year 1983 valued at $183·6 million. Initial operational capability (IOC) was scheduled for 1982, but in that year Congress withheld production funding, reportedly because the reliability factor achieved was below the 80 per cent first round hit rate specified.

In 1984 the LAT success ratio was 71 firings, with 63 hits, and 88·7 per cent reliability. In 1985 (to April) 13 firings with 13 hits for 100 per cent reliability. By the end of 1984, 7720 rounds had been delivered.

The fiscal year 1985 DoD Budget showed planed procurement of Copperhead rounds (with funding in $ millions in brackets) as follows: 1983, 1100 (55), 1984, 1415 (71·3) and 1985 2253 (102·8). The contractor reported in early 1984 that 5000 rounds of a projected total of 30 462 had been delivered.

Martin Marietta Orlando PO Box 5837, Orlando, Florida 32855, USA.

3988.111
SADARM SYSTEM

The US Army SADARM (sense and destroy armour) anti-tank sub-munition system is a project to design and develop a weapon for use against massed enemy armour beyond the forward edge of the battle area (FEBA). It is intended to be delivered by conventional current 8-inch and 155 mm calibre artillery.

SADARM, in its XM836 8-inch original version, is 203 mm in diameter and about 1·14 metres long, it is cylindrical, consisting of a standard M509 8-inch cargo-carrying shell in which are contained three sub-munitions. No external guidance or control system is required and there is no need for target illumination (eg laser). The SADARM round, after reaching the target area, ejects the three sub-munition canisters over the grouped targets and a vortex ring parachute is deployed from each canister to position the latter so that during its descent a sensor can scan the target area at an angle of 30° from the vertical. The acquisition range of individual sensors is in the region of 75 metres radius, and if the sub-munition descends in an area of this size containing a vehicle, the millimetric wavelength sensor is automatically switched on. When the sensor detects its target, it fires the canister's armour-penetrating warhead at the target's top surface. The sub-munitions will incorporate the self-forging fragment (SFF) type of warhead.

By packaging four sub-munitions in an M483A1 carrier projectile equipped with an M577 fuze, a 155 mm calibre SADARM shell is obtained, designated the XM898. The warhead in this role has a novel dual (top/bottom) attack capability which enables each one to serve as either a downward firing weapon to attack tanks from above, or if a target is not presented on release from the carrier shell, the Skeet falls to the ground to remain as a run-over mine.

The ESM/SADARM deployment does not rely on parachutes, but individual sub-munitions are ejected from the rear/base end of the carrier shell and each follows a pre-computed precession-imparted search pattern caused by their rate of spin.

STATUS

A successful concept demonstration test firing of the SADARM was carried out in June 1979 at Albuquerque, New Mexico, USA.

Current SADARM round procurement as detailed in the fiscal year 1986 DoD budget indicates an emphasis on the 155 mm calibre round. This is based on figures for procurement of M483 carrier shells for fiscal years 1985-87: 555 ($239·8 m), 689 ($299·8 m), and 531 ($247·2 m) respectively. The corresponding numbers for the 8-inch M509 carrier are: 1985-153 ($130·3 m), 1986-nil, and 1987-85 ($77·8 m).

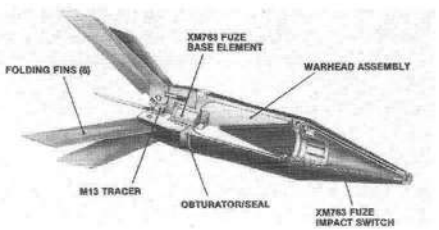
4758.111
XM815 HEAT-MP-T PROJECTILE

The XM815 105 mm HEAT-MP-T projectile is a multi-purpose artillery round being developed by Avco as a companion to the kinetic energy rounds M-774 and XM833. The sponsoring body is the US Army Tank Main Armament Systems Project Office, and the work is based on earlier efforts by ARRADCOM. The XM815 will replace the current 105 mm HEAT, HEP and APERS rounds.

A novel fin folding design combines high stability with low drag and this is claimed to result in significantly higher accuracy than is obtained with the M456 predecessor round. The new round incorporates the latest precision shaped charge technology, and reaches a muzzle velocity of almost 120 m/s, without excessive heating, barrel wear or muzzle blast.

The XM815 is designed for use with M68 cannon on the M48A5, M60, and M1 series MBTs against targets such as enemy BTR-60 and BRDM vehicles, or other targets such as bunkers or military structures.



The fuzing mechanism employed is the XM763 fuze system, which is a point initiating, base detonating assembly. Its major components are a crush type switch, a base element safing and arming device, and an interconnecting cable between these two elements. The crush type switch provides full frontal area impact sensitivity to the prescribed targets, while maintaining insensitivity to brush contacts, rain, and other non-impact conditions. Advanced components and energy devices enable the XM815 to survive the shock loads and other environmental stresses of launch.

STATUS

Development project. Test rounds have been fired, reportedly with good accuracy. It is stated that a high priority has been placed on getting the XM815 into service quickly and an initial operational capability (IOC) by the last quarter of 1986 is planned.

HY-2 (CSS-N-2) COASTAL DEFENCE WEAPON

Soon after it became known that the Soviet Union had supplied the People's Republic of China with SS-N-2 anti-ship missiles (**1155.221**), it was disclosed that China had embarked on a plan to deploy this missile for defence of her extensive coastline. This programme has been followed since perhaps the early 1970s, and although it is still not known to what extent it has been fulfilled, or the numbers of missiles available for this purpose, the existence of a missile coastal defence force has now been officially confirmed by the release of a few photographs of units armed with the CSS-N-2.

More recently it was confirmed that China has its own indigenous production facilities for this weapon, which has the official designation HY-2. In 1984 the Chinese Government made this system available for export.

So far as can be gathered, the missile itself is virtually unchanged from its shipborne configuration, and the performance must also be similar. The overall system is configured in transportable, mobile form, with the missile on wheeled trailor that carries a launching ramp that can be slewed in azimuth and adjusted in elevation. Maximum effective range is stated as 95 km, at high sub-sonic speed.

Apparently there are three variants produced, the main known differences being in the guidance methods used: the basic HY-2 uses active radar homing, while HY-2G adds a radio altimeter to permit a lower penetration altitude, and the third model, HY-2A, relies on an IR homing head to counter radar countermeasures. Estimated mid-course cruise altitudes for the three versions are 100, 50 and 30 metres. The truck-mounted radar associated with the HY-2 system provides surveillance and target detection facilities and is also stated to perform target tracking. The design apparently originates from a Soviet naval search radar and probably operates in the C-band of the spectrum.

Mobile radar for use with Chinese HY-2 coast defence missile system

HY-2 launch

STATUS

Operational and in production in the People's Republic of China. Available for export and thought to have been supplied to some African states.

In late 1984 the Chinese authorities revealed a new anti-ship missile that was claimed to be employed in both ship-launched and coast defence roles. First use of this weapon, the C801 (**4891.221**), in the latter role may well be in mixed batteries with the HY-2 at selected sites.

EXOCET COASTAL DEFENCE WEAPON

The MM40 coastal defence version of the Exocet anti-ship missile system is now fully operational. It uses the current shipborne MM40 missile, with the same propulsion arrangements that give a boost phase of 2·4 s followed by a sustainer burn time of 220 s, resulting in a cruise phase that is about 100 s longer than that of the MM38. Folding aerodynamic surfaces permit the use of much smaller tubular launcher-containers made of wound glass-fibre. The dimensions of the new tubular containers are such that four can be accommodated in the same volume as that required for a single conventional MM38 metal housing.

The Exocet coastal defence system can be deployed as a mobile battery, all the equipment being carried on military vehicles. The target acquisition and designation radar will usually be located on high ground to ensure adequate range. Three or four launcher vehicles will occupy predetermined locations to cover the desired firing area, with supply trucks ready to replenish them, and maintenance vehicles under cover. For engagement of targets beyond the radar horizon of the shore radar, target data supplied by a consort, (aircraft, helicopter, or ship) can be used. In this case, the consort automatically transmits the target data to the shore radar installation.

Launch of MM40 from a coastal battery firing vehicle

CHARACTERISTICS

Type: MM40
Length: 5·78 m
Launch weight: 850 kg
Range: 70 km

STATUS
The MM38, AM39, and MM40 are operational with French and 26 other navies or air forces.

Any type of coastal maritime surveillance radar can be employed for target detection and designation.

CONTRACTOR

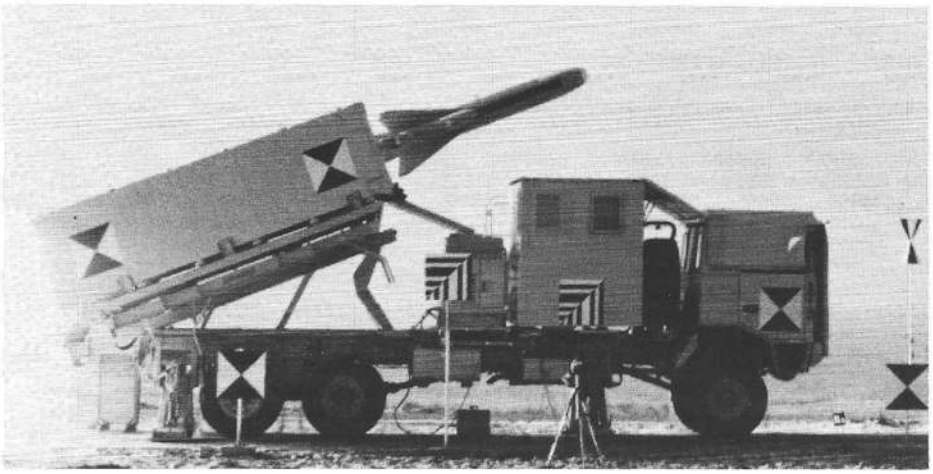
INTERNATIONAL



1337.121
OTOMAT COASTAL DEFENCE SYSTEM (FRANCE/ITALY)

The Otomat coastal defence system (OCDS) uses the Otomat anti-ship missile, developed by Matra (France) in collaboration with OTO Melara (Italy), and fitted in numerous warships. An operational range of over 100 km is obtained with no more than initial target designation ('fire-and-forget'), while the use of the 'fire-and-update' technique permits ranges of more than 160 km. Salvo firing achieves similar improvement of the effective range. The 210 kg semi-armour piercing warhead has a significant destructive effect due to penetration and explosion within the target. Tactical use is facilitated by the angled firing capability (gyrodeviation) which ensures complete freedom with regard to launch axis and target azimuth.

A more detailed description and illustrations of the missile are given in the Shipborne Weapons section (**1336.221**).

The OCDS is composed of one or more Otomat coastal defence units (OCDUs) carried on cross-country vehicles. Each OCDU comprises a command group, and two to four firing groups. The command group includes one control cabin, a surveillance radar (each carried on its own truck), one command car, and an operational maintenance vehicle. The firing group consists of one firing vehicle with two missiles in containers, and one reload vehicle fitted with a hoist and two spare missiles in containers. One command group can control up to four firing groups. The basic vehicle used is the six wheel drive truck RVI GBD 6 × 6 fitted with sand-duty tyres and having an empty weight of ten tons. Maximum road speed is 75 km/h and range 1000 km.

The command vehicle houses the tactical display console, missile control panel, various communications equipments and the telecommand transmitter. The console enables the tracking of several targets, and the control panel permits the setting of initialisation data into the missiles anations and authorising their firing by the firing vehicles. The latter vehicles are equipped with a north-seeking gyro-compass to assist initial survey and battery setting up, and an optical sight for reversionary mode use.

Otomat launch from coastal defence launcher vehicle. Ranges up to 180 km can be obtained

VHF radio links are provided between the vehicles permitting flexible dispersion of the OCDU. The problem of over-the-horizon target designation has been solved by employing an external radar, either a relay ship, helicopter or fixed-wing aircraft. The relay platform measures target bearing and range and transmits them via data link to the control cabin. The latter measures range and bearing to the relay plaform and computes the co-ordinates with respect to the firing vehicle. A course correction transmitter allows for in-flight updating of the co-ordinates. Airborne target detection makes it possible to reach extended ranges, thus permitting a single OCDU to cover 360 km of coast line.

An Italian version of the Otomat coastal defence system was revealed in some detail at the Mostra Navale exhibition held in May 1982. In this version an Otomat coastal battery consists of six OTO C13 tracked vehicles on each of which are two Otomat missiles housed in glass-fibre launcher containers. These are linked by cables or radio to a command post vehicle on another C13 chassis, from where, it is reported, one man can control the entire battery using an SMA MM/SPQ-2F search radar mounted on top of the command post. There can be up to 20 km between the command vehicle and the others of the battery, and it is also possible to employ a naval helicopter such as the Agusta AB 212 equipped with Otomat over-the-horizon guidance facilities for engagement of distant targets. In such a role a range of more than 160 km is claimed.

STATUS
The Otomat coastal defence system is in operational service with the Egyptian Navy, and several others are contemplating acquisition of the system.

At the beginning of 1985, the French manufacturer reported an order book of 800 missiles, all for export customers.

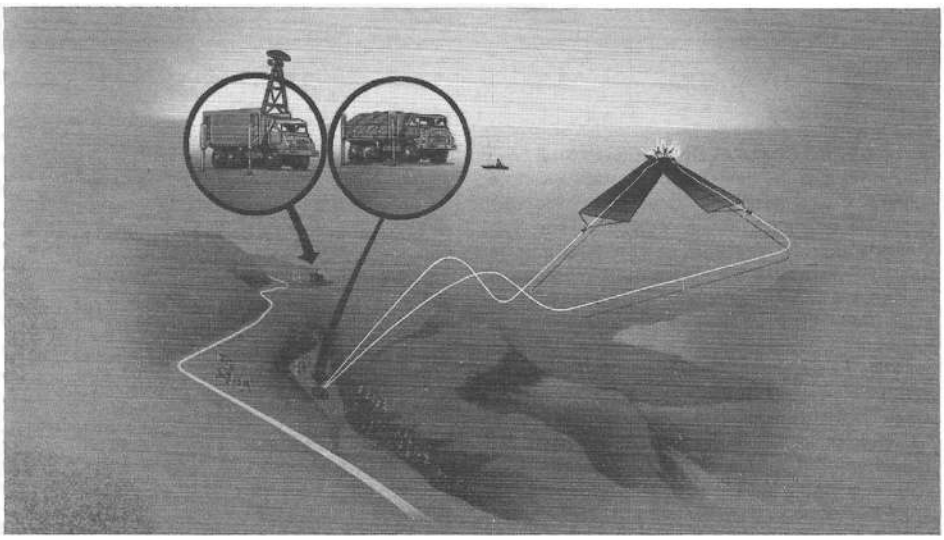
NORWAY



3074.121
PENGUIN COASTAL DEFENCE SYSTEM

The Penguin surface-to-surface anti-ship missile (**1339.221**) is in the process of being reconfigured to serve in a number of coastal defence roles, in either fixed or static versions.

The land-based Penguin missile weapon system consists of a fire control system, the missiles and missile control system. In permanent, fixed installations the system consists of a radar or optical sensor, a missile control cabinet incorporating a special purpose computer, a power supply, a firing panel, and a number of missiles. Very simple launching arrangements can be employed, largely depending on the nature of the site.

Alternatively, Penguin can be adapted as a self-contained, autonomous, mobile coastal defence unit. Vehicle-mounted surveillance radar, is used to provide target detection and designation for batteries of Penguin anti-ship missiles deployed on the 'flat-beds' of similar six-wheeled trucks to those carrying the radar. Four missiles can be carried, mounted transversely across the rear of the chassis, while the crew of three and the radar and missile control systems occupy the front cab. A range capability of 30 km is claimed for the Penguin in this role.

CHARACTERISTICS
Number of missiles: 4, or more
Missile data
Weight: 340 kg
Length: 300 cm
Wingspan: 140 cm
Diameter: 28 cm
Speed: High subsonic
Warhead: 120 kg
Fuze: Impact
Trajectory: Variable
Homing: Passive terminal
Range: 30 km

Schematic diagram of coastal defence system based on vehicle-mounted surveillance radar and Penguin launching units

DEVELOPMENT
Penguin was originally developed as a ship-to-ship weapon system for the Royal Norwegian Navy by the Norwegian Defence Research Establishment and A/S Kongsberg Vaapenfabrikk.

STATUS
Studies of various configurations of coastal defence systems based on the Penguin missile have been conducted for several years by the Norwegian authorities, involving a number of practical demonstrations.

RB 08 COASTAL DEFENCE WEAPON

The Swedish RB 08 surface-to-surface cruise missile is intended for use either as a shipborne weapon or for coastal defence.

Detailed information on this system will be found in the Shipborne Weapons sub-section below (**2366.221**).

RB 08A boosted off its launcher

4878.121
HELLFIRE SHORE DEFENCE SYSTEM

In late 1984 Rockwell International was awarded a $7·7 million contract by the Swedish government to adapt the Hellfire modular missile, already developed for helicopter operation (**1391.311**) and battlefield use (**4877.111**), for the shore defence role. Under this two-year adaption phase, Rockwell will act as the prime contractor with responsibility for systems integration in collaboration with Swedish industry.

Although it has been stated by the manufacturer that this application of Hellfire will entail some modification to the production missile to make it more suitable for shore defence operations, it would appear that there will be a significant degree of commonality between the Swedish system configuration and the anti-armour battlefield system tested by the US Army (see illustration) apart from the use of vehicle mounting in the latter version.

It is believed that in the first instance the laser homing version of the Hellfire modular missile will be employed in the Swedish shore defence application, and in most respects the basic characteristics and performance will be very similar to those of the ground-launched anti-armour version of the system (**4877.111**).

STATUS
Development project under Swedish Government contract awarded in 1984. First foreign sale of Hellfire.

HSIUNG FENG COASTAL DEFENCE MISSILE

Hsiung Feng is the name given by the Taiwanese authorities to a missile designed to engage ship targets at estimated ranges of 30 to 40 km. It is thought that in addition to the land-mobile configuration of this weapon, which is the only one so far revealed in public, shipborne versions of it also exist. Very little in the way of performance, construction, or technical details have been released but from the few photographs which have appeared Hsiung Feng bears a very striking resemblance to the Israeli Gabriel system (**6019.221**), extending also to the container/launchers which are employed for the coastal defence version of the Taiwanese missile. Three missiles are housed, each in its own container, on a triple rotatable launcher unit which is mounted on a semi-trailer which is towed by a heavy tractor unit (see illustration), the triple launcher in the Gabriel III system having a weight of about two tonnes. Despite the Taiwanese reports that Hsiung Feng is of local manufacture, in view of the many and close similarities between this weapon and the Israeli Gabriel system, it is thought that Hsiung Feng is in reality a licence-built product manufactured in Taiwan, or a normal overseas procurement of the Gabriel system.

2951.121
SAMLET CRUISE MISSILE

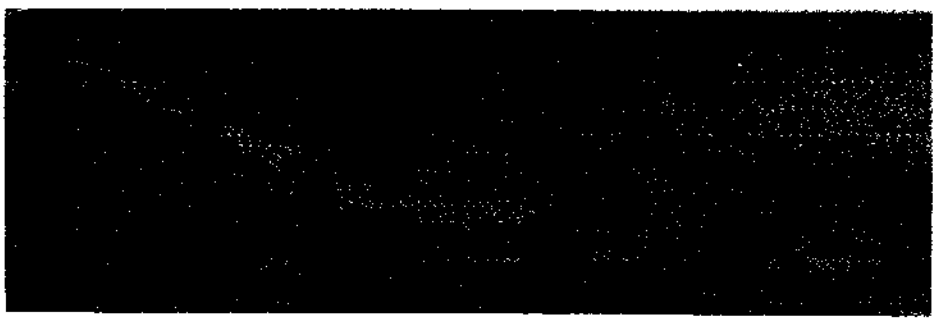
Like Salish, the missile known to NATO as Samlet and SSC-2B in the American system (Soviet designations are understood to be 4K-87 and/or S-2), is a surface-to-surface version of the air-to-surface jet-powered cruise missile whose NATO code-name is Kennel. It has been operational in the USSR, Egypt, Poland, and Cuba as a coastal defence weapon. When shown publicly Samlet has been mounted on what appears to be its launching ramp constructed as a trailer. But other photographs indicate that a more permanent launch emplacement also exists. For launching a JATO bottle is necessary.

Samlet, like Salish, has a radome over its jet air intake. The radome is larger than that on Salish and Samlet also has what seems to be an electronics pod mounted on its tail fin. The radome is assumed to cover a radar homing seeker; the other device may contain the receiver and associated apparatus of a command guidance link. Apart from these differences the two missiles appear very much alike and the following approximate data are probably equally true of both.

CHARACTERISTICS

Length: Approx 7 m
Wing span: Approx 5 m
Weight: Believed about 3 t
Cruising speed: Mach 0·8 – 0·9
Range (Samlet): Possibly as much as 200 km with mid-course guidance.

Samlet coastal defence missile preparation



STATUS

An undisclosed number of Samlet missiles are reported to be operated by the coastal frontier force of the German Democratic Republic Navy. These are probably in the process of being supplanted by the recently reported SSC-3 (**4890.121**) coastal defence missile, below.

2975.121
SEPAL MOBILE CRUISE MISSILE (SSC-1B)

Sepal is the code-name (SSC-1B in the American system) for the land-based version of the shipboard Shaddock surface-to-surface weapon. (The Soviet designation is reported to be P35.) Too little has been seen of this missile on public display for it to be described with confidence. The general view seems to be that it is a ramjet or turbojet-powered cruise missile with hinged wings that open out when the missile leaves its cylindrical launcher. Initial boost is provided by two rocket units under the rear of the fuselage. Length of the missile is estimated at about ten metres and the diameter of the fuselage is probably around one metre.

Shaddock is best known as a naval weapon and is described as such below (**2976.221**). It appears, however, that it is used by the land forces of the USSR, and this view is reinforced by the appearance of the container/transporter illustrated here which is clearly capable of elevating the missile to an inclined launch position.

Launch of Sepal coast defence anti-ship missile

While no doubt it could be used as a ground-to-ground weapon, however, it seems rather more likely that it would be used as a coastal defence weapon, if only because of its ability to cruise at speed at low altitude over water.

Guidance is by radio-command with active radar homing. Range capability is in the order of 450 km, but mid-course guidance by aircraft or helicopter would be necessary for such a long mission. Each coastal defence battalion is reported to be equipped with between 15 and 18 missiles (inclusive of reloads).

STATUS

Unofficial but reliable sources have suggested that there are probably about 100 Sepal SSMs operated by the Soviet Union Navy's coastal artillery and rocket troops. These are thought to protect principal naval bases and main ports.

4890.121
SSC-3 COAST DEFENCE MISSILE SYSTEM

Certain Warsaw Pact countries in 1984-85 began operating a new type of coast defence missile system, but in common with most Pact weapons it appeared in public without any known identification. As yet, no NATO un-classified code-name has been assigned. The only two Pact states known to operate the system are East Germany and Yugoslavia, the latter identifying it as BROM (Baterije Raketa Obala, More). In view of the fact that the transport system is based on the MAZ-543 prime mover which is manufactured in the Soviet Union (as probably is the associated radar sub-system) it is likely that this system is used by Soviet Forces also, although no details of deployments have been obtained.

The missile employed is either a standard Styx anti-ship missile (**1155.221**) in its folding-wing SS-N-2B version or the coastal defence model as it is encountered in the Chinese HY-2 system (**3984.121**), or a near derivative of one or all of these (possible Soviet designations applied to missiles of this family are 4K-40 and P-15). From what is known of these systems, the SSC-3 can be expected to have a maximum range of 80-90 km at high subsonic speeds, cruising at heights between 15 and 100 metres above the sea surface. Guidance options that include active radar homing, with or without a radar altimeter, and passive IR homing almost certainly are available. Other details of the missile itself are probably essentially the same as for the parent system(s).

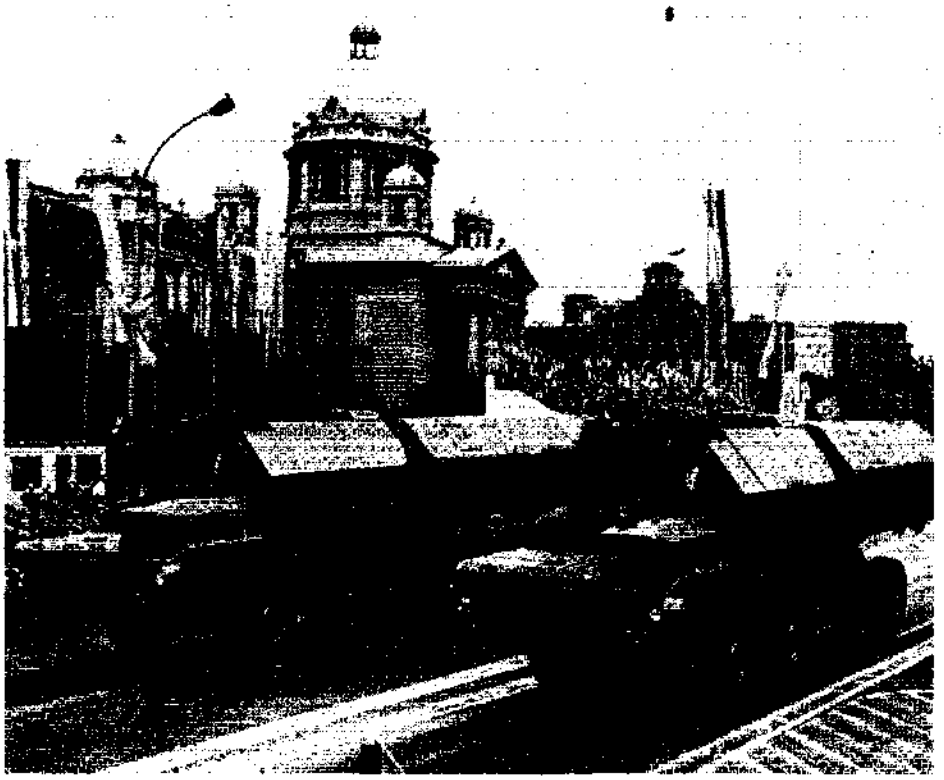
On its own, the choice of a MAZ-543 based vehicle as the means of transporting the SSC-3 system ensures an impressive appearance, when this is allied to a design that apparently incorporates the search and target designation radar equipment, operating/control cabin, and two missiles in individual container/launchers on a single 8 × 8 wheeled chassis the impression of a highly effective design is complete. If performance characteristics confirm this, the system's originators will have achieved a notably cost-effective solution.

From photographs of the SSC-3 system deployed and on the move it is possible to speculate on the likely construction and mode of operation. On the eight-wheeled MAZ chassis, immediately behind the driver's cab is a large enclosed housing that contains the radar and electronic equipment and is assumed to accommodate the operations cabin. Recessed into the forward side of this container is the radar scanner mounting consisting of a telescopic mast which is surmounted by the turning gear and the scanner itself. The last of these is a typical coastal radar scanner with a sheet metal reflector about 2·4 metres wide illuminated by an overhanging feed. Operation is presumed to be in the X-band and the principal function surface target detection. In the lowered position, for travelling, the scanner faces the front and is positioned over the driver's cab. In this position, the radar only increases the vehicle's overall height by a few centimetres.

The rear portion of the chassis carries a turntable on which is mounted either one large missile container/launcher housing for two Styx-type anti-ship missiles or 'Siamesed' twin launcher/container for the missiles. Each missile launch ramp housing has its own doors front and rear which opens upwards

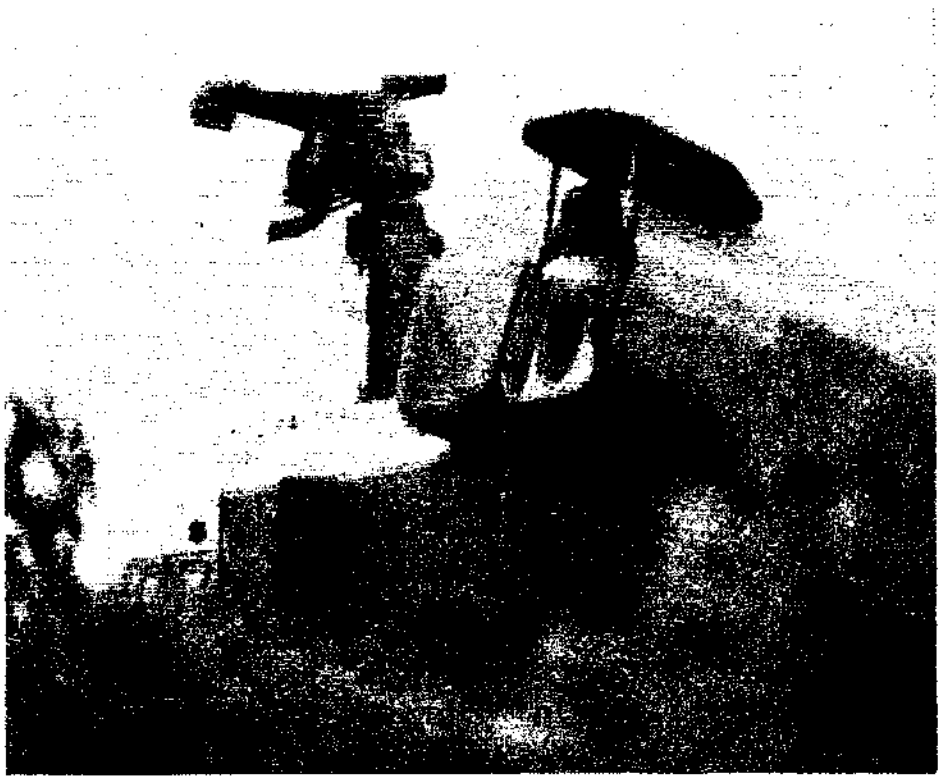
Crew members prepare SSC-3 coast defence missile for firing

to lie flat on top of the container. When deployed for operation, the missile container is slewed by the turntable to roughly 90 degrees of the vehicles longitudinal axis and elevated by 15 degrees or so for firing. The reloading operation is probably a variation of that employed for Styx missiles fitted in small naval vessels, ie with the aid of a small crane and manhandling into each launcher cell, possibly with some power-assisted mechanical devices.



Apparently the complete operating crew of the SSC-3 does not travel with the carrier vehicle when on the move, as the driver's cab is too small, and it seems likely that an accompanying truck forms part of a complete operational SSC-3 unit. Indications are that in Yugoslavian service a full crew consists of ten men, of which perhaps half their number are naval personnel for management and operation of the missile system, one is the commander, and the others are the soldier vehicle crew. The East German manning arrangements are not known.

STATUS



The hardware although undoubtedly fresh to Western eyes, is by no means intrinsically new, though the combination may be. Therefore, this and the evidence of sufficient quantities for appearances in ceremonial parades in East Germany and Yugoslavia, would seem to warrant the assumption that the operational stage has already been reached. Production lines for the missile employed are known to exist in a number of countries (within the Warsaw Pact and elsewhere), and the radar is not thought likely to incorporate or require any exceptionally advanced technology, so that the only limitation on production numbers is the capacity of the MAZ chassis facilities in Minsk.

Operational deployment with Yugoslav and East German coastal defence forces can be assumed to have begun in the 1984-85 period, in the latter case possibly as replacements for the SSC-2B Samlet missiles previously employed in that role. The extent of Yugoslav procurements and deployment is not known, and neither is there any indication of Soviet use of the SSC-3 system.

In July 1985 it was reported that deployment of the SSC-3 had started in Syria, where a coastal defence regiment was said to be operating the system in the Latakia region.

Two SSC-3 coastal defence missile units during a ceremonial parade. Front housing contains radar gear and operations cabin; rear housing is on a turntable and contains two Styx anti-ship missiles on separate launch ramps. Note radar scanner in lowered position for travel

SSC-3 coast defence missile system ready for operation, with target detection radar in elevated position

Shipborne Weapons

INTRODUCTION

This section deals with shipborne surface-to-surface weapons for anti-ship and shore bombardment purposes. In certain cases it will be found that the missile employed in such systems has other roles, and the practice in these instances is to cross refer to the appropriate entries for other applications of a given missile. In general it will be found that the most comprehensive description of the missile as a 'round' will appear under the entry for its principal function, but adequate data for an appreciation of a missile's performance is given in the entry for each system in which it is employed.

Naval guns and unguided bombardment rockets are contained in the Equipment section of this volume, and naval fire control systems are described in a separate section.

CHINA (PEOPLE'S REPUBLIC)

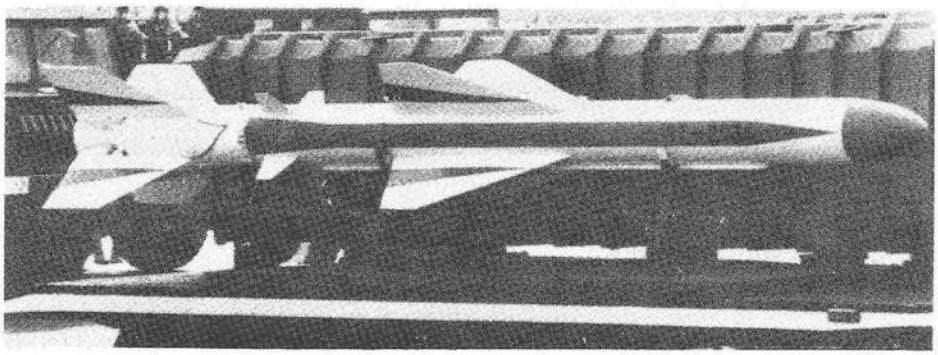
4891.221

C801 SURFACE-TO-SURFACE ANTI-SHIP MISSILE

In late 1984 The People's Republic of China revealed the existence of an hitherto unknown anti-ship missile of a new design, which it was stated to be employed in both the coastal defence role and aboard ships, although no details of fittings in the latter role have been obtained to date. Similarly, no technical details or specifications have been disclosed by the manufacturers.

The external resemblance to the French Exocet weapon (**1156.221**) was soon noted by Western observers and will be readily appreciated from the nearby photograph by readers of this volume. It will also be noted that the C801 has a large booster rocket motor, most probably to assist launch and initial acceleration, as well as providing a valuable extension to maximum range.

When displayed at a Peking military parade, the C801 was presented with a container/launcher which appears to be virtually identical to those first seen with the French Exocet ship launchers, which suggest further parallels between the Chinese and French weapon systems. These may well extend to broadly similar performance figures (apart from any variations that might be anticipated from the use of the large booster with the C801) and there is some evidence that the Chinese weapon incorporates a radio altimeter, indicating a roughly comparable sea-skimming capability.



STATUS

The C801 has apparently been produced in sufficient quantities to justify the assumption that it has reached operational status, although details of deployment as yet are singularly lacking. Chinese authorities have been quoted as claiming that the system has been fully operational for some years, but this has not been corroborated, nor amplified. Nethertheless, fitting in suitable ships need not be an unduly long process provided adequate deck space is available for bolting down the launcher/containers, and appropriate target designation facilities can be provided.

The latter should be available already for coast defence applications of C801, with the HY-2 (**3984.121**) system which has been operational for some time. Therefore it is reasonable to expect first operational deployments to appear in this role.

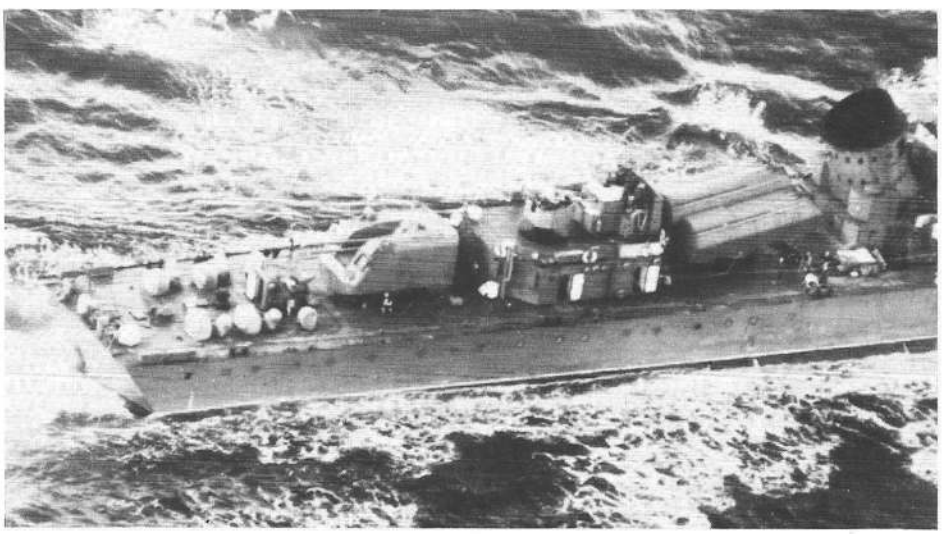
CONTRACTOR

China Precision Machinery Import & Export Corporation, 17 Wenchang Hutong Xidan, Beijing, People's Republic of China.

One of the first public appearances of China's new anti-ship missile, the C801, at a Peking military parade. Note the similarity with the French Exocet weapon, and the large booster motor. It is believed to be employed in both shipborne and coast defence roles

3973.221

HY-2(CSS-N-2) NAVAL SURFACE-TO-SURFACE MISSILE



As a former client of the Soviet Union, the People's Republic of China received a number of SS-N-2, Styx anti-ship missiles (**1155.221**), and it is now confirmed that this weapon forms a major element of the Chinese inventory. It is extensively employed in both the shipborne surface-to-surface role and mounted on shore-based launchers for coastal defence purposes (**3984.121**).

So far as can be ascertained, few if any changes have been made to the original Soviet design, although indigenous production is now being undertaken and the possibility of internal detail changes can hardly be ruled out. Chinese-built missiles of this type are designated Hai Ying (Sea Eagle), HY-2, and they were offered for export in 1984. On the 'Luda' class and 'Anshan' class Chinese vessels on which the HY-2 is currently deployed, the launcher arrangements are obviously of local origin. The former class of ship has two triple trainable launchers, while the latter class has two trainable twin launchers.

As described in the entry (**3984.121**) for the coastal defence version of this system, on an earlier page of this volume, the HY-2 is produced in three versions, these principally differing in their guidance sub-systems. The basic HY-2 employs active radar homing, and the HY-2G has the active radar plus a radio altimeter for better sea-skimming performance. Passive homing using IR techniques is employed by the HY-2A version. Cruise altitudes vary between the models from 30 to 100 metres. The maximum range quoted is 95 km.

STATUS

Operational and production continues. 'Luda' class destroyers have two triple launchers for HY-2 missiles and converted 'Anshan' class destroyers have two twin launchers although there have been reports of some of these ships having been fitted with triple launchers. Chinese 'Jianghu' class frigates have two twin launchers and frigates of the 'Chengdu' class have one twin launcher. Two main classes of fast

Chinese 'Luda'- *class destroyer with triple launcher for HY-2 missiles* (G. Jacobs)

Twin trainable launchers for HY-2 missiles fore and aft of funnel of 'Jianghu'-class frigate (G. Jacobs)

missile boat are operated by the Chinese Navy, both derived from their Soviet 'Osa' and 'Komar' class prototypes. The former 'Hola' class, of which there are over 100, have four single HY-2 launcher/containers while the 'Hegu' class boats, numbering more than 80, have two single launchers.

MM 38/40 EXOCET SURFACE-TO-SURFACE MISSILE

Exocet MM 38 and MM 40 are surface-to-surface tactical missiles designed to provide surface warships with all-weather attack capability against other surface vessels. They can be fitted in major and minor warships including fast patrol boats and hydrofoils.

The missiles are in the form of a streamlined body equipped with four cruciform wings and four tail control surfaces in the same planes as the wings.

Propulsion is provided by a two-stage, solid-propellant motor.

The MM38 Exocet's range is about 23 nm (42 km), flying at very low altitude. Its cruising speed is high subsonic and it carries a high explosive warhead.

Missiles are stored in box-type containers which also serve to launch them. These launcher-containers are mounted on deck in suitable positions.

The missile flight consists of a pre-guidance phase during which it flies towards the target, whose range and bearing have been determined by the fire control computer and set up in the missile pre-guidance circuits before firing, and a final guidance phase during which the missile flies directly towards the target under the control of its active homing head. Throughout the whole flight the missile is maintained at very low altitude by a closed-loop control system comprising a radio altimeter and the inertial guidance platform. The radio altimeter is produced by TRT under the designation RAM.01.

The terminal guidance phase (approximately the last 10 km) is by means of the ADAC radar homing head developed by Electronique Serge Dassault.

Subsequent to the introduction of the original MM 38 model, a number of derivative versions evolved, several of which have been produced in quantity. The air-launched AM 39 model is described in **1770.321** which appears in the section on air-to-surface tactical weapons later in this book. The surface-launched MM 40 variant is the result of combinations of alternative propulsion motor configurations, new container/launchers of wound glass-fibre construction, and folding wings and tail surfaces. The basic warhead and guidance elements remain unchanged.

The MM 40 has a longer steel-cased sustainer motor than the MM 38, thus resulting in a further increase in range. The MM 40 homing head also has a wider angle target search and acquisition 'gate' commensurate with the needs of its greater range (more than 70 km). It is carried in a tubular glass-fibre container/launcher. Four of these launchers can be mounted in the space required for one MM 38 housing.

Essential differences between the four models of Exocet are illustrated in the following table.

To launch Exocet the ship's fire control system is normally connected to the ITS (installation de tir standard, or Exocet ship system). The ITS is assembled by the Ruelle establishment (DTCN) under SNIAS as prime contractor, with several British sub-contractors. Among others, ITS is fitted on the French, British, and West German ships armed with Exocet. The Thomson-CSF Vega fire control system (**1053.281**) can be used in association with an inertial platform. An updated, digital firing installation, known by the initials ITL (installation de tir légère) is now being produced. It is capable of use with both the MM 38 and MM 40 versions.

Deliveries are made to the French Navy of a submarine-lauched version, SM 39. The SM 39 missile is essentially identical to the AM 39 model, but for operation from submarines a powered and guided launcher/container known as the VSM (véhicule sous-marin) has been developed. This is 5·8 m long and can be discharged from a submarine torpedo tube. In addition to the Exocet missile, with wings folded, it contains a gas generator which powers the VSM in the water and into the atmosphere. The container then breaks up as the missile motor ignites to take the SM 39 over the in-air phase of its flight to the target. Weight of SM 39, in the VSM is approximately 1345 kg.

The TRT RAM.01 radio altimeter carried by the Exocet missile, in conjunction with inertial guidance, is reported to be capable of permitting safe flight at a height of between 2 and 3 m above the sea at a speed of about Mach 1. All Exocet missiles are stated to have a fire-and-forget capability in that they are entirely autonomous in operation with a claimed hit probability near 100 per cent at all distances.

DEVELOPMENT

Development has been carried out by Aérospatiale in collaboration with the French Government military research establishments, to meet French Navy requirements.

STATUS

Development of the several versions of Exocet is now completed, as follows: MM 38 (1974), AM 39 (1979), MM 40 (1981) and SM 39 (1984).

By the end of 1984, over 2000 rounds of Exocet in all its versions had been ordered by some 27 countries, among them being: Argentina, Belgium, Brazil, Brunei, Chile, Ecuador, France, West Germany, Greece, Malaysia, Morocco, Oman, Peru and the UK. More than 1300 missiles had been manufactured by January 1982.

Combat experience has been gained with the Exocet system in the South Atlantic campaign of 1982, and more recently in the Gulf war. In late 1984 two successful launches of SM 39 Exocets from the submarine *'La Praya'* were made from periscope depth at the French Centre d'Essais de la Mediterranée (CEM).

MM 15 ANTI-SHIP MISSILE

In the 1980-81 edition of this book, under entry number **3974.121** a coastal defence application of the AS.15 TT anti-ship missile system was described. The manufacturer subsequently declared that work on this project had been discontinued, and the entry deleted. However, interest in surface-launched roles for this missile were revived with the presentation at the 1984 Farnborough Air Show of a version of the system for use with small naval craft and designated MM 15.

As before, the system is based on the AS.15 TT air-launched missile described in entry **3359.311** carried in four-cell launcher/containers which are bolted to the deck, and associated with a shipborne version of the Thomson-CSF Agrion 15 radar (**3298.353**). An effective range in the region of 15 km can be deduced for the system, based on the published performance characteristics.

STATUS

Nothing has been reported of contracts or further progress on this project since the Farnborough announcement.

CONTRACTOR

Aérospatiale, Division Engins Tactiques, 2 rue Beranger, 92322 Châtillon Cédex, France.

INTERNATIONAL

4446.221
ANS ANTI-SHIP MISSILE

The ANS (Anti-Navires Supersonique) anti-ship missile project was initiated by Aérospatiale and MBB as a replacement for the abandoned ASSM/ASEM programme (**3331.221**) to develop a successor within NATO for the Exocet and other anti-shipping weapons. The Franco-German programme is intended to result in a missile which will rely on high speed (Mach 2 or more) and high manoeuvrability (+10 *g*) to penetrate ships' defence systems in the future. Other design requirements include long range engagement without requiring monitoring or guidance participation by the operator; incorporation of programmable microprocessors to permit adaptation to evolving operational procedures and techniques; and the ability to be used with various types of ship or aircraft launch platforms.

In order to reach the cruise speed of Mach 2 soon after launch, ANS will be propelled by a ramjet motor augmented by a powder accelerator integrated into the combustion chamber of the ramjet. A new solid propellant propulsion system is being developed by MBB, and the missile system by that company's Dynamics Division.

Two experimental vehicles were flown in 1981 for testing the solid-propellant ramjet. For these tests they were equipped with a guidance and control system that incorporated a strap-down gyro platform, a mode computer, and control vanes, all monitored by a comprehensive telemetry system. The high-energy ram jet unit uses boron propellants, and for the tests it was assisted to cruising speed by a tandem booster consisting of an Honest John artillery rocket motor. The boron propellants were developed by Bayern-Chemie.

STATUS

Pre-development project.

1336.221
OTOMAT ANTI-SHIP MISSILE (FRANCE/ITALY)

Otomat is an anti-ship missile intended initially for launching from naval platforms of any size from fast patrol boat upwards, but also capable of land deployment (fixed or mobile). Weight is identical in both applications.

CHARACTERISTICS

Length: 4·46 m
Diameter: 46 cm
Wingspan: 1·35 m
Weight: 770 kg
Speed: Mach 0·9
Range: 60 km (effective) 180 km (max)
Warhead: 210 kg including 60 kg of explosive
Fuzes: Impact and proximity
Guidance: Inertial cruise, active radar homing
Propulsion: Solid boosters; turbojet cruise

Otomat missiles are delivered in containers which also serve as launchers, the containers being mounted on prepared locations. Propulsion during cruise is by a Turboméca turbojet engine, the four air inlets for which are in the wing roots. Two lateral jettisonable boosters are attached for the launch phase. Target information can be derived from radar, active or passive search systems, or external data sources such as data link. The ability to gyro-angle the missile through ±200° obviates the need for any ship manoeuvres at launch.

Firing of a Matra Compact Otomat from an 8-cell launcher installation

Since stemming from a common origin in a joint Franco/Italian collaborative development programme begun in 1969 (see below), the Otomat system has evolved in several distinct Italian and French versions. However, considerable commonality exists between the OTO Melara and Matra models. The following paragraphs summarise the main differences.

A new homing head produced by the Italian SMA (Segnalamento Marittimo ed Aero) company allows Otomat to follow a sea-skimming flight path up to the point of impact with the target.

A Mk II version of the Italian Otomat has been developed by OTO Melara, the principal feature of which is the provision for mid-course guidance updating, thus permitting increased range (up to 200 km). This version has been adopted by the Italian Navy in which Service it is designated TESEO (see below).

Subsequent to launching, the Otomat follows a cruise phase towards the target's predicted position, flying at low-level under radio altimeter control and autopilot guidance. An active homing head is used for the terminal phase.

The Otomat is compatible with any normal target designation radar and fire control system.

The Otomat Mk II as used by the Italian Navy employs a command system that provides over-the-horizon operation. The complete sub-system comprises a shipboard guidance set (TG1), a missile transponder and an aircraft transmitter (TG2). Both the shipboard and airborne elements are comprised of items from the Marconi Italiana PRT 400 Series midcourse guidance system.

The PRT401 comprises a high-gain directional antenna, stabilised in pitch and roll, and below-deck equipment. The latter includes all control command and tracking units, and a high-power microwave transmitter, a high-sensitivity receiver and a four-channel position plot data extractor, all interfaced with the system main computer. In the missile, the PRT402 equipment consists of receiver and transmitter antenna heads and a transceiver with RF sections and signal processor facilities. The PRT403 consists of two units, a high-gain rotating microwave antenna, and a transmitter, for mid-course missile guidance purposes.

There are several additional items in the PRT 400 series to extend the Otomat range of operational facilities. A lightweight shipborne guidance system, PRT 404 consists of a solid-state transceiver unit and a two-axis stabilised high gain antenna. The former contains a receiver, four-channel position data plot extractor and a klystron-powered transmitter, all interfaced with the system main computer. The PRT 404 is suitable for Otomat installations in hydrofoils, such as the Italian *Sparviero*, or fast patrol craft.

The PRT 405 is a helicopter tracking and two-way data link for use in Otomat midcourse guidance beyond the horizon. There are three separate units: transceiver, omni-directional antenna, and a display/keyboard panel. Total weight is under 14 kg and the system is thought to have been fitted in Italian AB212 helicopters.

To enable the Otomat guidance system to be used for operation of Ikara anti-submarine missiles (**6002.241**), a missile transponder that is located in an Ikara tail fin has been developed, designated the PRT 406. This is an all solid-state unit weighing less than seven kg.

A new folding-wing version of the Italian Otomat missile, and new smaller lightweight launchers were revealed publicly in 1984. At the same event (Mostra Navale, Genoa) a project to develop a system that will combine Otomat with the Ikara ASW missile system was disclosed. For the latter scheme a different type of launcher is employed to house a folding wing version of Ikara and the Otomat guidance system is used to provide both anti-ship missile and ASW guidance facilities.

The French Otomat Compact system also employs folding wings and a lightweight launcher, and this Mk II system uses the ERATO (extended range automatic targeting of Otomat) guidance system that can control up to eight or 16 missiles on four or eight launcher deck mountings. The main feature of this system is its value in utilising the full operational range of the Otomat missile by virtue of the update procedure. It allows salvo firing, with two successive missiles fired at three second intervals; several missiles in flight can be handled at the same time, attacking one or several targets.

In this technique the helicopter or maritime patrol aircraft measures the bearing and range of the surface target and transmits them by data link to the launch ship. Meanwhile the latter measures the bearing and range of the helicopter and computes the co-ordinates with respect to its own position. After firing, in the midcourse phase of missile flight, a fresh complete detection and calculation process is carried out and correction commands are sent to the missile by a telecommand transmitter. Two-axis active radar terminal homing is an advantage, permitting choice of sea-skimming or climb-and-dive attack profile.

DEVELOPMENT

Development was started in 1969 with OTO Melara and Matra working in collaboration. Manufacturers' tests were carried out from 1970 to 1974. The production of series missiles began in 1975-76 for the Italian Navy and several other customers.

Milestones in the French development include:

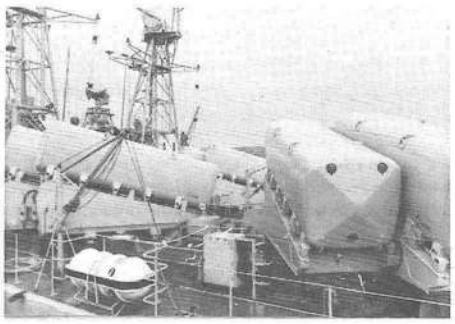
1979: Qualification at sea board the frigate *Le Basque*.

1980: First firing (in May) beyond 100 km in the 'fire and update' mode.

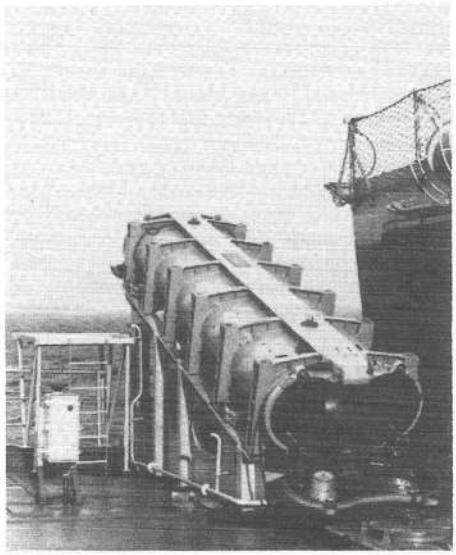
1983: In November final qualification tests at sea of Otomat Compact with the latest version of the Erato ship-to-ship FCS for export sales completed with successful 100+ km firing from *Ile d'Oleron*.

STATUS

In series production in France and Italy. Operational with a number of navies.



It is not possible to identify the respective Italian and French production or sales figures, but the total number of missiles ordered by March 1984 was well in excess of 750 rounds which will be deployed on more than 80 ships of various classes belonging to at least seven navies. There are also coastal batteries which use Otomat (**1337.121**). The Teseo/Otomat system is being procured for Egyptian, Iraqi, Italian, Libyan, Nigerian, Peruvian, Saudi Arabian, and Venezuelan forces.



In April 1985 a French Otomat Compact missile was given an offset launch under Saudi Arabian command at the French Mediterrannean Test Centre from the Frigate '*Madina*'. The ERATO guidance system was employed with target designation from the ship's Dauphin helicopter and a moving target was hit at a range of 107 km.

GABRIEL SHIPBORNE SURFACE-TO-SURFACE MISSILE

Gabriel is a shipborne anti-ship missile developed in Israel and designed for installation in ships from about 50 tons upwards.

A sea-skimmer, the missile is transported in, stored in, and launched from hermetically sealed, reinforced fibreglass containers which also hold the missile launching rail and the hydraulically-operated container door. The missile is pre-adjusted and tested and requires no further tests or adjustments after installation. The standard launcher is a single fixed cell. An optional configuration is three missile cells mounted on a single, rotatable pedestal. The missile, whose general configuration can be seen from the accompanying photographs, is powered by a solid-propellant rocket motor.

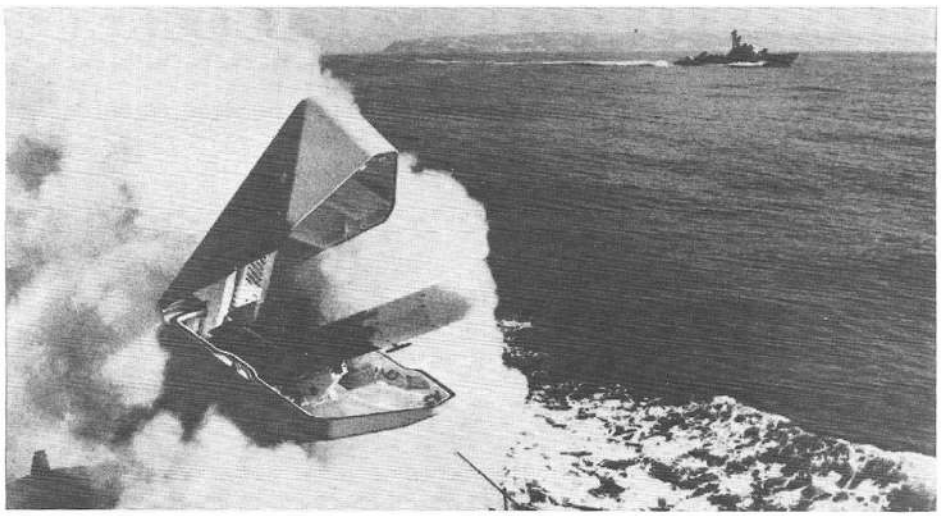
A sophisticated guidance and homing electronics system is carried by the missile, which was developed in Israel.

After initialisation, using target data obtained from the launching vessel's own sensors, Gabriel is launched on a cruise flight path to the target area under twin-gyro platform plus radio altimeter control. The first part of the trajectory is flown at about 100 m followed by a descent to about 20 m for the major part of the flight. After target acquisition, and depending on sea state, the missile may descend to a still lower height for the terminal homing phase. Despite

Latest Gabriel anti-ship missile seeker uses planar scanner and modular electronics (T.J. Gander)

statements that semi-active radar homing is employed, it is thought that the basic terminal guidance mode is I/J-band (former X-band) active radar, together with additional optional modes such as 'home-on-jam', and optical plus command link. A frequency-agility capability in the radar homing system has been reported.

A manual/optical alternative control system is available for use in conditions where radar guidance is not practical, provided the ship is fitted with the requisite sensors.



Three models of Gabriel have been produced, the Mk II having approximately double the range of the Mk I model (ie about 36 km) but in most other characteristics being the same or very similar. The Mk III model ,however, has a longer range but also is larger and heavier, using active radar guidance, and has enhanced performance.

Three modes of operation have been outlined for Gabriel Mk III, known to the manufacturers as:

(1) Fire and forget (F & F)
(2) Fire and update (F & U)
(3) Fire and control (F & C)

In the F & F mode, target detection is by means of the launching ship's search radar and the missile is despatched to the target area to acquire and engage a designated target without additional data or actions after launch. Using the F & U mode, target data is updated by data link during the missile flight, this reducing uncertainty of target location, increasing hit probability and decreasing the effects of enemy ECM. For the final mode, F & C, the ship's fire control radar is used to provide more precise target data for use in guiding the Gabriel missile. Other ship's systems, eg optical fire directors, data automation systems, etc, may be linked with the Gabriel system in the F & C mode.

The missile control console is manned by one operator and incorporates: a PPI display of targets designated for engagement by Gabriel; search radar raw video PPI presentation; alphanumeric data display; target designation to missile facilities; and launch controls. A missile control unit (MCU) computes all pre-launch data and controls the firing sequence, and the automatic tracking computer (ATC) in the same unit computes track-while-scan data and designates targets to the FCS, using video signals from various sensors.

Launch of Gabriel III anti-ship missile

CHARACTERISTICS

Model	**Mk I**	**Mk II**	**Mk III**
Length	3·35 m	3·41 m	3·81 m
Diameter	34 cm	34 cm	34 cm
Wingspan	1·35 m	1·35 m	1·35 m
Launch weight	430 kg	520 kg	560 kg
Warhead	*c* 100 kg	*c* 100 kg	*c* 150 kg
Propulsion	Solid, 2-stage rocket		
Speed	Mach 0·7		
Range	18 km	36 km	36 km +

STATUS

Developed in Israel during the 1960s, the missile is now operational in fast patrol boats of the Israeli Navy, and is in service with at least five other countries, according to Israeli sources.

Sales and fittings of Gabriel are not widely publicised but it is no secret that the Israeli Navy operates the system aboard the 'Saar' class missile boats, and the 'Reshef' class boats. Other operators (some officially unconfirmed) are Argentina, Malaysia, Singapore, South Africa and Taiwan. One of the latest foreign users of the system to be identified was Brazil, whose new corvettes are fitted.

The Mk II Gabriel became operational in the mid-1970s and the improved Mk III version entered service in 1979/80. In the course of 1982 an air-launched version was introduced and this is illustrated and described in entry **4529.321**.

Military parades in the city of Taipei in Taiwan have revealed a number of missiles having a marked similarity to Gabriel, mounted on the backs of military trucks. These are claimed to be of Taiwanese design and manufacture, and were named Hsiung Feng (male bee). It has been stated that these were for coastal defence applications. A comparison of photographs leaves little doubt that the Hsiung Feng and Gabriel are virtually identical in design. Further details appear in entry **4442.121**.

In June 1985 it was disclosed that a long range version of Gabriel was being developed to have an anticipated maximum range of 200 km. Inertial mid-course guidance with data link up-dating and active radar terminal homing are among the advance details reported. Others include a turbojet cruise motor and solid propellant booster motor. The new Gabriel model is expected to have a larger diameter and increased weight and other dimensions.

SEA KILLER Mk 2

The Sea Killer Mk 2 is a surface-to-surface tactical missile; powered by two rocket motors it can be launched either from deck-fixed launchers or from a trainable five-round multiple launcher and uses beam-riding plus radar altimeter guidance supplemented by radio command guidance when required. The missile's ability to cruise close to the surface of the sea is operationally important.

Sea Killer Mk 2 is intended to be integrated with a conically scanning radar assisting a fire control system, the missile check out, firing, and guidance control being centralised in the missile control console. No launcher crew and no shipboard maintenance of missiles is required.

CHARACTERISTICS

Type: Shipborne medium-range surface-to-surface tactical guided missile
Guidance principle: Beam-rider/radio command/radio altimeter plus optical/radio command guidance in interference conditions
Guidance method: By control of movable cruciform surfaces at mid-point on body. Stabilisation by cruciform tail fins
Propulsion: Solid-propellant booster and sustainer. SEP 4000 kg st and SEP 100 kg st
Warhead: Semi-armour-piercing HE (70 kg). Impact and proximity fuzes
Missile length: 4·7 m
Missile diameter: Body: 0·206 m. Span: 0·999 m
Launch weight: 300 kg
Speed: Transonic. Subsonic after burn-out
Range: 25 km

Sea Killer Mk 2 launch

DEVELOPMENT

Development was initiated in 1965 and the first prototype was completed in 1969. The system was fitted in four Vosper Mk 5 frigates of the Iranian Navy but how many are operational now is not known.

The Mk 2 version is used in the Marte helicopter-launched anti-ship missile system (**1651.321**).

NORWAY

1339.221
PENGUIN ANTI-SHIP MISSILE

Penguin is a surface-launched anti-shipping missile primarily intended to provide small, fast naval craft with a powerful striking capability against larger vessels. It carries a 120 kg Bullpup ASM-N-7A warhead at Mach 0·8 over a range of at least 30 km. An impact fuze is fitted and the boost and sustainer motor is solid-propellant powered.

The missile is mounted on a simple launcher which is built into a container which serves as protection against weather and also serves as packing for transport to and from the ship. This unit, the box-launcher, is delivered as a sealed and tested item from the base to the ship. Combined weight of box-launcher and missile is about 650 kg. Typical ship installations comprise six or more deck-mounted box-launchers. These are located on prepared mounts which incorporate an umbilical cord connection. When fitted, the missiles are ready for immediate firing and no onboard service or repair is performed. Automatic testing can be effected from the missile control panel in the operations room.

OPERATION

The Penguin missile employs inertial guidance for the cruise phase of its flight path, with passive infra-red homing to the target for the terminal phase. After launch the missile is thus independent of the parent vessel which is thereby freed to take evasive action or engage a further target.

Design requirements include missile range comparable to the maximum effective radar range for fast patrol boats and a passive mode of operation. Target detection, acquisition, and designation is therefore by means of the launch vessel's radar and fire control system. Upon target acquisition, the fire control computer calculates the bearing to the predicted point of impact and the missile inertial guidance system is automatically slaved to the Kongsberg SM-3 computer data. The missile is then fired in the general direction of the target. After launch, the missile follows a programmed trajectory toward the predicted impact area. This programme can be varied.

Prior to acquisition of the target by the missile's infra-red homing system this operates in a search mode, scanning a sector ahead of the flight path. Upon detection of the target, the homing system tracks the target and generates signals which are used to direct the missile to the target.

The Norwegian operational requirements relating to the Penguin system call for a warhead capable of inflicting serious damage on a destroyer.

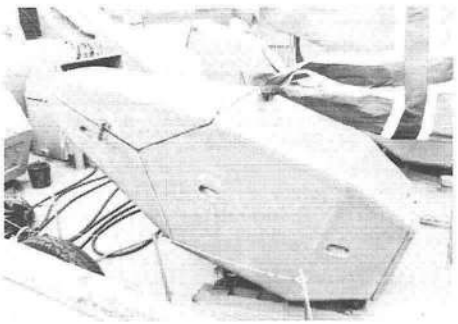
CHARACTERISTICS

Type: Shipborne surface-to-surface tactical guided missile
Guidance principle: Inertial en route guidance with infra-red terminal homing
Guidance method: Aerodynamic by moving canard surfaces
Propulsion: 2-stage solid-propellant motor
Warhead: 120 kg semi-armour-piercing. Impact fuze
Length: 3 m
Diameter: 28 cm
Span: 1·4 m
Launch weight: 340 kg
Weight with box-launcher: 650 kg
Cruising speed: Mach 0·8
Range: Mk 1, 20 km; Mk 2, 30 km (max); 2·5 km (minimum)

DEVELOPMENT

Development was initiated in the early 1960s at the Norwegian Defence Research Establishment as a response to an assessment of Royal Norwegian Navy requirements. These two bodies and A/S Kongsberg Våpenfabrikk have worked in close co-operation since the inception of the programme.

Although originally designed for deployment on smaller naval craft, the Penguin system is well suited to use on larger vessels. It is also being constructed for use in coastal defence and from helicopters. In the latter case, minor modifications only are stated to be necessary. Additionally, a redesigned version Mk 3 without the booster motor and with a smaller wingspan is now being developed for use from jet fighters such as the F-16.



STATUS

Operational in 'Storm', 'Snoegg', and 'Hauk' class patrol boats and 'Oslo' class frigates of the Norwegian Navy, and on 'Kartal' class patrol boats of the Turkish Navy. The Penguin missile system is also fitted in Royal Swedish Navy 'Hugin' class patrol boats, and in 'Combattante IIIB' fast patrol boats of the Hellenic Navy.

The USN has completed a full scale technical and operational evaluation at the Naval Weapons Centre, Dahlgren laboratory and at Noto, Cape Canaveral. Penguin installation is under study for USN ships and helicopters as well as for the US Coast Guard.

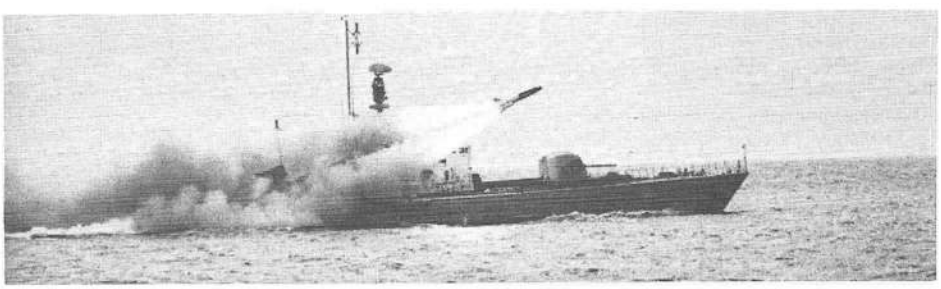
SKORPIOEN ANTI-SHIP MISSILE

Skorpioen is believed to be the name under which the South African Navy operates the Israeli Gabriel II anti-ship missiles (**6019.221**) which arm the first six 'Mod' class fast attack craft serving with the SAN. These vessels are similar to the Israeli Saar class and three of them were constructed in Haifa, reaching South Africa in July 1978. It has not been established whether or not facilities have been provided for manufacture of this weapon under licence in South Africa, but no other fittings of the system have been reported on other SAN vessels, which suggests that to date the quantities required have not called for any alternative to supply from Israeli sources. For details of operation, performance etc readers are referred to the entry for Gabriel.



SWEDEN

3976.221
RBS 15 ANTI-SHIP MISSILE

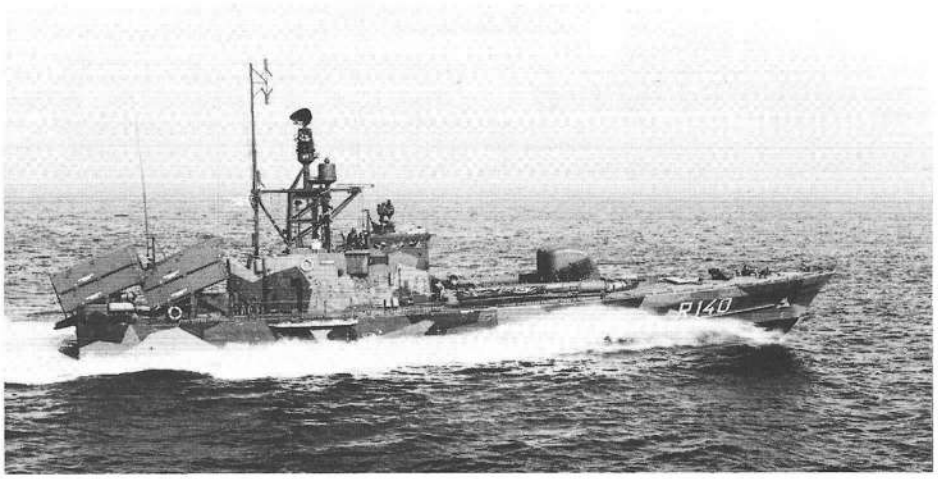
RBS 15 is the designation of a new generation Swedish anti-ship missile system suitable for use by both Swedish Air Force aircraft and Swedish naval vessels. The first installation has been completed aboard the Royal Swedish Navy 'Spica' class fast patrol boats, each able to carry eight missiles. They are housed in launcher/containers. The air-launch model (**3975.321**) programme is following, and the manufacturers' programme also includes a coastal defence version of the RBS 15.

The general configuration of the RBS 15 can be seen from the nearby illustrations and the air intake below the missile body will be noted. An air-breathing propulsion system has been decided on to provide long range allied to a high subsonic cruise speed at sea-skimming heights. Two solid-propellant booster motors will aid launch, but these will not be required in the air-launch mode. The mission profile can include a high-level cruise phase over a preset distance, a low-level cruise phase during which the seeker head is switched on and target acquisition takes place, followed by a sea-skimming final trajectory.

RBS 15 has a launch and leave capability and is

Launch of RBS 15 sea-skimmer anti-ship missile from Swedish Spica boat HMS Piteå

provided with an ECM-resistant homing head which will be delivered by Philips Elektronikindustrier. Prelaunch operations is minimal in scope and all calculations are performed automatically by an on-board computer. A radar altimeter ensures safe missile cruise at low levels above the sea surface.



CHARACTERISTICS

Length: 4·35 m
Diameter: 50 cm
Wing span: 1·4 m; 85 cm (folded)
Launch weight: 770 kg
Weight: 600 kg (without boosters)
Guidance: Probably programmed autopilot cruise with height hold, followed by active radar homing
Range: 150 km (estimated)
Cruising speed: >Mach 0·8

STATUS

Series production. A contract worth Skr600 million for the development and production of the naval version was awarded to Saab Bofors Missile Corporation (SBMC) by the Swedish Defence Material Administration in July 1979, and in June 1982 a contract was awarded for the air-launched version. SBMC, a company formed by Saab Missies AB and Bofors, is serving as the main contractor. Saab Missiles is the prime contractor for RBS 15.

The first export order for RBS15 was placed in March 1983 when a contract for the system to be fitted in new 'Helsinki' class fast patrol boats for the Finnish Naval Forces was signed. The RBS 15 will be the main armament of this class of ship.

Eight launcher/containers for the RBS 15 anti-ship missile system are fitted near stern of this Swedish fast patrol boat

RB 08A

RB 08A is a surface-to-surface long-range cruise missile system intended for coastal defence and ship-to-ship use.

Based on the Nord CT 20 target drone, the missile is a rocket-launched turbojet-powered monoplane carrying a warhead large enough to destroy an average freighter. The complete system comprises the missile, the fire control system, the starting box and the launchers; of these the missile and starting box are common while the fire control system and launchers used vary according to the type of system (static coastal, mobile coastal, shipborne). The missiles are easily transported: the wings fold, and the amount of other equipment required for a mobile battery is not great.

The range of the system is not disclosed, but it may be noted that the Nord CT 20 drone has an endurance of 60 minutes and a maximum speed of 900 km/h at 10 000 m. Since the all-up weight of the RB 08 is considerably greater than that of the CT 20 and since the RB 08 has the same power plant as that version of the CT 20 to which the figures above refer, a substantial reduction in endurance must be expected; nevertheless it seems probable that the system range is more likely to be limited by other factors than by the range capability of the missile.

SYSTEM DESCRIPTION

The target is detected (by radar or by other means such as patrol boats or reconnaissance aircraft) and the target data are sent to a fire control director assisted by a computer. On the basis of these data and missile performance, the computer gives orders to the launcher.

The missile is launched by a booster unit which separates when expended. After climbing and further acceleration the missile reaches cruising altitude and speed; the climb being interrupted at a pre-set altitude which is then held by a constant altitude device. In the last part of the flight the missile is guided towards the target by the homing equipment.

AUTOPILOT

The autopilot consists of a constant altitude device, a programmer, two free gyros, one rate gyro, a signal transforming head, and logic circuits. Signals from the homing head, the constant altitude device, and the gyros are converted to steering signals fed to the wing spoilers and the elevator actuator. Pitch demands are met by elevator movement; yaw demands are met by actuating the spoilers to roll the missile and then by elevator movement.

HOMING EQUIPMENT

No details have been released concerning the operation of the homing equipment, but it seems likely that it is a radar operating in one of the higher frequency bands and capable of distinguishing between the target vessel and the surrounding sea clutter. The homing head is mounted in the nose of the missile; the warhead is mounted in the middle of the fuselage. It has been reported in France that homing heads for the RB 08A are supplied by Thomson-CSF.

CHARACTERISTICS

Type: Surface-to-surface cruise missile system
Guidance principle: Directional launch, followed by autopilot control, terminal guidance probably active radar homing
Power plant: Turboméca Marboré IID (400 kg static thrust). Booster rocket assembly for launch
Span: 3·01 m
Length: 5·72 m
Height: 1·33 m
Missile gross weight: 900 kg
Booster unit weight: 315 kg
Total launch weight: 1215 kg

STATUS

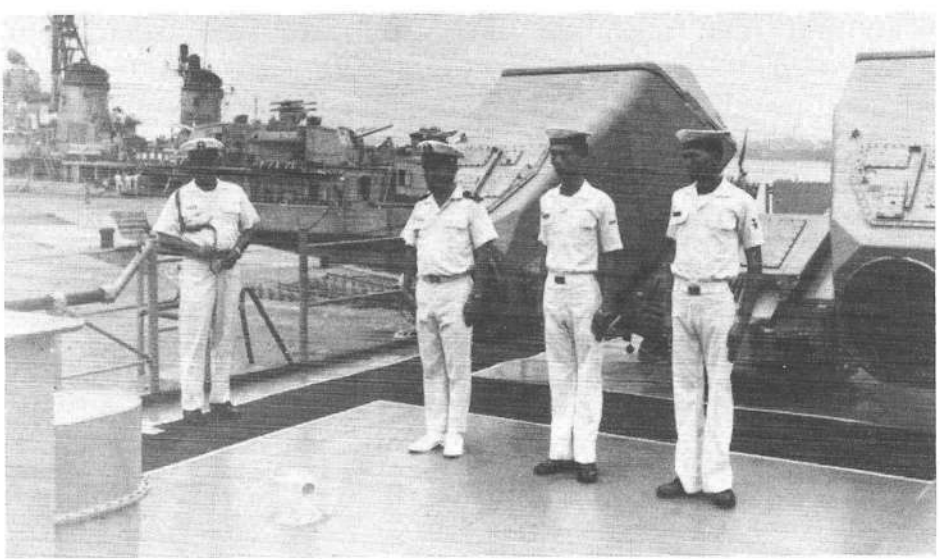
Operational with the Swedish Armed Forces but in the process of being replaced by a new advanced missile system (the RBS 15, **3976.221**) for fast patrol boats.

CONTRACTORS

Prime contractor: Saab Missiles AB, Linköping, Sweden.
Missile body and autopilot: Aérospatiale, France.
Turbojet engine: Turboméca, France.
Electronics: Thomson-CSF, France; Standard Radio and Telefon AB, Sweden; AB Jungner, Sweden.

TAIWAN

4443.221
HSIUNG FENG ANTI-SHIP MISSILE



This is apparently a licence-built Taiwanese version of the Israeli Gabriel anti-ship missile. As described in the entry for the coastal defence application of this weapon (**4442.121**) the many similarities between the Gabriel and the Hsiung Feng include the triple launcher which originally was a noteworthy feature of the Israeli system, and therefore the main performance characteristics and other details are assumed to be essentially identical. Readers are recommended to consult the above entry and that for Gabriel (**6019.221**) to enable the performance and operational features of Hsiung Feng to be estimated.

STATUS

Hsiung Feng anti-ship missiles are reported to be fitted aboard Taiwanese destroyers of the US 'Gearing' and 'Allen M Sumner' classes, in triple launcher configuration, and in single launchers aboard two classes of fast attack craft. In many installations the missiles are associated with Selenia Orion RTN-10X fire control radars.

CONTRACTOR

UNION OF SOVIET SOCIALIST REPUBLICS

1155.221

STYX SHIPBORNE SURFACE-TO-SURFACE MISSILE (SS-N-2)

The SS-N-2 Styx anti-ship missile is a short/medium range weapon which is very widely deployed by the Soviet Fleet and the navies of many of its allies. Entry into service was in 1959 or 1960, but despite the length of service this indicates, new Styx installations are apparently still being made. This weapon also has the distinction of being the first of its type to have been used operationally, in the 1967 war between Israel and Egypt, and later by Indian ships against Pakistan vessels in December 1971. More recently it has apparently been given a new lease of life by its employment in the coastal defence role with an entirely new ground system (**4890.121**) with East German, Syrian and Yugoslav forces.

The general configuration is that of a small aircraft, with a delta planform wing and a triple tail-surface arrangement. A jettisonable booster rocket is used for the launch and acceleration phases, after which an internal motor sustains a cruising speed of about Mach 0·9. Range of early models is estimated as about 20 nm (40 km) maximum.

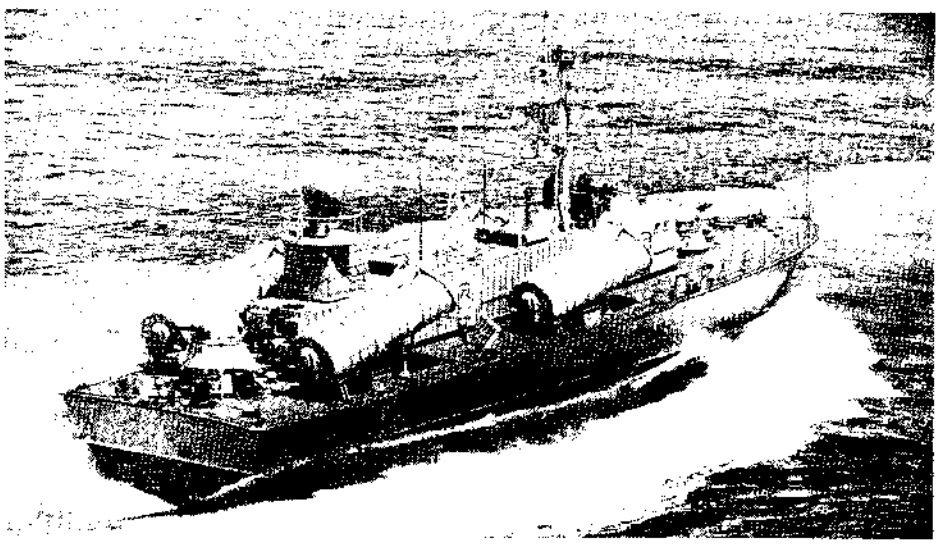
Three distinct versions have been reported, identified as the SS-N-2A, B and C models, respectively. Soviet designations applied to this series of Styx missiles include 4K-40 and P-15. The main known difference between the first two is that the SS-N-2A has fixed wings while those of the SS-N-2B fold, and this variation is reflected in the housing for the two different models. Less is known of the SS-N-2C apart from its performance characteristics, which are thought to include an increased range of some 80 km and a sea-skimming terminal trajectory. The latter can be preset to a limit of 300 m, and a third party (eg helicopter or fixed-wing aircraft) may be employed for guidance updating at extended ranges. The SS-N-2C is also credited with a heavier warhead.

During the relatively long service life of Styx it is probable that several guidance modes have been employed, and references probably relate to various combinations of the following alternatives: (1) the cruise phase could be carried out under either autopilot or radio command guidance; (2) the terminal phase could rely upon continuation of command guidance, active radar, or infra-red homing. Over the years, the launchers/hangars associated with Styx have undergone progressive changes and it seems reasonable to assume that the guidance apparatus also has received periodic updating, in which case all of the above methods may be employed in different installations.

The three types available with the Chinese-built version (HY-2, **3973.221** and **3984.121**) probably represent the methods most favoured by the originators and other operators of the system, and readers are referred to those entries for additional data.

CHARACTERISTICS (PROVISIONAL)

Length: 6·25 m
Diameter: 75 cm
Span (max): 2·75 m
Weight: 2300 kg
Warhead: HE 400 kg (2A/2B); 450 kg (2C)
Range: 40 km (2A/2B); 80 km (2C)
Speed: High subsonic



STATUS

Styx has been in operational service in its SS-N-2A version since 1959 or 1960 and is now widely deployed with Soviet Navy forces and those of numerous friendly states. Most widespread are the fittings on board the 'Osa' and 'Komar' class missile boats. The SS-N-2B model appeared in 1965.

Since the appearance of SS-N-2 missiles on 'Osa' and 'Komar' boats, there have been fittings on a number of other classes of ship, both Soviet and foreign. A later class of 'Osa' missile boat has also appeared ('Osa II') on which a new missile was deployed. This was (and in some quarters still is) known as the SS-N-11 but is more correctly designated SS-N-2B to acknowledge its relationship with the earlier Styx.

A total of more than 150 'Osa' class missile boats have been transferred to foreign navies, including those of: Algeria, Bulgaria, Cuba, Egypt, East Germany, Ethiopia, Finland, India, Iraq, North Korea, Libya, Poland, Romania, Somalia, Syria, South Yemen, Viet-Nam and Yugoslavia.

The People's Republic of China is another important user of SS-N-2 where it is produced as the HY-2 after having been supplied with initial quantities of Styx missiles and 'Komar' and 'Osa' missile boats. In addition, China seems to have been the first nation to add Styx to the armament of larger vessels. The 'Luda' class of destroyers of indigenous design, but based on the Soviet 'Kotlin' class in some respects, has launchers for Styx (Chinese version) amidships. China has a number of Styx missiles deployed as coastal defence weapons. (See also **3984.121** and **3973.221** for Chinese applications of the SS-N-2.)

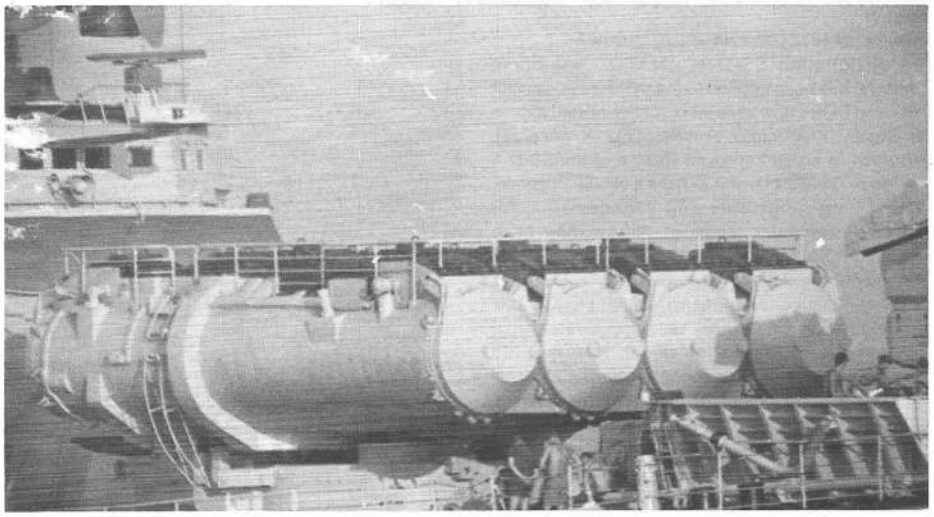
2976.221

SHADDOCK SHIPBORNE SURFACE-TO-SURFACE MISSILE (SS-N-3)

Shaddock is the largest of the Soviet cruise missiles. It is not known to what extent, if any, the missile that is installed in many surface vessels and submarines of the Soviet Navy differs from the Shaddock missile displayed (in its container) at Moscow parades and used by Soviet land forces (NATO code-name Sepal, **2975.121**), but it is generally assumed that there are some differences: moreover it appears that there are several different missiles of the Shaddock type in naval use. These have been designated SS-N-3A, SS-N-3B and SS-N-3C, while versions or derivatives fitted in later classes of ship have provisionally been numbered SS-N-12 in the American sequence and given the NATO name 'Sandbox'. Soviet designations that are or have been associated with this family of weapons include: P-6/P-7 with Shaddock, and P-35 with Sepal.



Shaddock launchers on a 'Kresta I' guided missile armed destroyer (USN)

Command guidance is used, and for surface vessel installations the missile is tracked by Scoop Pair radar (**1324.253**) and course corrections transmitted to it by radio. Soviet technical literature has described methods of terrain following for cruise missiles, without referring to any specific missile but it is quite probable that a measure of terrain following capability is provided for Shaddock in its overland role. This relies upon a radio altimeter which would also be useful in the anti-ship uses of Shaddock. For the terminal phase it is believed that infra-red homing is used: but it may be assumed with some confidence that this is one feature of the missile that will have been affected by modifications in the 10 years or so that these missiles have been in service, the most likely development being the provision of an active radar homing head.

Missile speed is believed to be transonic and range is limited mainly by radio/radar horizons. With mid-course guidance the maximum achievable range is believed to be at least 450 km, but practical ranges are nearer to 180 km for missiles launched from cruisers and less than that for submarine-launched missiles.

It is believed that the standard warhead is nuclear with a yield in the 350 KT range, although the existence of alternative warheads of about 1000 kg HE and a strategic 800 KT warhead has been reported.

One of the most interesting aspects of this weapon system is the extent to which it has been installed in submarines and the length to which the Soviet engineers have gone to find the most satisfactory form of installation. Of several types of submarine installation the most elaborate is the four-missile arrangement in the 'W' class 'Long Bin' submarine which involves the insertion of an additional section, about 6·5 m long, into the submarine hull and constructing thereon a streamlined conning tower in which are built four forward-firing missile launchers, in two pairs both inclined to the horizontal by about 15°. Other boats of this class have what is known as the 'Twin Cylinder' fitting, in which two missile containers are attached to the submarine's outer casing.

Close-up reveals massive proportions of quad Shaddock launcher aboard Kynda-class cruiser 'Grozny' (G. Jacobs)

STATUS

Shaddock-type missiles are installed operationally in 'Kresta I' and 'Kynda' class guided missile cruisers and in submarine classes 'E2', 'J', and 'W'. The nuclear-powered 'E2' submarines carry eight missiles in pairs, the launchers being let into the hull so as to present a smooth surface. The 'J' class non-nuclear submarines have similar launching arrangements for four missiles. In the 'W' class submarines two arrangements are still current, one being the 'Long Bin' arrangement described above and the other the 'Twin Cylinder' arrangement in which two launching tubes are mounted on the deck aft of the conning tower.

The 'Kynda' class carry quadruple launchers fore and aft and carry further missiles with which to reload the launchers. The 'Kresta' launchers and all the submarine launchers can be elevated for firing but cannot be trained. The 'Kynda' launchers, on the other hand, can be trained through about 250° and elevated up to about 30°.

Submarines are believed to be armed with the 'A' version, while the 'Kresta I' and 'Kynda' classes of surface ship have the 'B' model. The SS-N-3C is thought to be a strategic variant.

Shaddock is also deployed in a land-mobile role as a coastal defence weapon under the NATO designation 'Sepal' (**2975.121**).

2987.411

SS-N-7 SUBMARINE LAUNCHED CRUISE MISSILE

Little is known about this weapon other than that it is one of the family of cruise missiles developed in recent years in the Soviet Union, that it is carried by 'C' class Soviet nuclear submarines, on a scale of eight vertical tube launchers per submarine and that it can be launched while the submarine is submerged.

The missile is said to have autopilot control and assumed to employ a radar homing system. Range has been variously reported between 45 and 53 km and it has been suggested that over a large part of its flight path it operates as a surface skimmer. Other provisional characteristics attributed to the SS-N-7 are a length of about seven metres, either a 500 kg HE or 200 KT nuclear warhead, and a solid-propellant rocket giving a high subsonic cruising speed.

The submarine launch capability of this missile is undoubtedly one of the causes of the recent flurry of interest in submarine-launched tactical missiles among NATO countries. Most proposals currently under consideration in those countries, however, contemplate the use of standard torpedo tubes as launchers, presumably because of the difficulty of retrofitting anything larger without denying the submarine the option of firing conventional torpedoes.

1760.221

SS-N-9 (SIREN) SHIPBORNE SURFACE-TO-SURFACE MISSILE

The designation SS-N-9 has been allocated to the surface-to-surface missiles carried in the two triple launcher/containers aboard the Soviet 'Nanuchka' class missile boats which made their appearance in 1969. To date, no pictures or official details of the missiles themselves have been made public, and hence performance figures must be regarded as provisional. No other class of vessel has been definitely associated with the SS-N-9, to which the NATO code-name Siren has been assigned. It has been conjectured, however, that the anticipated new 'Papa' class of Soviet submarine may employ SS-N-9 or a derivative as its cruise missile armament, although the existing SS-N-7 may be retained for this class of boat.

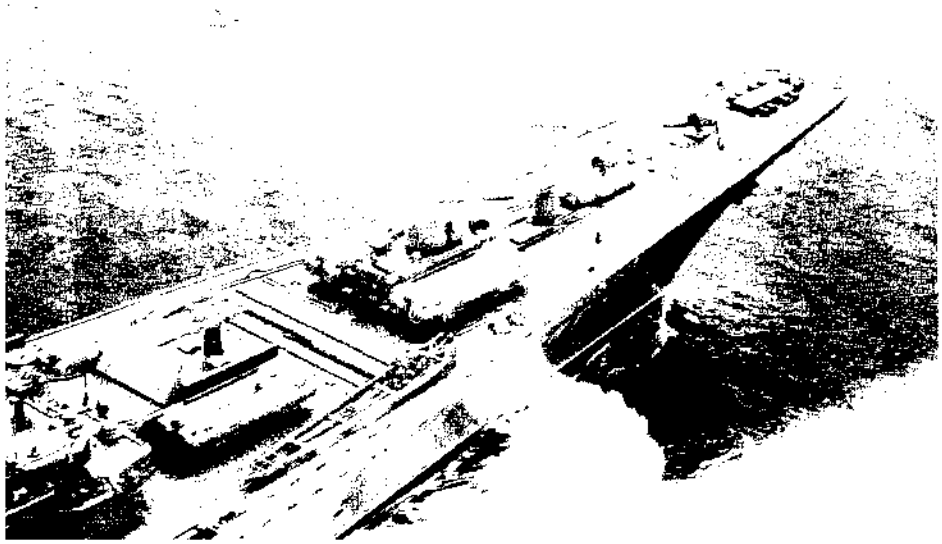
The original estimated range of the SS-N-9 of up to 150 nm (about 275 km) with external mid-course guidance by co-operating aircraft or helicopter was subsequently revised downward. A normal operating range of about 40 nm (about 75 km) seems likely and American and British sources quote a maximum of 60 nm (about 110 km). The missile is estimated to be about 8·9 metres long. Autopilot, with or without radio command link guidance, is the probable method of cruise phase control and active radar homing may be the normal terminal homing technique. The associated search and fire control radar group on 'Nanuchka' class vessels is reported to be code-named Band Stand.

Soviet 'Nanuchka' class missile boat. Triple launchers on each side of bridge structure house SS-N-9 surface-to-surface missiles. Also to be seen is the lid of the retractable launcher for the SA-N-4 anti-aircraft missile system on the foredeck (Novosti)

STATUS

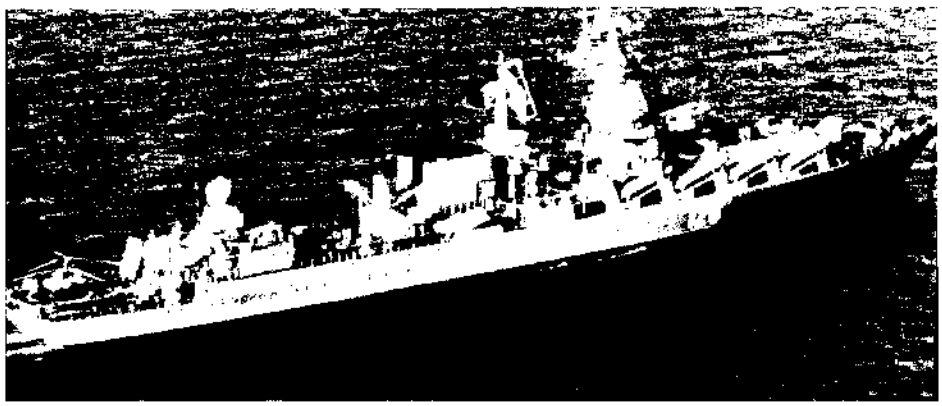
Fittings so far confirmed are confined to the 'Nanuchka' class of missile boats, each of which has two triple launchers, and 'Sarancha' class hydrofoils. However, the possibility of vertical launch SS-N-9 missiles in Soviet 'Papa' class submarines has been reported. 'Nanuchkas' have been supplied to the Indian Navy, but in place of the six SS-N-9 launchers, four container launchers for the SS-N-2B (**1155.221**) cruise missiles are fitted.

4445.221



SS-N-12 (SANDBOX) ANTI-SHIP MISSILE

The designation SS-N-12 (NATO code-name Sandbox) has been applied to the missile system that is housed in the new style of launcher noted aboard the Soviet 'Kiev' class vessels. This is generally presumed to be an improved version of the SS-N-3 Shaddock (**2976.221**), and to have a similar purpose, namely long-range anti-ship engagements. An estimated maximum range of 550 km has been suggested. So far there are no known publicly released photographs of the actual weapon housed in the SS-N-12 launcher/container so that there is little firm evidence on which to base speculative assessments of the performance. However, its considerable size can be gauged from the external appearance of the launchers and from this it seems reasonable to infer considerable payload/range characteristics. An assessment of late 1983 estimated missile length at approximately 10·8 metres, diameter 90 cm, and wing span 1·8/2·6 metres, (folded/deployed). Another source suggests a maximum speed of Mach 2·5 and, interestingly, an altitude capability of over 10,000 metres. Operating at levels such as this, a need for mid-course guidance assistance from a co-operating helicopter or fixed-wing aircraft might well be eliminated. Autopilot/inertial guidance, probably aided by a degree of command updating at intervals and active radar terminal guidance would appear to be the most likely form of operation. The relatively long range assumed would also suggest that facilities for mid-course guidance by a co-operating aircraft would be a useful capability in the SS-N-12 system.



This last feature would be particularly valuable in the case of Sandbox engagements which involve launches of SS-N-12 missiles from submarines, which would be less well equipped than major surface vessels for providing target designation facilities.

STATUS

The SS-N-12 Sandbox is understood to be deployed aboard aircraft carriers of 'Kiev' class, on which there are eight launcher containers on the foredeck, and the system has also been reported in some 'Echo II' class submarines. The 'Slava' class of missile cruiser was added to the SS-N-12 list of fittings when the first of class appeared with 16 launchers in 1982.

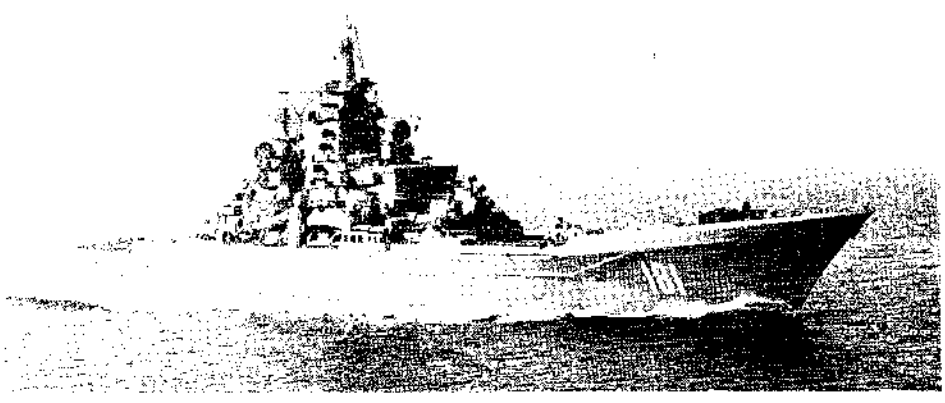
Soviet missile cruisers have 16 launchers for SS-N-12 anti-ship missiles



4196.221

SS-N-19 ANTI-SHIP MISSILE

SS-N-19 is the designation assigned to the vertically-launched anti-ship missile system deployed on the Soviet battle-cruiser *Kirov* and also on 'Oscar' class submarines. Both classes first appeared in 1980, and the former type has 20 launch tubes, while the submarines are able to launch 24 missiles. They could well be intended to operate together (with other vessels) as the nucleus of an 'ocean superiority' task force able to challenge western fleets over wide areas. *Kirov* and 'Oscar' class submarines are nuclear powered.

Very few details of the SS-N-19 missile system have been disclosed by official sources in the West (still less in Warsaw Pact states) but estimates that have been made are summarised here.

The main role is that of an anti-ship weapon, with a range of up to 550 km flying at supersonic speed (at least Mach 2·5 has been quoted, but this could well be an over-estimate), and both conventional HE and nuclear warhead payloads are thought to be available. Initially it was pointed out that no radar system associated with the SS-N-19 has been identified (on either 'Oscar' submarines or the *Kirov*), and with a range of 550 km such a sensor could be of only partial relevance, due to the line-of-sight range limitations of radar. However, later analyses have claimed an association between the SS-N-19 Sandbox and a radar code-named Trap Door, which is located in the deckhouse immediately aft of the RBU 6000 anti-submarine rocket launcher in the bow of the ship. The precise functioning of this radar is not clear as it is certainly not sited for maximum line-of-sight range performance. Possibly some form of initial missile capture after vertical launch is received to ensure the missile adopts the proper approach heading to the target. Thereafter it seems probable that inertial guidance, allied to an external target detection and designation system (satellite or aircraft, for instance), with self-contained homing is the likely guidance technique. Among the imposing array of sensors and antennas displayed by the *Kirov* battle-cruiser, it is more than likely that one or other is capable of providing data link or command link facilities for an outgoing SS-N-19 missile during its mid-course phase, for such purposes as target location updating or missile course correction. Clearly submarines would have much less capability in this respect, but if the postulate that *Kirov* and 'Oscar' class submarines are intended to operate together is correct, there is no reason why the submarines should not be employed merely as launch platforms with the surface ship (and its better sensor and communications facilities) acting as the directing and controlling element. It should be noted that the *Kirov* is well provided for helicopter operations; it is estimated that four or five Ka-25 helicopters could be accomodated, possibly including both 'A' anti-submarine and 'B' missile guidance versions.

The Soviet battle-cruiser Kirov, *despite an impressive multiplicity of sensors of all sorts appears at first glance to have little in the way of armament. This impression is aided by the fact that two of the latest Soviet weapon systems fitted in this ship (SS-N-19 and SA-N-6) are vertical launch systems and spend most of their time below decks* (RN)

4761.221
SS-N-22 ANTI-SHIP MISSILE

The designation SS-N-22 has been assigned to the missiles housed in the container/launchers noted aboard the recent Soviet 'Sovremenny' and 'Tarantul II' class ships which made their appearance over the past year or two. The former class fits a total of eight launchers (in two groups of four near the bridge), and the 'Tarantul II' missile corvettes are fitted with two twin launchers.

The assumed role is that of a naval surface-to-surface weapon with a main operational mission of anti-shipping engagements, and until more definite evidence is forthcoming it seems reasonable to accept the general conjecture that the missile itself is a developed version of the SS-N-9 Siren (**1760.221**) first noted in 'Nanuchka' class ships. The first of the two new types to make its appearance (Sovremenny) is also fitted with the Band Stand radar associated with the SS-N-9 on the 'Nanuchka' ships, which tends to support the suggestion of a common lineage for the SS-N-9 and the SS-N-22.

The presumed range of the SS-N-22 is in the 120 km category, but this suggestion probably relates to the missile's autonomous range using own guidance and the shipboard equipment. 'Sovremenny'-class ships, however, have embarked helicopter facilities available that could be employed to provide extended range capability, and this might also be used to facilitate multiple target engagements.

No estimates of missile speed or payload are possible from the extremely limited information so far available, and for similar reasons conjecture about its appearance/configuration and other characteristics is an equally unrewarding exercise.

STATUS

Believed operational in 'Sovremenny' and 'Tarantul II'-class ships.

UNITED KINGDOM

4447.221
SEA EAGLE SL ANTI-SHIP MISSILE

Formerly known as the P5T the Sea Eagle SL is a ship-launched version of the Sea Eagle aircraft-launched anti-ship missile (for details see entry **3630.321** in the Air-to-Surface Missiles section of this book). It is intended for the arming of ships from 200 tonnes upwards and is capable of engaging a target well beyond the horizon. The system comprises missiles, launch boxes and fire control equipment.

Sea Eagle SL has a fire and forget capability derived from an on-board computer and an active radar homing head. Just before firing, target position information is fed into the computer which after launch shapes the flight trajectory. Mid-course correction is made using a bearing reference and the terminal phase is carried out using the active radar head. The homing head is activated by the computer to ensure optimum target acquisition probability with the minimum chance of enemy detection. Two rocket boost motors are used for launch and acceleration to flight speed at which point a small gas turbine provides further propulsion.

On board ship the Sea Eagle SL round is treated as a normal piece of ammunition with no need for first-line maintenance. The missiles are housed in boxes for environmental protection and the boxes also act as launchers. Inside the box the missiles are suspended from an overhead rail with anti-roll guides on the boost motors. The boxes can be arranged in groups of one to six on launch box mountings. Lightweight Sea Dart mountings can accommodate Sea Eagle SL. Salvo firing is possible.

STATUS

Late development.

CONTRACTOR

British Aerospace (BAe) Dynamics Group, Bristol Division, PO Box 5, Filton, Bristol BS12 7QW, England.

4553.221
SEA SKUA SL ANTI-SHIP MISSILE SYSTEM

The Sea Skua ship launched (SL) anti-ship missile is a variant of the Sea Skua helicopter air-to-surface missile (see entry **1530.321** in the Air-to-Surface Missiles section) intended for use on naval vessels as small as 20 metres long. Sea Skua SL comprises the Ferranti Seaspray surveillance and illuminating radar or equivalent and a control console and deck-mounted launch boxes for the missiles.

The control console is operated by one man and would normally be located in the vessel's tactical control centre or on the bridge. The deck launcher is a lightweight unit mounted on the deck and holding one or more launcher boxes for firing. The launcher boxes can be treated as conventional ammunition rounds and double as transport containers. A two-box launcher, with missiles, weighs 850 kg and would be 2·5 metres long and 1·1 metres wide. The control console weighs 140 kg.

In operation Sea Skua SL uses the radar to locate and later illuminate the target. To commence an engagement the console operator selects the missile to be fired (ripple firing is possible) and sets the missile terminal sea skim height. When armed and ready the missile can be launched. During the boost phase the azimuth and height guidance loops are closed and the homing head locks on to the target illumination radar returns. When the boost phase is complete the sustainer motor maintains flight and the missile descends to an interim sea skim height under radio altimeter control. Later in the flight path the missile descends still further to the terminal sea skim height as selected before release. Four heights can be selected by the operator. The homing head then guides the missile in azimuth to target impact. The maximum range of the Sea Skua is 15 km.

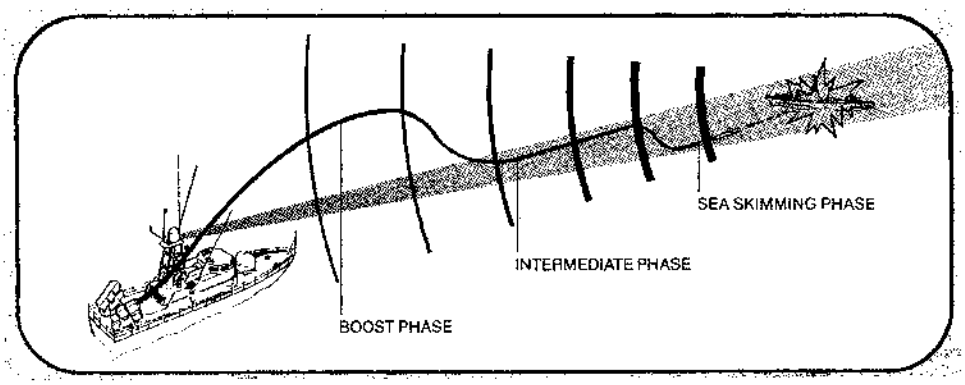


Diagram of typical Sea Skua SL engagement

CHARACTERISTICS

Length: 2·5 m
Body diameter: 0·25 m
Wing span: 0·72 m
Speed: High subsonic
Range: Up to 15 km
Weight of two-box launcher (with missiles): 850 kg
Deck area: 2·5 m long × 1·1 m wide
Console (weight): 180 kg
Console dimensions: 975 × 600 mm × 1 m

STATUS

Possible procurement of the system by India has been reported.

4197.221
TOMAHAWK SEA-LAUNCHED CRUISE MISSILE (BGM-109)

The General Dynamics BGM-109 Tomahawk is the USN's long-range cruise missile. This entry is concerned with the predominantly tactical role currently envisaged for Tomahawk by the USN, though sight should not be lost of the fact that Tomahawk has been selected for use by the USAF in NATO for the Ground-Launched Cruise Missile (GLCM) role (**4194.111**) as a major element in the NATO Theatre Nuclear Force modernisation programme.

Studies for the USN Tomahawk Sea Launched Cruise Missile (SLCM), designed for launch from submerged submarines and surface ships, were started in 1972. For submarine use the missile can be fired from a torpedo tube, while for surface ship applications armoured box launchers on deck or vertical launching systems can be employed. The Tomahawk family of cruise missiles incorporates a high degree of commonality in the basic airframe and major system components. Ahead of the mid-section on which are mounted the 'flip out' wings, a forward body contains the warhead and the guidance section, while the rear section houses the turbofan jet engine. A rocket booster motor is attached to the tail cone in the case of the SLCM and GLCM versions to propel the missiles from their tubes and accelerate them to flying speed and altitude where the turbofan can be started to sustain flight.

The SLCM is designed to be able to carry out both land attack and anti-ship missions using either nuclear or conventional high explosive warheads, and there are alternative guidance systems for each mission. These consist of the original advanced TERCOM (terrain contour matching) system which is used for both the land attack SLCM and the USAF GLCM versions of Tomahawk, and a specially modified version of the Harpoon (**2641.221**) missile radar guidance system for use in the anti-ship version of the SLCM. The latter enables Tomahawk to be launched in the general direction of the target area to which it flies at low altitude to avoid detection by hostile radars, and at a pre-programmed distance the missile's active radar is switched on to detect and acquire the target ship. The TERCOM system used in the land attack version of Tomahawk uses inertial navigation to guide the missile to the target using the known location of the launch vehicle and that of the target, this being inserted immediately prior to launch. A pre-programmed flight path is followed to the target, with the terrain profile characteristics encountered by the missile along its flight path being compared automatically by the TERCOM equipment with computer-stored terrain data covering preselected segments of the route to confirm and adjust the Tomahawk's flight path.

For submarine launching, Tomahawk is loaded into a stainless steel capsule which provides protection

On-board camera view of Tomahawk anti-ship missile striking the target after launch from a submerged submarine and flying more than 100 miles to the target. This was the first combined development/operational test of the weapon

during handling and underwater launch. At the moment of firing, the SLCM is ejected from the capsule and the torpedo tube. The boost motor propels the missile through the water and to the surface, and once in the air the boost motor burns out and is jettisoned. The turbofan cruise motor then sustains flight for the remainder of the mission.

CHARACTERISTICS

Length: 6·4 m
Diameter: 53 cm
Wing span: 2·61 m
Cruise engine: Williams International Corp 275 kg thrust turbofan
Boost motor: Atlantic Research Corp 3170 kg thrust solid-propellant rocket
Range: 2500 km (land attack version); 450 km (anti-ship version)
Cruising speed: 885 km/h
Guidance: TERCOM-aided inertial (land attack); modified Harpoon active radar homing (anti-ship)
Warhead: HE or nuclear (land attack); HE (anti-ship)

STATUS

In January 1981 the DoD stated that full-scale engineering development of the Tomahawk land attack missile with conventional HE warhead (TLAM/C) was going ahead for use aboard USN nuclear attack submarines, and the potential of optical scene matching area correlation terminal guidance techniques, allied to a conventional warhead, offers a promising method of attacking fixed targets on land. Operational objectives for this variant, which will be deployed on nuclear attack submarines and surface ships, are to provide naval forces with a long-range cruise missile capable of attacking and neutralising enemy facilities and to degrade their defensive capabilities without resorting to nuclear weapons.

It was also stated that the USN intends to procure both the land attack and the anti-ship versions of Tomahawk for deployment on submarines and surface ships.

In July 1981 a BGM-109C Tomahawk cruise missile completed the first submarine-launched strike against a land target, located about 480 km from the launch position off the Californian coast. The target was at the Tonopah Test Range in Nevada, and it was reported to have been hit by the inert warhead carried by the Tomahawk, which was fully guided throughout the flight. Well over 50 previous test and evaluation flights of Tomahawk missiles, of various models, had been carried out successfully prior to this flight.

Readers are also directed to entry **3993.001** in the Strategic Weapon Systems section for further information and background on US cruise missile activities.

The 1984 report by the US Secretary of Defense stated that Tomahawk had experienced some quality assurance problems in production, and that production had been slowed down from earlier projections until these problems are completely resolved. Once assured of this, it is DoD's plan to procure and deploy the missile in large numbers. The programme for fiscal years 1984-88 requested funding for procurement of 1861 missiles. Projected procurement for 1984 and 1985 was 124 and 353 missiles, respectively.

In 1982 McDonnell Douglas became a co-producer of the Tomahawk, when the Joint Cruise Missiles Project Office awarded McDonnell Douglas and General Dynamics contracts to exchange Tomahawk technology, in March 1982.

2641.221
HARPOON SHIPBORNE SURFACE-TO-SURFACE MISSILE (RGM-84A)

Harpoon (RGM-84A) is a high-subsonic anti-ship tactical cruise missile operational with the USN.

This missile is officially regarded as the principal anti-ship weapon and has been designated for launch from P-3 and A-6 aircraft, BB-61 class battleships, FF-1052 class frigates, DD and DDG class destroyers, CG and CGN class guided missile cruisers, FFG-7 guided missile frigates, PHM patrol hydrofoils, and SSN submarines. The airborne version is described elsewhere in this book (**1301.221**) and the following description relates primarily to the shipborne version. The submarine version was described in **2441.421** in 1976 and earlier editions of *Jane's Weapon Systems*, where details of the alternative launching arrangements will be found.

An all-weather system, Harpoon has been specified in a way that is intended to achieve operational flexibility and adaptability to existing systems. The main body of the missile with its cruise-phase propulsion and guidance systems, homing and terminal manoeuvring systems, ECCM facilities and warhead is common to all applications. The aerodynamic surfaces of this part of the system exist in several forms for compatibility with various aircraft, shipboard, and submarine launchers. All surfaces are designed for quick attachment, are interchangeable, and in some cases folded for storage.

For all other than airborne launchings an additional boost section contains a solid-propellant boost motor. This propels the missile on a ballistic trajectory which it follows until the booster separates; after which the missile descends to a low cruise altitude, determined by its altimeter, and flies to the target under the power of its turbojet cruise engine. In the terminal phase the missile may execute manoeuvres to evade close-in enemy defences and enhance the effectiveness of its warhead. Aerodynamic control throughout is by four movable fins on the main missile body.

Harpoon four-tube Mk 141 launcher (W. Donko)

Launch of RGM-84 Harpoon missile from USS Fletcher

The weapon control system for Harpoon AN/SWG-I(V), is produced by McDonnell Douglas, with Sperry as subcontractor. Targeting data provided by shipboard systems are interfaced with the missile through this command and launch system. The Harpoon data processor, a general-purpose digital computer, receives targeting and attitude data from standard shipborne equipment (or from a third party for over-the-horizon operations) and computes the necessary missile and launcher orders. After launch, en route guidance is provided by a missile-borne system consisting of a strap-down attitude reference assembly and a digital computer; no data inputs from the ship are required by the missile after it has been launched. Cruise altitude is monitored by a radar altimeter and flight control commands are interpreted by electromechanical actuators operating on the fins. This guidance system is designed to operate satisfactorily when the missile is launched at any angle up to 90° from the required course line.

Terminal guidance is achieved by means of a Texas Instruments DSQ-28 active radar homing system which maintains its lock until final impact. Included in the terminal guidance system is provision for the terminal manoeuvre referred to above. It should be noted, also, that the high degree of manoeuvrability implicit in this terminal pattern also means that the missile is capable of engaging targets that are taking high-speed evasive action. The radar homing system is frequency-agile and this facility, coupled with extensive on-board computer logic circuitry, provides considerable ECCM capability to the missile in the terminal phase.

CHARACTERISTICS
Type: Shipborne surface-to-surface tactical guided missile
Guidance principle: Pre-programmed attitude reference plus radar altimeter in cruise phase; active radar homing
Guidance method: by electromechanical control of 4 moving fins (±30° travel)
Propulsion: Solid-propellant booster. Teledyne CAE J402 turbojet cruise engine
Warhead: HE penetrating blast type
Missile length: With booster 4·58 m; without booster 3·84 m
Missile diameter: 34 cm
Launch weight: With booster 681 kg; without booster 519 kg
Range: Over 50 nm (90 km)
STATUS
The USN operational evaluation was completed successfully in March 1977, and Fleet introduction was started immediately on surface ships and submarines. The airborne P-3 and A-6 application was implemented in the autumn of 1979 and 1981, respectively.

In June 1982 the USN took delivery of the first of an advanced version of the Harpoon, designated Block 1B. Based on the advanced guidance design developed for the RN, the Block 1B Harpoon flies toward its target at lower altitudes, making detection and defence more difficult for the target. In late 1982 flight test development for a still more advanced version, Block 1C model RGM-84D, was completed. This model provides increased range, waypoints, and selectable terminal trajectories.

By April 1984 more than 3400 Harpoon missiles had been ordered, of which over 2900 had been delivered. At that time it was confirmed that the Royal Navy intended fitting Harpoon in new Type 22 and 23 frigates. Submarine and aircraft launched versions already serve with British forces.

In addition to the US, 16 other countries operate the system and nine of them are NATO members.

The 1985 US DoD Budget indicated procurement of a total of almost 440 Harpoon missiles in fiscal year 1985 at a cost of $367.4 million.
CONTRACTORS
Programme Direction: US Naval Air Systems Command supported by the Naval Sea Systems Command.

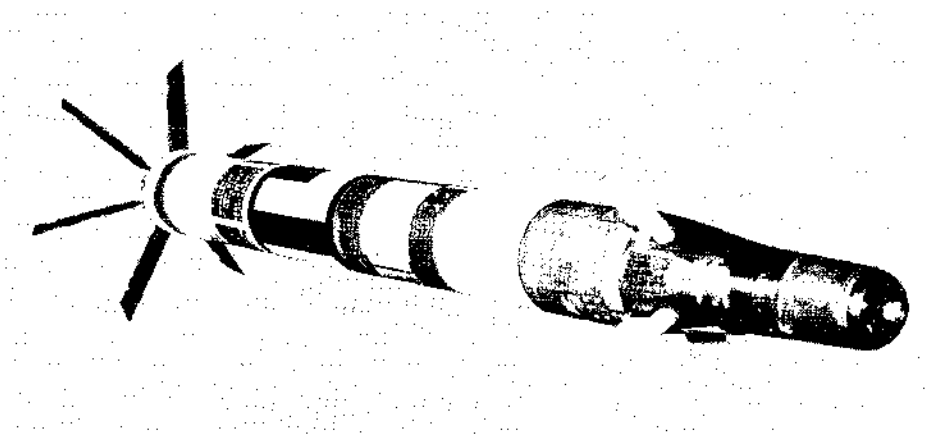
Propulsion: Teledyne CAE (turbojet), Aerojet Tactical Systems (booster).

Guidance: IBM, Lear Siegler, Texas Instruments, Northrop.

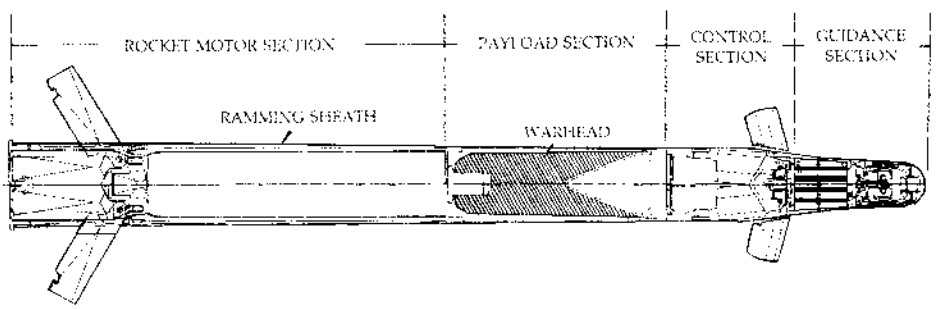
Radar Altimeter: Honeywell.

4213.211
USN 5 INCH GUIDED PROJECTILE



The USN's 5 inch guided projectile represents the initial implementation of a potential family of laser homing projectiles for use with standard USN ordnance pieces of various calibres from the 5 inch upward. The original operational requirement (OR-S0957-SH) was dated 15 April 1977 and a four- to six-year programme was envisaged. The operational objectives were to improve naval gunfire systems when used in support of army and marine corps amphibious assault operations by effectively improving accuracy against fixed and certain moving targets designated by laser target marking systems deployed on ships, aircraft or by ground forces. This would also yield considerable reductions in the number of rounds of ammunition consumed. Precision guided artillery missiles of this type will also be available for use against surface vessels, and to supplement ships' point defence anti-aircraft weapons against air targets. A range of munitions is foreseen which includes the 5 inch projectile with which this entry is concerned, and later 8 inch and 16 inch versions.

The 5 inch guided projectile will be employed with the Mk 42 and 45 5 inch/54 calibre naval gun, and it features a semi-active laser seeker used in conjunction with laser designators such as the Modular Laser Equipment (MULE), the new Seafire shipboard designator, or airborne equipments such as the A-6 target recognition attack multisensor (TRAM) or laser designator-equipped OV-10 aircraft. The projectile is fired from the ship into an acquisition 'basket' where its sensor acquires the reflected energy from the designator laser and automatically homes onto the target.



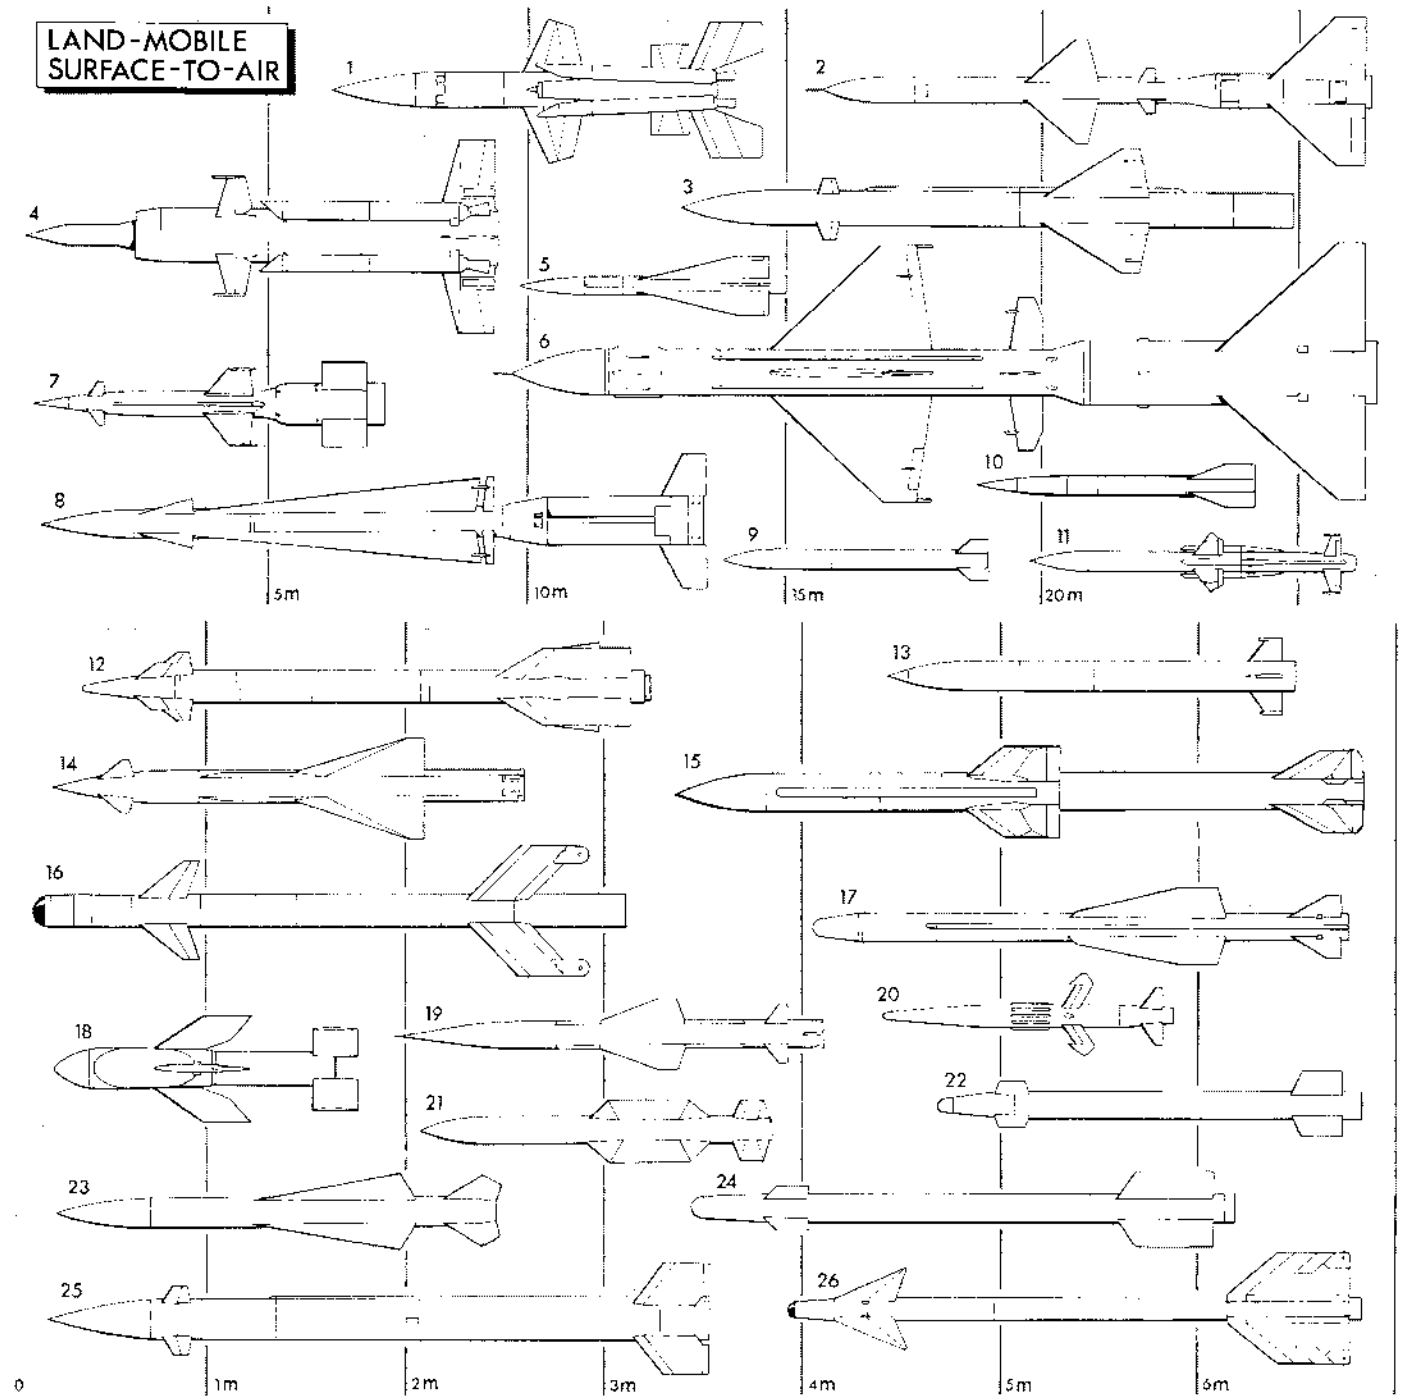
The projectile consists of four main sections: guidance, control, warhead, and rocket motor. A ramming sheath is provided to protect the tail fins and to assist the loading process. The guidance section houses the laser seeker head and processing electronics necessary to detect, acquire, process, track, and follow the reflected laser energy to the target. It also provides the preselected impact or height-of-burst fuzing mode for the warhead. The control section of the projectile contains a cold gas control actuation system, and batteries for the main system and timer. The payload section normally contains a 13·6 kg fragmentation/shaped charge warhead, but this space can be used for a telemetry package during tests, or trials.

The rocket motor section consists of a nozzle/fin assembly, a motor case tube loaded with liner and propellant, and a slip obturator. The rocket motor is ignited after launch from the gun barrel and provides a significant extension of the typical range of some 24 km that can be obtained with conventional 5 inch shells and Mk 42 and 45 guns.

Technical advances that were instrumental in achieving this performance included the design and development of miniaturised and shock-hardened electronics able to withstand the high loadings imposed by the firing of these shells (up to 16 000 *g* acceleration and 25 000 *g* shock) and the production of a new hardened gyro. Microminiaturisation of the seeker electronics achieved a packaging density roughly 17 per cent of the Copperhead land-based artillery laser guided shell, to fit into the 76 mm diameter nose required for automated loading into the gun aboard ship.

USN 5 inch semi-active laser homing guided projectile

Cross-sectional diagram of the 5 inch guided projectile



CHARACTERISTICS
Length: 3·54 m
Calibre: 5 in (127 mm)
Weight: 47·5 kg
Guidance: Semi-active laser homing, proportional navigation
Control actuation: Cold gas pneumatic
Warhead: 13·6 kg dual mode fragmentation/shaped charge
Range: >24 km

As mentioned above, 8 inch and 16 inch models have been considered and brief characteristics of these versions are included in this entry for general interest.

CHARACTERISTICS		
Nominal calibres	**8 in**	**16 in**
Length	2·3 m	3·7 m
Weight	189 kg (~22·6 kg sabot)	1179 kg
Payload	51·2 kg	363 kg
Range	44 km	67 km
Launch acceleration	4000 *g*	3500 *g*

STATUS
The 5 inch guided projectile (GP) programme was started in 1977 and the planned initial operating capability (IOC) in July 1981. The latter date was allowed to slip by a few months as a result of reprogramming the funding in 1980. The 1982 DoD budget allocated funds for manufacture, test and procurement of 5 inch/54 and 76 mm rounds. Operational test and evaluation was completed in 1981 with successful results, and production contracts valued at $25 million were awarded to Martin Marietta in December 1983.

2290.131

INTRODUCTION

Described in this section are weapons having a wide range of sizes and performance capabilities. All are suitable for use against hostile aircraft, and a few also have an anti-missile capability. All are to some extent mobile, and some are man-portable, but some of the larger systems take several hours to bring into action and are better suited to a semi-static defence role (eg of airfields or base installations) than to operations in defence of forward units.

Among the more recently developed systems there has been a noticeable emphasis on fast-reaction short-medium range weapons for defence against low-flying aircraft and tactical missiles; there have also been interesting developments in man-portable weapons capable of giving infantry units a degree of self-protection against aircraft attack that they have never previously known.

For convenience of system comparison, these mobile systems have been divided into three sub-sections – one dealing with mobile (but not portable) guided weapon systems, one dealing with mobile gun and rocket systems, and a third dealing with portable guided missile systems. While the first and third sub-sections are concerned with guided weapons which can be unambiguously distinguished from unguided weapons, there is some difficulty in defining the border between self-contained AA gun systems – which are described in the second sub-section below – and associations of AA guns with separate fire control systems. While we have endeavoured to follow a consistent line here, the reader may find it useful to consult Army Fire Control Systems in the Systems section, as well as the Land-based Air Defence Systems section where incidental references to some specific surface-to-air weapons may be found.

Mobile Surface-to-air Guided Missile Systems

CHINA (PEOPLE'S REPUBLIC)

4889.131
HQ-2J AIR DEFENCE MISSILE

The use of a version of the Soviet-originated SA-2, Guideline air defence missile system by the People's Republic of China for some years is now well known, but the latest stage of development is the availability on the international defence market of an indigenously produced model of this system with the Chinese designation HQ-2J.

Photographs that have been obtained and published indicate that there are few major differences between this system and its Soviet predecessor. The liquid propulsion rockets are retained, and the radars are apparently similar, but modifications are stated to include a new type of warhead. Details of the original Soviet SA-2 will be found in **2942.131** later in this section.

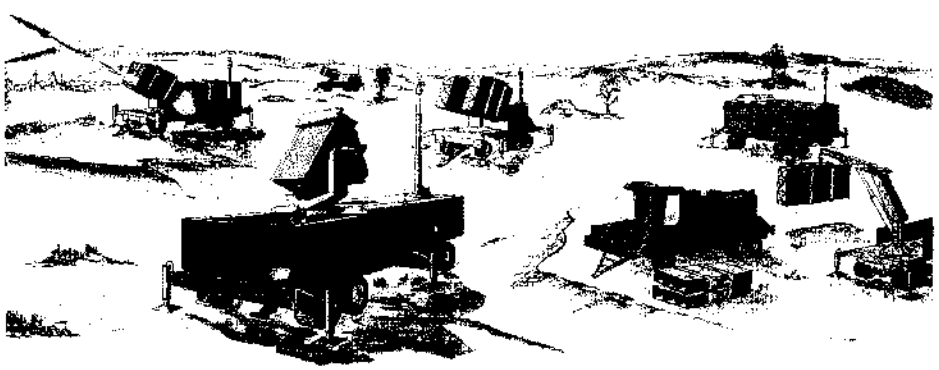
Chinese manufactured version of Soviet SA-2 air defence missile system is designated HQ-2J and is now offered for export

FRANCE

4771.131
SAAM SURFACE-TO-AIR MISSILE SYSTEM

Studies have been undertaken by leading French contractors since 1983 (or earlier) into the design and development of a new surface-to-air missile system that could be suitable for use as either a land-based air defence weapon or in a shipboard configuration for naval applications. Provisional designations of the proposed new weapon are SAMP (medium range surface-to-air 90) for the land-based version, and SAAM (surface-to-air anti-missile 90) for the naval model.



The principal collaborators in the study, Aerospatiale and Thomson-CSF, have signed a memorandum of understanding with the French Ministry of Defence providing for feasibility studies. Aerospatiale will be responsible for the SA 90 and SAN 90 missiles and the launcher(s), with Thomson-CSF taking care of the search and tracking radar(s) and the guidance system (including fire control).

As noted above, two versions of the system are planned: a future naval surface-to-air anti-missile system (SAAM) using the SAN 90 missile; and a land mobile medium-range ground-to-air system (SAMP) with the SA 90 missile. The two versions will inevitably differ appreciably because of their respective operational purposes, but the official concept appears to envisage a considerable degree of commonality between the two systems, and initially both projects are linked within a single programme. It is likely that as each version matures, it will evolve into a separate programme with its own timescale. This entry is concerned with the present combined programme, supplemented with details of the land-based SAMP version to the extent that these have been defined.

The threat to be addressed embraces saturation air attacks with aircraft and missiles, at all altitudes and from multiple azimuth angles. The targets may be expected to be capable of very high manoeuvring capabilities, calling for a defensive missile able to defeat attacking missiles capable of up to 15 g and speeds of up to Mach 2·5 or more. Dense and varied ECM and other countermeasures are expected, and high resistance to such challenges is essential, as is maximum autonomy of operation against multiple threats.

The ability to intercept several targets simultaneously and provide a short reaction time will be facilitated by use of a new X-band 3-D radar developed by Thomson-CSF. This will simultaneously carry out surveillance, detection, identification, threat evaluation, designation and tracking of targets, in addition to up-dating the missile inertial navigation system. Rotating at 60 rpm, this radar will incorporate frequency agility, and will be compatible with a missile launching rate of up to one per second. It is possible that electro-optical sensors may be added as a radar back-up and to provide for loss of target data as a result of jamming.

The SA(N)90 missile will be designed for exceptional manoeuvrability; three times that of potential targets is the estimated requirement, ie about 50 g. It will have a hybrid control system incorporating aerodynamic and direct-force control elements. Missile guidance will consist of two steps: the initial guidance phase during which the missile heads toward its target under the control of its on-board inertial system, and the terminal phase during which it will use a K-band active radar seeker.

Artist's impression of projected SAMP medium range air defence system using ramjet driven SA 90 missiles and new X-band 3-D radar

SAMP

This version is designed to protect sensitive areas against heavy air attacks, anti-radar missiles, and long-range low-level (eg, cruise) missiles. The lightweight SA 90 missile will be powered by a ramjet and will have a minimum interception range of 25 km when launched from a vertical launcher or from pre-orientated launchers. The complete system consists of a radar carrier vehicle fitted with a retractable antenna which simultaneously controls the fire of four mobile units, each of which will probably be six-round launchers with reload facilities. All the system elements are mounted on cross-country vehicles and it is intended that a unit should be operational within ten minutes of arriving on site.

STATUS

Feasibility study started in 1983. Development of the naval system (SAAM) is due to commence in 1986, with ground-based version (SAMP) following in 1987.

2074.131
CROTALE LOW-ALTITUDE GROUND-TO-AIR WEAPON SYSTEM (TSE 5000)

Crotale is the basis of a series of low-altitude surface-to-air defence systems designed for the all-weather interception of low-level targets. The system can be mounted on wheeled or tracked vehicles, on transportable shelters or on ships (see also **3972.131, 2111.231**). When vehicle or shelter housed, the complete system comprises an acquisition and co-ordination unit (ACU) linked with up to three fire units. Each of the latter is equipped with a launcher carrying four ready-to-fire containerised missiles and a tracking and guidance radar. The system is intended to counter saturation attacks on strategic or tactical positions or to ensure the protection of battlefield units. High mobility and a high degree of autonomy of logistics and operation contribute to considerable operational flexibility.

The short reaction time required of systems in this category is achieved by means of sophisticated automatic data processing and handling of the operational actions to be performed. The system is broken down into two units to maximise the efficiency of the target designation, target signal processing and detection system by using it in association with several fire units. The automatic processing system is also capable of co-ordinating several air defence systems (eg Crotale, AA guns etc) when saturation attack protection calls for deployment of defence resources in depth, while not increasing risks of either over- or under-kill.

Crotale is installed on wheeled cross-country vehicles that employ electric transmission, and are of two types: the ACUs which control and co-ordinate up to three fire units and form part of an anti-aircraft defence system; and the fire units. The former vehicles are each equipped with a pulse-doppler surveillance radar with fixed echo suppression; a data processing system based on a digital computer which can handle 30 targets, automatically evaluating and tracking the 12 most dangerous targets and designating these to the most appropriate Crotale fire units or to artillery fire control posts; an IFF system; and an inter-ACU co-ordination system. The fire units each have: a turret launcher with four Crotale missiles in containers (ready-to-fire); a monopulse fire control radar that automatically tracks the target and guides one or two missiles, using a very accurate differential angle-error measurement system; a digital computer; TV equipment which is used in clear weather or under jamming conditions for automatic guidance of the missile without radar transmission; an IR angle-error measurement system for aligning the missile on the line of sight to the target immediately after launch (radar beam gathering); and a command link that transmits manoeuvre orders to the missile.

All the vehicles are provided with an inter-vehicle communications system using cable and/or radio for the exchange of firing orders and data transmission, and a separate VHF radio system.

The canard-type missile is powered by a powder propulsion unit, and the rounds are housed in watertight containers which are used for transport and launching. The focused-splintering warhead weighs about 14 kg and is activated by a protected IR proximity fuze adjusted to operate according to the intercept geometry computations or on impact. Its lethal range is more than 8 metres, which is stated to be greater than the very low clearance distance provided by the accuracy of the angle-error measurement system (0·5 mrad). The system is therefore claimed to provide a kill probability of greater than 0·85 (0·96 for salvo firing).

Crotale fire unit vehicle

CHARACTERISTICS

Type: Land-mobile, automatic, all-weather, surface-to-air guidance weapon system

Guidance principle: Command to line of sight

Guidance method: IR missile gathering; secondary radar missile tracking by target tracking radar; command control of missile control surfaces via autopilot

Propulsion: Single-stage solid propellant motor

Warhead: 14 kg, HE, directed burst, fragmentation type with IR proximity fuze

Missile length: 2·94 m

Missile diameter: 16 cm

Span: 54 cm max

Launch weight: Approx 80 kg

Speed: Mach 2·3 reached in 2·3 s. 20 s time of flight to 8 km

Acquisition unit

Radar: E-band, tunable

Sub-clutter visibility: 60 dB

Target capacity: 30 processed per antenna revolution

Antenna rotation rate: 60 rpm

TWS: Automatic, 12 targets

Detection: 1 m² fluctuating target within 18·5 km

Inter-vehicle communications: up to 800 m cable; up to 3000 m radio link

Inter-sector co-ordination: 4 sectors separated by up to 10 km

Fire unit

Radar: J-band monopulse in diversity mode

Tracking: 1 m² fluctuating target within 16 km

Tracking accuracy: 0·3 mrad

Angle-error measurement accuracy: 0·2 mrad

TV tracking: 14 km range (max); field 3°

Typical target data

Speed: Mach 1·2

Altitude: 15 – 5000 m

Manoeuvre: 2 *g*/13 km

Radar cross-section: 1 m², fluctuating

Max engagement range: 13 km (50 m/s target); 10 km (250 m/s target)

Minimum range: 500 m

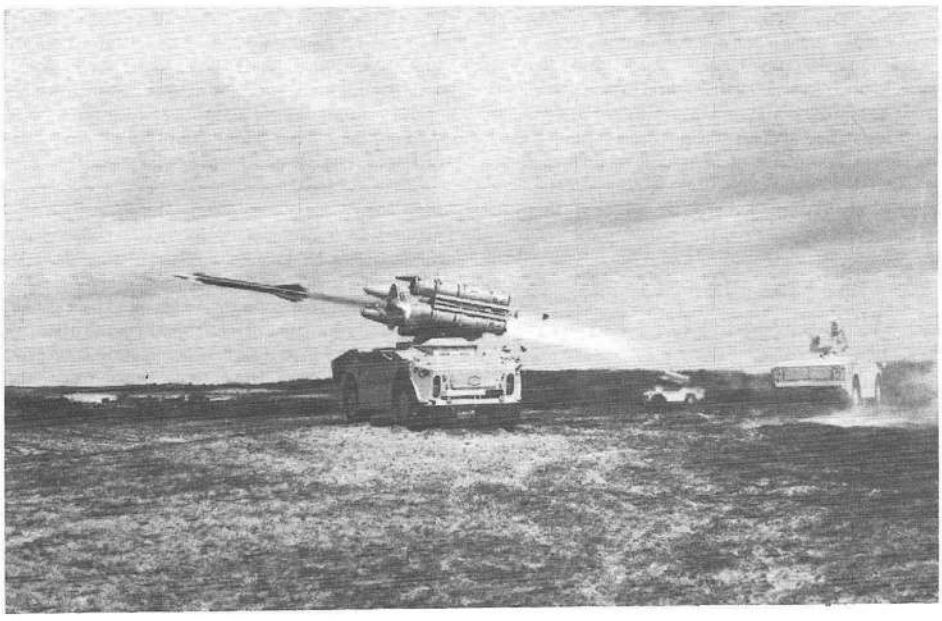
Max crossing range: Up to 6000 m against a 200 m/s target

Reaction time: 6 s from first detection to missile launch

DEVELOPMENT

Work started on the project in 1964 both at Thomson Houston and Engins Matra and a prototype missile was completed in the following year. Overall responsibility for the development lies with the Division Systèmes Electroniques of the Thomson-CSF group while full responsibility for the missile lies with Matra.

STATUS



Crotale is in production for the French Air Force and is reported to be in service or on order for the forces of about ten other countries, including Abu Dhabi, Chile, Egypt, Libya, Morocco, Pakistan, and Saudi Arabia.

The Crotale weapon system has been developed into at least two specific export versions. Cactus (**2341.131**) was supplied to South Africa some years ago, at an early stage in Crotale's development. More recently, another version was designed and has been supplied to Saudi Arabia as the Shahine. This is described in the following entry (**3972.131**). There is also a naval version (**2111.231**) which appears in the Shipborne Surface-to-air Weapons section of this volume. Crotale in vehicle or shelter mounted configuration has four ready-to-fire missiles. Shahine has six rounds ready-to-fire in vehicle or shelter version, and Naval Crotale has eight ready-to-fire missiles. In mid-1983 a version was revealed that incorporated additional launchers for the Matra SATCP (Mistral) (**4198.131**) mounted alongside the Crotale missile launcher/containers, and training and elevating with the latter.

---

3972.131
SHAHINE AIR DEFENCE SYSTEM (TSE 5100)

Shahine is a later, more powerful version of the Crotale air defence system (**2074.131**) which is being supplied to Saudi Arabia.

The system combines one or two acquisition and co-ordination units (ACUs) with two, three or four firing units each carrying six containerised ready-to-fire missiles with an effective interception range of more than 11 km. Its capability of controlling up to four independent but simultaneous interceptions, and its versatile, modular design, make Shahine an efficient weapon system against saturation air attack.

The Shahine system is a modular system which can be mounted on the AMX 30 type tank or any other tank similar to the ones to be protected; wheeled armoured vehicles; or (air) transportable shelters for the protection of fixed installations. The last version can be moved by C 160 Transall or C 130 Hercules aircraft.

The system consists of:

(1) *ACUs* which can control and co-ordinate up to four firing units each, be co-ordinated with other ACUs and integrated with an air defence network. Each of them is equipped with a pulse-doppler acquisition radar with moving target indication (MTI); a data processing system based on digital computer providing the simultaneous display of 40 targets, automatic threat evaluation and tracking of the 18 most menacing targets and their designation to the

best located firing units; a TV system featuring a TV turret concentric with and independent of the radar turret which provides ground monitoring of moving fire vehicles and optical target reconnaissance and possibly target designation

(2) *firing units* equipped with a turret carrying six containerised ready-to-fire missiles; a monopulse doppler fire control radar providing automatic target tracking and simultaneous guidance of one or two missiles with precise deviation measurement; a digital computer to manage the system; TV equipment designed to perform automatic tracking and missile guidance without any radar transmission, in clear weather or in case of electronic jamming; an IR localiser to gather the missile on the firing axis after launching.

All vehicles are fitted with a digital link for locating all the units of a Shahine formation and for the automatic exchange of data and orders, and there are radio links between Shahine units and external command posts and air defence centres.

The missile is of essentially the same concept as that used in the Crotale system described above, but in the Shahine application it is slightly heavier at a total weight of 105 kg. A more detailed description of Shahine appeared under this entry number in earlier editions of *Jane's Weapon Systems*.

CHARACTERISTICS

Acquisition range: 19·5 km against 1 m² fluctuating target

Tracking range: 17 km

Service range: 0·5 - 11 km against 250 m/s target

Vehicles: Cross-country tracked type or heavy duty wheeled vehicles

Reaction time: 6 s

Missile acquisition distance: 500 m

Crossing range: 6000 m

Warhead: 14 kg

Kill probability: 0·9 (head-on target); 0·99 (two-round salvo)

STATUS

The Saudi Arabian Shahine successfully completed its trials programme with firing tests which took place in late 1978 and early 1979. Deliveries to Saudi Arabia began in late 1981.

Shahine firing unit on AMX-30 tank chassis

As a significant element of a large inter-governmental contract between France and Saudi Arabia which was agreed in 1984 and known as Al Thakeb, two new versions of the Shahine system are being supplied. Announcing the estimated $4000 million contract in 1984, Thomson-CSF stated that of the two new Shahine versions, "one of them mounted on AMX 30 chassis for accompanying battlefield forces... while the other will be carried on air-transportable shelters for defending strategic bases and key installations. By comparison with the Shahine systems which are already operational with the Saudi armed forces. In the latest versions, numerous improvements have been embodied, relating to increased detection, guidance accuracy, ECCM performance and inter-battery auto co-ordination.

GERMANY (FEDERAL REPUBLIC)

4772.131

MFS-2000 SURFACE-TO-AIR MISSILE SYSTEM

The West German programme to design and develop a successor to the existing Hawk air defence missile system in the Federal Republic is currently carried out under a collaborative study project known as the MFS-2000. This designation refers to a feasibility/design study for a surface-to-air missile system to operate in the 15 to 30 km range bracket. The broad requirement is thought to have many aspects in common with the French SAM 90 project (**4771.131** in this section of *Jane's Weapon Systems*) and it is possible that eventually there may be a more formal and stronger connection between the two systems if there is a merger of the projects along the lines of other successful Franco-German weapon programmes such as Roland and Milan etc.

German contractors known to be co-operating on the MFS-2000 system concept are AEG-Telefunken, MBB (leadership) and Siemens. MBB will be responsible for the missile and vertical launch unit, Siemens mainly for the ground radar and fire control unit, and AEG, among other components, for the active radar seeker missile head.

STATUS

Design/feasibility study programme. Many aspects similar to French SAM 90 project; possible eventual merger of French and German efforts thought to have been considered.

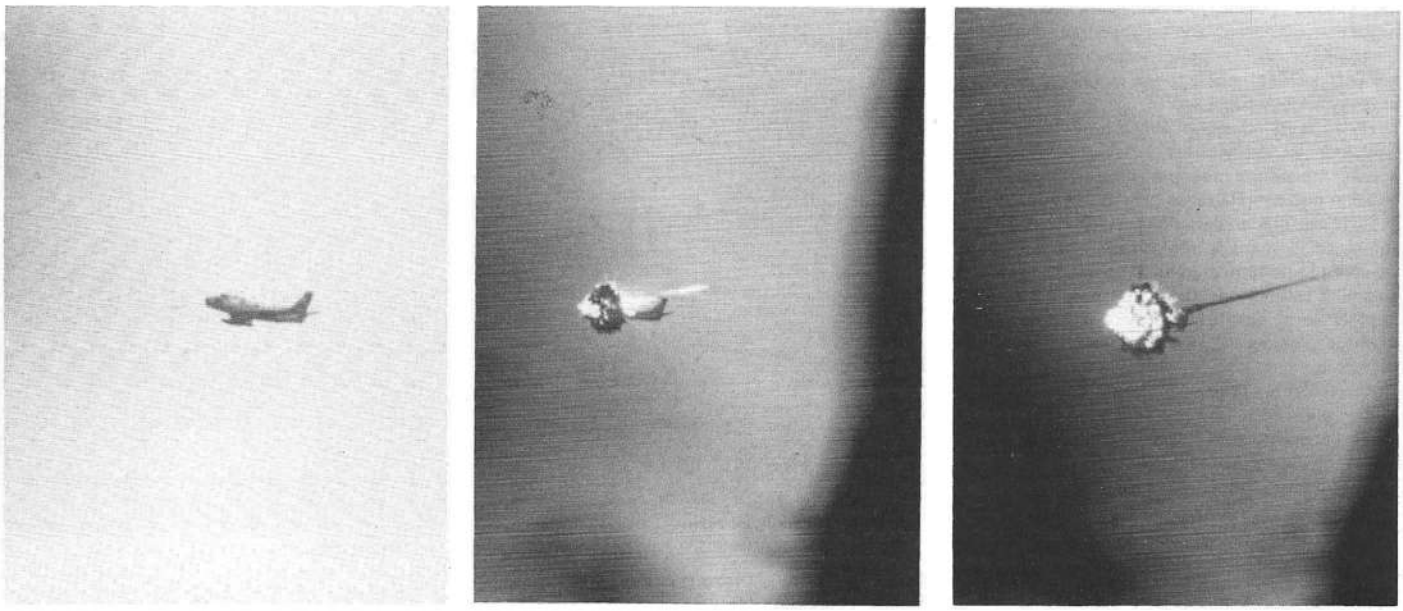
INTERNATIONAL

4158.131



ADATS ANTI-AIRCRAFT MISSILE

ADATS is an international project being jointly undertaken by Martin Marietta and Oerlikon with the aim of developing a highly accurate, day/night and adverse weather missile system having a true dual target capability, for engaging air targets or for use in an anti-tank role. The name derives from this dual-mode use: Air Defence, Anti-Tank System - ADATS.

The ADATS prototype configuration consists of an unmanned turret comprised of electro-optical sensor head containing FLIR, TV, laser range-finder and laser guidance sensor, and on which are also mounted a search radar and four missile launcher/canisters on each side. The complete assembly can be rotated in azimuth and elevated remotely from operator positions in the vehicle. The search radar antenna on top is free to rotate independently for surveillance purposes. Alternative mounting arrangements available allow for installation on a variety of wheeled or tracked vehicles and for shelter or container housed systems. In the prototype M113A2 system the commander and

ADATS firing at White Sands Missile Range, April 1984 (Martin Marietta)

Remotely piloted target drone is destroyed by ADATS missile in tests at White Sands Missile Range, New Mexico, USA in April 1984 (Martin Marietta)

gunner sit side-by-side at the radar and E-O consoles, respectively.

Each ADATS vehicle is regarded as a self-contained, autonomous fire unit, using its own radar for early detection of low-flying aircraft targets, or alternatively being incorporated into a network of larger radars for command and control. On detection of a target, it is handed off to the passive optical tracking system (either TV or thermal-imaging IR may be employed) which is immune to both anti-radiation missiles and ECM. Following passive tracking of the target, the missile is launched when the former is within range, subsequent guidance being by beam-riding using a coded carbon dioxide laser beam radiated from the launch vehicle. The dual-purpose warhead, with fragmentation effects against air targets and shaped charge for armoured targets, is detonated by an impact fuze or an electro-optical proximity fuze (aerial targets only).

CHARACTERISTICS

Missile

Length: 2·05 mm

Diameter: 152 mm

Weight: 51 kg (approx at launch)

Warhead: Shaped charge, dual-purpose fragmentation 12+ kg (approx)

Fuze: Impact and laser proximity

Guidance: Laser beam-riding

Propulsion: Solid, smokeless, rocket motor

Max speed: Mach 3+

Range: 8+ km

Ceiling: 5000 m

Search radar: Dual beam, integrated IFF

Search range: Over 20 km

Target acquisition: Radar, FLIR, TV, optical sight

Passive target tracking: FLIR, TV

Crew: 3 (commander, gunner, driver)

Ready to fire missiles: 8 with number of reloads dependent on vehicle type

STATUS

The first ballistic flight of an ADATS missile took place at White Sands Missile Range, New Mexico, in June 1981. This was followed by an intensive system and tactical test programme involving nearly 40 test firings, the last of which occurred in mid-1984. In 1983 helicopter mounted applications of ADATS were being studied.

2218.131

ROLAND MOBILE ANTI-AIRCRAFT WEAPON SYSTEM

The surface-to-air all-weather or clear-weather Roland weapon system is designed for defence against medium, low and very low altitude aircraft or helicopter attack. It is designed for incorporation into various types of armoured vehicles with the aim of including all operational weapon system equipment and functions within a single unit, such as: surveillance radar, tracking radar, optical sight, command computer and command transmitter link.

The weapon system is provided with two launch tubes each housing one missile, and eight missiles for reloading are stored in the magazine. After firing one or both missiles, reloading can be accomplished in about ten seconds.

US Roland leaves fire unit mounted on an Army M812A1 modified truck at White Sands Missile Range

Roland can be operated in either the clear-weather or the all-weather mode. Target detection is by means of a doppler surveillance radar with a PPI display. The commander sets the turret on to the designated target and then uses the tracking radar to achieve lock-on, or the gunner takes over target tracking and turret control. The target is tracked by optical line-of-sight (LOS) in the clear-weather mode, or by radar in poor visibility. The commander obtains fire authorisation from the fire control computer or passes authorisation to the gunner. The tracking radar follows the target and measures the angle between the LOS and the missile, while for optical guidance flares aid the IR sensors of the sight. Missile guidance commands are sent to the missile via a command transmitter.

CHARACTERISTICS

Surveillance radar: L-band pulse doppler

Detection velocity range: 50 – 450 m/s

PRF: 8·82 kHz

Scan rate: 60 rpm

Detection range: 90% on 1 m² target at 1·5 – 16·5 km

Pulse duration: 5 ms

Power: 200 W (average); 4 kW (peak)

Tracking radar: Ku-band monopulse doppler

Frequency agility: 250 MHz

Power: 10 kW

Beamwidth: 2° (azimuth); 1° (elevation)

PRF: 5 kHz

Pulse duration: 400 ns

Range: 16 km

Optical sight: Monocular

Magnification/aperture angle: ×8/10° – ×12/5° reversible

Missile tracking: IR goniometer, aperture angle reversible

Command transmitter: Ku-band, 50 kW

Roland missile
Length: 2·4 m
Diameter: 16 cm
Span: 50 cm (max)
Weight: 66·5 kg
Propulsion: 2-stage solid; 2 s boost, 13·2 s sustain
Warhead: 6·5 kg HE with prox mity and impact fuzes
Range: 6000 m (max); 500 m (minimum)
Altitude: 5500 m (max); 20 m (minimum)
Speed: 500 m/s
Manoeuvrability: 12 - 16 g
Firing unit weight: 6 t
All-up weights: 32 t (AMX-30); 32 t (SPZ); 25 t (M812A)

A version known as US Roland, evolved as a result of the American decision to adopt the a l-weather system for licence production in the USA. US sources state that this version is modified to give increased resistance to ECM and has a re-designed fuze. The fire unit can be mounted either on a tracked vehicle (XM975) or on a truck. The current US production conf guration is on the M812A truck.

A different configuration has been evo ved to meet the needs of the Federal German Republic Air Force and Navy. Known as the FlaRakRad Roland, th s version is characterised by an eight-wheeled military chassis (10 T MIL GL) on which a special Roland shelter is mounted. This contains all the operational weapon system equipment, and is essentially the same as the Federa German Army vers.on of Roland.

In the following descript ve passages, the Ro and I and II versions only are considered.

OPERATION

Target detection in azimuth is performed by a Siemens/Thomson-CSF pulse-doppler surveillance radar on the launch vehicle. Threat evaluation is accomplished within a single antenna scan, and IFF facilities are provided by either a Siemens MSR-400/5 (West Germany) or an LMT (France) interrogator equipment. The former is produced under licence in the USA by Hazeltine for the US Roland.

The weapon system commander is also the operator of the acquisition radar. He selects the target and, in the Roland I configuration, directs the opt cal sight to the target azimuth. The gunner then searches in elevation and acquires the target, whereupon a missile may be launched. After launch the gunner maintains the LOS to the target and the missile is gathered to the LOS guided along this track by an IR guidance technique (TCA) which is described in more detail in the entry for HOT (**2212.111**).

In the Roland II configuration a Thomson-CSF tracking radar is used in addition to the periscope sight, otherwise the principle of operation s the same. Since one of the features claimed for the system is that rapid transition from radar to optical or optical to radar tracking is possible, it is reasonable to assume that the radar and optical axes are maintained in alignment.

The tracking radar is a monopulse type with a magnetron transm tting valve and doppler receiver circuits to reduce clutter returns. It is said to have a parabolic cassegrain antenna and to use circular polarisation. The antenna is gyro-stabilised in bearing and elevation – necessary because the radar is required to have a high resolving power and the weapon system is intended to be used, if necessary, on the move.

FlaRakRad Roland II vehicle for West German Forces

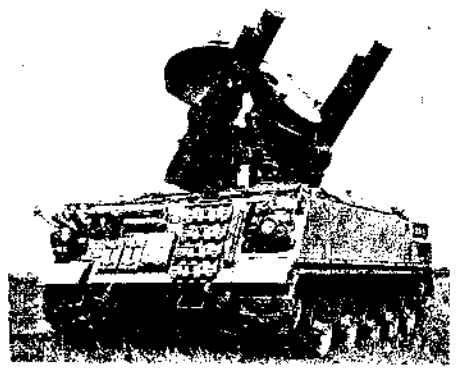
The radar deals simultaneously with the target and the missile, missile position in relation to the radar beam being established by continuous-wave transmission from the missile beacon.

Command signals are passed to the missile in flight by a radio link and the commands are interpreted as steering movements of vanes in the efflux from the sustainer motor. This command link is a microwave system.

DEVELOPMENT

In Europe a bilateral major improvement programme is in progress. For example: missile performance will be increased (range 6 to 8 km), and speed (500 to 650 m/s), and sub-systems having a direct bearing on either of these two missile parameters are to be upgraded accordingly.

Roland III



In mid-1985 the Euromissile subsidiary of MBB and Aerospatiale revealed the development of an updated version of the system known as Roland III. The principal differences between this model and its predecessors are summarised as follows:

The missile itself has been improved and Roland III rounds have increased range, higher speed and a heavier warhead, but dimensions are virtually unchanged so that Roland III rounds can be handled and fired from existing fire units. A new launcher system has been designed which allows four missiles to be launched without requiring any reloading operation, and this enables each vehicle to carry 12 missiles instead of ten. Other modifications include a new processor system that combines the functions of various weapon system sub-assemblies (including self-test) and can be used with Roland II or III missile types, and new interface units that permit connection to a co-ordination centre (CORAD), exchange of target data with other Roland systems, target designation to other attached weapon systems such as AA guns and man-portable SAMs.

A Roland Co-ordination Centre (CORAD) is being designed to provide co-ordination for several Roland systems, and possibly guns. In a rather similar programme in the USA, tests have been carried out into the use of the Roland fire control system and its surveillance radar to provide target data for friendly air defence systems such as the IR seeking Redeye and Chaparral missiles.

STATUS

The first Roland production hardware began initial evaluation trials with live firings in March 1976 and the first fire units began deliveries in November 1977.

Roland II on French AMX-30 chassis

Euromissile handed over the first production Roland FlaRakPz to the West German Army in June 1981. In the French Army, six regiments are already equipped with Roland. A shelter version has been ordered by Argentina and three other countries. Argentina used one such system in the Falklands against British air forces in 1982.

The Brazilian Army decision to adopt the Roland system was announced in October 1972, and the first system was delivered in July 1977; the partial licence agreement is understood to remain in force.

In March 1981 Iraq was stated to have agreed to purchase a number of Roland systems, provided the political considerations will permit such a transaction.

US Roland entered production in early 1982 and was completed in 1983. The fiscal year 1985 budget contained no additional funding for procurement for the US Army. The US Army 1984 Weapon Systems handbook, issued in January 1984, stated that the US Roland programme had been restructured to field a single light battalion to be activated at McGregor Range, New Mexico by the New Mexico National Guard. During 1985, 27 Roland fire units and 595 missiles were to be ready for duty with this element of the American Rapid Deployment Force.

It was revealed in April 1984 that Spain has decided to procure the Roland system, the initial purchase comprising 18 fire units and up to 500 missiles. Other nations which have been named recently as possible Roland purchasers, though confirmed details are still awaited, are Canada (LLADS) and Saudi Arabia. By mid-1985, nine countries had adopted the Roland system.

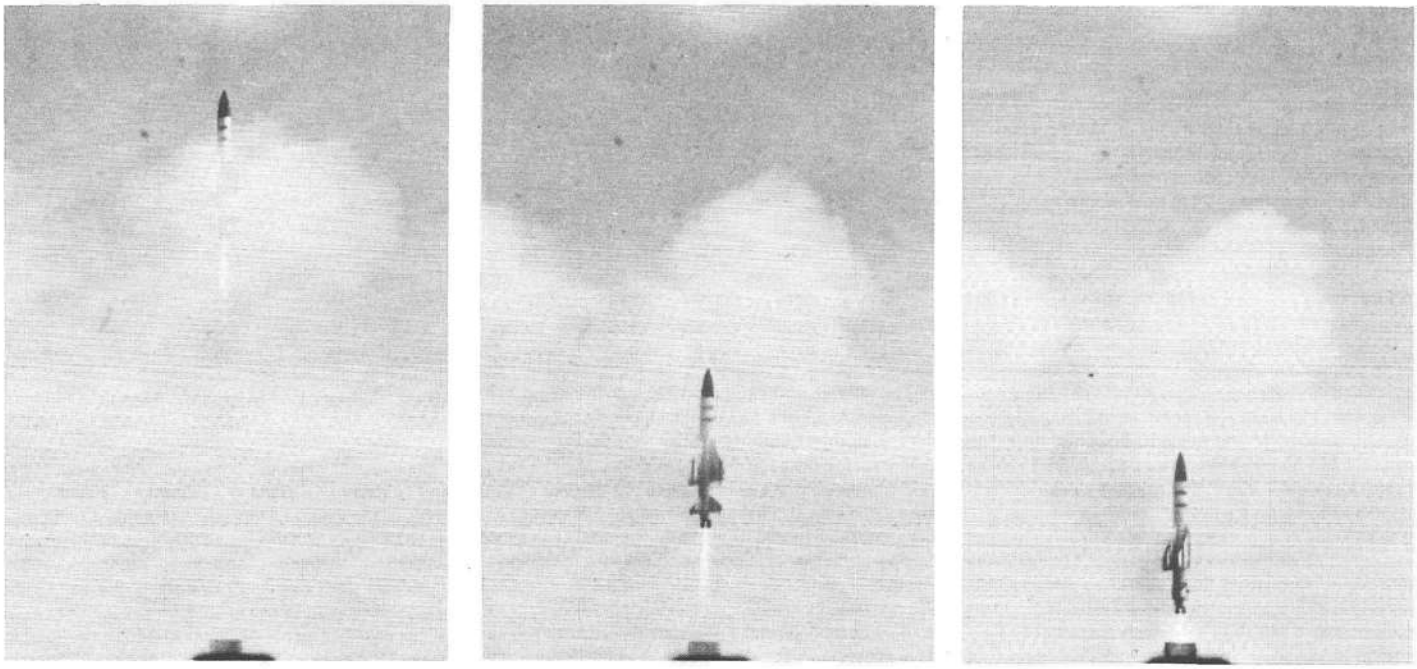
ISRAEL

4888.131
ADAMS AIR DEFENCE MISSILE SYSTEM

The Israeli Armament Development Authority, Rafael, is developing an anti-missile missile system for air defence purposes under the name of ADAMS (Air Defence Advanced Missile System). From preliminary information released, the system is intended to be mobile, self-contained, and is mounted on a LAV (8 × 8) wheeled cross-country vehicle.

Vertical launching is used for the missiles, which are the existing Barak air defence weapon, employed in this role with two rows of five vertical launch tubes. The carrier vehicle also mounts the target detection and tracking radars for use with the missiles, presumably together with the requisite control and ancillary facilities to give an autonomous system overall.



STATUS

Development project. Vertical launches and transitions had been carried out successfully at Rafael's test range in the Negev Desert by the end of 1984.

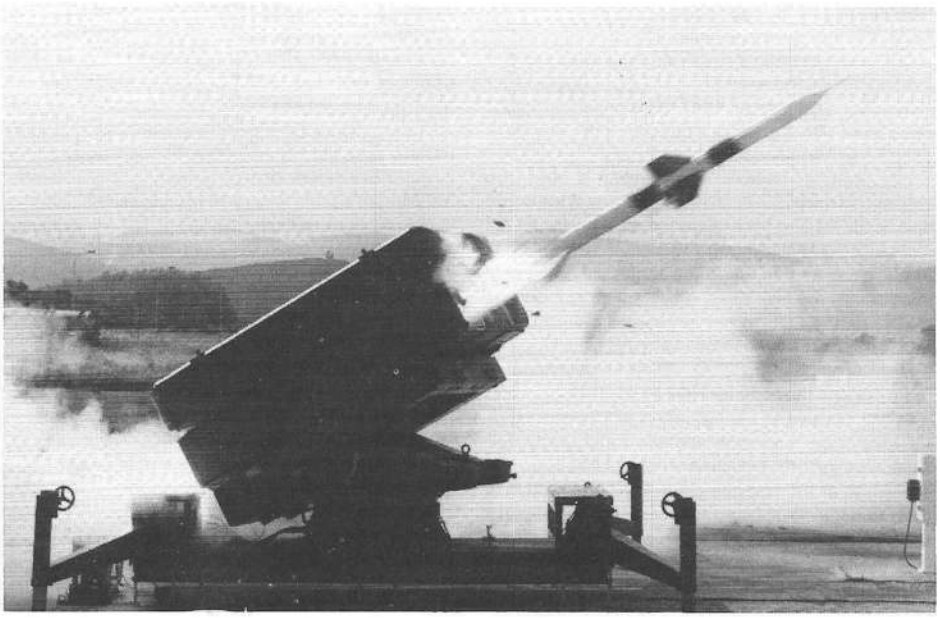
ITALY

2250.131
SPADA POINT DEFENCE MISSILE SYSTEM



Spada is a missile system developed under a contract awarded to Selenia by the Italian MoD (Air Force), for the close-in air-defence of relatively small permanent objectives of strategic importance (airfields, naval bases, power plants, bridges etc.) from air attacks characterised mainly by high speed and high manoeuvring instrumental approaches at low- and very low-altitudes along the most favourable direction of penetration, in a heavy ECM and all-weather scenario. Such a threat may be posed by close flying aircraft, in single or multiple formations, tactical air-to-surface, anti-radiation and cruise missiles, attack helicopters and RPVs.

Because of the sophisticated characteristics of the air threat, the extremely short time available for reaction and the high attrition rate required, Spada has been designed to provide the following characteristics: very good action co-ordination and reliable target identification capabilities, relatively short overall reaction time (in the order of ten seconds on first target and about five on the following targets), high fire power with up to four independent reaction centres and sustained action (up to 72 missiles ready to be fired without reloading the launchers), a high degree of automation to optimise action effectiveness, and an adequate degree of mobility for autonomous re-deployment or transfer to different sites.

Designed for operational integration via links with the national air-defence net, Spada employs the Aspide missile (**1656.131**), which has a high SSKP (better than 70%) and a relatively large coverage which is in the order of 15 km in range and 5 km in altitude, down to a few metres.

Fire control console inside Spada Firing Section FCC shelter

Aspide missile firing from Spada launcher

The system is modular in concept and its configuration can be adapted to optimise the deployment according to the dimensions of the objective, the topography of the surrounding terrain and the type of threat. Moreover the system has a great flexibility in siting because the various units can be deployed remotely one from the others, up to five km apart, for the best defence of the objective.

The Spada system is organised in two main modules: the Detection Centre (DC) and the Firing Sections (FS).

The DC consists of the Search and Interrogation Radar (SIR), made up of the SIR antenna pedestal and relevant equipment shelter, and the Operational Control Centre (OCC) shelter.

The FSs consist of the Fire Control Centre (FCC), made up of the Tracking and Illumination Radar (TIR) antenna pedestal, inclusive of an on-mounted optronic sensor (TV), the Control Unit (CU) shelter, for TIR and fire control equipment housing, and the Missile Launchers (ML) with six ready-to-fire Aspide missiles each.

The tasks of the DC are target search, detection, identification, evaluation and designation for engagement by the FSs. As SIR the Spada utilises the Selenia Pluto F-band radar (**3277.153**), suitably modified for the specific system purpose in its use of the available power. The SIR is a low altitude search radar, particularly suited for operations in dense clutter environment and in presence of severe ECM, which provides data for the OCC. The latter consists of three operational consoles, a data processing system with two NDC-160 interconnected digital computers and a number of communication links (digital data and telephone).

The main functions of the OCC operators are those of supervising the correct operations of the automatic systems, setting up some data relevant to the operational situation of the moment, manual intervention to substitute or correct automatic sequences, particularly in the presence of ECM, and selection of battery intervention criteria.

The tasks of the FS, which represents the reaction centre of the system, are the acquisition and destruction, through missile intercept, of the targets assigned by the DC. At the FCC the TIR carries out target acquisition, tracking and illumination for missile guidance. As an additional mode of operation the TIR provides for target search (360 degrees or sectorial scan), detection and self-designation. The TV sensor is used both as a backup to the radar and as an aid for target identification and discrimination as well as for kill assessment. The associated CU supervises these functions which are carried out

automatically with the possibility of manual intervention. The MLs provide for missile storing, aiming, selection and preparing to fire as well as for automatic launching. As TIR the Spada uses a pulse doppler monopulse radar derived from the Selenia Orion 30X radar (**1936.253**), in this role believed to be designated Orion 40X. It provides, through the same antenna, for target tracking and illumination for missile semi-active guidance, operating in I- and J-bands respectively. The TIR antenna group is available in two configurations: one mounted on a pallet type dedicated structure and the other, more compact, directly installed on the CU shelter roof. The CU consists of an operational console, a data processing system through an NDC-160 digital computer and a number of communication links (digital data and telephone). The MLs consist of a slewable stand which supports a frame type structure on which two rows of three missile canisters each are located. This structure can be moved in elevation both for firing action and for canister loading/unloading operations.

The main functions of the OCC operator are those of ensuring correct automatic operation, superimposing manual intervention when required, firing the missiles according to the action criteria ordered by the OCC and carrying out kill assessment. A typical Spada battery consists of one DC, with its SIR, linked to two or three FSs, according to the importance of the objective to be defended, with two six-missile launcher units each. The system's highest firepower configuration consists of four FSs under control of the same OCC; a maximum of three MLs can be connected to the same FCC, which allows a very long fire duration without taking any action for reloading the launcher units. The loading process is carried out by means of a small truck-mounted crane which substitutes the empty canisters with missile loaded ones. The sealed canisters are also used for missile transportation and storage.

STATUS

Field tests of prototype systems were completed in 1977, with production for the Italian Forces following immediately after. Technical and operational evaluation of the first of the series system took place in 1982-83 at the Italian Air Force base of Grosseto, north of Rome.

Two contracts, for a total of twelve systems were awarded to Selenia between 1983 and early 1985 respectively. The relevant batteries delivered up to now have already been deployed for the defence of the most important selected objectives. Present plans of both the Italian Air Force and Navy indicate acquisition of additional batteries for a minimum of at least twenty systems in all.

JAPAN

3619.131
TAN-SAM SURFACE-TO-AIR MISSILE (TYPE 81)

Toshiba (Tokyo Shibaura Electric) has developed for the Japanese army an IR homing air defence missile known as Tan-SAM (Tan = short, Surface-to-Air Missile) and officially designated the Type 81. The Japanese Ground Self Defence Force plans to deploy four Tan-SAM platoons of two quadruple launcher units and one fire control vehicle with each division. The quadruple launcher unit, which consists of a pair of launch ramps with a missile rail on the upper and lower surface of each, is carried on a Type 73 3·5-ton heavy truck. Each missile is loaded onto the launcher by an hydraulic loading mechanism on each side of the vehicle; the missile which is housed in a box container, is placed on the loader manually by the crew after removing the container cover. Four rounds can be loaded in three minutes.

The Tan-SAM missile is similar in appearance to the British Rapier and is powered by a solid-propellant rocket motor giving an effective range of about 7 km. The missile fuselage carries cruciform wings near the mid-point and there are cruciform control surfaces at the tail. The fire control system (FCS) is carried on a modified version of the Type 73 truck and consists of planar phased-array pulse-doppler three-dimensional radar for search and target detection and designation. The commander and radar operator are housed in a cabin equipped with three CRT displays, keyboards and other controls. The radar antenna is slewed mechanically in azimuth and elevation to face the threatened area. Each launcher vehicle can be separated from the FCS vehicle up to 1000 metres, but a distance of 300 metres is more usual; connections between the vehicles for the transmission of target designation, firing orders etc, are by cables.

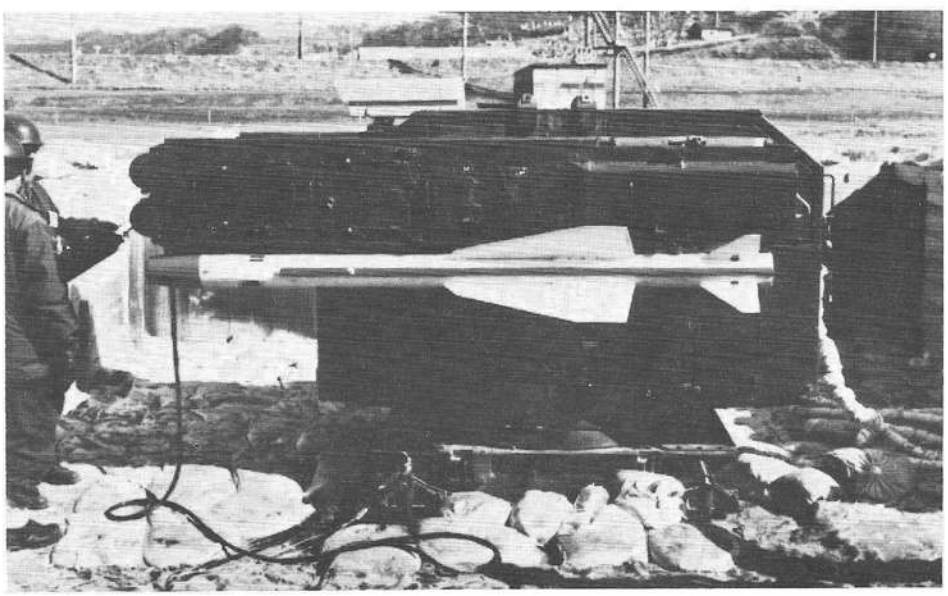
Up to six targets can be tracked by the radar simultaneously, and the radar detection range is estimated at about 20 to 30 km. All targets detected are displayed on the FCS PPI CRT and the commander selects those which are to be tracked. These are then separately displayed together with threat evaluation symbols. Two targets are selected for engagement and the appropriate launcher unit receives target designation data which activates a search pattern by the missile IR homing head and at the same time inserts a pre-programmed autopilot interception course for the missile when lock-on has been achieved. After launch, the missile flies the initial part of its trajectory under automatic pilot control until homing head re-acquisition of the target is accomplished. This in-flight lock-on facility enables dual engagements and rapid engagement of additional targets during the flight of previously launched missiles before they have reached their target(s).

Each launcher vehicle is equipped with an optical director for use as a standby target designator if ECM or other difficulties rule out radar designation. Special precautions are incorporated in the IF search pattern scanning program to reduce the problems of false acquisition due to the sun and much of this programming adjustment is performed automatically before launch by the computer in the FCS equipment.

CHARACTERISTICS

Type: Surface-to-air, short range
Length: 2·7 m
Diameter: 16 cm
Weight: 100 kg
Speed: Mach 2·4 (approx)
Effective range: 7000 m
Propulsion: Single-stage solid
Warhead: HE, contact and proximity fuzes
Guidance: Autopilot initial phase, in-flight IR lock-on and terminal homing. Radar target designation with optical director back-up

DEVELOPMENT



Development started in 1966 as a replacement anti-aircraft weapon for Japanese Ground Self Defence Force. First complete prototype constructed between 1971-76. Live prototypes produced between 1977-79. Experimental fire control radar built in 1970, with prototypes between 1972 and 1974. Development is estimated to have cost about £21 million.

STATUS

It was expected that Tan-SAM would be entering service for protection of Japanese airfields from 1982-83 onward and procurement plans have mentioned a total of 24 platoons, with deployment initially to the four northern divisions in Hokkaido.

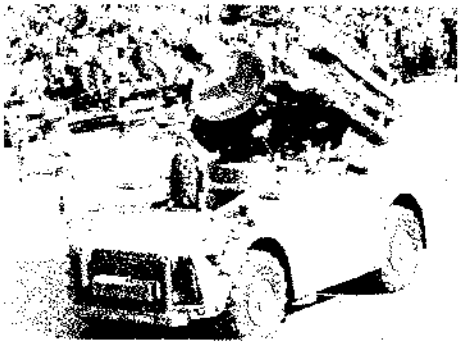
SOUTH AFRICA

2341.131
CACTUS

Cactus is the name given to one of the Crotale land-mobile surface-to-air guided weapon systems which is in service with the South African Air Force.



Crotale is described elsewhere in this section (**2074.131**). The Crotale system has undergone some changes in the course of development, and it may well be that the system in service in South Africa is rather different from that which has been supplied elsewhere.

It is interesting to note that the Cactus units in South Africa are linked directly to the early warning radar network which covers the north-east and north-west approaches to the Republic and which has its headquarters at Devon in the Eastern Transvaal. A Mirage interceptor squadron is also linked to the network.

In early 1981 it was reported that six Cactus units no longer required by the South African forces had been re-acquired by Matra and sold to Chile for use there.

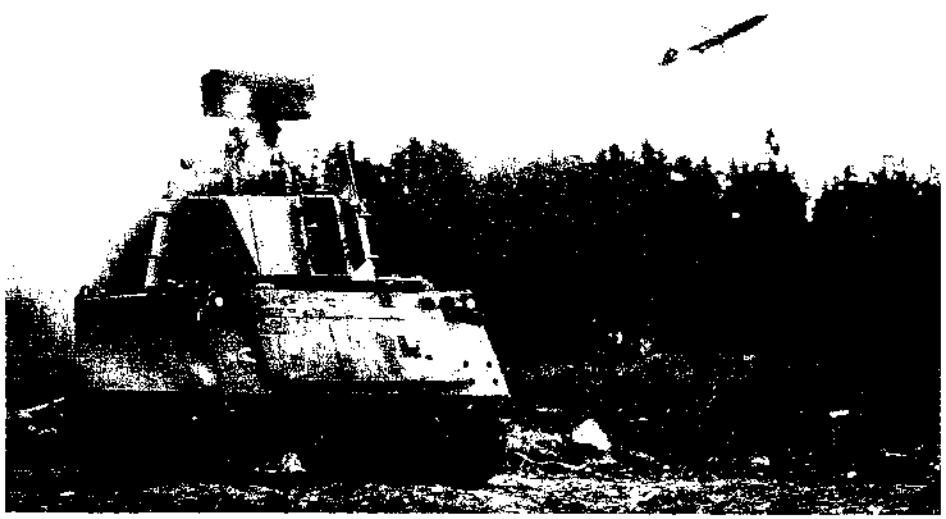
VEHICLE-MOUNTED RBS 70 RAY RIDER ANTI-AIRCRAFT MISSILE

Bofors has produced new versions of the well-known RBS 70 Ray Rider anti-aircraft laser-guided missile system. One is mounted on any suitable army vehicle and is known as the RBS 70 Ray Rider VL (vehicle launched) and another is mounted on an armoured vehicle and is known as RBS 70 Ray Rider ARMAD. Both systems are now completely tested and ready for production.

RBS 70 Ray Rider VL is very similar to the man-portable RBS 70 (**2348.131**). It mounts on a special stand secured to the floor of the vehicle. It can be folded down when in transit and covered with a folding hood. Six missiles are normally carried in the vehicle. The system is designed to accompany units on the move and is fitted to receive warning information from mobile search radars. When hostile aircraft are detected by the radar, an alarm is activated in the VL vehicle and the bearing and range of approaching hostile aircraft are received by a data link from the radar, on a target data receiver mounted in the vehicle cabin.

The crew consists of the commander and the missile operator/driver. When in motion the crew sits in the cab. When alerted by an alarm they drive the vehicle to the nearest suitable site to counter the attack. The operator then erects the stand with its sight attached, loads a missile and takes his position on the seat attached to the stand. The commander orientates the firing unit and then returns to his combat position in the cab and operates the target data receiver and his radio transceiver. The operator launches the missile and keeps his laser beam on the target while the missile is automatically guided to keep within the beam's direction. Set-up time for the VL from the moment of a radar warning alarm of an attack can be as short as 30 seconds.



RBS 70 Ray Rider ARMAD consists of an armoured three-man turret mounted on any suitable APC (Bofors have used an M113A1 as prototype). The fire-control system used with ARMAD is an Ericsson solid-state 3-D radar known as HARD, which can detect and discriminate hovering helicopter targets. It provides search, acquisition and track-while-scan functions. The box-shaped antenna can be elevated and is in operation all the time the vehicle is on the alert while on the move, and is electronically stabilised. The HARD radar provides the commander and gunner inside the turret with small displays on which distinct signals are provided for helicopters and strike aircraft. The radar system provides data to a central fire control computer, and from target acquisition to actually firing the RBS 70 Ray Rider missile the delay can be as little as four seconds. The radar provides ARMAD with a limited all-weather capability, for although the radar can track a target through cloud the gunner must be able to see the target in his sight to provide the missile its laser guidance.

The RBS 70 Ray Rider missiles themselves are stacked vertically inside the right-hand side of the turret and are loaded manually on to the launcher arm which swings up to a horizontal position above the roof passing through an automatically opening and closing armoured door. Once the missile has been fired the spent launcher tube is ejected and the arm lowers for a new round to be loaded. The turret holds seven missiles. The ARMAD crew comprises: commander, gunner and driver. The gunner uses a normal RBS 70 system laser sight. When not in use the antenna arm is lowered on to the turret roof.

RBS 70 APC. In addition to the RBS 70 ARMAD version, a simpler model suitable for use in the open hatch of an APC is also being developed. This consists of a sight and loaded missile container

Unmanned remotely controlled two-round launcher is a feature of RBS 70M Night Rider, seen here being set up

RBS 70 Ray Rider ARMAD version on M113 chassis. Turret carries missile launcher, HARD radar, missiles and crew of 2

mounted on a stand. When required for action the cover of the missile compartment is folded down and the stand and missile container is raised into the firing position.

RBS 70M Night Rider under Swedish government contracts amounting to between SKr 300 and SKr 400, a night/all-weather version of the RBS 70 system has reached the full-scale development stage. This has been designated RBS 70M, where M denotes Mörker, the Swedish word for darkness. This version is intended to support the daylight system that will carry the major anti-aircraft burden, since in the Swedish view daylight and good visibility conditions represent the most predominant threat until the advent of the 1990s. From then, however, the incidence of night/adverse weather attacks is likely to increase, and so to meet this the Night Rider version is designed to resolve AA tasks by day and night at ranges up to about six km, when there is an E-O line-of-sight to the target.

A local search radar, of new design, will provide target data, enabling targets to be tracked irrespective of visibility so that they can be engaged immediately they become visible. The launcher is unmanned and remotely controlled by the missile operator. This unit carries the sight and two missiles, and the first of these includes a laser guidance beam transmitter, TV camera and IR camera. The camera image is displayed for the operator on a TV monitor. In daylight, either the TV camera or the IR camera is used while in darkness and poor visibility only the latter is employed.

An improved missile that has a larger warhead and more powerful rocket motor is also being developed. There will be complete interchangeability between this round and its predecessors. Firings of RBS 70 were made from the deck of a Swedish naval vessel in early 1984.

The details given in the following table relate to the standard RBS 70.

CHARACTERISTICS
Length: 1·32 m (without booster)
Diameter: 106 mm (without booster)
Guidance: Laser beam-riding
Warhead: HE fragmentation
Fuze: Proximity, active laser
Range: 5 km
Altitude coverage: 3000 m
Reaction time: 5 s (RBS 70 VL deployed); 4·5 s (ARMAD deployed)
Time of flight to 3 km: 8·5 s
ARMAD radar: HARD, 3-D pulse-doppler
Frequency: I-band
Detection range: 9-10 km (helicopters); 10-12 km (aircraft) 90% probability
STATUS
Prototypes tested and ready for production.

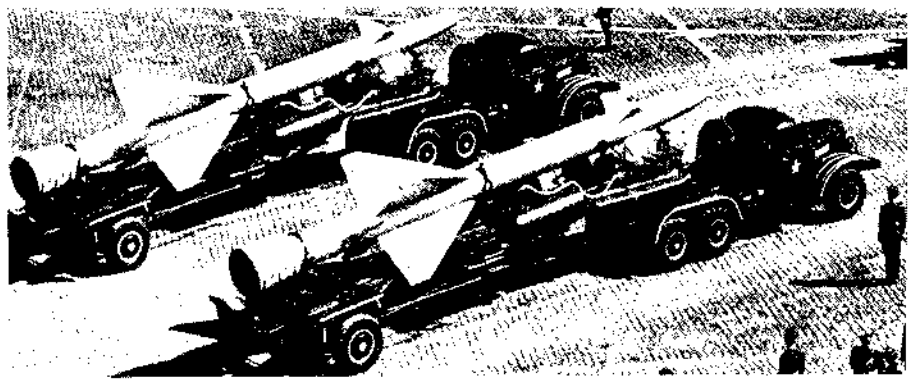
AB Bofors Ordnance Division, Box 500, 691 80 Bofors, Sweden.



UNION OF SOVIET SOCIALIST REPUBLICS

2944.131
SA-1 (GUILD) SURFACE-TO-AIR MISSILE

Guild is the NATO code-name for an anti-aircraft guided missile system first shown in Moscow in 1960 and identified by the number SA-1 in the US alpha-numeric sequence.

About 12 metres long and 70 cm in diameter, this missile has no separate booster stage and is said by official sources to be liquid-propelled. Movable cruciform foreplane surfaces are another feature of the missile that distinguishes it from Guideline (SA-2, **2942.131**), which has movable tail surfaces but which is otherwise generally of much the same size as Guild. A UK MoD report of April 1976 mentions a range of 32 km for the SA-1 which was confirmed in later official US sources but has since been increased to an estimated 50 km.

STATUS
It is doubtful if this weapon remains operational although it is possible that a small number might be retained on a reserve basis in the Soviet Union.

Guild missiles in May Day parade in Moscow (Tass)

2942.131
SA-2 (GUIDELINE) MEDIUM-RANGE SURFACE-TO-AIR MISSILE

Guideline is the NATO code-name for a medium-range, anti-aircraft guided weapon system, known also by the US alpha-numeric code as SA-2, which is standard equipment in the Soviet forces and which has been exported in large numbers to many countries outside the Warsaw Pact territory, including Cuba, Egypt, Indonesia, Iraq, Viet-Nam and Yugoslavia. Guideline missiles were used against US B-52 bombers during the bombing raids on North Viet-Nam prior to the peace settlement. Initially they scored a number of successes; but subsequently it appeared that the B-52 ECM equipment was more than a match for such ECCM equipment as the North Vietnamese had available.

The Soviet designation for the missile, or one version thereof, is believed to be V750VK and that of the complete weapon system, including radar and power supplies, V75SM. The system is land-mobile, the missile being mounted on a Zil 157 cross-country semi-trailer transporter-erector.

Various models of the missile have been observed over the years exhibiting relatively minor changes in external appearances. The details given below relate to a type that was supplied to Egypt, but it is known that later versions exist. In particular, one that was seen in Moscow in 1967 is somewhat longer and has a larger warhead.

SA-2 Guideline medium-range AA missile on semi-trailer transporter

CHARACTERISTICS
Type: Surface-to-air tactical guided missile
Guidance principle: Radio command
Guidance method: By control of movable tail surfaces
Propulsion: Solid-propellant booster with liquid propellant sustainer
Warhead: HE 130 kg, proximity fuze
Missile length: 10·7 m
Missile diameter: Booster 70 cm; second stage 50 cm
Launch weight: About 2300 kg
Slant range: 40-50 km
Speed: Mach 3·5 (estimated)
Ceiling: 18 000 m
OPERATION
The radio command guidance system is believed to be quite straightforward. Targets are tracked by radar which feeds data to a computer; this in turn produces signals which modulate the output of the command transmitter. Two sets of four strip antennas are mounted fore and aft of the missile wings to receive these signals.

Radar used in conjunction with these missiles is generally that known to NATO as Fan Song (**2866.153** and **2868.153**). It is said that one problem with the fire control and guidance system is that the missile must be gathered to the radar beam in the first six seconds of flight or it will not be acquired at all.

According to reports published in the American press concerning Israeli experiences with Egyptian Guideline installations, it was at first found that Israeli ECM devices were adequate to deflect the beam-riding missiles. Subsequently, however, improved missiles were introduced having terminal guidance radar with a wider range of frequencies than the Israeli ECM could handle. They were, however, able to obtain improved ECM pods from the USA which they successfully used to jam the missile acquisition, tracking, and guidance systems.

Various warhead and fuze arrangements have been reported. Most of the missiles have high-explosive warheads but contact, proximity, and command fuzes have been reported. Furthermore, the larger version

of the missile referred to above as having been first seen in 1967 is believed to have a nuclear warhead.

Recent reports refer to other modifications, including the introduction of optical techniques into the guidance system to give improved ECCM capabilities and low-altitude performance.

STATUS

Operational with the armed forces of the USSR since 1958, and in many other countries. Since the Soviet authorities generally appear reluctant to discard from their inventory any weapon which continues to work reasonably well, it is likely that Guideline will remain in service for some years but the number deployed in the USSR is expected to decline in the coming years. Despite various modifications, however, it is now technologically obsolescent and unlikely to be very effective against an enemy able to deploy reasonably sophisticated ECM equipment.

Soviet client countries reported to have received the SA-2 Guideline include: Afghanistan, Albania, Algeria, Bulgaria, China, Cuba, Czechoslovakia, Egypt, East Germany, Hungary, India, Iraq, North Korea, Libya, Poland, Romania, Viet-Nam and Yugoslavia. Some of these nations may well have introduced modifications of varying degrees to suit their own purposes, and China is thought to have established its own production line at one time.

2938.131

SA-3 (GOA) SURFACE-TO-AIR MISSILE

Goa is the NATO code-name for the SA-3 anti-aircraft guided missile used both by the Soviet Army and the Soviet Navy.

Small enough to be carried in pairs on the vehicle that is used as a tractor for the trailer transporters of both Guideline and Guild, Goa is a two-stage missile that is thought to have been intended for much the same operational role as the US Hawk, that is to say, short-range defence against low-flying targets.

Control of the missile in flight is by movable foreplane surfaces, the rear mounted wings of the second stage being fixed. Considering the operational role suggested above it seems possible that the missile has some form of homing; however, it seems fairly definite that Goa is a command-guided weapon.

In addition to the original twin launcher associated with the SA-3 there is now in use a triple missile launcher, which was first noted at Yugoslav air defence batteries. It is not known if this development was initiated by Yugoslavia or by the Soviet Union. Still more recently a four-round launcher installation of Soviet origin has made its appearance and is progressively replacing twin launchers in the USSR.

SA-3 Goa air defence missiles are usually transported on specially converted military trucks

Goa is used in conjunction with an I/J-band fire control radar whose NATO code-name is Low Blow (**2884.153**) and is commonly associated with an acquisition radar code-named Flat Face (**2874.153**).

In addition to its land-based uses Goa is deployed on ships of the Soviet Navy. Further details can be found in the Shipborne Surface-to-air Weapons section (**2939.231**).

CHARACTERISTICS

Type: Shipborne or land-based surface-to-air guided missile
Guidance principle: Probably command-guided but a homing system may be incorporated
Guidance method: By control of movable foreplane surfaces
Propulsion: 2-stage solid-propellant
Warhead: HE, proximity fuze
Missile length: 6·7 m
Missile diameter: Booster 60 cm; second stage 25 - 45 cm
Launch weight: 636 kg
Range: 25 km
Speed: Mach 2+ (estimated)
Ceiling: over 13 000 m

STATUS

Introduced into service in 1961 and now widely deployed in the USSR and Warsaw Pact states.

Goa has been supplied to a number of other states, among them Egypt, Finland, Iraq, Libya, Syria, Uganda, Viet-Nam, and Yugoslavia. Its use can be expected to increase both within and beyond the Warsaw Pact.

2934.131

SA-4 (GANEF) SURFACE-TO-AIR MISSILE

Ganef is the NATO code-name for a surface-to-air missile launched from a tracked vehicle that was first seen in public in Moscow in 1964. Its US alpha-numeric code is SA-4.

Alternative designations associated with this weapon by other sources are the Soviet name 'Krug' and the description *Zenitniy Upravlyayemiy Raket* (ZUR) or guided anti-aircraft missile. Different models are believed to have the following Soviet numbers, ZUR: 3M8, 3M8M, 3M8M1 and 3M8M2, of which the last two apply to the two versions that appear to be those now in use. The 3M8M1 model is the variant noted by Western observers and dubbed the 'long-nosed' Ganef, and this believed to have a longer range and higher ceiling than the 3M8M2. These notes refer essentially to the obvious external differences and there are likely to be significant variations internally or in performance characteristics to warrant the four designations given here.

Despite its appreciable (by most standards) range capability, the SA-4 is classed as a medium-range air defence weapon by the Soviet Union (ZRK-SD: *Zenitniy Raketniy Kompleks - Srednoye Deistvie*, anti-aircraft missile system - medium range), and is deployed with special air defence missile brigades that are allocated one to each front or army. A brigade consists of three air defence battalions, each of three batteries.

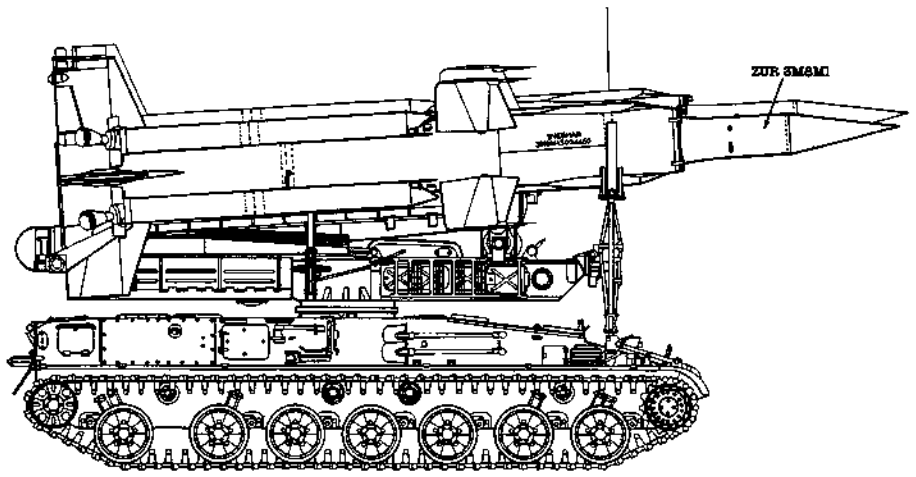
The system comprises five distinct elements, three of which are special to the SA-4 system, and the other two are employed with other Soviet weapons. The latter two are the Long Track search radar (**2937.153**) deployed at brigade level, and Thin Skin nodding height-finder radars (**3292.153**) at the brigade and one per launcher battalion. These radars are also encountered with other air defence systems such as the SA-6 Gainful, for example.

The other (three) elements are: the SPU (*Samokhodnaya puskovaya ustanovka*) mobile launcher unit, TZM (*Transportna-zaryazhyuscha maschina*) transporter-loader vehicle, and the SSNR (*Samokhodnaya stantsiya navedeniya raket*) mobile missile guidance station, known to NATO as Pat Hand (**2936.153**).

The missiles are carried in pairs on the first of these three vehicles, and the SPU/ZRK-SD is a fully tracked, transporter- erector-launcher equipped with a 360-degree trainable mount with elevation mechanism. The two caliper clamps which support the missiles during transit are separately released by manual operation of a worm-screw on the underside of the clamps. Handles for the worm-screws are clipped to the tubular framework carrying the clamps. This frame folds forward into the horizontal position for firing. Reloading of the launcher vehicles is by means of a mobile crane, and there is a special two-point attachment yoke for lifting. Wheeled transporter vehicles may be used for re-supply purposes, each carrying one missile.

Each Ganef battery has one TZM transporter-loader vehicle, capable of carrying one reload missile and transferring it to the launcher by means of a crane. Further reload rounds are carried by the brigade, these being transported on semi-trailers which are normally distributed at battalion or brigade headquarters.

The SA-4 missile configuration is fairly typical of the period (early 1960s): a large centre body containing a ramjet main propulsion motor with a prominent nose cone unit, cruciform wings, four wrap-around booster rockets, and four large tail fins. The boosters are solid propellant units, while the ramjet main motor uses kerosene fuel. A transponder to assist missile tracking during an engagement is located on one of the missile tail fins, and there are four interferometer antennas on the leading edges of the wings to enable the missile to home onto reflected energy from the target illuminating radar. Other missile details appear in the table below.



The Pat Hand guidance radar group operates in conjunction with the battery Thin Skin height-finder and Long Track search radar. Once a target is acquired by the latter two equipments, target data is transmitted to the Pat Hand which operates in the H-band and is thought to employ CW illumination for missile guidance as well as target tracking, supplemented by a command link.

CHARACTERISTICS

Type: Land-mobile surface-to-air tactical guided missile
Guidance principle: Command guidance, plus semi-active radar homing
Guidance method: By control of moving wings on forepart
Propulsion: Ramjet sustainer with four solid-propellant boosters
Warhead: HE, 100-135 kg proximity fuze
Missile length: 8·8 m
Missile diameter: 0·9 m
Span (tail): 2·6 m
Span (wings): 2·3 m
Launch weight: About 2500 kg
Range: About 70 km
Speed: Mach 2·5
Ceiling: 24 000 m

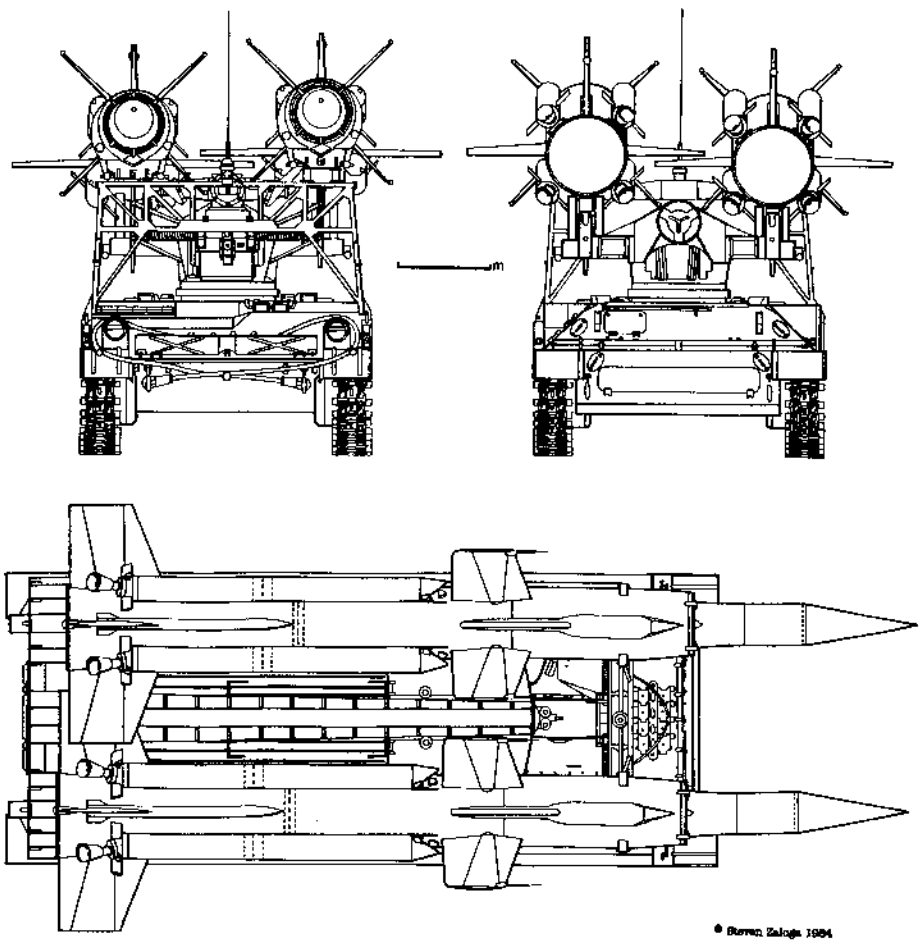
STATUS

Deployed operationally since the early 1960s, initially with Soviet formations only but later with Egyptian forces, before being withdrawn and replaced by the SA-6 Gainful. Within the Warsaw Pact states until recently the SA-4 has been noted only with East German and Czechoslovakian ground forces, but these have now been joined by Bulgarian units.

General arrangement drawing of SA-4 Ganef mobile launcher unit (SPU/ZRK-SD) (Steven Zaloga)

2940.131

SA-5 (GAMMON) LONG-RANGE AIR DEFENCE MISSILE



Griffon was widely accepted as the NATO code-name for a large surface-to-air weapon first displayed in public in 1963 which became associated with the designation SA-5. However in later years little more was seen or heard of Griffon and current practice is to link the designation SA-5 with the NATO code-name Gammon, and a very different looking missile. According to US assessments it is a weapon about ten metres long, probably with four wrap-around boosters to assist launch and initial acceleration. SA-5 Gammon is estimated to have the longest range of the Soviet SAM inventory with a maximum range of some 300 km. American authorities believe that deployments of the SA-5 have shown a steady increase over the years, as has the improvement and upgrading of the system. Current efforts in this direction are thought to relate to enhancements to suit SA-5 for working in conjunction with the SA-10.

CHARACTERISTICS

Type: Long-range surface-to-air guided missile
Propulsion: Solid-propellant
Missile length: Approx 10 m
Range: About 300 km
Ceiling: About 29 km

STATUS

Operational since 1967, Gammon provides point defence for a number of major areas of strategic importance. The current Soviet deployment plan appears to be based on use of Gammon as the high-altitude missile and the SA-3 Goa (**2938.131**) as the low/medium-altitude weapon for the strategic air defence of the Soviet Union. Official US sources in 1984 reported SA-5 deployments in Eastern Europe, Mongolia and Syria (see below). For further discussions of Soviet ABM and air defence systems see **3214.181** (**2945.181**, and **2989.181** in 1976 and earlier editions).

© Steven Zaloga 1984

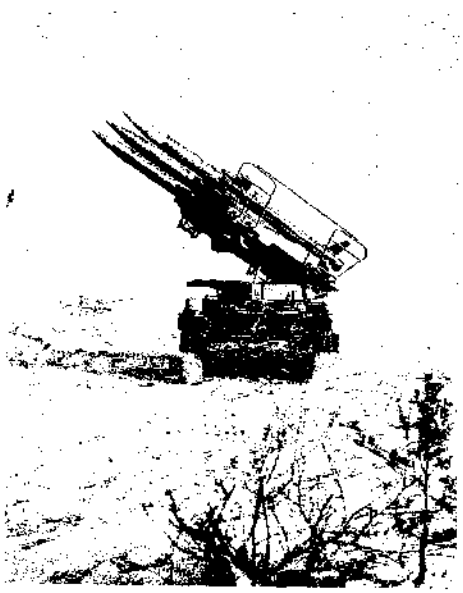
2930.131

SA-6 (GAINFUL) SURFACE-TO-AIR MISSILE

Gainful is the NATO code-name for an anti-aircraft missile system known in the US alpha-numeric code as SA-6 and first publicly shown in Moscow in 1967.

Until the 1973 Arab-Israeli war little was known about Gainful in the West. The missile system was, however, used extensively in that war – this being, so far as is known, its first operational use – and scored a number of successes in the early phases of hostilities.

Gainful is both a command guided and a homing missile and is fully mobile, both missile launchers and fire control radar systems being mounted on separate tracked vehicles. The fire control system is both sophisticated and, it would seem, effective. It comprises a primary search and acquisition radar, a target tracking and illuminating radar, a command link with secondary radar response for missile tracking and a missile-borne semi-active homing system. In ECM conditions some of the tracking functions can be performed optically.



The ground equipment of this complex is known by the NATO name Straight Flush (**2885.131**). Its limitation would appear to be restricted search capability when operating without the support of other types of surveillance radar, but it is normal practice to include such longer range radar units in combat formations to obviate this difficulty.

Other radars known to be associated with SA-6 operation include Flat Face and Long Track target acquisition radars (**2874.153** and **2937.153**) and the Thin Skin height-finder (**3292.153**). Straight Flush itself is understood to have a short-range target acquisition capability.

The basic SA-6 unit is a regiment comprising five missile firing batteries. The main elements of such a battery include a Straight Flush radar for target acquisition and fire control and four TELs (transporter-erector-launchers), each of which carries three missiles. Six reload missiles are usually held in reserve on two missile transporter-loader vehicles.

The missile is constructed as a single-stage body containing a dual-thrust integral rocket-ramjet propulsion system. In the boost phase the missile is powered by a solid-propellant rocket motor which accelerates it at about 20 *g* to about Mach 1·5. With the completion of this rocket burn, the tail cone of the missile, which contains the booster nozzle, is jettisoned and the rocket propellant chamber becomes the combustion chamber for the ramjet, ram air being supplied through four intakes disposed symmetrically around the centre section of the missile. The ramjet takes the speed up to almost Mach 2·8.

Two sets of cruciform fins at the centre and tail of

SA-6 Gainful tactical surface-to-air missile launcher vehicle deployed

the missile provide stability and aerodynamic control, pitch and yaw being controlled at the centre and roll at the tail. The tail fins also carry the command link receiver antenna and the beacon transmitter antenna. The nose of the missile is an ogival radome for the homing head.

CHARACTERISTICS

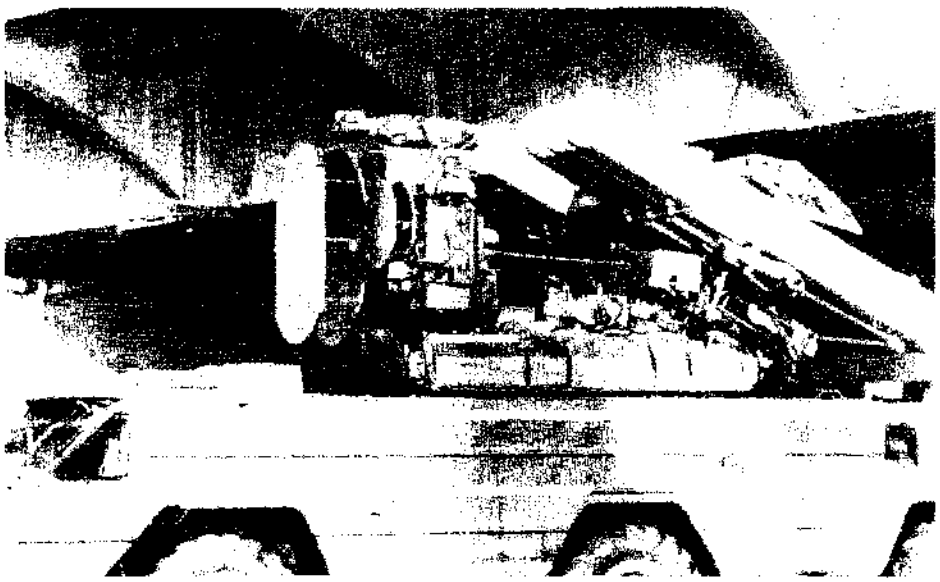
Type: Surface-to-air tactical guided missile
Guidance: Ground command plus semi-active radar homing. Aerodynamic control
Propulsion: Integral rocket ramjet
Warhead: HE, probably 80 kg total with 40 kg HE
Fuze: Proximity and impact; possibly also command
Missile lengths: 6·2 m including tail cone; 6 m without
Diameter: 33·5 cm
Tail span: 1·24 cm
Launch weight: About 550 kg
Ranges: Max. high altitude possibly 60 km; low altitude probably 30 km. Max altitude about 18 km. Minimum engagement about 4 km
Speed: Mach 2·8
Ceiling: 18 000 m

STATUS

Operational with Soviet forces and supplied to Algeria, Angola, Bulgaria, Cuba (possibly), Czechoslovakia, Egypt, German Democratic Republic, Hungary, India, Kuwait, Libya, Mozambique, Poland, Romania, Syria, Viet-Nam, South Yemen and Yugoslavia.

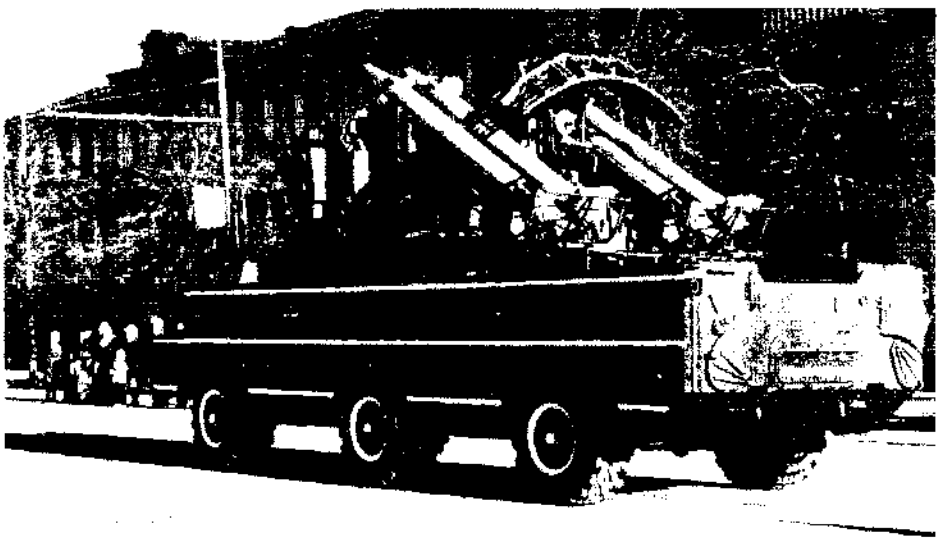
3209.131

SA-8 (GECKO) SURFACE-TO-AIR MISSILE



The SA-8 (Gecko) low-altitude surface-to-air missile is a command guidance system, and in addition to antennas for the search and tracking functions, the radar group (NATO designation, Land Roll) features two separate beacon tracking antennas and two transmitting horns for the command guidance signals. The main target tracking radar is a cassegrain type array, possibly using conical scan and a pulsed transmission waveform, and the two smaller cassegrain antennas flank the main tracker. They are mounted to provide a limited degree of movement relative to the main array and are assumed to be missile trackers. The command link horns for each are mounted beneath the missile tracker antennas.

Frequency use associated with the Land Roll radar group claims H-band for target acquisition and J-band for tracking purposes. Both semi-active radar and IR homing techniques have been postulated as the terminal guidance method, and either is feasible. Until better information is available it is not possible to be dogmatic about this aspect.



This arrangement indicates provision for simultaneous firing of two missiles with separate guidance for each. One possible use of this facility would be to enable simultaneous engagement of two separate targets within a formation, and another is to allow 'split' engagements with one target being tracked by the radar and another by the optical tracker which is incorporated in the system. There are other possibilities but it seems certain that a multiple target capability exists.

Both the missile launcher arms and the search radar antenna fold down for reduced transit height. The nature of the reloading arrangement cannot be ascertained from the evidence so far available, but the hull of the six-wheeled vehicles built to carry the SA-8 should be able to accommodate at least one full reload of four missiles and one source estimates as many as eight reload rounds. Two versions of the carrier vehicle have been noted, both about 9 metres long but differing slightly in overall length.

Control is by four small canard surfaces and there is a cruciform tail assembly of about 60 cm span. The design is probably optimised for high acceleration, maximum speed, and manoeuvrability rather than range.

SA-8B, Gecko mobile surface-to-air missile system on road. Note search radar folded

SA-8A Gecko mobile air defence missile unit on the move. Note folded down search radar

CHARACTERISTICS

Type: Mobile autonomous tactical air defence missile
Guidance: Radar command
Propulsion: Solid
Warhead: HE, proximity fuze
Length: 3·2 m
Diameter: 21 cm
Launch weight: 190 kg (estimated)
Range: 12 km
Speed: Mach 2
Ceiling: 6000 m

SA-8B

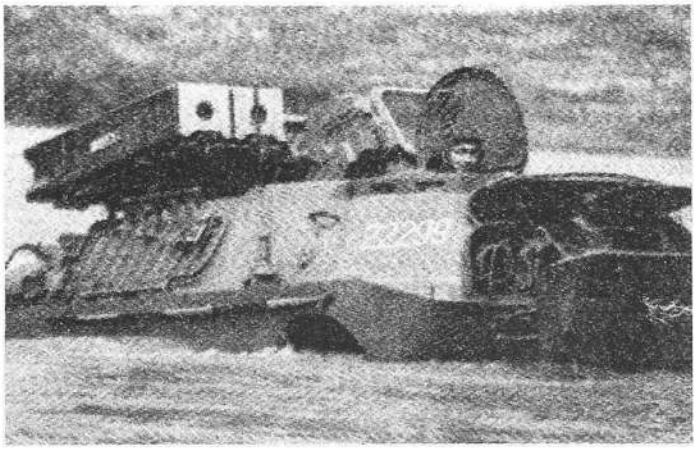
In a military parade in 1980 a new version of the Gecko system appeared in which the two twin missile launcher rails on the vehicle have been replaced by two triple launcher/containers, thereby increasing the ready-to-fire capacity by 50 per cent. This version was later confirmed as the SA-8B but as yet it is not known if a new NATO reporting code-name will be assigned to this model.

In appearance the six missile containers look slimmer than might be expected from photographs of the original exposed missile installation, and it is possible that the SA-8B missiles are provided with folding tail surfaces to enable their enclosure in the container/launchers. A special vehicle that carries reload missiles accompanies SA-8B fire unit vehicles. Gecko is usually deployed in batteries of four vehicles, each Soviet motor rifle and tank division having five batteries forming an air defence regiment.

STATUS

In service with the Soviet forces since the mid-1970s and operating with armoured and motorised rifle divisions. The level of deployment is reported to be approximately 20 vehicles per division.

In early 1983 it was confirmed that SA-8 systems supplied to the Jordanian forces were operational, and other deployments in this region include Syria where SA-8s have been operated in company with other Soviet SAMs such as the SA-2, SA-3, SA-5 and SA-6.



3072.131

SA-9 (GASKIN) SURFACE-TO-AIR MISSILE

The SA-9 Gaskin designation refers to what at first was generally thought to be an SA-7 Grail (**2941.131**) derivative, but subsequent indications suggest this assumption to have been incorrect.

Gaskin is commonly encountered in vehicle-mounted form, on a BRDM-2 type four-wheeled cross-country vehicle. The usual installation comprises four launcher containers with an aimer's position incorporated in the base. The launcher containers are individually loaded manually on to the tubular construction mounting frame carried by the turret. When operated in an autonomous mode, the method of target acquisition is presumed to be by visual means with subsequent aiming of the weapons by optical systems. The launcher containers fold down and lie flat on the roof of the vehicle during transit, and each BRDM-2 is able to carry a full load of eight SA-9 missiles, ie one reload round for each launcher. Although the normal configuration is with four launchers per vehicle, a small number of BRDM-2s with only two are reported to have entered service.

It has been reported that when used as part of a larger air defence column, SA-9 vehicles can be linked to search radars to assist in target acquisition, and another method could be that of using radio

SA-9 Gaskin launch vehicle with launcher complete with four missile canisters folded flat for transit

Gaskin launcher vehicle with four-canister mount in ready-to-fire position

communications links to 'tell off' targets to individual SA-9 firing units.

It has also been reported that versions of the SA-9 have been seen equipped with the Gun Dish fire control radar (**2876.153**) mounted in front of the SA-9 turret, presumably to provide a degree of 'blind fire' capability for night and adverse weather operations. This was probably a reference to the later SA-13 system (**4471.131**, below) which externally resembles the SA-9 to which a radar antenna has been added between the two pairs of missile containers.

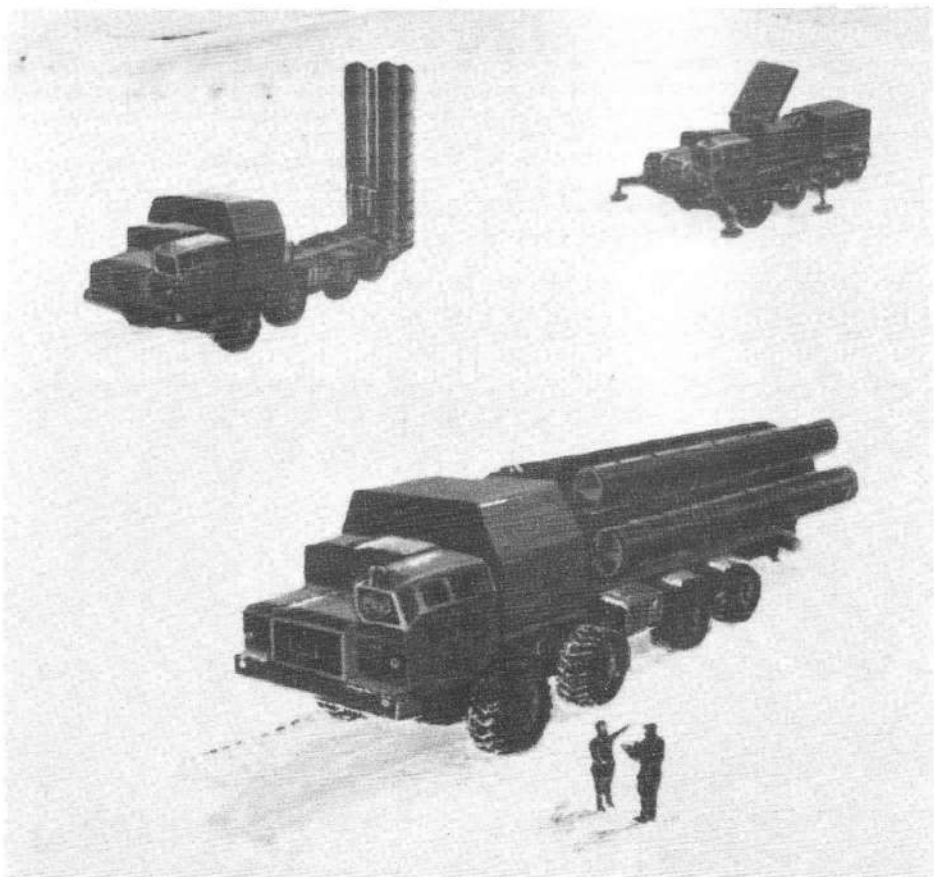
CHARACTERISTICS

Type: Mobile short-range tactical air defence missile
Guidance: IR homing
Propulsion: Solid
Warhead: HE
Length: 2 m (approx)
Diameter: 12 cm
Launch weight: 30+ kg
Range: 8 km (approx)
Speed: Mach 1·5+
Ceiling: 4000 – 5000 m

STATUS

US sources claim that the SA-9 was first deployed by Soviet forces in 1968, but since then this weapon has been observed with the forces of Algeria, Hungary, Poland, Syria, Viet-Nam and Yugoslavia. In Soviet formations, for regimental air defence SA-9s are deployed at a level of 16 per division (four per regiment).

3620.131



SA-10 (GRUMBLE) SURFACE-TO-AIR MISSILE

SA-10 (NATO-code Grumble) is the designation of one of the latest generation of Soviet air defence missiles, but so far no photographs or other information have been made public by Soviet sources. However, for several years this weapon has attracted a good deal of attention in official US circles suggesting that considerable importance is attached to it.

If public statements and other information issued by the US DoD are any indication, quite considerable intelligence gathering efforts have been expended on the SA-10, but while certain conclusions reached by the American evaluators have been widely distributed, the evidence on which they are based remains severely restricted. Over the past few years SA-10 has been described as having been designed specifically to engage low-level targets such as attacking cruise missiles, and as a strategic air defence missile with high performance at both high and low altitudes.

The following paragraphs are based on what constitutes the current official assessments of SA-10 capabilities and estimated characteristics.

The SA-10 is a modern advanced surface-to-air missile system apparently designed for the air defence of the Soviet Union, and is believed to be an 'all-altitude' weapon, which may exist in both semi-permanent and mobile versions. The 1984 edition of the official US publication *Soviet Military Power* states that "the Soviets are developing a mobile version of the SA-10 SAM . . . (which) could be used to support Soviet theatre forces, but, more importantly, if deployed with the territorial defence forces, would allow the Soviets to change the location of those SA-10s in the USSR. The mobile SA-10 could be operational by 1985". Elsewhere in the same document it is stated that the SA-10 is now in series production. The obvious implication is therefore that 'A' and 'B' versions of the SA-10 either exist or are about to.

SA-10 Grumble mobile air defence missile system includes planar array radar and transporter-erector-launcher units on wheeled chassis according to US analysts

The SA-10A would be the non-mobile (though probably not fixed, ie transportable or semi-permanent) model which is stated by the US DoD to be operational now at about 40 sites with nearly 350 launchers. Deployment is said to have been in progress since 1980.

The missile is understood to be about 6·25 metres long, with a diameter in the region of 45 cm and a maximum range of some 100 km. US drawings of the mobile version of SA-10 suggest that the missile is transported in tubular canisters which elevate to the vertical for launching. The canisters are carried in groups of four on a large wheeled transporter. There is apparently no provision for slewing in azimuth to aim the missile towards the target so that a vertical launch technique is implicit in the US artist's impression (reproduced here). From this drawing it will also be noted that associated with the SA-10 is a planar array guidance radar on a similar wheeled vehicle.

If the above assumptions are correct, and the vertical launch technique is employed, then the semi-permanent SA-10 installations might well utilise a form of silo launcher arrangement with a number of silos installed around important targets for their protection. The silos might or might not be permanently loaded with SA-10 missiles, and similar considerations could apply also to the associated radar(s), these items being deployed to the fixed site only at times of tension or threat, for example. At other times missiles and radars could be deployed elsewhere to meet other threats, for exercise, into hiding, or into storage etc.

Based mostly on US evaluations of intelligence data and their published findings, there is some similarity between this system (SA-10) and the possibly newer SA-X-12 system (**4774.131**), but these may have arisen by having been illustrated by the same artist as much from the similarity of the presumed roles of the two systems. Judgement must be reserved until more evidence is forthcoming.

STATUS
Believed to have been deployed in 1980 and operational with PVO Strany (Home Air Defence Command) in the USSR since 1981. In early 1984 official US sources stated that there were about 40 operational SA-10 sites with some 350 missiles. The SA-10 is in series production. A mobile version could be operational by 1985 according to the US DoD.

4470.131
SA-11 GADFLY SURFACE-TO-AIR MISSILE

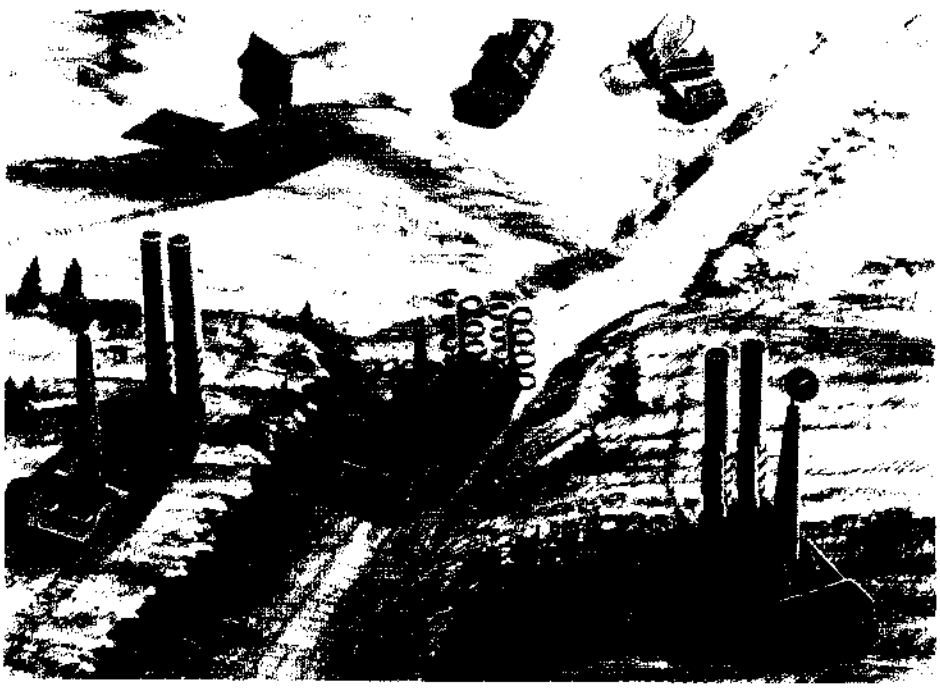
The Soviet SA-11 (NATO-code Gadfly) is believed to be a new land-mobile short-range surface-to-air missile system thought to have begun initial troop trials in 1978-79. There are few firm details of the missile itself or its performance. The launcher vehicle is based on that employed for the ZSU-24-4 mobile anti-aircraft radar directed quadruple 23 mm gun system. In this later application the vehicle carries a turntable mounting which can be rotated through 360 degrees, on which there are provisions for the carriage of four ready-to-fire SA-11 missiles. Estimated performance figures include a speed of Mach 3 and minimum and maximum range of 3 and 28 km, respectively. Targets flying at altitudes between 30 and 14 000 metres can be engaged, and radar guidance has been assumed.

An associated vehicle, also on a ZSU-23-4 tracked chassis, carries a 3-D acquisition radar called Clamshell in the NATO designation system, and a tracking radar designated Flap Lid.

STATUS
Official US assessments in 1985 were that the SA-11 Gadfly system was entering service at divisional level.

4774.131
SA-X-12 SURFACE-TO-AIR MISSILE SYSTEM

SA-X-12 is the designation assigned to an air defence missile system under development in the Soviet Union that is expected to reach operational status soon. No details have been made public by the Soviet authorities, and official US sources have published only the partial results of their assessment of the intelligence data on the SA-X-12 system that has been obtained, rather than any of the evidence or photographs themselves.



The system has been identified as both a tactical surface-to-air missile and anti-tactical ballistic missile, by which is meant an ability to intercept intermediate range nuclear weapons such as the US Lance and Pershing II missiles. Unofficial US observers have apparently used this DoD assessment as a basis for an extrapolation to arrive at estimated performance characteristics that include an acceleration capability of 50 *g*, and a slant range of more than 550 km. (Both reasonable values, given the declared operational capability, but the DoD range estimate is lower at 100 km.)

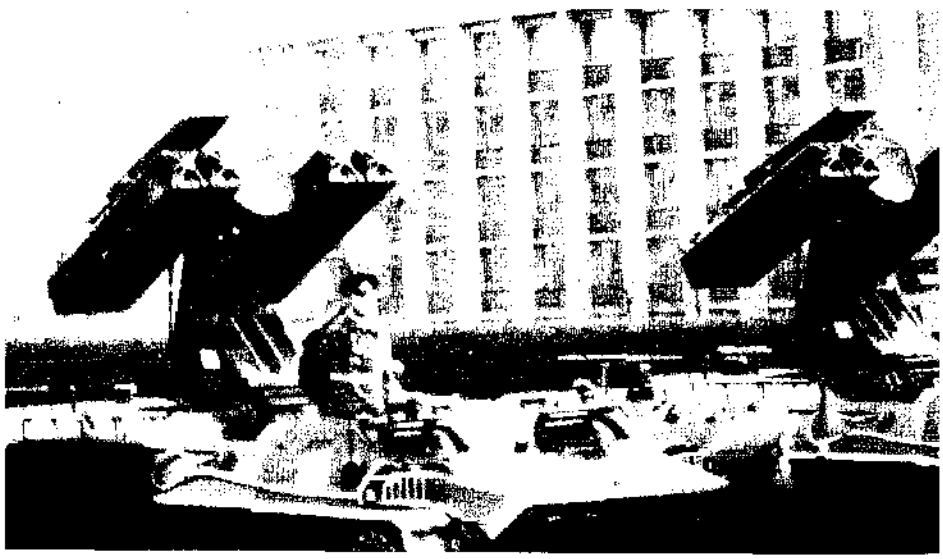
Another possible role foreseen for the SA-X-12 is as a successor to either replace or augment the SA-4 Ganef front/army surface-to-air missile system (**2934.131**), as a tactical air defence system. An artist's impression of the SA-X-12 (reproduced here) shows the entire complex carried on a series of tracked armoured vehicles, with one type carrying two missiles in tubular launcher canisters as well as a guidance radar mounted on a retractable tower. The vertical launch technique is apparently employed as there is no provision for altering the launch azimuth once the vehicle has been halted to launch the missiles. The SA-10 surface-to-air missile (**3620.131**) in its mobile version is thought to use a vertical launch also.

With the two transporter-erector-launcher vehicles is a resupply vehicle, also tracked, which is equipped with a crane and supports for transporting and manipulating four reload missiles. Other vehicles that can be seen are two planar array radars which probably fulfil search/target detection and designation functions, and what could be either a crew or command and control vehicle.

US sources have likened the SA-X-12 to the US Patriot surface-to-air system (**2800.131**), which could imply an advanced type of guidance and control system. This would certainly be in keeping with the presumed design and development time-scale, and would probably be essential to fulfil the demanding performance characteristics erected to the system.

STATUS
Field trials believed to have been completed by mid-1984. No deployment information obtained, but system is thought to be operational soon.

Mobile SA-12 surface-to-air missile system is expected to be capable of engaging both high performance aircraft and missiles such as Lance and Pershing. Vertical launch technique is implied in this US artist's impression



---

4471.131
SA-13 (GOPHER) SURFACE-TO-AIR MISSILE

The SA-13, NATO code-name Gopher, is a low altitude air defence missile system which is intended to replace or supplement the SA-9 Gaskin system (**3072.131**) for the protection of Soviet mechanised formations. Both systems have a very similar configuration, with the SA-9 mounted on a wheeled chassis and the SA-13 on a tracked vehicle. Initially it was thought likely that the two systems shared a common missile that might have been based on an air-to-air missile such as the AA-8 Aphid (**3339.331**), but in both respects these ideas are now considered incorrect. Later evidence indicates that the SA-13 missiles are slightly larger than those of the SA-9 system (see diagram).

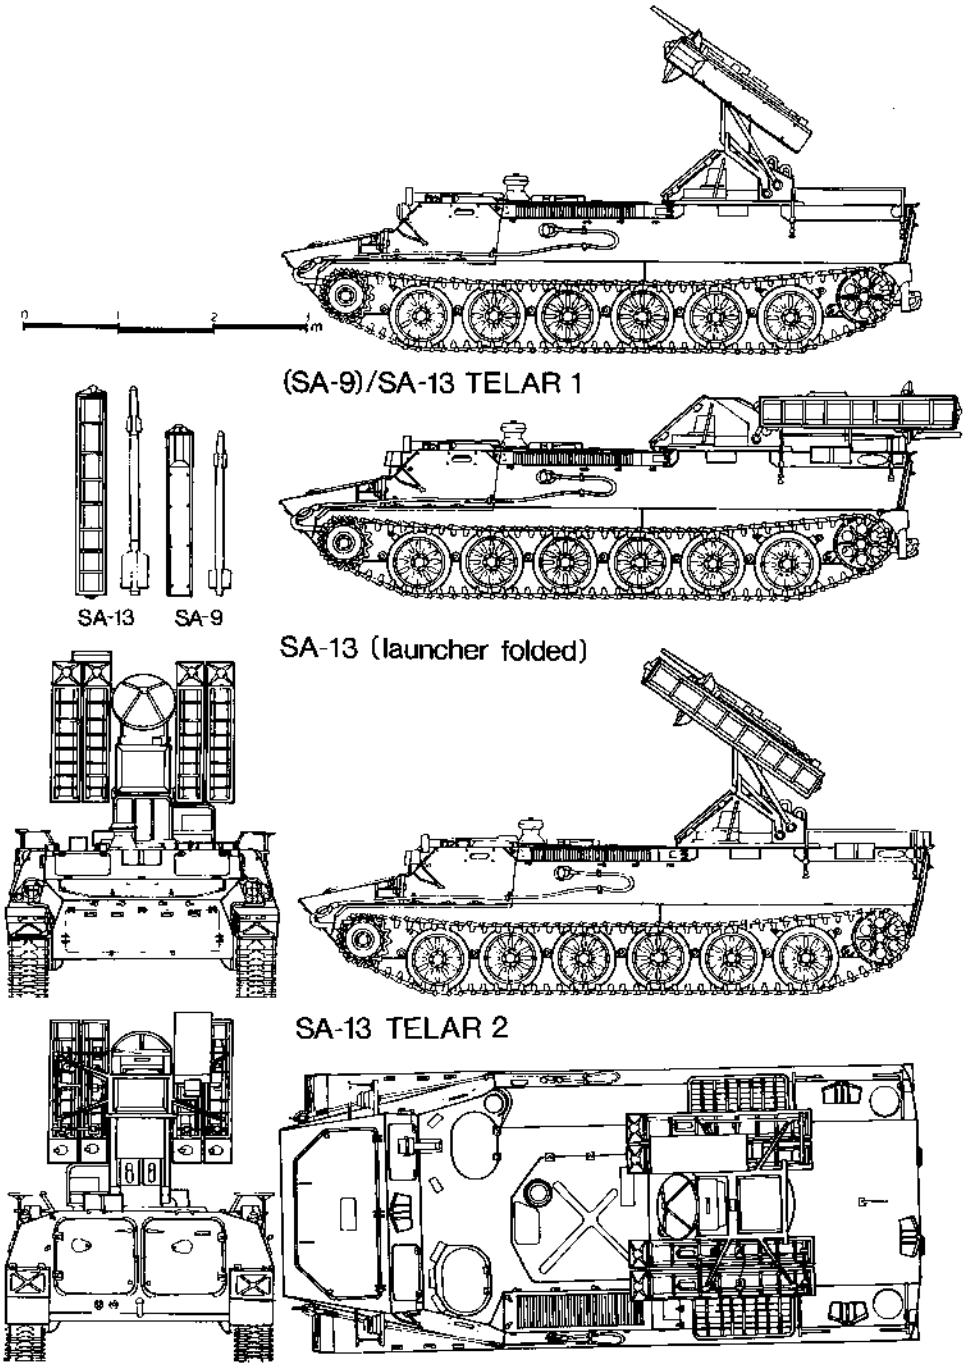
Two versions of the SA-13 have been noted, these being referred to as TELAR 1 and TELAR 2, where TELAR stands for transporter-erector-launcher-and-radar. This term embraces several of the main features of the system, namely, mobility; the folding retraction arrangement of the four-canister launcher; and the radar dish mounted between the two pairs of missile canisters.

The radar is assumed to be a range only equipment that operates in conjunction with the SA-13's passive IR homing head for missile guidance, but at this stage

Ceremonial appearance of SA-13 Gopher mobile SAM vehicles

it would be unwise to rule out other possibilities such as a target tracking mode for the radar perhaps to assist multiple target engagements. In such a mode of operation, optical fire control could be expected to provide one line-of-sight channel, and radar the other, and provided the missile IR seekers are locked onto their respective targets before launch, thereafter they would effectively operate in a 'fire-and-forget' mode.

Another function of the radar as a range-only device that has been suggested is that its use would enable the crew to ensure that only targets within lock-on range of the IR seeker would be engaged, thereby avoiding wastage of missiles.



It is believed that as many as 12 to 14 reload missiles could be carried internally in each TELAR. The TELAR vehicle is fully amphibious, and the only significant external difference between the two models is that TELAR 1 carries four small box-shaped units at the corners of its top deck which are thought to be ESM antennas for the Hat Box system, although other observers have suggested alternatives for this feature, such as a data link for communication with other vehicles of a formation. Inter-vehicle communication within formations of this kind, under battle conditions could be an important requirement, as would be some form of IFF, and these are other possibilities for the Hat Box role. TELAR 2 apparently does not have the Hat Box items.

CHARACTERISTICS

Length: 2·2 m
Diameter: 12 cm
Span: 40 cm
Launch weight: 55 kg
Speed: Mach 1·5+
Range: 10 km (max); 500 m (Minimum)
Max altitude: 5000 m
Warhead: HE 6 kg
Guidance: Passive IR homing

STATUS

Thought to have been deployed with Soviet forces since 1975, but first seen in public in 1982.

GA drawings of two SA-13 Gopher system versions, with SA-9 and SA-13 missiles and canisters for comparison (Steven Zaloga)

4524.131
GUARDIAN AIR DEFENCE SYSTEM

Guardian is a proposed long-range surface-to-air missile system based on the Sea Dart naval missile (**6004.231**). It provides land-based area air defence against attacks from both high and low altitudes. The system can be supplied in versions either for operation from fixed sites, or as a fully mobile system capable of rapid deployment from semi or unprepared sites.

The system may also be employed in a surface-to-surface role, for instance in the defence of coastal installations against attack by surface vessels.

A Guardian air defence system consists of a number of co-ordinated batteries. Each battery typically comprises two firing troops, controlled by a battery headquarters with an associated surveillance radar. A firing troop has a troop command post and four launchers, each having four boxed missiles. Thus each troop has 16 ready to fire missiles.

A firing troop consists of a troop command post, a tracking/illuminating radar (TIR), four launchers, missile re-supply vehicles, generators and servicing facilities.

Each troop command post includes a lightweight TIR and a weapon control console to co-ordinate the four launchers. When commanded to engage, the TIR acquires and tracks the target, having been supplied with target indication data by the surveillance radar.

The missile is the well proven Sea Dart missile, propelled by a tandem mounted solid-propellant booster and ramjet sustainer motor. It has a cruciform wing and rear mounted control fins, with four flip-out stabilising fins mounted on the jettisonable boost section.

STATUS

The Guardian system has been proposed to various overseas countries and for use in the Falkland Islands.

CONTRACTOR

British Aerospace Dynamics Group, Bristol Division, Filton, Bristol BS12 7QW, England.

2406.131
BLOODHOUND Mk 2 SURFACE-TO-AIR WEAPON SYSTEM

Bloodhound Mk 2 is a second-generation mobile anti-aircraft guided weapon sub-system suitable for incorporation in a comprehensive air defence system. The basic unit, a missile section, typically comprises eight guided missiles and their launchers, a target illuminating radar (TIR), and a launch control post (LCP). The guidance principle is semi-active homing, the missile detecting and homing on the radiation reflected by the target when illuminated by the TIR.

Basic input required by the missile section is target location information from a surveillance radar which may be directly associated with the Bloodhound sub-system or may be part of the central equipment of a larger complex. This information is supplied to the TIR, which then searches for, acquires, and automatically tracks and illuminates the target. Simultaneously, it interrogates the target for positive identification and transmits the appropriate information to the LCP. Alternatively, the TIR may operate autonomously should data be unavailable from a surveillance radar.

At the LCP, which is the control centre of the missile section, sits the engagement controller assisted by a technical supervisor. A computer in the LCP processes the output data from the TIR to determine the optimum conditions for target engagement. This computer also performs routine

tasks concerned with the state of readiness of the system; both the engagement controller and the technical supervisor are provided with displays and communications equipment to enable the former to take rapid operational decisions and the latter to maintain maximum equipment serviceability.

In the role for which it was first designed, the Bloodhound missile section is normally equipped with the Firelight TIR (**2413.153**) which is readily mobile and air-transportable. The whole equipment is contained in a single cabin and the antennas are mounted on a retractable pedestal on the roof. For static operations, or where system mobility is not a prime consideration, there is an alternative TIR, the Scorpion (**2428.153**), which is a larger radar giving a longer range. It can be broken down into transportable units but cannot be brought into or taken out of operation as quickly as the Firelight. Both radars are I/J-band CW doppler systems having good performance in the presence of natural or ECM interference.

CHARACTERISTICS

Type: Surface-to-air land-based GW system. Land-mobile. Air-transportable

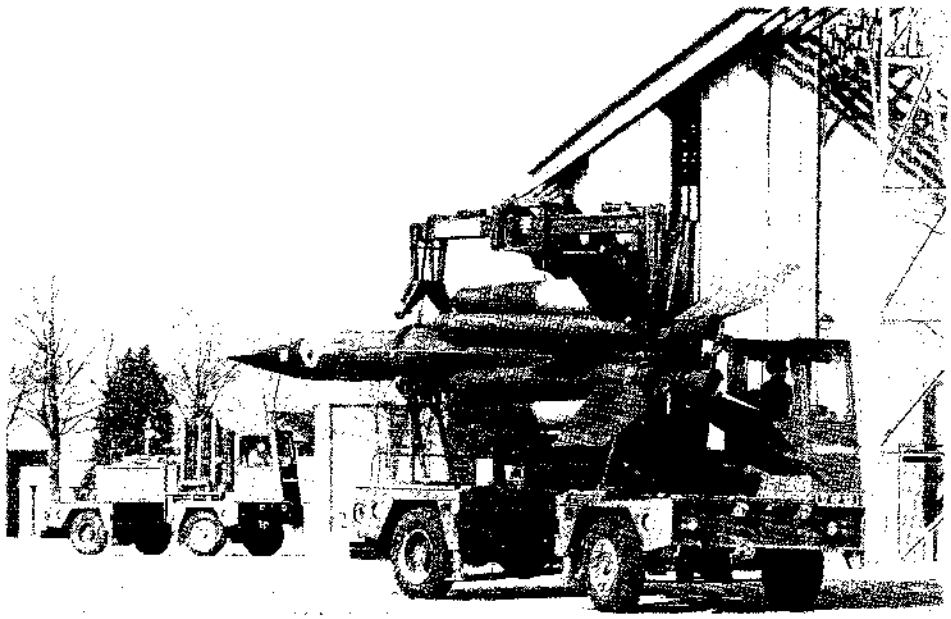
Guidance principle: Semi-active homing. Receiver in missile nose detects and follows radiation reflected by target when illuminated by TIR

Guidance method: Twist-and-steer by pivoting wings

Propulsion: Ramjet with solid-propellant boosters

Warhead: HE, with proximity fuze

Launch control: From LCP by computer using data from TIR



Radar: Choice of 2 TRs – Firelight or Scorpion

Range: >80 km

DEVELOPMENT

Bloodhound Mk 2 is the successor to Bloodhound Mk 1 which first went into service with the RAF in 1958, development having been started by the Bristol Aeroplane Co Ltd and Ferranti Ltd in 1949. Bloodhound 1 was also exported to Australia and Sweden.

The first design study for the Mk 2 version was started in 1958; the new version went into service with the RAF in 1964. In the same year the equipment also went into service with the defence forces of Sweden and Switzerland (designations RB68 and BL-84, respectively).

Bloodhound air defence missile at an RAF depot

In late 1969 BAe was awarded a £10 million contract from the Singapore Government for the refurbishing of the Bloodhound system previously operated by the RAF in that area.

STATUS

The RAF has Bloodhound sites in the UK as part of the NATO and UK Air Defence network, overseas Bloodhound units elsewhere having been withdrawn completely. In 1977 it was announced that the number of Bloodhound sites in the UK was being increased to strengthen the national air defence capability. This has been achieved by adding Bloodhound Mk 2 units withdrawn from service in West Germany to existing Bloodhound missiles deployed in the UK, a move completed by March 1983. In August 1978 a UK MoD programme drawn up to extend the useful operational life of Bloodhound was announced.

Bloodhound Mk 2 is also in service with the Swiss armed forces who operate about 64 launchers, and the Singapore Air Force with 24 launchers. In early 1984 BAe received a contract from the Swiss Government for a further supply of Bloodhound boost motors, indicating a significant continuation of the system's existing 15-year life in Swiss service.

CONTRACTORS

The following manufacturers are known to have been associated with the system:

Overall system, missile airframe etc (consortium leader overseas): British Aerospace Dynamics Group, Bristol, Avon, England.

Overall electronic system, missile homing system, LCP computer etc, Firelight TIR: Ferranti Ltd, Edinburgh (TIR) and Oldham (remainder).

Ramjet propulsion system: Rolls-Royce Ltd.

Missile fuze: Thorn-EMI Electronics Ltd.

Scorpion TIR: Marconi Radar Systems Ltd.

2424.131

RAPIER MOBILE LOW-LEVEL ANTI-AIRCRAFT MISSILE SYSTEM

The four current members of the Rapier family of low level air defence weapon systems are based on the use of the Rapier missile and all use CLOS guidance. Different methods of target and missile tracking are used in each of the four types of Rapier, and allow operation in either all weather, clear day and night or clear day only conditions.

Rapier Missile

The Rapier missile is a lightweight highly manoeuvrable directly hitting missile, capable of high g turns, which maintains a speed of Mach 2 out to its maximum range of approximately 7 km. The direct action fuze explodes a small warhead inside the target and this combined with the considerable force of impact of the missile ensures destruction of even heavily armoured targets. The fuze is immune to ECM or detonation by ground echoes.

Although Rapier has been developed in step with new technology over the years, the missile has remained basically unaltered and has been retained because of its proven high lethality and aerodynamic performance which gives an extended cover against fast crossing targets.

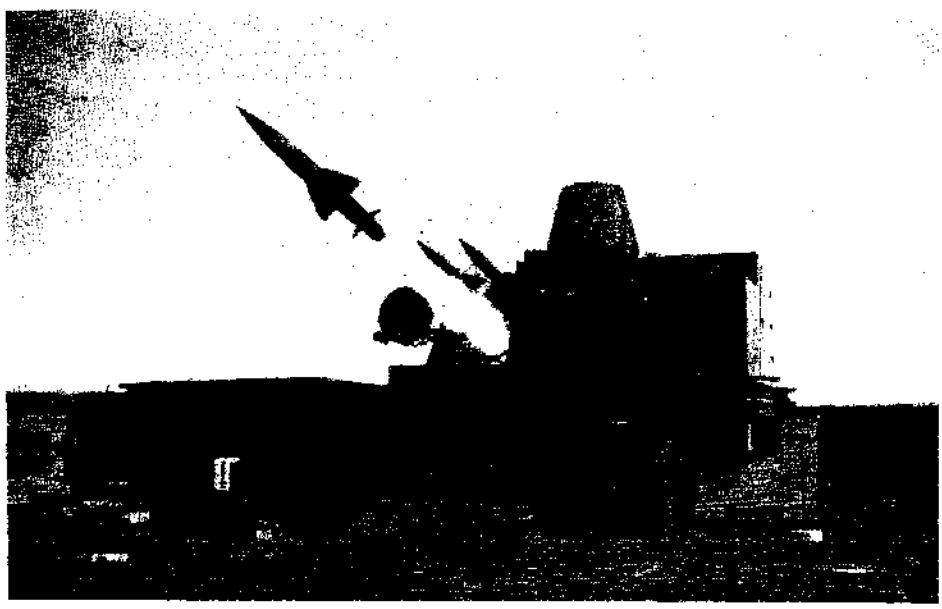
CHARACTERISTICS

Range: 7 km (approx)

Launch weight: 42 kg

Speed: Mach 2

Propulsion: Integral 2-stage solid propellant motor

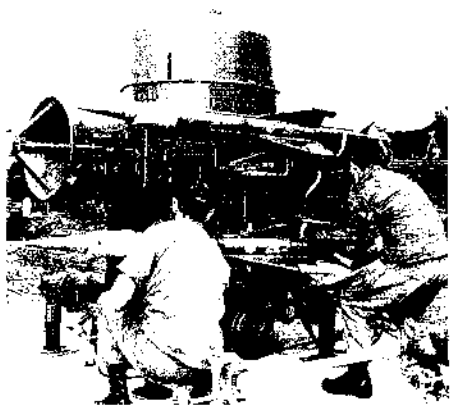


Fuze: Direct action crush fuze

Rapier is designed for defence against fast (Mach 1+) manoeuvring low-flying aircraft and helicopters. It has the fast reaction time required to engage these targets which may appear suddenly at short range from behind terrain screening. It also has the range to destroy aircraft which are either directly approaching or crossing at heights over 3000 m.

Towed Rapier (optical daylight only)

The main operational units of the optical system are, a launcher which contains the surveillance radar, an optical tracker, a secondary sight and a tactical control unit (TCU), all of which are interconnected by cable. The surveillance radar and co-located IFF are built into the launcher, the aerial rotating under a radome for concealment. The launcher also contains the system computer, the command transmitter aerial and holds four ready to fire missiles.



The fire unit is lightweight and composed of small easily handled units, it can be deployed in fire positions, such as the flat roofs of tall buildings or positions in mountainous country, which are often inaccessible to the heavier SHORADS equipments.

Evaluation firing of Rapier Laserfire at MoD Test Range at Aberporth in Wales

Once the four missiles have been loaded (a two-man task) one man can operate the system. When there is a mix of friendly and enemy aircraft, or in ECM conditions, it is usual to use a crew of two (an operator and a tactical controller).

When the surveillance radar detects a target it automatically interrogates it with the IFF. Only hostile targets will alarm the system by alerting the operator and slewing the launcher and optical tracker to the target azimuth. The operator uses his optics to search for the target in elevation and having acquired it, tracks the target using a joystick control. On receiving an 'In Cover' signal from the computer, the operator

Two men can reload the Rapier launcher unit

fires the missile which is automatically aligned to fly on to the line of sight (LOS). During the engagement the operator continues to track the target, while the TV camera automatically tracks flares on the missile and measures any missile deviations from the LOS. These measurements are fed to the fire unit computer which generates and encodes signals for the command transmitter to send to the missile to maintain it on the LOS until impact.

The TCU is used by the detachment commander to ensure that the system does not engage friendly aircraft which are flying in pre-arranged safe lanes at safe heights. The system's 360 degrees coverage is divided into 32 sectors each of 11·25 degrees. By operating switches blind arcs can be set, or priority arcs for the fire unit should this be required. Should a hostile target be identified in the safe lane, Rapier can revert to its normal mode and engage it. The TCU also includes facilities which are used to eliminate or greatly reduce ECM.

Optical Rapier is towed by a lightweight vehicle (¾ or 1 ton) which also carries the optical tracker and four missiles in sealed containers. A second vehicle tows a missile resupply trailer carrying nine reload missiles in sealed containers. A complete system can be transported by medium lift helicopters as under slung loads or carried internally by heavy lift helicopters such as the CH53.

Blindfire Rapier

In circumstances where there is a threat of day/night and all-weather attack, a radar tracker (designated DN181 **2439.153**) can be added to any optical fire unit to give an all weather capability.

The Blindfire radar (DN181) developed by BAe in conjunction with Marconi Space and Defence Systems (**2439.153**) is mounted on the same type of chassis as the launcher and with its own generator is towed by the same type of lightweight vehicle. A Blindfire fire unit carries 17 missiles in containers and has the same cross country mobility and air portability as the optical fire unit.

The monopulse pulse radar tracker operates at a very high frequency and produces an extremely narrow beam. Frequency agility is used to reduce the effect of target glint and as an effective ECCM. The radar tracks the target and the missile in the same beam using differential tracking techniques giving great accuracy to produce a very high 'single-shot kill probability', even in the most adverse conditions. The use of the very narrow beam gives excellent discrimination against aircraft flying in close formation and allows targets flying nap of the earth courses to be engaged without ground echo interference.

An engagement is carried out in the same manner as an optical engagement, except when following a surveillance radar alarm. The operator selects 'Radar', the radar tracker is slewed to the target azimuth and carries out an automatic elevation search and locks on the target. When the operator receives the signal that the radar has locked, and the 'In Cover' Signal, he presses the fire button to launch the missile, then the engagement sequence is automatic requiring no operator action.

When the missile is launched it is gathered into the radar beam and the radar tracks the missile and target simultaneously. The radar measures any missile divergance from the radar bore site which is encoded by the system computer and sent to the missile by the command transmitter in the same way as in an optical engagement. Blindfire's high lethality has been proved in thousands of service firings world-wide.

As an add-on facility, the Blindfire radar gives great flexibility as it can be deployed with those optical fire units defending targets such as airfields, bridges and other fixed installations which may be liable to be attacked at night or in adverse weather. As an example, the British Army has only a 33 per cent Blindfire capability to defend units in the field whereas the RAF Regiment defending airfields has 100 per cent Blindfire capability.

Swiss Rapier

A £200 million contract for a version of Towed Rapier specifically configured to meet the requirements of the Swiss Army was awarded in December 1980, and the first of these systems was officially handed over in June 1984. In the course of meeting this contract, Marconi Space and Defence Systems Ltd delivered the 100th Blindfire radars supplied for use with Rapier.

To meet the particular requirements of the Swiss Army and its operating environment, a special version of the standard Towed Rapier was designed in response to the contract awarded to BAe in December 1980. The Swiss Army required an improved acquisition and tracking capability in mountainous terrain, a special-to-Swiss ECCM capability, a PPI tactical display, a Swiss IFF system, and the use of the standard Pinzgauer vehicle as the towing and support vehicles. The following significant modifications were developed to meet Swiss Army requirements:

(1) the launcher was modified to accommodate and operate with the Swiss IFF unit

(2) the radar tracker was modified to give the special ECCM required, and improved detection circuits fitted to enable operation in the presence of the heavy ground clutter experienced in mountainous country. It was also modified to provide a lower negative tracking angle when sited on high ground to allow engagement of targets below the level of the Rapier fire unit

(3) surveillance radar data processing was altered to provide multiple target plotting and ECCM capabilities for use on the tactical display

(4) the Swiss version is the first Rapier model to incorporate a display unit, by giving the operator a PPI display using TV techniques. The display enables him to see alternative targets, together with a number of command functions, to enable a complex scenario to be assessed. There is also a facility that provides for presentation of ECM data to the operator. The radar display unit, launcher data processor and surveillance radar data processor are linked by a data highway

(5) the fire unit generators have been modified to suit the peculiarities of the Swiss climate, and adapted for carriage in the Pinzgauer vehicles.

Each of the Swiss Army mechanised divisions is responsible for its own air defence, and is being equipped with one battalion armed with 20 mm AA guns and another with the Rapier. The latter battalion is divided into a mobile headquarters battery, and two AA guided missile batteries. The mechanised divisions are responsible for the co-ordination, training and deployment of Rapier with all the other units being protected.

Modifications

Since it came into service Rapier has been modified to give greater reliability, ease of maintenance and repair, and the performance and ECCM facilities have been adapted to meet the changing air threat now and in the forseeable future. A continuing UK MoD financed programme to keep Rapier in service until at least the year 2000 has resulted in the following additions and modifications, in addition to or in place of the changes made for the Swiss authorities.

(1) the introduction of a planar array aerial in the surveillance radar to give more accurate data and to provide a high degree of immunity to ECM

(2) improvement to the IFF system by a method of interrogator side lobe suppression (ISLS) to reduce anomalies in the interrogation and identification of targets

(3) an automatic code change for the IFF which allows 24 codes to be pre-set and changed at the required intervals

(4) the introduction of microprocessing for self test and diagnostics in the field

(5) a safe lane indicator computing system (SLICOS) has been added to the Blindfire radar to give greater safety to friendly aircraft using safe lanes without reducing the system's coverage.

These and a number of ECM improvements have increased system availability and effectiveness.

SYSTEM CHARACTERISTICS

Type: Surface-to-air GW system, land-mobile, air transportable.

Guidance: CLOS

Guidance method: Optical or radar CLOS, optical target tracking, automatic TV missile tracking. Computer calculates corrections to keep missile on LOS transmitted over command link. Hot gas servos actuate missile fins, or Blindfire radar tracks target and missile in same beam to give automatic engagement

STATUS

Rapier has been operational for some years, and has been adopted for the inventories of the armed services of 13 countries, as well as being under consideration for others. Those countries which are

Towed Blindfire Rapier deployed in the field

understood to have Rapier in service or have placed contracts include Abu Dhabi, Australia, Brunei, Iran, Oman, Qatar, Singapore, Switzerland, Turkey, UK, USA, Indonesia and Zambia. As detailed previously, some of these have more than one version of the Rapier system in service eg Towed/Optical, Towed/Blindfire, Tracked Rapier etc.

As noted under this entry number in *Jane's Weapon Systems 1983-84*, Rapier was credited with a number of successful engagements in the Falklands campaign of 1982, and the system has been selected for the protection of certain US Air Force missile bases in Europe.

The Australian Rapier low level air defence system was completed in late 1983, by which time a total of 20 fire units had been supplied, supplemented by ten Blindfire radars.

In June 1984, BAe announced the development of a battery command post processor, intended primarily for use with the Rapier low-level AA system. It eliminates the manual processing associated with missile battery siting, and the software can be changed to accommodate other air defence systems, anti-tank defences, data base management or other functions.

Tracked Rapier

Members of the M113 family of vehicles (manufactured by FMC) have been chosen for Tracked Rapier; in particluar an armoured version of the M548 cargo carrier (known as the RCM 748) is used as the launcher vehicle. The use of this vehicle means that Tracked Rapier is highly mobile and can accompany tanks and other armoured vehicles over difficult terrain and, being amphibious, can cross inland waterways. The mobility and quick into action times makes Rapier available to defend mobile forces in battle against attack by fast low flying aircraft and anti-tank helicopters.

The launcher vehicle is based on the M548, the main alteration being the addition of an armoured cab. The aluminium armour provides the crew and equipment with protection to APC standards. The system has been designed to be operated by personnel wearing nuclear, biological and chemical protective clothing. The vehicle commander is provided with a cupola which enables him to use the Ferranti helmet pointing system for passive target acquisition. An air cooling unit is positioned immediately behind the cab and the vehicle cab also has a heater. To the rear of the cab is the shield which protects the forward part of the vehicle from blast effects when a missile is fired.

The Rapier elements are mounted on the RCM 748 to form the launcher vehicle. The optical tracker is mounted in the cab roof and all but the top of the rotating head is armour protected. The tactical control unit and built-in-test equipment are also situated in the cab. The H-30 diesel engined generator set is situated to the rear of the vehicle engine bay. The launcher is installed on anti-vibration mounts at the rear.

Eight missiles are carried, four on each side, with armour plate protection. The turntable and base of the launcher are also protected to APC standards by armour plate. The command antenna is mounted on an elevating mechanism which allows missiles to be fired and guided at low elevations over the cab. The Blindfire radar is fully compatible with Tracked Rapier system, and can be cabled in to provide an all weather capability should this be required.

A day and night capability is the more likely requirement for the army in the field and this is provided by giving the optical tracker an IR capability, when it is known as TOTE (Tracked Optical Thermally Enhanced). This combines the optical tracking facilities already available to Tracked Rapier with a thermal imaging device working in the IR spectrum. The tracker has been redesigned to accommodate three new major units: a passive IR telescope scanner which is consistent with the existing optics, an electronics pack for processing the IR signals and a monitor unit on which the target is displayed to the operator.

TOTE, which will be retrofitted to existing Tracked Rapier, will allow the system to operate in an entirely passive mode by providing an automatic passive search with the surveillance radar switched off. In daylight conditions the operator has the choice of optical or IR tracking.

In the IR mode the target is detected by means of TOTE, which can traverse automatically in azimuth. The operator acquires the target, the system is switched to track, and the operator tracks the target using the crosswires as in the optical system. Missile firing and target destruction then occurs in exactly the same way as with the optical system.

This new addition has the added battlefield advantage of enabling target detection to be carried out at night and also through fog and smoke in daylight conditions.

CHARACTERISTICS

(Tracked Rapier)

Mobility: Low ground pressure, low centre of gravity, high power-to-weight ratio, giving excellent cross country mobility. Amphibious. Helicopter lift by CH53E and air-transportable, combat ready in C-130 or similar transport aircraft

Armour protection: For crew and equipment up to APC standards

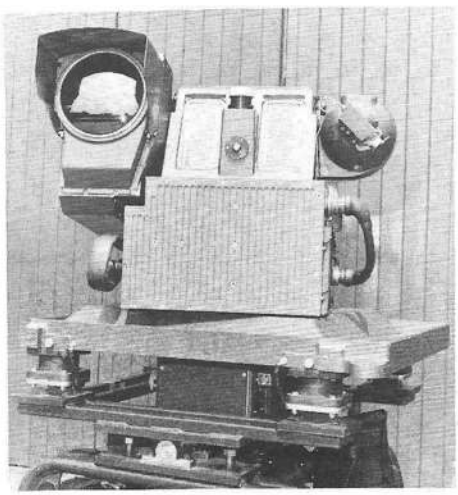
Survival: Low silhouette (height under 2·8 m). Surveillance aerial rotates under radome for concealment in action

Coverage: 360° cover gives a lethality zone of over 140 km². Minimum range 400 m

Fire power: Eight missiles ready-to-fire, quickly and easily reloaded by the detachment in under 5 minutes without cranes or special handling aids

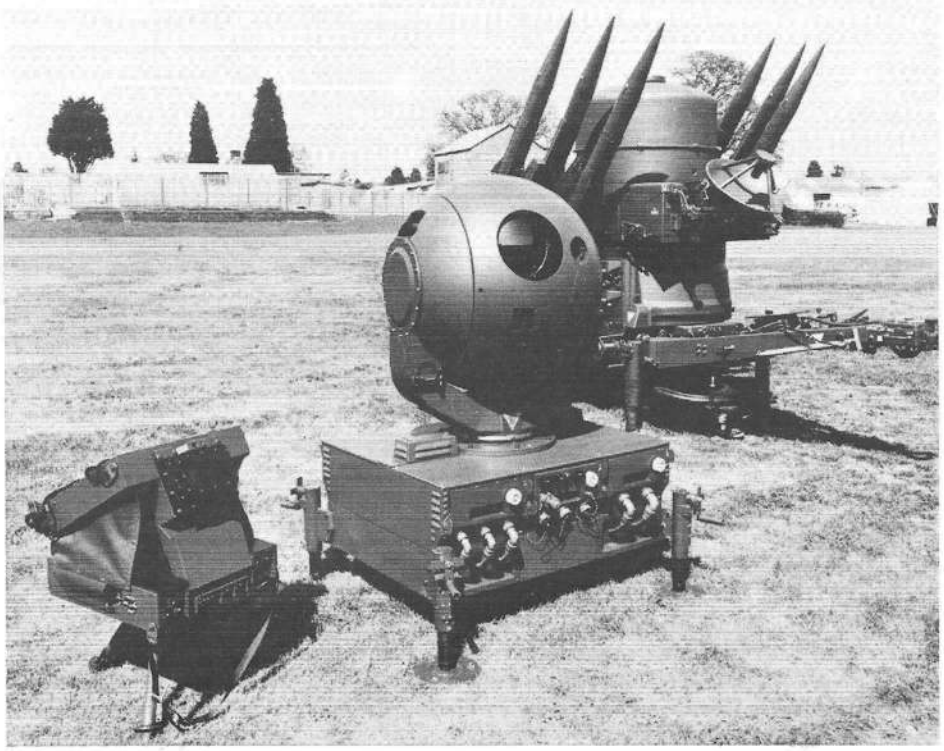
Operating conditions: Day and night capability with TOTE, add on Blindfire radar gives all weather capability

In and out of action time: Under 15 s



STATUS

Tracked Rapier entered service with British Army in 1983. A total of 70 fire units on order or delivered.



Rapier Laserfire

In 1983 BAe Dynamics Group, backed by UK MoD, introduced Rapier Laserfire as a new member of the Rapier family. Laserfire uses the Rapier missile and guidance loop but with significant changes from earlier Rapier systems, the most significant being the incorporation of an automatic laser tracker and millimetric surveillance radar, both of which contribute to the system's high resistance to ECM, and provide a completely automatic engagement sequence day and night.

The system fits on a single turntable pallet which can be mounted on any medium size military vehicle, wheeled or tracked, capable of a 3 to 4 tonne payload. The vehicle used for design proving was a standard British Army Bedford MJR1 4 × 4 equipped with a simple fold-flat modification to the cab, allowing a full 360 degree azimuth coverage. The pallet may be vehicle or trailer mounted, or can be operated deployed from the ground. Two vehicle-mounted systems or four palletised systems can be carried by a C-130 aircraft. The vehicle-mounted system can be transported by a Chinook helicopter and the palletised version by any medium lift helicopter, as underslung loads in both cases. The main elements of the system are, a surveillance radar, automatic laser tracker, a two man crew cab with system controls and displays, computer associated sub-systems, four ready-to-fire Rapier missiles, and a command link. The millimetric wavelength surveillance radar is designed and produced by Racal Defence Systems providing target detection out to 10 km and altitude coverage to heights of 3000 metres. Use of the millimetric frequency ensures very accurate target data and a high degree of immunity from ECM. The radar is lowered from its operating position for travelling. BAe designed and manufactured the automatic laser tracker unit which includes two automatic tracking systems to track the target and missile in flight. A Ferranti laser is used for automatic target acquisition and tracking, while a standard Rapier TV system tracks the missile flares. The laser beamwidth is very narrow, in the order of a few milliradians, and this and the use of common optical paths for missile and target tracking ensures accurate guidance. The complete automatic laser tracker is gyro-stabilised, thereby eliminating the need for

TOTE for Tracked Rapier is a redesigned optical tracker with added IR capability

Rapier 90 units. This new version features an increased range surveillance radar, six-round launcher, an electro-optical IR tracker and other modifications

steadying jacks and time-consuming setting up procedures, and contributing to a typical 'ready-for-action' time of under three minutes, although using crash action drills the equipment can be ready to fire in 1½ minutes.

The cab houses the crew of commander and operator, and a window in front of the former allows him to observe the progress of an engagement. A hatch in the cab roof also enables the commander to use an optical auxiliary sighting system to acquire targets under 'radar silent' conditions. The TV may also be used to lay the laser tracker on the target if required. Both crew members have access to controls for manual selection or rejection of computer selected targets, setting of priority or safety zones, system status checks etc, as well as being able to operate the fire button. The computer, which controls all the Rapier Laserfire sub-systems during the automatic engagement sequence, also controls the extensive built-in testing, monitoring and diagnostic facilities. A MIL Standard 1553B data highway is used for all data communications and allows other systems to be linked with the Rapier Laserfire for the exchange of information.

Rapier Laserfire uses the same command link as that used in other Rapier systems. The antenna for the command link is being mounted alongside the four missile launcher rails. Commands from the system computer are transmitted to the missile in flight where these are decoded and used to guide the missile along the laser LOS until it strikes the target.

The engagement sequence commences with detection of a target in azimuth and elevation by the surveillance radar, which results in the system turntable automatically slewing onto the target bearing. At the same time the laser tracker and missiles elevate to the target, if necessary, the laser tracker starts an automatic search for the target. After acquiring the target, the laser tracker automatically tracks it and the computer determines when the target comes within range. This is signalled to the operator who then presses the fire button to launch the missile. Thereafter guidance to impact is automatic.

British Aerospace have declared that their design aim for Laserfire is to produce a low cost automatic system which is not dependent on operator skills, capable of day and night operations with a performance comparable to the other Rapier systems.

Laserfire is well into its evaluation programme aided by the fact that the missile and guidance loop have already been proved, and the laser and mill metric radar are adaptations of equipment already developed for other purposes. It is expected that the system will be in service early 1987.

Rapier 90

In May 1985 British Aerospace revealed yet another version of the system, designated Rapier 90, in which the most obvious difference compared with earlier models is the provision of a six-round launcher. This and other external differences can be seen from the illustration which shows a new tactical control console with an electro-optical tracker. The command guidance system is the same as for other versions, but the surveillance radar is reported to have an increased range.

Rapier 90 trials are continuing, with entry into UK service planned for the latter part of 1986.

CONTRACTORS

The following manufacturers are known to have been associated with the system.

Weapon system: British Aerospace, Dynamics Group, Stevenage, Hertfordshire, England.

Safety and arming system: Marconi Space and Defence Systems Ltd.

Surveillance radar and command guidance: Racal-Decca Defence Systems (Radar) Ltd.

Secondary radar IFF: Cossor Electronics Ltd.

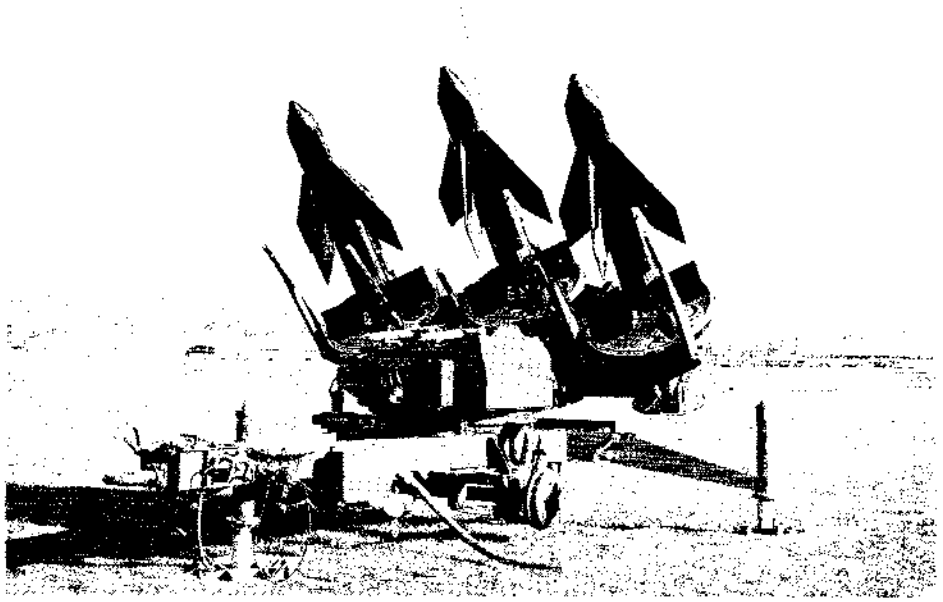
Servo-optical tracking system: Barr & Stroud Ltd.

Blindfire radar attachment: Marconi Space and Defence Systems Ltd.

Missile rocket motor: Imperial Metal Industries Ltd.

2465.131

TIGERCAT CLOSE-RANGE AIR DEFENCE SYSTEM



Tigercat, the land-based version of Short Brothers' widely fitted Seacat, is an autonomous ground-to-air guided missile system for low-level close-range air defence.

In the design of both Seacat and Tigercat the policy was to create a simple guided weapon capable of instant readiness. With any kind of radar warning system there is always the possibility of aircraft approach without detection to a range that permits little time for firing sequences. With Tigercat no prefiring sequences are required on the launcher and auxiliary power services within the missile are activated at launch. The system is thus capable of engaging and destroying at close range even rapidly manoeuvring targets.

Tigercat is compact and mobile and has cross-country capability. The basic fire unit comprises a director trailer, a launcher trailer, and two towing vehicles. These vehicles carry the fire-unit crew of five men, generating equipment, missiles and miscellaneous items. The launcher trailer consists of a two-wheel chassis integral with a three-missile launcher.

The principle of operation is that after a target is acquired by the aimer the missile is launched into the aimer's field of view. The aimer then directs the missile to fly along the line-of-sight to the target by manipulating a thumb-operated flight controller which applies up, down, left, and right commands to the missile by means of a radio link. Flares at the rear of the missile help the aimer to keep it in sight. As with Seacat the system is also suitable for operation using either radar or TV guidance.

Tigercat has been developed with the facility to accept a 'button-on' fire control radar to provide dark or blind fire in addition to visual operation. The director trailer in this mode incorporates the manually operated pedestal director of the lightweight Seacat system as a combined director and missile aiming sight with Seacat guidance equipment. When in radar control the 'dark fire' aimer's station is in the radar cabin where he is provided with a TV control console. The TV camera is aligned to the radar bore sight and provides optical information on the target being tracked. The system comprises a conventional camera and display and a data processing unit which permits automatic gathering of the missile to the target sightline. It can be integrated with any mobile radar system and also has the facility to receive target information via radio link when employed in the autonomous visual mode.

Tigercat firing unit

CHARACTERISTICS

Type: Surface-to-air close-range tactical guided missile

Guidance principle: Command link with optical or radar/TV tracking

Guidance method: Aerodynamic by movable wings

Propulsion: 2-stage solid-propellant motor

Warhead: HE

Missile length: 1·48 m

Missile diameter: 19 cm

Launch weight: 63 kg

STATUS

Tigercat is in production and is in service with or has been ordered by several overseas countries including Argentina, India, Iran, Qatar and South Africa. At least one foreign Tigercat customer is operating the radar-enhanced version of the system, the Marconi ST850 radar being supplied in 1981. Argentinian Tigercat missiles were thought to have scored hits on British aircraft during fighting in the Falkland Islands in 1982.

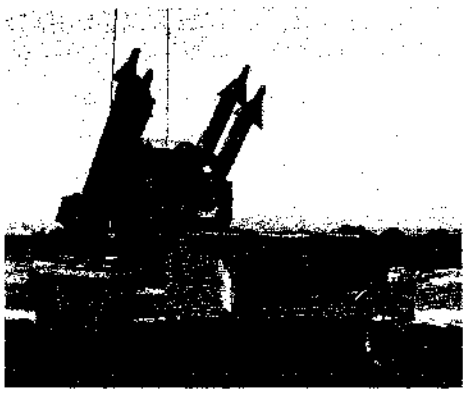
CONTRACTORS

Short Brothers plc, Belfast, Northern Ireland makes the complete system including special test and training equipment. Other manufacturers known to be associated with the system are IMI Ltd which makes the rocket motor, EMI Ltd which makes the fuze and Marconi Radar Systems Ltd which supplies the ST850 radar employed in the radar-enhanced version of Tigercat.

UNITED STATES OF AMERICA

2542.131
CHAPARRAL SURFACE-TO-AIR WEAPON SYSTEM

Chaparral is a ground-to-air IR heat-seeking missile system which has been developed to meet US Army requirements for a low-altitude air defence weapon.



The system consists of a launch and control assembly, vehicle, and missile. The missiles are carried on and fired from a turret mounting four launch rails. Eight additional missiles are stored for ready access in the pallet. The gunner in the turret mount aims the missile at the target using an optical sight. Once locked-on to the target and fired, the missile guides itself to the target's heat source automatically. The Chaparral missile evolved from the US Navy-developed Sidewinder 1C, which has been modified for ground-to-air rather than air-to-air launch as now used by the Navy. The Navy procured the original inventory of missiles for Army use.

The launch and control assembly is a self-sustaining unit, capable of operation independent of the carrier vehicle in a ground emplacement mode. For missions requiring full-tracked mobility the fire unit is mounted on an M730 self-propelled tracked vehicle. It is amphibious when a 'swim kit' is used, will carry a crew of five, and can travel at up to 64 km per hour on the road.

One of the operational configurations is the association of Chaparral with the Vulcan air defence gun system (**2850.131**), the latter being a six-barrelled 20 mm Gatling gun adapted for ground use and mounted on a modified M113 personnel carrier. Forward area alert radar (FAAR - **1526.153**) can be deployed with Chaparral/Vulcan to provide early warning and IFF identification within the detection area.

CHARACTERISTICS

US Army designation: M48 (self-propelled); M54 (ground emplaced)
Type: Land-mobile surface-to-air guided missile system
Guidance: IR homing after optical aiming
Missile designation: MIM-72A; MIM-72C/F (Improved Chaparral)
Propulsion: Solid-propellant rocket motor
Warhead: HE, blast fragmentation
Missile length: 2·91 m

Lightweight towed version of Chaparral air defence system

Missile diameter: 13 cm
Span: 64 cm
Launch weight: Approx 84 kg
Speed: Supersonic

In addition to the SP and ground emplaced versions of Chaparral (M54 and M48) and improved models of this standard system, two new variants have been added: Night Chaparral and Sea Chaparral.

The former consists of a Chaparral system enhanced by the addition of a forward looking infra-red (FLIR) sensor and an associated display and control panel for the operator to give a night and adverse weather engagement capability.

Chaparral FLIR

This is a thermal imaging device designed as part of the Chaparral (M48) improvement programme. It provides considerably improved target acquisition for the operator as well as improved capabilities during daylight poor-weather conditions in addition to making night operation possible.

The Chaparral FLIR is comprised of US Army standard common modules (**3823.093** and related entries in the Electro-optical Equipment (Land) section contain additional details) specifically the following LRUs: IR receiver; receiver power supply; tracking signal processor; camera/video signal processor; control panel; video display.

The resulting Chaparral FLIR night sight is planned for installation on all M48 guided missile systems.

The Sea Chaparral employs a slightly modified launch station and can be operated either with the gunner in the mount or under the control of a remote gunner in the ship's operations room or similar fire control facility.

During 1982 a lightweight towed version of Chaparral emerged which weighs approximately 5445 kg and is capable of being transported by cargo aircraft or helicopter, as well as towing by heavy duty vehicles. The launcher turret on the towed Chaparral has the full 360° azimuth and −10 to +90° elevation launch rail and this assembly is identical to the SP Chaparral.

STATUS

Chaparral is destined to be the US Army's forward area low-level air defence missile up to the end of this century, according to DoD.

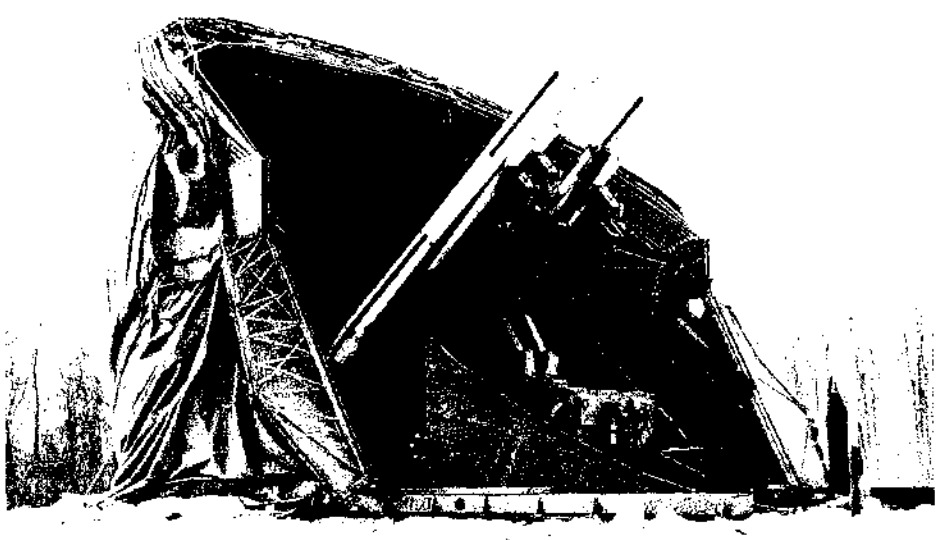
Funding for Chaparral research and development, and procurement contained in the Report to Congress for fiscal year 1985 by the US Secretary of Defence was as follows:

Fiscal Year	R & D ($m)	Procurement ($m)
1984	20·2	-
1985	17·5	32 (12)
1986	17·7	109 (300)
1987	-	154 (1095)

In the three years ending in 1986 it is proposed by the DoD to spend at least $55 million on Chaparral system modifications, including replacement of the propellant in the rocket motors and modifying the system with FLIR for engaging targets at night and in poor weather. A guidance system with increased resistance to IR countermeasures and which will have improved target acquisition and engagement range is being developed.

Overseas users include Egypt, Israel, Morocco, Taiwan and Tunisia, while US users are the US Army. Sea Chaparral has been selected by one foreign navy for close-in ship defence.

CONTRACTORS



Complete system and improved missile: Aeronutronic Division, Ford Aerospace & Communications Corporation, Newport Beach, California 92660, USA.

Vehicle: FMC Corporation, San Jose, California, USA.

4177.131
HAWK SURFACE-TO-AIR MISSILE

Hawk is an operational missile system providing air defence against enemy air attacks. Designed for effectiveness at medium- to low-altitude targets, Hawk uses a CW radar homing guidance system to discriminate against ground clutter and to achieve effective interception of the lowest flying aircraft.

The missile flies to intercept at supersonic speeds and is effective against the full spectrum of attacking aircraft at tactical speeds and in ECM environments. The system is mobile, helicopter transportable, and designed for use in rugged environments. The Hawk system entered service in 1960 and has served with the field units of the US Army, US Marine Corps, seven NATO nations, and 11 other countries. The system has been proven in more than 5000 flight tests. Every aspect of the system performance envelope has been verified, and the Hawk system has been used successfully in actual combat.

Hawk three-round static launcher in its Koni shelter, in half-open position, at a European NATO site

The system was improved in the late 1960s to counter advanced threats and to take advantage of the technological advances that had developed since the employment of the basic system described in **2640.131** in earlier editions. Two primary advances were made to the basic Hawk: (1) the no-field-test-or-repair certified round missile, and (2) the addition of a digital automatic data processor (ADP) for target processing, threat ordering, and target intercept evaluation.

There are two battery configurations of the Hawk system: the standard battery for normal field army operations and the Triad battery for situations requiring increased fire power. The standard battery includes two firing platoons, each with a tracking radar and three triple launchers. The Triad battery comprises three firing platoons. Improved assault fire units can operate autonomously when greater mobility is required.

The Hawk missile has a cruciform configuration with trailing edge control by rear elevons. Its guidance uses proportional navigation with CW, semi-active, all-the-way homing. It is a certified round requiring no field maintenance or testing. Certification is maintained through periodic batch acceptance testing, annual service firing and periodic batch sampling at special maintenance facilities operated by the contractor. The guidance system uses the latest state-of-the-art design and an array seeker antenna. The warhead is a blast fragmentation pattern design which provides a high single-shot kill probability.

CHARACTERISTICS

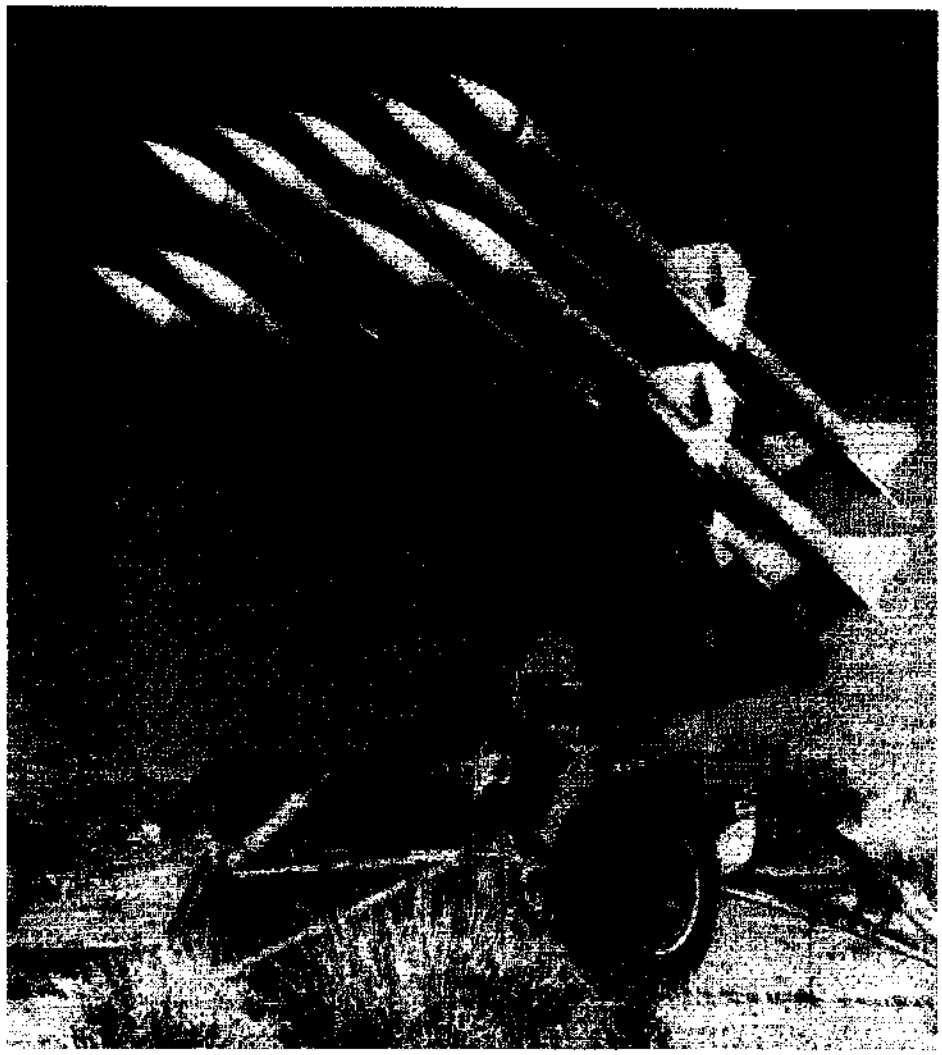
US Army designation: MIM-23B
Type: Mobile surface-to-air guided weapon system
Guidance: Semi-active homing with proportional navigation
Propulsion: 2-stage single chamber solid-propellant motor

Warhead: HE, blast fragmentation
Length: 5·03 m
Span: 1·19 m
Diameter: 0·36 m
Weight: 627·3 kg
Speed: Supersonic
Engagement envelope: Altitude from <30 m to >16 km. Range up to 40 km

MAJOR GROUND EQUIPMENT DESCRIPTION

Pulse Acquisition Radar (PAR)
The PAR is the primary source of high-to-medium aircraft detection for the battery. The L-band frequency allows the radar to perform in an all-weather environment. The radar incorporates a digital MTI to provide sensitive target detection in high clutter areas and a staggered pulse repetition rate to minimise the effects of blind speeds. The PAR also includes several ECCM features and uses off-the-air tuning of the transmitter.

CW Acquisition Radar (CWAR)
Aircraft detection at the lowest flyable altitudes in the presence of heavy clutter is the primary feature the CWAR brings to Hawk. The CWAR and PAR are synchronised in azimuth for ease of target data correlation. Other features include FM ranging, built-in test equipment (BITE) and band frequencies. FM is applied on alternate scans of the CWAR to obtain target range information. During the CW scan, range rate minus range is obtained. The ADP in the ICC processes this information to derive target range and range rate. This feature provides the necessary data for threat ordering of low altitude targets detected by the CWAR.



Battery Control Central (BCC)
The BCC provides the facilities for the man-to-machine interface. The tactical control officer (TCO) is in command of all BCC operations and maintains tactical control over all engagement sequences. The TCO monitors all functions and has the authority and facilities to enable or pre-empt any engagement or to change established priorities. The tactical control assistant assists the TCO in detection, identification, evaluation and co-ordination with higher commands. The tactical control console gives these two operators the necessary target and battery status information and controls required.

The azimuth-speed operator has the sole mission of earliest possible detection of low altitude targets. The azimuth-speed indicator console, a separate radar B-scope display, provides CWAR target data for this purpose. Targets selected for manual engagement are assigned to one of the two fire control operators. Each operator uses the fire control console display and controls for rapid HPI target lock, target track, missile launch, and target intercept evaluation.

Information Co-ordination Central (ICC)
The ICC is the fire control data processing and operational communications centre for the battery. It provides rapid and consistent reaction to critical targets. Automatic detection, threat ordering, and IFF followed by automatic target assignment and launch functions are provided by the ICC. The ICC contains an ADP, IFF, battery terminal equipment, and communications equipment.

The ADP is comprised of an electronic data processor (EDP) and a data take-off unit (DTO). The DTO forms the interface between the other system equipment and the EDP. With the exception of inputs from a solid-state reader and outputs to a printer, all communication with the EDP is through the DTO. The EDP is a militarised, general-purpose digital computer especially adapted to this role.

Platoon Command Post (PCP)
The PCP is used as the fire control centre and command post for the AFU. It can also be used to replace an ICC. The PCP provides manual and automatic target processing, IFF, intra-unit, intra-battery and army air defence command post communications, and the displays and fire control equipment for the three-man crew. It is essentially an ICC with a tactical display and engagement control console, a central communications unit, status indicator panel, and an automatic data processor. The tactical display and engagement control console provides the man/machine interface for the AFU. The interior of the shelter is divided into two compartments: the tactical officer, radar operator, and communications operator occupy the forward compartment with the display console, status panel, power distribution panel, and communications equipment; the rear compartment contains the ADP, air conditioning unit, and IFF equipment.

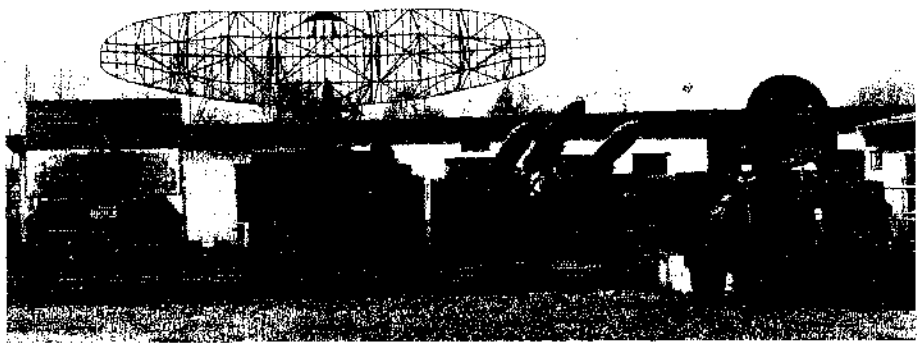
Sparrow Hawk launcher enables nine Sparrow missiles to deployed on a modified three-round Hawk launcher

High Power Illuminator (HPI)
The HPI automatically acquires and tracks designated targets in azimuth, elevation and range rate. It serves as the interface unit supplying azimuth and elevation launch angles computed by the ADP to up to three launchers. The HPI X-band energy reflected off the target is also received by the Hawk missile for guidance. A missile reference signal is received directly from the HPI. Target track is continued throughout missile flight, and after intercept, HPI doppler data is used for kill evaluation. The HPI receives target designations from the BCC and automatically searches a given sector for rapid target lock-on. The HPI incorporates ECCM and BITE.

Range-only Radar (ROR)
This is a K-band pulse radar that provides quick-response range measurements whenever the other radars are denied range data by enemy countermeasures. During a tactical engagement, the radar is designated to obtain ranging information which is used in the computation of the fire command. The ROR reduces its vulnerability to jamming by transmitting only when designated.

Launcher (LCHR)
The LCHR supports up to three ready-to-fire missiles and is activated only upon the initiation of the fire cycle. When the fire button is activated in the BCC or PCP, several launcher functions occur simultaneously: the launcher slews to designated azimuth and elevation angles, power is supplied to activate the missile gyros, electronic and hydraulic systems, the launcher activates the missile motor and launches the missile. The launcher is equipped with electronic cut-outs and sensing circuits that allow firing in all emplacement situations.

PHASED PRE-PLANNED PRODUCT IMPROVEMENT PROGRAMMES (PIPs)
A series of PIPs to increase operational readiness and system effectiveness were announced by Raytheon in October 1978. In Phase I the CWAR transmitter, the Army Tactical Data Link (ATDL) and the PAR MTI performance capabilities were improved. Phase II provides reliability and maintainance improvements for the HPI and new optical tracking augmentation. Phase III streamlines the battery and reduces manpower and logistic support requirements.



Phase I: The CWAR improvements involve a new klystron transmitter, new BITE and modifications to the antenna housing and other elements of the sub-system. Advantages are: more than doubling of transmitter MTBF, a 25 per cent improvement in radar reliability; and a doubling of output power which increases detection range.

ATDL improvements include an increased memory capacity and re-formated data language. These changes provide a computer-to-computer interchange of data between a Hawk battery and a high level (battalion) fire distribution system. Modifications in this programme are to the ICC/PCP and BCC elements of the system. Benefits of this programme are more target tracks and threat ordering information, greatly reduced system reaction time, improved reliability and increased capabilities as a defensive weapon.

The PAR improvement implements a new digital MTI programme. Hardware changes include a modern solid-state control oscillator, modifications to the power distribution and the indicator azimuth range subassemblies, and addition of a digital signal processor to replace the single comparator. Performance benefits are increased detection capabilities in clutter environments, a wider range for automatic detection, a reduction in the number of adjustments and elimination of blind speeds.

Started in 1977, Phase I was fielded in 1979.

Phase II: This was approved for production in 1983. It involves modifications to the HPI. A major reliability and maintenance design was implemented that improved the reliability of the HPI by more than 300 per cent. This technology update replaced tube-type equipments with solid-state modules and the design

Hawk battery subject of PIP (product improvement programme) by the European 'GRIP' consortium

made failure replacement much easier and reduced the number of user adjustments. Other improvements are emission control for operating in an anti-radiation missile environment, an ECCM update and a new TAS.

Tracking Adjunct System (TAS)

The Tracking Adjunct System is an electro-optical tracker system developed as part of the Phase III product improvement for the Hawk fire control system. It was developed from TISEO (Target Identification System, Electro-Optical) in production and used by the US Air Force and a number of foreign countries (**1806.363**).

TAS is described in greater detail in entry **4240.183**. It provides a passive tracking capability to the Hawk fire control radar with remote real-time video viewing, and it is intended to serve as a back-up and aid to the tracking radar. Optical tracking can be coincident or independent of the radar line-of-sight, manual or automatic acquisition and tracking, rate memory and preferential target illumination are key features. Operational benefits include positive identification, threat assessment, kill assessment, spectre recognition, tracking in minimum doppler, silent tracking and independent tracking. The TAS operates in conjunction with the Hawk's radar and assists in the discrimination between several targets approaching at the same time or between low-flying targets and features on the horizon. It also counters some of the countermeasures which may be employed by the targets to confuse radar. TAS engineering development began in 1976. Production for the US Army and Marine Corps commenced in March 1980 and the equipment is currently being fitted to US Army Hawk batteries in the field.

Phase III

Hawk Phase III will modernise and update Hawk for both the US Army and Marine Corps. The former will deploy this version in a new platoon formation to provide Hawk air defence coverage for US air bases and logistic complexes in Europe and provide air defence for the rapid deployment forces. The Marine Corps will field Hawk Phase III in a modernised battery configuration to support amphibious forces and base defence missions. Distributed data processing using a common data processor in several major items, and major fire control improvements, offer a new optional operating mode to yield increased fire power and reduced logistic and training burdens.

The optional operating mode called LASHE (Low Altitude Simultaneous Hawk Engagement) employs a fan beam antenna on the HPI radar to provide a wide angle, low-altitude illumination pattern which enables the operator to implement multiple engagements against saturation raids. Another modification provides for single scan target detection by the CW acquisition radar. The high power illuminator radar is provided with a new microprocessor which enhances its performance and adds fresh facilities such as an automated search adjunct, determination of the presence of multiple targets within the tracker's radar beam, and the ability to control in-flight missiles so as to home onto still active targets in a multiple target engagement.

Production prototype hardware has been manufactured and tested in preparation for early series production, but no details had been released in time for publication. For the future development and exploitation of the Hawk system, and its evolution into a system for the early 2000s, the next step foreseen by the manufacturer is the introduction of an agile CW acquisition radar (ACWAR). This will improve the autonomous detection capability of the system, and Raytheon is to provide an ACWAR prototype for Army testing. This will provide all-altitude detection in an ECM environment within an airspace volume compatible with Hawk's engagement zone whilst enabling the radar to survive possible enemy anti-radiation missiles. A 3-D radar, it will have considerable frequency agility and phased array elevation scanning of multiple simultaneous beams. These will be rotated in azimuth to search the required zone and will be able to track-while-scan targets in the zone. Later, and with certain missile modifications, the data from ACWARs could be used for missile mid-course control and eventually this radar could be coupled with the Hawk fire control system and housed in a single vehicle (Command Surveillance Vehicle). In this configuration, an IR sensor will be integrated and the radar will be carried on an erectable mast.

Sparrow Hawk

Another evolutionary Hawk project is a system called Sparrow Hawk, because it combines elements of both these Raytheon-produced missile systems. The standard Hawk three-round launcher is modified to allow nine Sparrow missiles to be placed on the same launcher. In January 1985 at the Naval Weapons Centre, China Lake, California, a modified three-round Hawk missile launcher was used for field demonstration tests of the system and a fire unit manned by a US Marine Corps team who successfully fired Sparrow missiles, when two unmanned aircraft targets were intercepted. Earlier tests were carried out at the US Marine Corps Air Station, Yuma, Arizona.

DEVELOPMENT

Development of basic Hawk began in 1954 and the system first became operational in 1959, the programme having been under the control of the US Army Missile Command, Huntsville, Alabama. Engineering of the system was performed at Raytheon's laboratories at Bedford and Wayland, Massachusetts, and at White Sands, New Mexico. US production of the missile and equipment has been principally at Andover and Waltham, Massachusetts.

STATUS

Hawk systems are currently deployed throughout the world, and in the US Army and Marine Corps it will remain the mainstay of field air defences until replaced by Patriot (**2800.131**, below).

The American programme to up-grade the Hawk for the US Army and Marine Corps continues, including installation of a new missile motor and provision of a multi-engagement capability. The US fiscal year 1986 DoD budget showed scheduled and planned Hawk procurement and expenditure for 1984/85/86/87 as follows (quantities in brackets) and funding in $ millions: (400) 97, (500) 126·1, (550) 140·1, and (550) 156·6.

Countries operating Hawks are: Belgium, Denmark, Egypt, France, West Germany, Greece, Israel, Italy, Japan, Jordan, Kuwait, Netherlands, Norway, Saudi Arabia, Singapore, South Korea, Spain, Sweden, Taiwan, United Arab Emirates and the USA.

CONTRACTORS

For European manufacture of the Improved Hawk air defence system Raytheon is systems contractor under the direction of the NATO Hawk Management Office (NHMO) in Paris, France. In the USA, Raytheon produced the missile guidance and control units and limited quantities of ground equipment. European contractors (see below) produced ground equipment, certain missile parts, final missile assembly, and overhaul and conversion of the basic Hawk equipment. A Raytheon subsidiary, Raytheon European Management and Systems Company (REMSCO) serves as NHMO's European programme management contractor for 16 major European industrial activities. NATO nations participating in the programmes are Belgium, Denmark, France, West Germany, Greece, Italy and the Netherlands.

Complete system development and US production: Raytheon Company, Lexington, Massachusetts, USA.

Rocket motors: Aerojet General Corporation, El Monte, California, USA.

Wings and elevons: Northrop Corporation, Beverly Hills, California, USA.

Warheads: Iowa Ordnance Depot.

NATO Improved Hawk: Belgium - ACEC; France - SNPE, SODETEG, Thomson-CSF; Federal Republic of Germany - AEG-Telefunken, MBB; Italy - Aeritalia Aerochemie, Selenia, Sigme, MES, FIAR.

Japanese production: Mitsubishi Electric Corp and Toshiba.

2800.131

PATRIOT (MIM-104) TACTICAL AIR DEFENCE SYSTEM

Patriot is an advanced guided weapon system intended as a replacement for certain Hawk and Nike Hercules systems. The Patriot fire unit contains all the elements necessary to conduct an engagement: the radar set, engagement control station, electric power plant, and eight launching stations. Each launching station contains four missiles in their firing canisters, which also serve as shipping and storage containers. The US plans to deploy Patriot battalions in Europe and the continental USA, each battalion consisting of six batteries equipped with eight four-tube launchers (a total of 192 missile tubes). The Patriot radar set AN/MPQ-53 is a multi-function, phased array device, which performs all of the surveillance, IFF, tracking and guidance functions which currently require nine separate radars in the Hawk (**4177.131**) and Nike Hercules (**2723.131**) air defence systems. Radar target identification is performed by an AN/TPX-46(V)7 interrogator, using supplementary antenna arrays on the main AN/MPQ-53 radar antenna unit. The engagement control station AN/MSQ-104 houses the weapon control computer which automatically sequences the system through all tactical engagement operations, monitors the operational status of the hardware, conducts automated fault detection and location as required, and provides the man-machine interface for human control. The engagement control station is the only manned station and remotely controls the other elements of the fire unit. The electric power plant AN/MJQ-24 includes two 150 kW turbine driven generators. The launching station M-901 includes its own independent 15 kW diesel generator and radio link to the engagement control station. The guided missile MIM-104 is a certified round, which is shipped, stored and fired from its canister without testing or maintenance in the field. Periodic lot sampling of guided missiles on launchers and in storage will provide assurance of their capability. The tail-controlled missile carries a high explosive fragmentation warhead and is capable of outmanoeuvring and destroying any manned aircraft, according to the manufacturer.

CHARACTERISTICS

Type: Land-mobile, surface-to air guided weapon system

Guidance principle: Command guidance and semi-active homing. Track-via-missile (TVM)

Guidance method: By control of 4 aerodynamic control surfaces
Propulsion: Single-stage solid-propellant rocket motor TX-486
Missile length: 5·31 m
Missile diameter: 41 cm
Warhead: Nuclear or HE
Speed: Supersonic

DEVELOPMENT

Patriot is the successor to two earlier study programmes managed by the US Army Missile Command's Research and Development Directorate. These studies were concerned with systems known as the Field Army Ballistic Missile Defense System (FABMDS) and the Army Air Defense System for the 1970s (AADS-70s).

In January 1965 the SAM-D requirement was specified and a study was directed towards defence against high-performance aircraft - at all altitudes - and short-range missiles. SAM-D was placed under project management at the US Army Missile Command in August 1965 and shortly thereafter the contract definition process was initiated by the DoD. In February 1970 the missile successfully completed its first launch environmental test. The US Army planned to begin engineering development in fiscal year 1971, but the advanced development phase was not completed until March 1972 when engineering development started.

STATUS

The Patriot engineering development programme was initiated in 1972. In 1974 the programme was stretched to emphasise demonstration of the TVM guidance system with the minimum necessary hardware development to permit programme continuation. Authority to resume full-scale development was given in early 1976, following a successful firing programme of 12 complete successes and one partial success in 14 firings. A 49-month $425 million contract was initiated in August 1976 to complete the development programme. The firing programme was resumed in December 1976 with the first tactical prototype ground equipment. US Army developer testing, and field operational exercises conducted with troops in US Army operational tests had been completed by the end of 1981. Following completion in 1980 of the development programme, limited production of Patriot systems was authorised. Following parallel confirmation tests on development equipment in 1981 and production hardware in 1982 and 1983, authorisation of increased production was granted.

The stringent 1984 FOE III (follow-on evaluation) programme culminated in four hits for four firings in a severe countermeasures environment with high- and low-manoeuvring targets. These results demonstrated the reliabilities and troop proficiency levels required for the final deployment decision which occurred in late 1984.

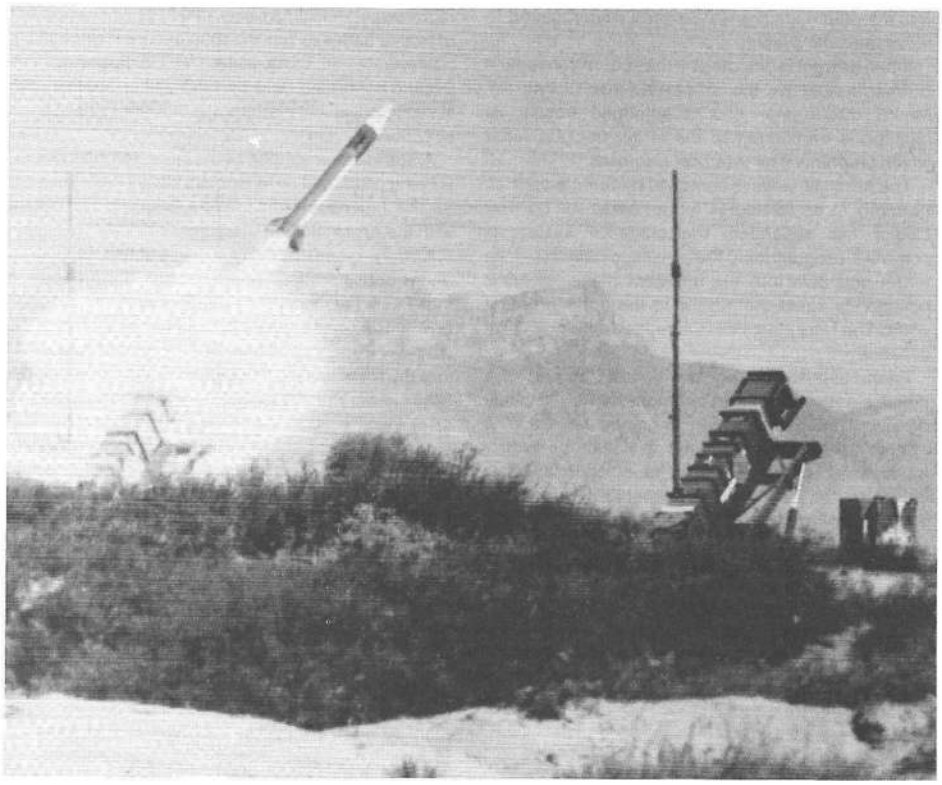
The fiscal year 1986 budget indicated allocations of $78·3, $61·1, $53·1 and $38·8 millions for continued development in fiscal years 1984-87. The projected procurement of fire units and missiles, and the related budget allocations for the same four years is as follows:

Fiscal Year	Fire Units	Missiles	Funding ($m)
1984	12	440	963·5
1985	12	440	1045·8
1986	12	585	1063·9
1987	12	700	1055·2

In early 1983 Belgium deferred participation in the programme under which European member states of NATO would procure Patriot systems for air defence. In 1984 the Netherlands decided to procure four Patriot fire units and 160 missiles through a foreign military sales (FMS) agreement with the USA. Funding for the first fire unit was included in fiscal year 1984 funds.

In the same year West Germany also decided to procure the system and agreed to procure 14 fire units and 779 missiles via FMS from the USA. Two fire units and 105 missiles were included in the fiscal year 1985 budget. Through a supplementary compensation agreement, the USA will provide an additional 14 fire units and 840 missiles from its own inventory.

Patriot was also selected by the Japanese Defence Agency in 1984, and during 1985 the governments of Japan and the USA are expected to complete a memorandum of understanding covering the procurement of the system by Japan.



Recent reports have referred to 26 Patriot fire units for the Japanese, expectations of initial negotiations for procurement of Patriot between the USA and the Italian Government, and resumption of negotiations with the Belgian Government.

NIKE HERCULES (MIM-14B) AIR DEFENCE MISSILE

One of the earlier surface-to-air guided weapon systems still in commission, the Nike Hercules missile, successor to the Nike Ajax, was widely deployed in the USA and other countries. It first became operational in the USA in 1958.

Nike Hercules, a second-generation missile, possesses greater destructive ability and has a better performance than Nike Ajax. It has proved successful against high-performance aircraft at a variety of altitudes and has successfully intercepted short-range ballistic missiles and other Nike Hercules missiles in tests.

System units are a low-power acquisition radar, a high-power acquisition radar, a target tracking radar, a missile tracking radar, electronic data-processing equipment and remote-controlled launchers. A later innovation, the high-power acquisition radar (HIPAR - **2499.153**), enables Nike Hercules mobile units to get the same full target detection capability as batteries at fixed sites. The HIPAR's three vans house radar gear transmitter, receiver, and control equipment. One of its two semi-trailers hauls the 43 foot (13·1 metre) wide, fan-shaped antenna. The other semi-trailer carries power generators. Before the mobile HIPAR

Nike Hercules (MIM-14B) surface-to-air missile in S Korean Army service (G. Jacobs)

was adopted more than 20 vehicles were required to move the radar system.

When a target is detected by the acquisition radar it is interrogated by the associated AN/TPX-46 IFF Mk XII interrogator and if adjudged hostile its location is transferred to the target tracking radar which pinpoints it for intercept purposes.

The Nike Hercules is launched by remote control, normally at an 85-degree angle. When the booster cluster has separated, the guidance system is activated, programming the missile to roll toward the target and dive into the intercept plane. Steering commands direct the missile to the optimum burst point. The Nike Hercules is equipped with an ECCM capability.

Each Hercules battery can operate as part of a defence network or as an autonomous unit, capable of detecting, tracking, and engaging targets. The system operators are located in a battery control trailer, a tracking radar control trailer, and a launcher control trailer. The Hercules is capable of operating in an ECM environment.

CHARACTERISTICS

Type: Surface-to-air, strategic, guided missile
Guidance: Command
Propulsion: 2-stage solid-propellant rocket motor
Warhead: Nuclear or HE
Missile length: 12·1 m
Diameter: 80 cm
Launch weight: 4858 kg
Speed: Supersonic
Range: >140 km
Ceiling: >45 km

STATUS

Major improvements were made to this system in 1961 when new radars and modifications were added to enable the system to remain operational until replaced by the Patriot (**2800.131**) missile. The number of active batteries has steadily declined since 1963, however, when there were 134 US batteries. The decline continued, and by 1980 all continental USA Nike Hercules installations are thought to have been abandoned.

A non-nuclear version of the Nike Hercules missile is being produced by Mitsubishi Heavy Industries Ltd for the Japanese Army under a licensing agreement with the American manufacturer.

A more recent possible enhancement said to be under consideration by the Japanese contractor is that known as Nike-Phoenix. This concept is based on integration of the complete guidance system of the US Navy Phoenix air-to-air missile system (**1099.331**) into the Nike System. This would entail equipping the Nike missile with the seeker from the Phoenix missile, and this would be complemented by the incorporation of the AN/AWG-9 radar (**1100.353**), modified for ground use from its original airborne application. The AWG-9 would become part of the Nike installation to replace the existing target and missile tracking radars, to provide for simultaneous engagement of up to six targets with separate missiles.

Apart from Japan, Nike Hercules is also widely deployed in NATO and other countries with which the USA has friendly military relationships. Countries believed still to have the missile in strength are Belgium, Denmark, West Germany Greece, Italy, Norway, and Taiwan. The US Nike Hercules batteries in Korea have been transferred to the Republic of Korea, where, it is believed this missile is also operated in an alternative surface-to-surface role.

Due to funding difficulties, from July 1984 the number of Belgian Nike units based in West Germany (eight) was reduced to four, but if an agreement proposed by the USA is concluded these will probably remain in service until replaced by Patriot units in the late-1980s.

In 1981 contracts were placed for a number of improvements to the existing Nike Hercules systems. McDonnell Douglas is refurbishing and modifying NATO Nike Hercules missiles, and the contract also provided for a series of test launches from the NATO test range at Salto di Quirra, Sardinia. A related element of this Nike Hercules updating programme is the digital computer system (DCS) which is being supplied by Norden Systems. The DCS is based on the PDP-11/34M mini-computer and it receives missile and target position inputs from tracking radars, solves the intercept problem and issues guidance commands to the missile. It also performs various other routines, such as fault diagnosis. By replacing the earlier analogue system with the new digital computer, reliability of the Nike Hercules system will be improved and maintenance simplified. DCS deliveries began in late 1981 for NATO batteries and supplies to Far Eastern installations are expected to follow. The complete DCS programme could cost $15 million.

4839.131
TA25/RA20 S AIR DEFENCE SYSTEM

The TA25/RA20 S weapon system is intended for the defence of mobile units and vulnerable points against low and very low altitude air attack. It may be installed on a wide variety of light armoured vehicles, eg. VAB, AMX 10, AMX 13, etc.

The system consists of a 'leader' vehicle fitted with a TA25 turret (twin 25 mm anti-aircraft guns) and an RA20 S radar and one or two 'satellite' vehicles fitted with TA25 turrets, with or without radars. The RA20 S radar can detect and track targets without interrupting surveillance of the airspace by means of the track-while-scan (TWS) facility. It can automatically assign the 'leader' turret to a target and via radio link (modem and transceiver) the 'satellite' turrets.

The fire control system is fitted with a laser subsystem that computes the lead angle. The computer is a digital equipment and the servomechanisms are of the electro-hydraulic type. Weapons are gyro-stabilised when firing to avoid aiming errors due to vehicle movements. It is also possible to engage land targets.

CHARACTERISTICS
Weapons
Guns: 2 × KBB 25 mm, with dual feed
Rate of fire: 800 rounds/minute per gun
Firing modes: Bursts at weapon rate or slow rate; single rounds for one gun or both
Ammunition: 250 rounds per gun (200 AA + 50 HE rounds for surface targets)
Effective range: 2500 m
Turret
Weight: Under 2·7 t (in combat order)
Turret track diameter: 1·52 m
Turret emergence height: 1·2 m
Radar
Max range: At least 12 km (combat aircraft, or helicopter in forward flight)
Radar weight: 85 kg
STATUS
Development.
CONTRACTOR
ESD - Electronique Serge Dassault, 55 quai Carnot, 92214 St Cloud, France.

TA25/RA20 S air defence system installed on RVI VAB-VDAA vehicle

3332.131
AA 20 WEAPON SYSTEM

This system is a semi-mobile configuration comprising a number of towed small-calibre anti-aircraft guns, used in conjunction with a truck-mounted fire control centre for the low-level point defence of targets such as airfields, bridges etc.

The fire control centre consists of a radar-equipped cabin mounted on a light tactical truck. The RA20 S radar is similar to that of the ESD TA20 turret which is used in other French mobile AA systems. Cable or VHF FM radio links connect the fire control centre to up to four gun positions. Other parts of the overall system are the radar data processing and parallax computation elements.

Two firing modes are possible:
(1) autonomous, whereby each gun operates independently, firing parameters being estimated by the gunner
(2) central control mode, in which the fire control centre performs a search with the radar, threat evaluation and target designation, and transmission of firing parameters to the computer of each gun.

The principal characteristics of the radar are a range of 12 km against a typical tactical support aircraft target, an antenna rotation rate of 40 rpm, and simultaneous tracking of up to two targets.
STATUS
Development.
CONTRACTOR
ESD - Electronique Serge Dassault, 55 quai Carnot, 92214 St Cloud, France

4502.131
TWIN 20 mm AA WEAPON SYSTEM TA20/RA20 S

Electronique Serge Dassault has designed and manufactured the TA20 mobile gun system which, in association with the RA20 S search and target designation radar, provides the means of defending moving formations or vulnerable positions against air attack. Only one RA20 S radar is required for a two- or three-vehicle platoon, and this radar may be installed in any one of the vehicles, which then becomes the 'leader', the other one or two vehicles being the 'satellite(s)'. All vehicles are linked by an automatic radio transmission system.

The radar detects low-flying aircraft and assigns a designated target to the leader, to a satellite or both, and automatically transmits the target co-ordinates. This data is fed to the fire control system. Trajectory information is calculated by a processing unit in each vehicle. Separation between vehicles is normally less than 1000 metres. The TA20 system is operated by a crew of two: a radar operator who is also the vehicle commander and platoon commander and a gunner, alone in the turret.

The main components of the system are:
(1) two Oerlikon KAD-B rapid firing 20 mm guns delivering 2000 rounds/minute
(2) a Galileo P56T optical sight
(3) turret with a rotational speed of 80°/s
(4) gyro-stabilisation equipment for guns during firing
(5) control units for turret and gun operation.

The system is installed in the Renault VAB/VDAA; Panhard M3 VDA; AMX 13 and also the Urutu, Sibmas and MOWAG vehicles. It permits engagement of enemy aircraft at a range of 1800 metres, the RA20 S radar detection envelope providing for targets attacking at altitudes between ground level and 2000 metres to be acquired at a range of 12 km.

CHARACTERISTICS

TA20 turret
Track diameter: 1500 mm
Total height: 1200 mm
Combat weight: 1940 kg
Ready use rounds: 2 × 300
Rate of fire: 1000 rounds/minute/gun
RA20 S radar: E-band pulse doppler
TWS: 2 tracks
Antenna unit weight: 60 kg
Range: 12 km

STATUS

Believed to have been ordered for export.

CONTRACTOR

ESD - Electronique Serge Dassault, 55 quai Carnot, 92214 St Cloud, France.

TA20/RA20 S short-range anti-aircraft defence system installed on RVI VAB/VDAA vehicle

2164.131
M3-VDA AA GUN SYSTEM

This Panhard/ESD system combines the firepower of many heavier SP AA gun systems with the low weight and high mobility of the Panhard M3 vehicle. It comprises a one-man gun turret mounted on the specially adapted M3 and carrying a pair of HSS 820 SL guns; a weapon control system with a display for the vehicle commander; and the vehicle itself which is driven by the third member of the crew. The system is also known under the ESD designation TA20, and other variants are the AA 20 system (**3332.131**) which is a transportable version employing towed AA guns, and the VDAA (Véhicule d'Auto-Défense Anti-Aérienne) which is essentially the same as the M3-VDA but mounted on a different carrier vehicle in place of the Panhard M3.

The weapon control system comprises a radar (or alternatively an optical observation system), a computer sight, and high-speed controls for the twin guns and feed system.

The ESD radar is an I/J-band pulse doppler surveillance/acquisition device with a detection range of about 8 km (2 m² target) and a rotation rate of 40 rpm. Targets are displayed on the commander's console, and in target designation the radar feeds target bearing to the optical sighting system and range and target velocity to the Galileo computer sight. The gunner keeps the optical sight trained on the target and the computer calculates lead angle and favourable engagement conditions.

For the simpler (and cheaper) version of the equipment the radar is replaced by two optical observation posts, one for the commander and one for the gunner, with overlapping arcs of observation to give full 360° coverage. When one or other observer is tracking a target the tracking movement generates signals from which the computer calculates lead angle and engagement data as before. The absence of direct range and velocity measurements, of course, makes smooth tracking essential if reasonable accuracy is to be achieved and to this extent the non-radar version is more demanding than the other.

Panhard M3-VDA anti-aircraft vehicle

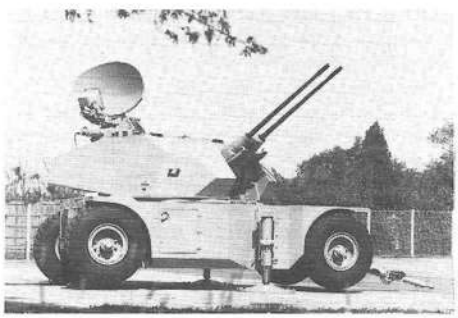
CHARACTERISTICS

Vehicle characteristics: Generally similar to the M3-VTT
Combat weight: 6300 kg
Road speed/range: 90 km/h/1000 km
Armament: 2 HSS 820 SL or similar 20 mm cannon. HSS weapon has MV 300 m/s, slant range 2000 m, maximum engagement altitude 1500 m. Rate of fire 800-1050 rounds/minute, 600 rounds (2 × 300 belts) carried
Radar: ESD pulse doppler
Computer sight: P56-Galileo

STATUS

Series production in progress for the armed forces of several foreign states.

CONTRACTORS



System: Société de Constructions Mécaniques Panhard et Levassor, 18 avenue d'Ivry, 75013 Paris, France.
Radar: Electronique Serge Dassault.

4512.131
SABRE TWIN 30 mm AA GUN TURRET SYSTEM

The function of the Sabre AA gun system is to protect advanced battle corps units or critical points such as river crossings, transport or communications hubs, concentrations of armour in combat, rear bases and depots, target defence systems etc, against air threats posed by low or very low altitude attacks by ground attack aircraft or armed helicopters.

The Sabre turret system is designed to provide an omni-directional radar search capability and to identify, track, acquire and destroy targets. The system is capable of destroying these targets due to the following characteristics:

(1) search surveillance at 15 or 22 km of targets flying at 20 to 300 m/s
(2) quick reaction time enhanced by automatic slewing, TV tracking
(3) fire power provided by two 30 mm guns, 20 rounds/s or high-rate bursts
(4) accuracy provided by gyro-stabilised sight, low-dispersion ballistic rangefinder

Sabre turret on air-transportable trailer/shelter

(5) availability ensured by equipment reliability and easy maintenance up to second level
(6) autonomy ensured by on-board munitions (600), spare parts and electric power supply system.

System performance and short reaction time make the Sabre gun system an ideal complement to missile air defence systems. The turret is of the armoured rotating casemate type. It is equipped with two automatic Oerlikon 30 mm KCB guns, Type 230, with two link belt ammunition bearers and a burst limiter permitting the following firing modes: single-shot firing; 5- or 15-shot bursts.

Close-up of Sabre turret showing Oeil Vert radar and electro-optical sight installation

The ammunition allocation is 300 rounds per weapon, making a total of 600 rounds in the turret. It also supports the Oeil Vert omni-directional search radar used for threat evaluation and acquisition of targets flying at altitudes of not greater than 3000 metres and at radial velocities between 30 and 300 metres/second; the turret can also be equipped with an optional IFF system. Fire control is provided by:

(1) stabilised electro-optical sight which ensures optical tracking of targets
(2) laser rangefinder which ensures highly-accurate target range measurement
(3) automatic TV tracking system
(4) digital computer which receives the data from the radar, TV tracker, rangefinder and calculates firing data and carries out autotest of the equipment.

The Sabre turret is operated by a crew of two: the tank commander who controls the data provided by the radar and orders firing; and a gun-layer/firing operator who controls optical aiming and firing. The turret is autonomous in operation and can be mounted on a variety of carriers such as: tracked vehicles, AMX 13, AMX 30, Kurassier and Marder (see **3679.131** below); wheeled armoured vehicles AVX 10 RAA or MOWAG; towed and/or air transportable shelters; or casemates.

OPERATION

The different operational phases of the Sabre 30 mm twin gun system are as follows:

(1) **Omni-directional search, identification, designation**

Early warning is given by the radar forming part of the system or by radio information from the surveillance net. When the radar is in the 'long-range search' mode, it covers a range 1 to 15 km with Oeil Vert and 1 to 22 km with Oeil Vert Plus, from 0 to 3000 metres in altitude, for a target with a speed varying from 30 to 300 metres/second. As soon as the target is detected by the radar, the computer evaluates the threat and identifies enemy targets (optional IFF system).

(2) **Target acquisition**

In bearing: The tank commander selects the target by overlaying a marker on the echo using a joystick. This operation initialises automatic radar tracking of the target in range and bearing by means of a track-while-scan system. When deemed necessary by the tank commander, at 10 km for example, he slews the turret in the direction of the tracked target.

In elevation: Acquisition is carried out automatically or manually. The gun-laying/firing operator acquires the target in elevation using the stabilised electro-optical sight which includes the TV camera system installed in the turret.

(3) **TV tracking and extrapolation**

Target tracking is by an optical sight and a TV electro-optical system. Automatic or manual system operation is selected by the operator. For automatic operation, all turret movements are slaved by the TV angle-error measurement system which uses the camera video signal to provide angle-error data, ie the position of a target selected by the operator on the TV image with respect to the image centre. The data supplied by the tracking, radar and angle-error measurement system is processed by a digital computer which generates the fire data required to align the two guns on the future target.

(4) **Final engagement**

The tank commander makes the final engagement decisions demanded by the current air situation. As soon as the target comes within the range of the weapon system and firing is authorised, the guns can engage. The guns are continuously supplied with ammunition, thereby permitting several bursts without reload.

CHARACTERISTICS

Weight: 6·5 t (turret)
Surveillance radar
Oeil Vert range: 15 km
Oeil Vert Plus range: 22 km
Sub-clutter visibility: >52 dB
Weapon: 2 × 30 mm KCB guns
Rate of fire: 600 rounds/minute/gun
Burst length: 5 to 20+ rounds
Effective range: 3300 m
MV: 1080 m/s

STATUS

Prototypes have been built and are under comprehensive evaluation in several configurations. More than 50 examples of the TG 230A twin 30 mm turret, which the Sabre succeeds, were built and this earlier version was described in some detail in previous editions of *Jane's Weapon Systems*.

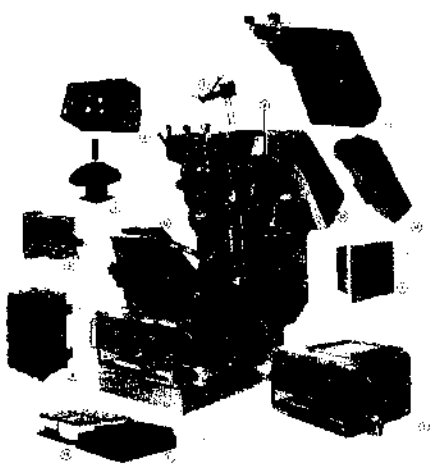
BPTSG MODULAR FCS FOR AA GUNS

The BPTSG modular fire control system (FCS) has been designed for twin 20 mm anti-aircraft guns such as the GIAT 76T2, 25 mm twin guns, or 30, 35 and 40 mm systems. The main elements of the BPTSG FCS are (see illustration): a gyro-stabilised sight unit (1) and its associated electronics (2); a mechanical sight for target acquisition (3); a laser rangefinder and a control and display unit (4); a joystick control (5); digital computer (6); voltage chopper/amplifiers for driving the gun (7); electrical DC motors and gears (12); an alternator with a combustion engine for driving the alternator (9); an electrical accumulator group (10) and (11); a simulation box for training, including a TV camera and a miniature viewer (8).

The digital computer performs calculations for accurate computation of lead angles, limitation of firing range etc, and provides an interface for remote control and target designation. There is also an interface for the laser rangefinder.

CHARACTERISTICS



Sight
Field/magnification: 30°/× 2; 15°/× 4
Elevation deflection: -10° to +85°
Azimuth deflection: ±32°
Laser rangefinder
Range: 10 km
PRF: 5 - 20 Hz
Wavelength: 1·06 μm
Performance (on twin 20 mm carriage)
Max azimuth rate: 1·7 rad/s
Max elevation rate: 1·3 rad/s
Max azimuth acceleration: 2·5 rad/s²
Max elevation acceleration: 4 rad/s²
Minimum stable rate: < 0·1 mrad/s²

STATUS

Development.

WILDCAT TWIN 30 mm AA WEAPON SYSTEM

The Wildcat (formerly AAAT anti-aircraft armoured truck) is a highly mobile, fast road/cross-country vehicle capable of providing anti-aircraft defence for mobile formations, and key installations such as airfields. It is based on the use of a slightly modified Daimler-Benz TPZ1 six-wheeled armoured truck chassis carrying a twin 30 mm automatic cannon turret. Five versions have been considered, among them: one with a surveillance radar and an electro-optical system that includes a TV tracker and laser rangefinder; another an all-weather version with full day/night capability, using surveillance and tracking radars. The crew consists of three men: the commander who is in tactical control of the system, the gunner who conducts engagements, and the driver.

A surveillance radar scans the surrounding airspace at a rate of once per second, whether the vehicle is on the move or stationary. Aircraft and helicopters within range are displayed on the radar PPI and automatically identified by IFF. After a target has been selected on the surveillance radar display and its elevation established, it is tracked automatically by the TV tracker/laser rangefinder unit (daylight/clear weather version) or by tracker radar (all weather, day/night version). The fire control and functional sequences are controlled by a digital computer. This determines the laying of the cannon taking into account target data, vehicle cant and actual meteorological data. When the target enters the engagement zone this is signalled to both the vehicle commander and the gunner. The weapon control system is the responsibility of Hollandse Signaalapparaten. The same concern also provides the LIOD target tracker and SMR micro-computer. Details of the radar, in several applications, will be found in the Flakpanzer entry (**3330.131**) later in this section, the Flycatcher air defence fire control system (**2301.181**), the Goalkeeper naval fire control system (**3516.261**), and in entry **2302.153** in the Ground Radar section of this volume.

CHARACTERISTICS

Vehicle: TPZ1 (modified)
Combat weight: 18·5 t (approx)
Length: 6·88 m
Width: 2·98 m
Overall height: 2·74 m (radar stowed)
Ground clearance: 41 cm
Engine: Mercedes-Benz 8-cylinder, 320 hp
Max speed: 80 km/h
Operating range: 600 km approx
Cannon: 2 × Mauser Mk 30F, automatic belt fed
Calibre: 30 mm
Rate of fire: 1600 rounds/minute (combined)
Ammunition: HEI/SD-T/APDS-T
Ammunition capacity: 500 rounds
MV: 1100 m/s (HEI/SD-T)
Traverse: 360° continuous
Elevation: –5 to +85°
Fire control equipment
Surveillance radar: Pulse doppler, digital MTI
Frequency: J-band (about 9 GHz)
Range: 18 km
Data rate: 1 Hz (60 rpm)
IFF: Integrated
Fire control computer: Digital, 24-bit
Tracking radar: All-weather version only
Frequency: Ka-band (about 35 GHz)
Range: 8 km
Antenna: Cassegrain monopulse
E-O director: (Clear weather version)
TV tracker: Militarised daylight television camera, video format to CCIR standard (625 lines, 25 frame/s, 2:1 interlace)
Field of view: 2·4° wide × 1·8° elevation
Laser rangefinder: Neodymium-YAG transmitter, 1·06 micron
Firing rate: 10 Hz
Beam divergence: 1·2 – 1·5 mil
Periscope: Fixed monocular eyepiece
Magnification: ×2, ×8
Field of view: 27°, 7°
Traverse: 360° (continuous)
Elevation: –10 to +70°

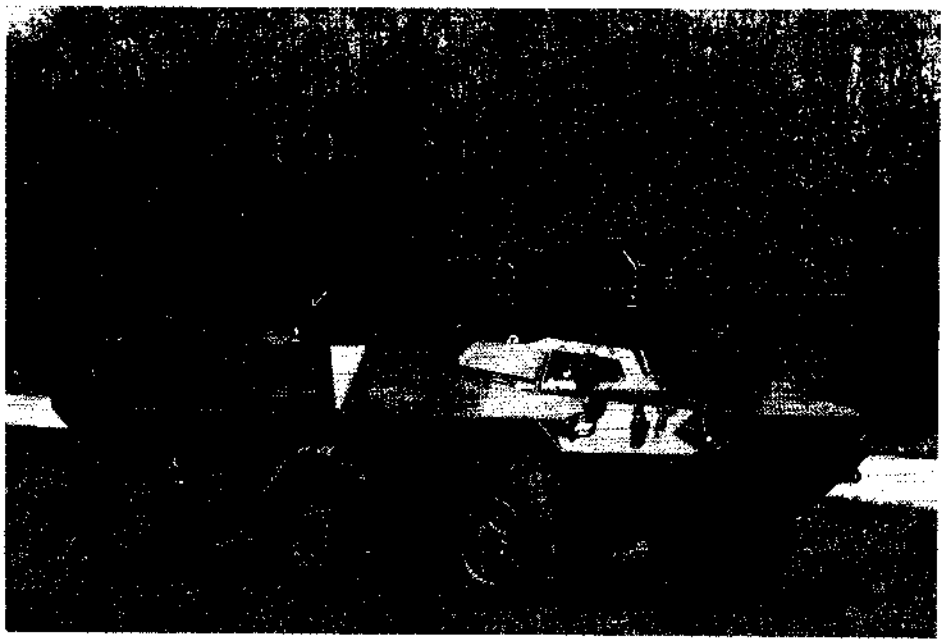
STATUS

Development project. In May 1981 the project was officially named Wildcat and it made its public debut in prototype form the following month at the Paris Air Show. No contractual details have been released. Missile versions have also been studied.

CONTRACTORS

System main contractor: Kraus-Maffei Aktiengesellschaft, Ordnance Division, Kraus-Maffei-strasse 2, 8000 Munich 50, Federal Republic of Germany.

Fire control equipment: Hollandse Signaalapparaten BV, Netherlands.



Twin 30 mm cannon: Mauser-Werke, Federal Republic of Germany.

Surveillance radar: Siemens AG, Federal Republic of Germany.

Ammunition feed system: Kuka Wehrtechnik GmbH, Federal Republic of Germany.

Turret/weapon drives: AEG-Telefunken, Federal Republic of Germany.

Chassis: Krauss-Maffei AG, Federal Republic of Germany.

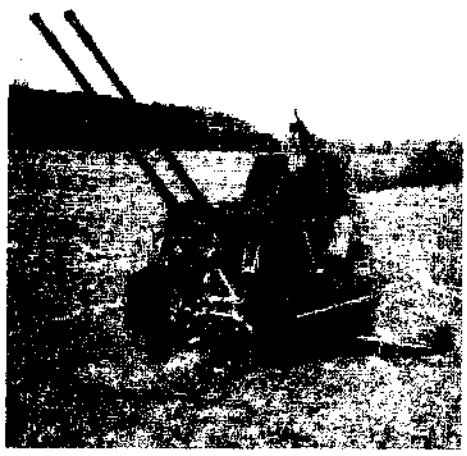
Prototype Wildcat (formerly the AAAT anti-aircraft armoured truck vehicle)

2182.131
20 mm TWIN GUN ANTI-AIRCRAFT SYSTEM

The AA 20 mm Twin Gun is a light highly mobile automatic system for engaging low-flying aircraft. It can also be used to engage ground targets.

Comprising two automatic rapid-fire guns with an analogue computer sight mounted on a transportable chassis that incorporates the gunner's seat, the system is suitable for rapid deployment in forward areas. The system is operated by a single gunner; to replenish ammunition two men are required and to bring the equipment into or out of action a third man is necessary.

The fire control system is the well-known P 56 computing sight and gun laying equipment made by Officine Galileo in Italy. It consists of the following main assemblies: monocular optical sight with swivelling objective prism for laying the gun against air and ground targets; electronic analogue computer for the calculation of kinematic lead values; joystick with two degrees of freedom for speed control of the line of sight; input panel for the target speed and crossing-point distance of air targets or the target distance of ground targets; hydraulic servo drive for the gun traversing and elevating gears; manual traverse and elevation mechanism; mechanical auxiliary sight.



To engage an air target the gunner first sets estimated target speed and aiming point distance on the input panel then acquires the target in his open sight using the joystick to control the gun. He then changes over to the optical sight and uses the joystick to bring the reticle into coincidence with the nose of the aircraft. Holding the sight in this relative position by means of the joystick he then presses the joystick down to put the guns under control of the computer. Thereafter he keeps the optical sight on the target and the computer points the guns with the degree of lead needed for successful firing. Firing will, however, be inhibited when appropriate by the taboo programme which can be inserted into the sight computer.

The taboo facility which can be programmed by the gunner is a safety device to prevent friendly objects from being accidentally engaged. It divides the field of fire into a combat zone and a neutral zone.

When engaging ground targets it is necessary only to set the estimated range on the input panel and to bring the target into the reticle of the optical sight before firing.

The guns used in the system are Rheinmetall Rh 202 20 mm rapid-fire (**5600.103** in 1982-83 and earlier editions). These are precision weapons that have a very high rate of fire (600 to 1000 rounds per barrel per minute) and a low recoil force. Both gun and ammunition feed are gas operated and independent of weapon and breech movement. In the AA weapon system, cartridges can be fed selectively so that either or both guns can be employed during an engagement.

Twin ammunition boxes containing a total of 550 ready rounds are mounted on either side of the gun assembly and fixed on the upper mount. This

Twin 20 mm gun system with MK 20 Rh 202 guns

ammunition supply enables the weapon to be used for long periods without replenishing the boxes. Ammunition types available are HEI, HEI-T, API-T, API, APDS-T and training and practice TP and TP-T.

Power for the computer and gunlaying systems is provided by an air-cooled engine with a centrifugal governor and a manual starter. This is installed at the rear of the mounting in a cage under the gunner's seat. The complete system is mounted as a two-wheel trailer for towing and can be towed by any vehicle capable of handling an unbraked trailer weighing 2500 kg; the wheels are removed for firing and the mounting is supported on three feet.

CHARACTERISTICS

Cannon: 2 × 20 mm MK 20 Rh 202

Laying system: Hydraulic with emergency manual controls

Elevation: -3·5 to +81·6° (hydraulic); -5·5 to +83·5° (manual)

Traverse: Unlimited

Max laying speed: 80°/s (elevation); 48°/s (traverse)

Max acceleration: 220°/s (elevation); 120°/s (traverse)

Optical system: ×5 magnification; 12° field

Length: 5·035 m (travelling)

Width: 2·36 m (travelling)

Height: 2·075 m (travelling)

Weights: Approx 2160 kg (travelling, less ammunition); 1640 kg (travelling in firing order with ammunition)

Ready rounds: 2 × 280, including 10 on each belt frame

Data input to computer: Target speed 60 - 350 m/s; crossing point distance 100 - 600 m; ground target distance 100 - 2000 m

Generator output: 5·8 kW at 4500 rpm

STATUS

In service with Argentina, Federal Republic of Germany, Greece, Indonesia, Portugal.

ARTEMIS 30 TWIN 30 mm AA GUN SYSTEM

Following a contract awarded by the Greek MoD, Hellenic Arms Industry SA designed the Artemis 30 anti-aircraft system to meet the requirements of the Greek Army. It was first shown publicly during the Defendory Exhibition in Athens in October 1982.

The twin 30 mm cannon carriage was designed in collaboration with Kuka GmbH of the Federal Republic of Germany while the twin 30 mm cannon and the associated ammunition came from Mauser, also of the FRG. The fire control system has been designed by Philips of Sweden and the acquisition radar system by Siemens AG of the FRG.

The Artemis 30 fire unit is a twin 30 mm cannon system towed on a twin-axle split type carriage. The axle nearest to the draw bar carries the generator which powers the cannon system in action. Once deployed, this axle/generator assembly is removed and placed at a distance from the mount. The deployed mount is lowered and levelled by means of three hydraulically operated pads, two of them on outriggers, while the rear axle is power retracted upwards.

The weapons are mounted each side of a horizontal drum assembly, which elevates the two cannons. This assembly is placed on a central support which is mounted on a traversing turntable. Circular ammunition hoppers holding 500 linked rounds (250 for each gun) are also mounted on the central support. Each cannon receiver is contained in a protective housing that covers the cannon to the base of the barrel. Each of these boxes can be hinged open to reveal the mechanisms for clearing jams or for routine servicing. By removing the gun barrel the entire receivers can be swung outwards for more involved repairs and maintenance. The linked ammunition is fed from the hoppers upwards through the central drum and into the feeders from the inside. Spent links and cases are ejected through slots in the cannon housings. The weapons are the Mauser 30 mm Model F, described elsewhere in this volume. The twin cannon upper mount assembly has an unlimited 360 degree arc in traverse while the elevation arc is from -5 to +85 degrees.

Artemis 30 field AA mount carries twin 30 mm Mauser automatic guns. Tubular containers beside carriage lower side members house replacement gun barrels to sustain operations remote from ordnance depots

The mount has three distinct modes of operation:

(1) via a remote fire control system

(2) via a gunner seated directly behind the central mount support. In this mode the gunner is provided with all necessary controls including a periscope for ground targets and also a gyroscopic angle prediction sight for air target engagement

(3) emergency operation via the gunner but with no power supplied to the mount. Weapon aiming is accomplished by means of handwheels with firing by a foot pedal. The ammunition used is the well-known GAU-8 family.

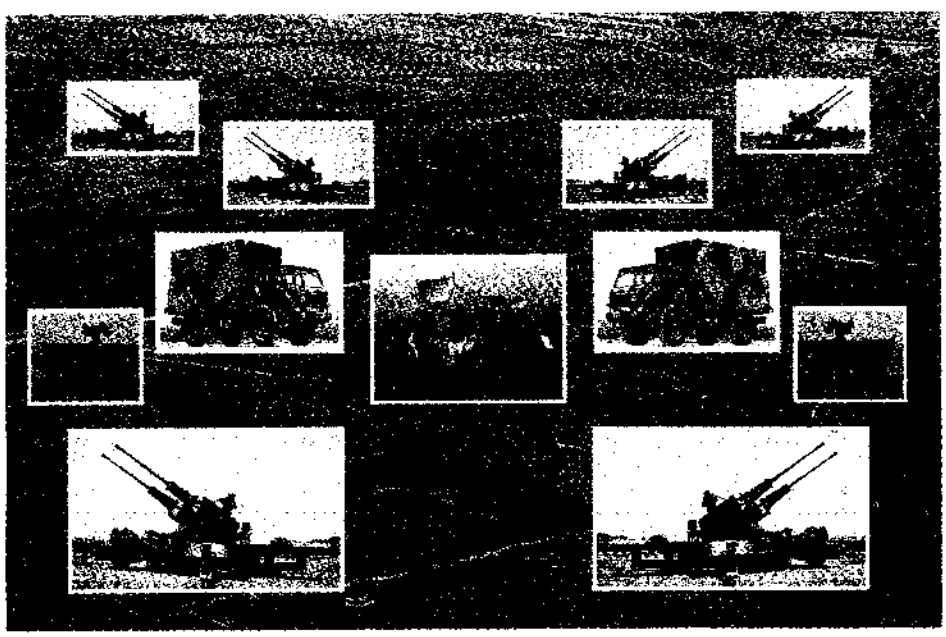

Diagram of typical Artemis 30 deployment showing six twin 30 mm guns, two fire control centres and E-O tracker units, and battery co-ordination post

It was established early on that the Artemis 30 would not be completely dependent on radar fire control, but it was decided that any selected type of fire control would be modular so that radar could be incorporated. The simple state-of-the-art approach adopted is based on an electro-optical technique, which, despite its relative lack of sophistication, is considered to provide the weapon system with all that is required for local and area defence roles.

Philips contributed a system modified from its original design that uses a compact laser/electro-optical head mounted on a small single-axle trailer, which presents a video picture to the operator in the fire control centre. The fire control centre is usually housed in an air conditioned shelter carried on a light truck. The shelter also houses the system computer and all necessary communications equipment. The digital computer processes all incoming data and transmits gun-laying data and firing commands to the guns via land line(s). Programs for training and fault finding are handled by the digital computer and all signal processing is digital. A fire control centre

usually controls three or four guns spread over an area about the size of an airfield with each gun operating over a range of 2000 to 3000 metres with a maximum engagement range of 5000 metres.

Being modular in concept the Artemis 30 fire control system can be expanded and adapted to suit varying operational requirements. For use at night an infra-red sensor can be added and for all-weather use an amplitude modulation monopulse tracking radar can be installed on the director. The system may also be adapted to handle up to four twin 30 mm cannon carriages, or for use with rocket or guided missile AA systems. In the long term it has not been entirely ruled out that the Artemis 30 system will encompass some form of surface-to-air missile component. Target information is usually supplied to the fire control centre from an acquisition radar system, combined with a battle co-ordination post. All systems comprising the Artemis 30 system are fully mobile.

CHARACTERISTICS
Calibre: 30 mm
Weight: 7·1 t
Ready-use ammunition: 500 rounds
Rate of fire: 1600 rounds/minute (two guns)
Traverse: Unlimited
Traverse acceleration: 200°/s²
Traverse speed: 100°/s
Elevation: −5 to +85°
Elevation acceleration: 166°/s²
Elevation speed: 75°/s
Overall carriage accuracy: Better than 1·5 mrad
Max towing speed: 80 km/h

STATUS
Entering production. The company has proposed a version of the system mounted on the chassis of the Steyr 4K 7FA APC which is already manufactured under licence in Greece for the Greek Army.

CONTRACTOR
Hellenic Arms Industry SA, 160 Kifissias Avenue, Athens, Greece.

INTERNATIONAL

3679.131
DRAGON 30 mm TWIN GUN AA SYSTEM

Dragon is the name of a joint Franco-German project to produce a twin 30 mm anti-aircraft gun system similar to the French AMX-30 SA system (**2138.131** in 1982-83 and earlier editions) but mounted on a Thyssen Henschel tracked carrier vehicle instead of the AMX-30 chassis. The weapons and fire control sights and equipment are the same in both systems, but in place of the SAMM TC230A turret employed in the French system, the Dragon system has a welded steel SAMM/GIAT turret.

The system is operated by a three-man crew: commander, driver, and gunner. Its function is to provide protection from low- and very low-level air attacks against advanced battle corps units, vulnerable points and armoured formations. The chassis is a member of the TH301 medium tank family, providing excellent cross country capability over ranges of up to 600 km. It is thus able to escort tanks as well as other, faster, vehicles.

The turret is an armoured rotating casemate structure carrying two automatic HSS831A 30 mm guns. Optical observation and sighting equipment and a Thomson-CSF Oeil Vert surveillance and tracking radar (**3197.153**) are also mounted on the turret. There are two operating positions within the turret: the commander's with a panoramic sight and radar control panel, a direct aiming periscope for air defence, an M250 for ground defence, angular vision blocks, and levers for turret steering and gun firing; and the gun-layer's station with a × 6 sight, an aiming periscope for ground engagement, angular vision blocks, and duplicated levers for turret steering and gun firing.

After optical target acquisition, the gunner keeps the reticle centre of the sight on the target by means of the gun steering control. Firing data, complemented by the Oeil Vert radar, are inserted into the fire control computer which calculates the appropriate aim-off angles. The radar has two surveillance modes:

Prototype Dragon 30 mm twin gun AA vehicle

remote, extending to a range of more than 15 km; and close-in, with a range of 7·5 km. There are five range channels in each mode, and the latter mode will be used mostly for 'pop-up' targets of opportunity. Automatic tracking in range and bearing of the target selected by the commander is possible using a track-while-scan facility, this taking place simultaneously with the surveillance function.

Firing rate of the HSS831A automatic gun is 620 rounds/minute, and the ammunit on allocation is 300 rounds per weapon, giving a total of ready-use of 600 rounds in the turret, with more than 1500 rounds accessible in the turret, backed by a reserve of about 900 rounds. Muzzle velocity is 1000 metres a second and the maximum effective range is 3500 metres, with an absolute maximum range of 10 000 metres.

STATUS
Prototype. No procurement details have been revealed.

CONTRACTORS

ISRAEL

4508.131
SPIDER II AIR DEFENCE ARTILLERY SYSTEM

The SPIDER II is a ground-based mobile fire control system designed for use against both high- and low-flying targets, aircraft, helicopters or missiles. The system searches for, designates and tracks aircraft and missiles and controls automatically the aiming and firing of six twin 30 mm cannon turrets. It is claimed to detect low altitude, small radar cross-section targets up to a maximum range of 19 km and will predict ballistics automatically for guns of calibres from 30 to 57 mm.

The basic system consists of a fire control console, tactical control console, search radar, tracking director and a processing unit. These units are normally mounted on a military truck, or housed in a standard shelter/container suitable for transport on a flat-bed vehicle. The search radar is designed primarily for detection of low-flying aircraft and uses coherent pulse doppler techniques. The tracking director is a combination of fire control radar and electro-optical systems with the latter incorporating two TV cameras and high rate and power laser rangefinder. The fire control console provides the operator with monitoring control of the system by

TCM 30G gun mount used in Spider II air defence system

means of a keyboard and a video display. The tactical control console is normally positioned at the commander's station, and displays essential data for fire control monitoring by means of a tactical display of battlefield area and targets detected by the various sensors providing informat on to the system.

The system is being offered currently with the TCM-30G cannon, but can be used with other weapons such as twin 35 mm Oerlikon or Bofors 40 mm guns.

During 1983 the Spider III version was revealed. This embodies missiles instead of guns to engage air targets and is described elsewhere in this edition.

CONTRACTOR
Israel Aircraft Industries Ltd, Electronics Division, Yehud Industrial Zone 56000, Israel.

4590.131
TCM MK3 LIGHT AA SYSTEM

Based on the considerable experience gained with the 20 mm twin cannon TCM-20 anti-aircraft system, Israel Aircraft Industries have developed a successor system known as the TCM Mk3. This new mount meets all the requirements of the Israel Defence Forces for mobile air defence, and is capable of deployment in both ground-based and naval applications.

The mount itself has the simple structure, operation, and maintenance demands of the TCM-20 supplemented by advanced sub-systems such as more modern drives and the ability to employ the latest sighting systems. The new gun system can be integrated with the fire control system developed and manufactured by MBT Systems and based on a computer sight with laser rangefinder.

Using suitable adapters, the TCM Mk3 mount can accept virtually any light 20 - 25 mm AA gun, and aboard ship it may be used as either the main weapon system or as secondary armament to engage air, shore or surface targets.

Command and control of the mount is through a variable speed joystick mechanism. Mechanical movement of the joystick by the gunner is converted into electrical signals that are passed to servo amplifiers for subsequent conversion into drive commands for the training and elevating motors. The TCM Mk3 has a new drive system consisting of two separate but similar drive units (traverse and elevation), each of which includes a 24 V servo amplifier, torque limiter, gear, and feedback system. This arrangement is very sensitive to joystick demands, enabling the gunner to track fast-moving targets as easily as very slow targets.

Towed TCM 20 gun mount for AA defence

RAM V1-L combat vehicle with TCM Mk3 turret with HS-404 guns

The TCM Mk3 mount can be installed on towed or self-propelled carriages, and a wide range of guns such as the HS-404, HS-804, HS-920, Rh-202 and F-623, have been allowed for in the design. A typical system (towed version with 2 × HS-404 guns) weighs 1350 kg ready for action. The basic version is provided with an M-18 reflex optical sight, but other options include a ×4 magnification 'starlight' sight for night operation, or the MBT FCS which incorporates a computer sight and integral laser rangefinder.

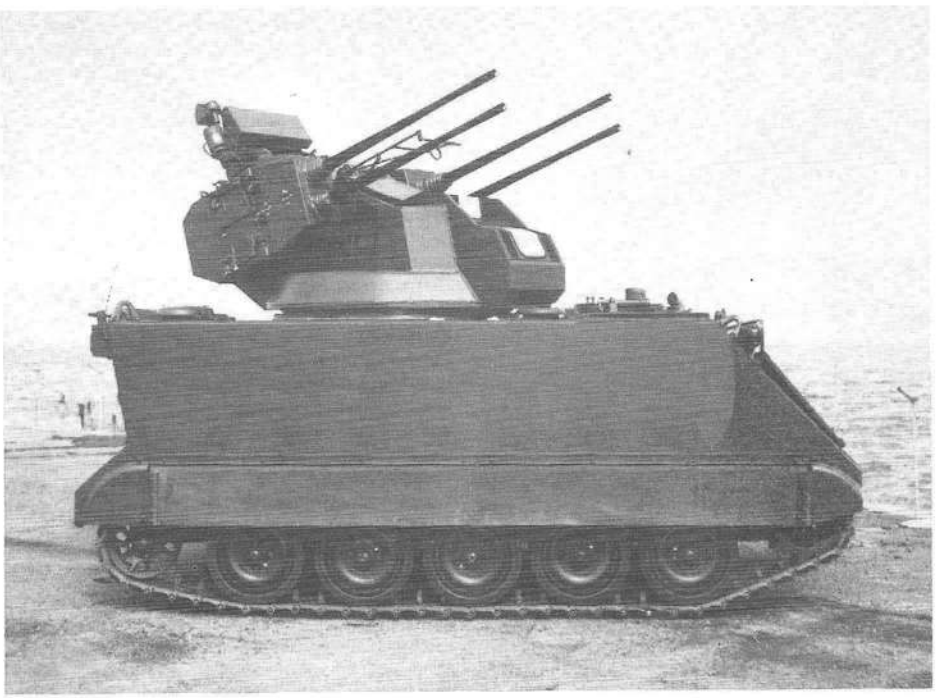
CHARACTERISTICS

Traverse: Unlimited 360°
Velocity: 0·25°/s, 75 - 80°/s max
Elevation: -10 to +90° (mechanical); -6 to +85° (electrical)
Weight: 1350 kg (2 × HS-404, towed model, ready for combat)
Power supply: 24 V DC
Primary source: 2 × 12 V DC, 80 Ah batteries
Auxiliary source: 28 V DC, 2·8 kW generator

STATUS

In production and operational with Israeli Forces.

CONTRACTOR



Israel Aircraft Industries Ltd, Ben Gurion International Airport, 70100, Israel.

ITALY

4535.131
SIDAM 25 AA TURRET

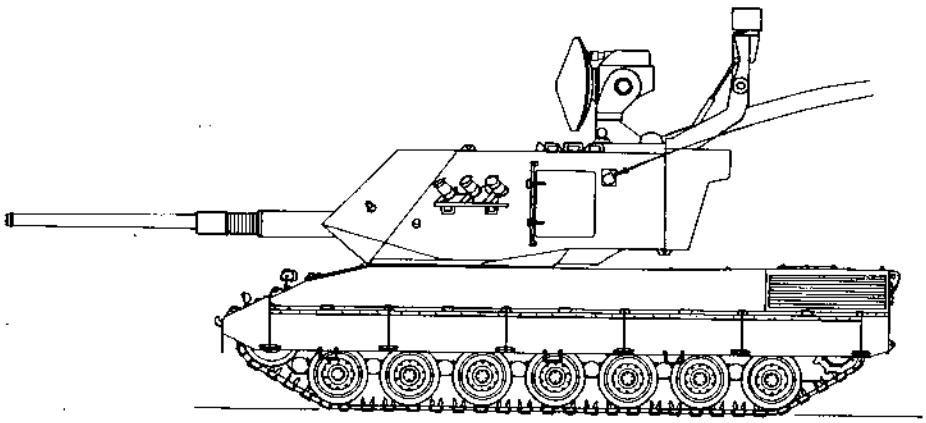
This is a one-man, powered turret mounting four Oerlikon KBA 25 mm automatic cannons, equipped with an electro-optical fire control system, and designed as the main armament for armoured personnel carriers. The system is intended to provide effective protection against air attack for troops, armoured columns and other tactically significant targets. Because of the optical sight and the gun calibre, it is also suitable for ground fire purposes.

The turret is constructed of welded aluminium alloy and carries two symetrical, externally mounted elevating masses, each of which is equipped with two 25 mm automatic guns. Each barrel has a rate of fire of 600 rounds/minute, and the rate of fire is selectable to provide single shot, 15- to 25-round controlled bursts and full rate firing. Two of the four cannon have dual feed capability for high explosive and armour piercing discarding sabot (APDS) ammunition, and 600 rounds HE and 30 APDS belted ready-to-fire rounds are provided in the turret ammunition magazines. The mode of fire (single shot, 15/25-round bursts, or continuous) can be selected from the gunner's control panel, and the system can be operated entirely from within armour protection. Selection of the types of round to be fired is performed mechanically under the control of the gunner.

Prototype Sidam 25 AA turret installed on M113 chassis

The turret has hydraulically powered traverse through 360° and the elevation limits are -5 to +87°. The design allows easy installation, with minor modifications of the vehicle, in a variety of APCs and the first prototypes employed the M113, although it is understood that several other vehicles have been considered.

The system includes an Officine Galileo electro-optical sight that includes a self-stabilised optical dual periscope with a daylight TV camera, low-light TV camera and laser rangefinder, installed in the turret with an IFF device. An electronic tracking unit connected to the sight performs the angular tracking of the target, and target designation from an external source can be accommodated by a target alert display set. The fire control computer is fitted inside the vehicle in the gunner's console, together with an inertial attitude sensor. The fire control system is designed for two operators: the commander sitting in the turret and the gunner in the vehicle hull.



From acquisition by the commander, the target is assigned to the gunner, who carries out automatic or manual tracking by means of a joystick control. All these operations (except firing) can be carried out with the vehicle on the move. Modular design provides for the later enhancement of the system by the addition of such devices as a video compatible FLIR, an inertial navigation system, or passive IR to provide a 24-hour search and detection capability.

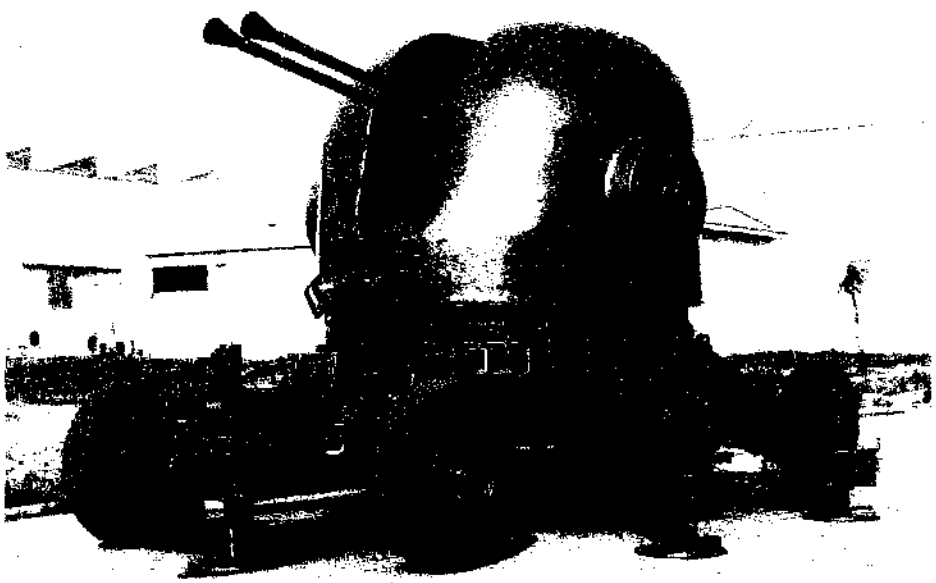
CHARACTERISTICS
Turret
Armament: 4 × 25 mm KBA dual-feed cannons
Rate of fire: 2400 rounds/minute (max)
Traverse: 360° continuous
Speed: 90°/s
Acceleration: 150°/s²
Elevation: -5 to +87°
Speed: 90°/s
Acceleration: 120°/s²
Fire control system: Electro-optical with laser rangefinder and computer. Attitude sensor
External designation: Automatic lock-on from external designation via data link
Weight: 3200 kg (combat ready)
DEVELOPMENT
The turret was built by Oto Melara in co-operation with Oerlikon Italiana and Officine Galileo, under an Italian armed forces programme.
STATUS
Firings for the Italian Army were carried out in May 1983, using two prototypes on M113 vehicles.
CONTRACTORS
Turret: Oto Melara SpA, 15 via Valdilocchi 1, 19100 La Spezia, Italy.
Automatic cannon: Oerlikon Italiana, Milan, Italy.
Fire control: Officine Galileo, Florence, Italy.

4594.131
OTOMATIC 76/62 SPAAG
Oto Melara is developing a new self-propelled anti-aircraft gun system using the OF-40 BMT chassis with the Oto 76 mm 62 calibre gun as the weapon. The design also incorporates an all-weather opto-electronic fire control system by Officine Galileo, linked with an S-band surveillance and tracking radar provided by SMA. A major design consideration was an ability to detect and engage aircraft targets (ground attack helicopters in particular) at ranges greater than the anti-tank weapons the aircraft might be carrying, eg 6000 metres or more.

The general arrangement of the Otomatic 76/62 SPAAG can be seen from the drawing, from which it will be noted the radar installation is turret mounted. It is understood that this turret will also prove suitable for fitting to other chassis. The turret is constructed of welded steel, with the commander and gunner seated on the right and the loader on the left. An AA 7·62 machine gun can be fitted to the turret top for local protection.

A modified version of the Oto OF-40 tank chassis is employed, and an operating range of 600 km with a maximum speed of 60 km/h is available from a 1000 litre fuel capacity. Elevation and traverse of the 76 mm gun are hydraulically actuated, with manual mechanical operation for emergency use. Elevation limits are +60 and -5 degrees, while there is unlimited traverse (360 degrees in either direction). A total of 28 rounds of ready use ammunition is carried, with a further 52 rounds in reserve in the turret and 20 in the hull. The ready use ammunition consists normally of 25 rounds AA and three anti-tank rounds.

General arrangement of Oto Melara Otomatic 76/62 SPAAG



Six types of ammunition are available: HE active projectile with point detonating fuze; HE active projectile with proximity fuze; preformed fragmentation (PFF) active projectile with point detonating fuze; PFF projectile with proximity fuze; dummy with tracer and dummy fuze; and an APFSDS anti-tank projectile. The gun is capable of a cyclic rate of fire of 120 rounds/minute, and the AA projectiles have a typical muzzle velocity of 900 metres/second.

The SMA search radar operates in the S-band of the spectrum and facilities include MTI, track-while-scan (TWS), and provision for IFF. A TV camera is associated with the tracking radar which operates in the Ka-band. Other fire control system features include a computer, the Galileo optical sight and tracking facility, and a separate system for engaging ground targets.
STATUS
The first prototype (without fire control system) is due for completion in 1985, with a second prototype (with FCS) due about a year later.
CONTRACTOR
Oto Melara SpA, 15 via Valdilochi 1, 19100 La Spezia, Italy.

4589.131
BREDA TWIN 40L70 AA FIELD MOUNTING
Breda Bresciana has introduced a field mounting version of its well established twin 40 mm naval anti-aircraft gun for use against low-flying aircraft and missile targets. The gun is fully automatic in operation and there is no need for any on-mount crew when the gun is in action. It is suitable for use with a wide range of fire control and target acquisition systems, for example the Signaalapparaten Flycatcher (**2301.181**).

Two Bofors 40 mm L/70 guns are combined to form a twin elevating mass within a specially designed cradle to comprise the Breda Twin 40L70. The barrels of standard Bofors guns are located 30 cm apart to reduce elevating mass recoil forces. The mounting consists of a 360-degree traverse training platform supported on a wire race bearing. The platform has parallel vertical lightweight aluminium alloy trunnion supports, and also carries the servo and ammunition feed motors together with the upper feed mechanism, firing mechanism and system junction box. The upper portion of the mounting is completely enclosed within a watertight reinforced glass-fibre cupola which is provided with three access hatches, at the rear and on each side.

Ammunition is stored in a magazine beneath the mounting platform, within the carriage, and rounds are fed to the guns via separate hoisting chains for each gun. The magazine trains with the mounting, and the system is arranged so that if either gun is out of action the other can continue to fire. The forward section of the magazine supplies the left-hand gun and the rear section supplies the right-hand gun. The system is driven by a 400 V AC motor powered from an external generator; fast or slow drive facilities are provided. The slow drive operates the magazine conveyors and the scuttle transferring the rounds to the lower chain hoist; the fast drive operates the ammunition hoists and the scuttle at the top of the hoist. Rounds are fed into the lower magazine manually via the side hatches. DC electric motors driving epicyclic gearboxes are used for gun elevation.

Towed Breda Twin 40L70 40 mm AA mount

CHARACTERISTICS
Calibre: 40 mm
Barrel length: 2·8 m
Total weight: 9900 kg (less ammunition)
Weight of ammunition: 1100 kg
Length: 8·05 m (travelling)
Width: 3·2 m (travelling)
Height: 3·65 m (travelling)
Training velocity: 90°/s
Training acceleration: 120°/s²
Elevation velocity: 60°/s
Elevation acceleration: 120°/s²
Magazine capacity: 444 rounds
Rate of fire: 660 rounds/minute (both barrels)
STATUS
Production. In service with Venezuelan forces.

BREDA LIGHTWEIGHT AA FIELD MOUNTING

The Breda twin 30 mm mounting is a new lightweight anti-aircraft towed field mounting introduced in 1983 to provide defence against air attack for troops, and other deployed ground forces. It is provided with an autonomous power supply unit and an electro-optical sighting system supplied by Officine Galileo. The latter system incorporates a laser rangefinder and infra-red facilities for night tracking of targets in addition to daylight optical tracking. Aim-off is applied automatically in optical tracking.

The guns fire standard GAU-8 high explosive ammunition at a maximum rate of 1600 rounds/minute, but API and APDS ammunition is also available for use against enemy armour and there are frangible rounds for engagement of aircraft targets.

The Breda twin 30 mm AA field mounting is suitable for integration with a variety of gun/missile air defence systems such as the Roland Co-ordination Centre (RCC).

CHARACTERISTICS
Calibre: 30 mm
Barrel length: 2·458 m
Carriage: 4-wheeled with two outriggers
Shield: Yes
Weight: 145·5 kg (gun, complete)
Length: 6·46 m (travelling)
Width: 1·76 m (travelling)
Height: 1·94 m (travelling)
Ground clearance: 0·43 m
Wheelbase: 3·5 m
Elevation/depression: +85°/–5° at 60°/s
Elevation acceleration: 90°/s²
Traverse: 360° at 80°/s
Traverse acceleration: 120°/s²

Breda lightweight twin 30 mm AA towed field mounting deployed

Flight time to 3000 m: 5·2 s
Rate of fire: 1600 rounds/minute (2 barrels)
Muzzle velocity: 1040 m/s

STATUS
Ready for production.

JAPAN

3724.131
AW-X SELF-PROPELLED TWIN 35 MM AA GUN SYSTEM

The Japanese Ground Self Defence Force (JGSDF) initiated in 1978 the development of a self-propelled twin anti-aircraft gun system based on a pair of modified Oerlikon KDA 35 mm automatic guns, mounted on a tracked chassis, either the Type 61 MBT hull or the Type 47 MBT chassis.

A radar fire control system based on the equipment used with Japanese Oerlikon 35 mm L 90 guns will be developed by Mitsubishi-Denki, who will also provide data processing and display equipment.

DEVELOPMENT
The AW-X was originally intended to use obsolescent Type 61 chassis for reasons of economy but maintenance problems and lack of internal space and vehicle agility have been cited as reasons for considering alternative platforms for the system. The obvious alternative of the Type 7 MBT would make possible the desirable 'fire-on-the-move' capability, but cost may rule this option out.

A contract worth about $4 million was awarded in 1978 to start the AW-X project, with modification of the Oerlikon 35 mm guns being the responsibility of Nippon Seiko-Jyo (Japan Iron Works) Company, and development of the fire control system going to Mitsubishi Electric Co.

STATUS
The first fire control system was due for delivery in March 1980. Modified KDA 35 mm guns have been delivered since September 1979, and the 1979 budget allocated a total of $1·75 million for prototype manufacture of the fire control system and display units. Prototype turret, turret stablisation and drive systems manufacture were covered by the 1980 budget. Initial operational capability is planned for service deployment in 1987.

Mitsubishi-Denki (Mitsubishi Electric) Company.

SPAIN

3208.131
MEROKA ANTI-AIRCRAFT SYSTEM

Meroka is a novel close-in air defence weapon system that has been under development for a number of years by the Spanish authorities. Both land-based and naval versions have been designed, the latter is described in entry **3176.203** in the naval ordnance section of this volume. Some of the background to the programme has appeared under the above entry number (**3208.131**) in 1983-84 and earlier editions.

The weapon used in both versions is a twelve-barrelled arrangement of 20 mm/120 calibre Oerlikon machine cannons, grouped together in two horizontal rows of six barrels. A salvo of 12 rounds can be fired in a time of 0·08 seconds, which amounts to a theoretical rate of fire of 9000 rounds/minute. The main purpose of this high rate is less the delivery of a large total of projectiles on to a target but more to meet a need for maximum density of fire when engaging certain categories of air targets, such as low-flying ground attack aircraft, and sea-skimming anti-ship missiles in the naval application. The normal practice is for each salvo to be fired as four groups of three rounds. This minimises the total recoil force applied to the mount as well as having other beneficial operating characteristics.

The group of 12 barrels forms a single rigid unit which is traversed and elevated as a conventional gun, mechanical rigidity being aided by a number of steel bands (two in the army version, four in the naval version) that determine the spacing between the individual barrels. This feature is also used to adjust the dispersion of fire and fire pattern. Ammunition is brought to the 12 guns by two belt feeds which are supplied from a hydraulically powered rotating magazine with a capacity of 720 rounds. Elevation limits are -5 to +85 degrees, and the gun can traverse in azimuth through 360 degrees at a rate of 90 degrees/second.

A simple electro-optical fire control system that incorporates a TV camera, laser rangefinder and digital computer is used, this system being bore-sighted to the gun barrel axis. Aim-off to compensate for target motion is automatically injected when the fire button is pressed after having tracked the target for several seconds.

The prototype land-based Meroka AA gun is mounted on a towed four-wheeled carriage, and incorporates the gunner's position and a self-contained two-stroke engine that drives the hydraulic power unit for gun slewing and elevation, ammunition feed etc.

CHARACTERISTICS
Weapon: 12-barrel 20 mm Oerlikon
Barrel length: 2·4 m (120 cal)
Recoiling mass: 300 kg
Theoretical rate of fire: 9000 rounds/minute
Magazine capacity: 720 rounds
Elevation: -5 to +85°
Traverse: Unlimited 360°
Effective range: 3000+ m
Time into action: Approx 2 minutes
System weight: Approx 5 t, ready for action

STATUS
Prototype(s) completed and initial evaluation trials continuing.

BOFORS ARMOUR TRINITY

Trinity is the name given to a new Bofors weapon system designed for use in both land-based and naval application for close-in air defence purposes. The name derives, according to the manufacturer, from advances made in all three main elements of the system - fire control, the 40 mm gun, and the ammunition. Although initially conceived as an air defence weapon system, in the course of design parallel developments in all three aspects led to it becoming an all-purpose system.

The land-mobile version is known as Armour Trinity. The system is configured to accommodate most of the major elements within an armoured turret which is suitable for mounting on a variety of AFVs such as the MOWAG Shark, TAD, Steyr-Daimler-Puch etc. The gun can be controlled from either the vehicle itself, via a TV viewing the target through the gun sight, or from an armoured cab to the left of the barrel. A tracking radar may be fitted to the right of the barrel and the sight can be equipped with an IR tracker. An on-mount local search radar is regarded as a highly desirable addition.

Trinity has an integrated fire control system in which search and tracking radars can be combined with a digital computer, a Bofors-developed μBOF 8016 machine, and other sensors to provide a modular FCS. In addition to primary radar(s) for search and tracking functions, it is possible to integrate IFF. Other sensors that may be incorporated include laser rangefinder, optical day and night channels and gyro reference and motion sensors for example.

Armour Trinity installation on MOWAG Shark

Austrian Steyr APC fitted with Bofors Armour Trinity turret

There is an integral sight for all visual lines of sight, daylight, night vision or IR, and laser rangefinder. The fire control computer inhibits fire until it has calculated a sufficiently high kill probability. This results in a need for only short bursts, normally five to 15 rounds, which means that 100 on-mount rounds are normally sufficient for ten engagements.

An important function of the computer complex is the fuze setting program devised by the Swedish Philips organisation. This enables each individual round to have its fuze setting programmed while it is in the final stages of ammunition feed. in this way, the pre-programmed burst of fire can be suited to the nature of each target. Each burst under proximity fuze control can cover 180 m² of airspace with lethal fragments. Using ten-round bursts it is possible to ring an aircraft or missile target to ensure a kill.

An improved version of the L/70 40 mm gun is used in the Trinity system, which yields a further enhancement of accuracy by better muzzle energy from the use of new 40 mm Trinity 3P ammunition that gives reduced ballistic dispersion. The 3P round is all-purpose ammunition, with an adequate anti-armour capability against light armour, thanks to projectile and fuze developments. A penetrator round is projected which will deal with APCs or side-armour of battle tanks.

CHARACTERISTICS

Weapon: Single barrel 40 mm
Rate of fire: 330 rounds/minute
On-mount ammunition: 100 rounds
Fire control: Digital, radar search and tracking, plus optical and E-O lines-of-sight

STATUS

Prototype installations were nearing completion 1984-85. First deliveries expected in 1987. Proposed for Canadian LLAD project.

AB Bofors, Ordnance Division, Box 500, S-691 80 Bofors, Sweden.

2349.131
BOFORS 40 mm BOFI GUN SYSTEM

Based on the Bofors mobile 40 mm L/70 gun (**2360.203**) this new system incorporates an all-weather fire control instrument of the multi-sensor type, BOFI (**2378.181**), integrated with the gun. The system also includes a built-in motor generator and proximity-fuzed prefragmented ammunition. The BOFI gun system is entirely autonomous, each gun forming an individual firing unit able to engage its own targets.

As the main sensor a Ku-band (J-band) radar is used, which, after target designation from a central search radar or optical target indicator, acquires the target fully automatically on fixed frequency with MTI, and thereafter switches to frequency agility during the tracking mode to provide the greatest possible tracking accuracy. By this means the same high precision as achieved with semi-automatic electro-optical tracking using a laser rangefinder and optical sight can be maintained. The tracking radar and the electro-optical sensors are independent of each other and switching between them can be done to match any tactical situation.

For simple and easy training of the gunners, a target simulator equipment (**3593.193** in 1982-83 and earlier editions) can be attached to the gun. Different flight paths can be selected and gunner performance measured.

A central search radar, such as the Giraffe (**1957.153**) or the Reporter system which also acts as a combat control centre for the battery of autonomous guns, contributes to the high effectiveness achieved. To further increase the defence potential a combat control radar can lead a mixed organisation comprised of BOFI guns and RBS 70 missile units. Such a mixed battery has considerable tactical flexibility.

Principal characteristics of the systems are:

(1) all-weather capability
(2) automatic acquisition and tracking
(3) high resistance to jamming
(4) capability of individual combat of targets
(5) highly effective against aircraft, helicopters, missiles and ground targets
(6) tactical flexibility and endurance
(7) short deployment and re-deployment times.

CHARACTERISTICS

Weight: 5500 kg
Rate of fire: 300 rounds/minute
Tactical range: 3700 m
Ammunition supply: 118 rounds on gun - sufficient for 12 engagements

Latest version of Bofors 40 mm BOFI anti-aircraft gun system incorporates multi-sensor fire control, a computer and power generator

System accuracy: 3 mrad
Radar accuracy: Ku-band (J-band) monopulse MTI or frequency agility
Frequency: 15·9 - 17·1 GHz
Frequency agility: 1000 Hz
Lobe width: 1·9°
Laser rangefinder: 10 Hz Nd YAG
Night sight: 3-stage image intensifier
Day sight: Telescope

Ammunition
Type: Proximity fuzed prefragmented (PFHE)
MV: 1025 m/s
Weight of shell: 880 g
Explosive weight: 120 g
Type: High capacity high explosive (HCHE)
MV: 1030 m/s
Weight of shell: 870 g
Explosive weight: 165 g

STATUS
The fair weather version of the system has been in production since 1976. The all-weather BOFI gun system completed its design tests during 1979.

Design of proximity-fuzed ammunition was completed during 1974 and is now in large scale series production.

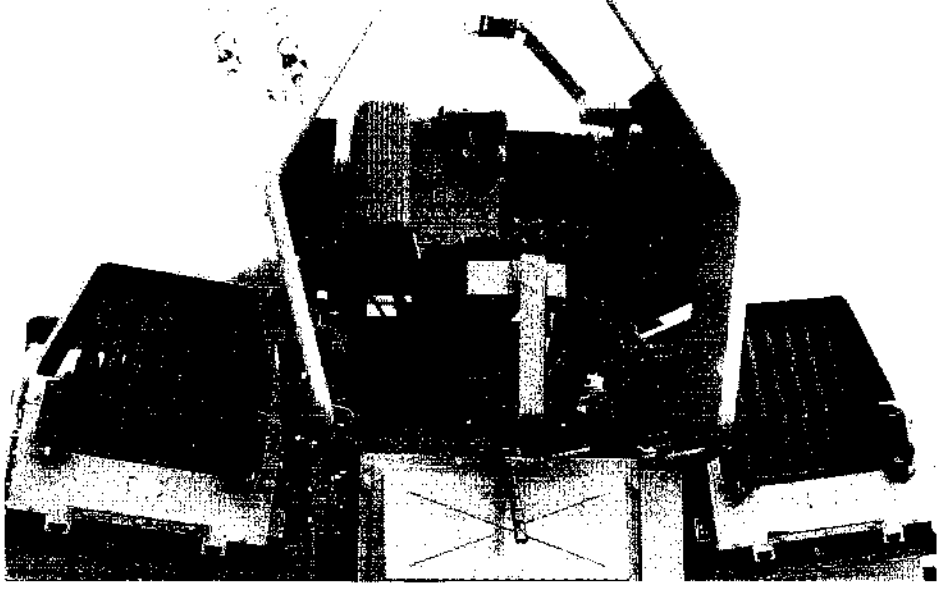
SWITZERLAND

4537.131
OERLIKON TWIN 35 mm AA FIELD GUNS GDF

The Oerlikon twin 35 mm anti-aircraft field gun system has been produced and delivered in considerable numbers over a long period, frequently for use in either the Super-Fledermaus or the Skyguard air defence system. The system has been described in **2374.131** in earlier editions of *Jane's Weapon Systems*, and in related entries. More recently the manufacturer has introduced a range of improvements for the Type GDF 35 mm guns and these are available as kits for updating existing guns, or the modifications may be incorporated in GDF series guns to be delivered new. Three levels of modification have been developed, referred to as Kits NDF-A, -B, or -C, and at the same time the company has introduced a new generation of 35 mm AA ammunition comprising fragmentation shells with electronic or mechanical impact base fuzes designed to ensure full detonation inside aircraft targets. The full NDF-C kit includes the following items, while omission of certain items results in the NDF-A and NDF-B modification kits:

(1) weapon cover with integrated, automatic weapon lubrication system
(2) optimised automatic cannon function which stabilises rate of fire
(3) automatic ammunition replenishers
(4) integrated power supply unit
(5) Gun-King minisight with laser and digital computer for 3-D target tracking
(6) new gun control system.

Oerlikon GDF-003 twin 35 mm AA field gun incorporates NDF-C kit improvement features such as Gun-King minisight, new ammunition/reloading provisions, and power supply unit



The newly developed cover provides an improved, built-in protection of the automatic cannon against dust, sand, snow and water. An automatic weapon lubrication system is built into the cover. New mathematical models studied by the company based on new forms of threat from the air indicate that longer bursts of fire may be necessary in the future. The gas temperature (which is used to unlock the breech block in the 35 mm gas-operated cannon) will therefore increase and cause the rates of fire to increase. This increase is held within reasonable limits by rate-of-fire regulators so that wearing parts and the weapon functions themselves are not unnecessarily overtaxed. In this way automatic fire rate is limited to about 680 rounds/minute.

The automatic units are re-supplied with ammunition manually from the rear by the gun crew. The crew required on the gun is reduced from three to one; the gunner. The rounds are thrust into the ammunition feed system by hydraulic-mechanical devices. The barrel is elevated to 90° for the automatic replenishing cycle. Electrical and mechanical limiters prevent inadvertent firing during the replenishing procedure. The automatic replenisher substantially increases the available ready-for-firing ammunition supply. The ammunition supply on the 35 mm field AA gun is 238 rounds, 112 (56 each gun) ready-to-use rounds and 126 rounds (63 each gun) in the reserve containers. Transfer from the reserve containers into the ammunition feed is simple even while firing, provided adequate training has been given. This mode of operation requires three operators on the gun. To increase the quantity of ammunition immediately available on the gun and to reduce the men needed from three to one, the horizontally stowed automatic reloaders are mounted in place of the two reserve containers.

The power supply unit mounted on the gun is quite similar to that of the Skyguard fire control unit. When the gun is in operation, the power supply unit (which is located on the lower mount) is lowered to allow the barrel to turn freely even at the maximum angle of depression. The integrated supply unit simplifies taking up position since the single axle trailer formerly used is no longer required.

A new thyristor gun control system is located on the upper mount. Its coarse and fine transmission system operates through an on-gun microcomputer identical to that of the Gun-King sight. The new gun control system and the integrated power supply result in enhanced combat effectiveness, greater availability, assurance of continued availability etc, reduction in number of vehicles (from five to three per firing unit), and shorter times required to move into position. Diesel or petrol engines can be used (to provide power) as specified.

The minisight, known as Gun-King and developed by Contraves, is an autonomous device that carries out a 3-D electro-optical target tracking for each gun. It can be integrated in place of the XABA or the Ferranti sight. This greatly extends the autonomous operation potential of the gun under fair weather conditions. Sight operation is extremely simple; the gunner only needs to bring the periscope crosshairs into coincidence with the target. An acoustic signal indicates that firing can commence. A built-in laser measures the range of the target which, together with angular data, meteorological data and the continuously registered v_0 values, is processed by an integrated digital computer to give lead data which is then transmitted to the gun control system. The Gun-King sight, as well as featuring in the NDF combat improvement kit for GDF 35 mm AA guns, is also a

The Contraves Gun-King minisight is an autonomous optronic aiming device which can be integrated in the 35 mm gun system in place of the XABA or Ferranti sights

major element of the Diana 25 mm field AA gun system (**4525.131**). The main features of this new sight are as follows:

There is a common optical path in the periscope for the laser beam and for the aiming line of sight. These beams are deflected with high accuracy by a gimbaled mirror, thus a fixed eye piece is provided. The periscope has an extremely high light transmittance and is fitted with a multi-spectral optical system. Night operation is possible. Range finding is effected by a multi-divergence laser. For ground targets, the laser beam is narrowed by a divergency switch-over device, thus eliminating ground clutter.

The new Contraves high speed computer for Gun-King calculates not only all fire control data precisely with optimum control, filter and ballistic algorithms, but also controls the periscope, laser triggering during the tracking phase and the gun drive electronics. At the moment of optimum hit probability, the operator receives an acoustic alarm to open fire. Target changes can be effected very rapidly because target data is stored in the memory. Provision is made for the insertion of muzzle velocity and meteorological data. All data relating to weather and weapon parameters is entered into the computer and the operator can therefore immediately concentrate on precise target tracking. Sight and gun are commanded entirely by the control yoke which provides hands on control.

NDF Series improvements can be carried out on 35 mm AA guns as follows:

GDF-001, equipped with the XABA sight (No longer produced.)

GDF-002, equipped with Ferrant sight.

GDF 001/002, with NDF-A improvement kit integrated. (These guns have already been improved with assemblies that are also part of the NDF-C. Further combat improvements involve the remaining assemblies.) The same applies to the GDF-003 (series production of the 35 mm AA gun with NDF-A assemblies). Guns which have been up-graded with NDF-B improvement kits cannot be modified with the NDF-C kit.

STATUS

Deliveries of NDF-C assemblies are planned for late 1985 from the Group's Zurich plant and about a year later from Oerlikon Italiana.

Machine Tool Works Oerlikon-Bührle Ltd, 8050 Zurich, Switzerland.

3723.131

OERLIKON 35 mm SP TWIN AA GUN GDF-CO3/DO3

The 35 mm twin AA gun GDF-CO3/DO3 system is intended as a self-propelled autonomous air defence system that fills the gap between towed mobile AA guns such as the earlier 35 mm field AA system described in **2374.131** in earlier editions (but which is still widely operated in at least 20 countries), and the more expensive and later AA tanks. Operational applications envisaged include the provision of air defence protection for mechanised combat support troops (artillery, engineers etc) in action and during deployment; motorised formations; and sites of short-term tactical importance. Operationally, the GDF-CO3/DO3 is deployed within tactical units and engages targets independently. Primarily it is designed for deployment into reconnoitered emplacements and AA protection in an escort role is of secondary significance. The two versions, GDF-CO3 and DO3, differ only in the chassis on which the gun and sensor system is carried: a modified M548/6-Oe tracked vehicle for the CO3 model, and a 4 × 4 × 4 'giant' tyre vehicle (four wheels, all driven and steered) for the DO3 model.

The most important sub-systems are:

(1) twin 35 mm Oerlikon gun
(2) drum magazines
(3) high performance sight with FLIR
(4) search radar (consisting of sub-assemblies also employed in the ADATS system (**4158.131**)).

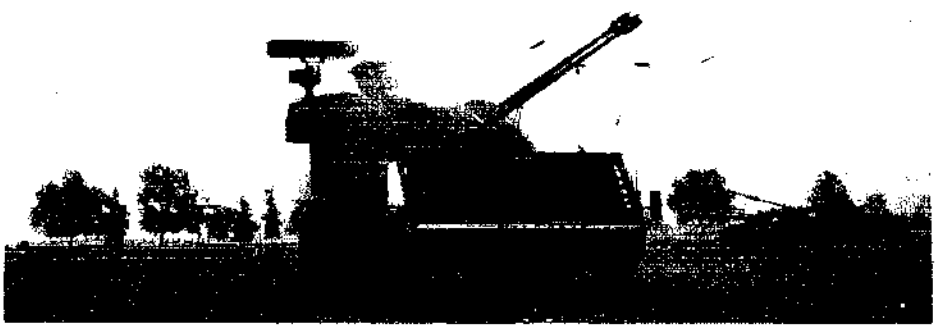
The gun is designed to engage aircraft, helicopters, drones and lightly armoured ground targets at ranges of up to 4000 metres. Three ammunition types with varying ballistics can be selected and fired. With regard to range, accuracy, response time and reliability, the performance of the system in airspace surveillance, target designation and fire control functions is optimised to the deployment spectrum. Even during target tracking, full airspace surveillance and IFF functions are maintained.

The GDF-CO3/DO3 mobile AA systems offer a high fire power solution where optimal weight, mobility, and cross-country ability are required. Effective splinter protection for crew members in the vehicle and gunner's cab is provided. All operating sequences are designed to allow operation of the entire weapon system by a crew consisting of commander, gunner and driver.

CHARACTERISTICS

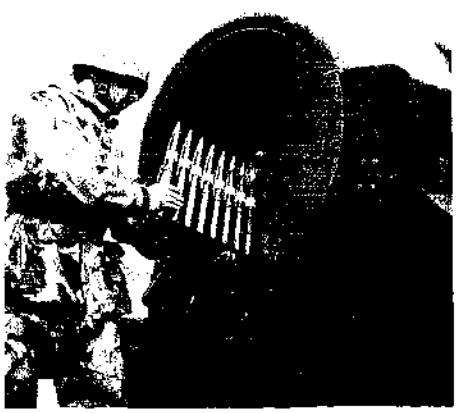
Calibre: 35 mm
Rate of fire: 2 × 600 rounds/minute
Ammunition: 430 rounds, up to 3 types selectable
MV: 1175 m/s (HEI); 1385 m/s (APDS-T/APFIDS)
Time for ammunition change: 4·5 s
Reload time: 4 minutes
Weapon range: 4000 m
Search radar: Track-while-scan
Range: 20 km
Antenna rotation: 60 rpm
Tracking system
Optical magnification: × 8
Field of view: 8°
FLIR: 5 km range
Laser range: 5 km
PRF: 12·5 Hz

GENERAL DATA



Type	GD-DO3 Wheeled	GDF-CO3 Tracked
Length	8·7 m	6·7 m
Width	2·98 m	2·81 m
Height (minimum)	3·94 m	4·0 m
Wheel base	4·74 m	—
Ground clearance (max)	0·78 m	0·56 m
Minimum soil compaction	0·7 kg/cm²	0·6 kg/cm²
Engine rating	335 kW	At 2800 rpm 155 kW
Max speed	120 km/h	45 km/h
Power/mass ratio	14 kW/t	8·6 kW/t
Range	600 km (with 480 l)	480 km (with 430 l)

STATUS



Prototypes of the basic GDF-CO2 version (tracked vehicle, without search radar), have been tested. A prototype of the wheeled version, GDF-DO3, was available in April 1984. In January 1984, deliveries of both versions were expected within 30 months.

Machine Tool Works Oerlikon-Bührle Ltd, 8050 Zurich, Switzerland.

GDF-DO3 in combat configuration

Two men can reload within three minutes

GDF-DO3 version is mounted on a 4 × 4 × 4 (four wheels, all driven and steered) vehicle fitted with 'giant' tyres seen here in levelled position to allow engagement of low-flying targets

3330.131
FLAKPANZER 35 mm AA TANKS

The 35 mm AA tank is an armoured escorting air defence weapon system. It provides armoured formations and mechanised units on the move and in combat operations with mobile, integrated, effective low-altitude, close-to-medium range air defence in the forward battle area, particularly against attack helicopters and fighter-bombers. The system can also be rapidly deployed for other anti-aircraft tasks such as the protection of critical assets, choke points, convoys in the rear assembly areas, forward airbases, and missile sites. It is capable of engaging ground targets in a self-defence mode.

The 35 mm AA tank was designed for full combat autonomy featuring its own search radar with integrated IFF for continuous air surveillance, a tracking radar for automatic target acquisition and tracking, and two persicopes combined with a target indicator for optical target acquisition/tracking. The 35 mm twin-barrelled Oerlikon gun assures a high combat effectiveness. Own armour, environmental ruggedness and high mobility make the weapon system most suitable for battlefield deployment in extreme terrains and weather conditions as well as in a contaminated environment.

The entire fire control and gun system is integrated in an armoured turret, leaving only the auxiliary power unit and some additional units such as the land navigation equipment to be placed in the hull. This makes the weapon system particularly adaptable to various existing MBT vehicles.

The 5 PFZ-B2 Gepard and 5 PFZ-CA1 versions – both modified Leopard vehicles – differ mainly in their radar equipment. ATAK-35, a recent development, is the follow-on generation to the Gepard-CA1 family, with enhanced capabilities. The standard ATAK-35 is integrated with the Oto Melara OF-40 chassis. It integrates with other MBT chassis such as the Leopard-1, Leopard-2 and M-60.

5 PFZ-B2 (Flakpanzer 1 - Gepard)

This model has a Siemens MPDR 12/4 fully coherent pulse-doppler search radar (**3286.153**) with integrated MSR 400 IFF equipment. In addition to its own search data display it can receive and display air situation information from an external surveillance radar. The tracking Siemens-Albis radar is a monopulse-doppler type. The miniaturised and transistorised analogue prediction computer of Contraves design calculates the gun lead angles taking into account the continuously measured muzzle velocity, the meteorological corrections and the vehicle's deck tilt. The computer furthermore gives the open-fire signal and determines the burst length of the gun for high hit probability and most economic use of ammunition.

RADAR CHARACTERISTICS
Search radar frequency: S-band
Switchable frequencies: 6
Max range: 16 km
Antenna rpm: 60
Sub-clutter visibility: ⩾57 dB
Tracking radar frequency: Ku-band
Switchable frequencies: 2
Max range: 15 km
Minimum range: 300 m
Sub-clutter visibility: ⩾23 dB
(for further details see **3286.153**)

5 PFZ-CA1 (Caesar)

This model has an integrated search and tracking radar of Hollandse Signaalapparaten manufacture, with a common transmitter for search and tracking. The search section is an MTI system with a digital double canceller. It too uses an integrated MSR 400 IFF system. The tracking section is of the monopulse-doppler type with a cassegrain antenna. There is an additional coaxial anti-image tracking channel. The rest of the fire control and gun system is practically identical to the B2-version.

RADAR CHARACTERISTICS
Search frequency: X-band
Tracking frequencies: X-band; Ka-band
Max range: 15 km
Minimum range for tracking: 300 m
(for further details see **2302.153**)

5 PFZ-B2 Flakpanzer 1 Gepard on Leopard chassis

5 PFZ-CA1 system on Leopard chassis (Caesar)

ATAK-35 35 mm AA tank with Oto Melara OF-40 MBT chassis. Contraves turret, Oerlikon guns, Signaal radar and Contraves optical tracking and digital FCS

ATAK-35

The combat capability of the ATAK-35 system is considerably higher than that of both 5 PFZ-B2-Gepard and 5 PFZ-CA1. The enhanced capability is mainly the result of the totally new onboard digital fire-control computer system. The radar, optical tracking and twin Oerlikon 35 mm gun systems of the CA-1 have been retained. A new generation of the Oerlikon 35 mm ammunition family can also be fired.

The new fire-control system, according to Contraves, offers the advantages of a shorter reaction time, increased hit probability against targets using

tactical manoeuvring flight profiles, improved capability against attack helicopters, improved system reliability, ease of maintenance in the field by the use of automated built in test system, reduced crew workload and further growth potential.

The ATAK-35 differs from the 5 PFZ-B2 Gepard and 5 PFZ-CA1 mainly in the following respects:

(1) fire control computer: an advanced new digital system replaces the earlier analogue computer. Application of the modern computer algorithms based on the Kalman filtering theory makes the system capable of acquiring and engaging tactically manoeuvring air targets. High hit-probability is assured
(2) system logic unit: a freely programmable system replaces the earlier permanently wired system. The programmable system logic unit is the nerve-centre of all logic signals resulting from the information supplied by the sub-systems
(3) testing facility: modern microprocessors have been employed and the built-in test equipment has been expanded. Testing in a dialogue mode is now possible. System maintenance has been made easier
(4) gun system: this is now capable of firing the existing as well as a new generation of the Oerlikon 35 mm ammunition family with improved combat performance
(5) ammunition loading: an improved concept considerably reduces the ammunition reloading time
(6) growth potential: pre-planned product improvement to increase the combat capability
(7) tactical/technical operation: various improvements have been achieved.

CHARACTERISTICS

Max aiming rates: Turret bearing 1600 mils/s; gun elevation 1000 mils/s
Gun calibre: 35 mm
Barrel length: 3150 mm (L90)
Rate of fire: 1100 rounds/minute (twin barrels)
MV: 1175 m/s and 1385 m/s
Tactical gun range: 4000 m
Ammunition types: HEI, SAPHEI, APDS, TP
Ammunition reserves: 640 rounds AA; 40 rounds AP
Combat/empty weight: 46/42.3 t (Leopard-1); 48/46 t approx (OF-40)
Length: 7.78 m (Leopard 1); 7.27 m (OF-40)
Width: 3.39 m (Leopard 1); 3.48 m (OF-40)
Height (radar retracted): 3.29 m (Leopard 1); 3.14 m (OF-40)
Road speed/cruise range: 65 km/h/550 km (Leopard-1); approx 65 km/h/500 km (OF-40)

OPERATION

An ATAK-35 fire unit is manned by a crew of three: commander, gunner and driver. The commander and the gunner perform AA operations from the fighting compartment within the AA turret, sitting in front of the operator's console. The commander evaluates threats and directs operations and the gunner engages targets. An intercom system connects the crew. The commander maintains radio communication with the higher command level and neighbouring tank units. In an emergency, one-man operation is possible.

In the primary radar operation mode, the search radar scans the airspace continuously through 360° once a second when the vehicle is stationary and in motion. A clutter-free display of moving air targets is obtained on the search radar PPI (plan position indicator). An IFF (Identification Friend/Foe) interrogation system identifies the detected targets and displays them accordingly on the PPI.

The commander, after evaluating the threat, designates on the PPI by means of his joystick the target to be combatted. As a result, the tracking radar automatically acquires and tracks the target. The vehicle halts meanwhile. The fire control computer calculates within seconds the prediction angles, and the guns are automatically trained on the future position of the target. As soon as the target comes within the effective range of the gun, the gunner receives the signal to open fire. The fire burst length is computer controlled, optimising the number of rounds fired.

The radars (search and tracking) and the optical system (periscopes, optical target indicator) offer redundant operation modes of the ATAK-35 system. Depending on the threat and the environment, an appropriate operation mode is chosen.

STATUS

The 5 PFZ-B2 Gepard has been in service with the Federal Republic of Germany and Belgium since 1977-78, and production is now complete. The 5 PFZ-CA1 has been in service with Netherlands Forces since 1977-78 and production of this model is also complete.

Development and validation tests of the ATAK-35 model are completed and systems are available for user trials.

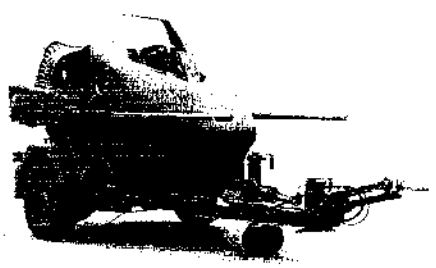
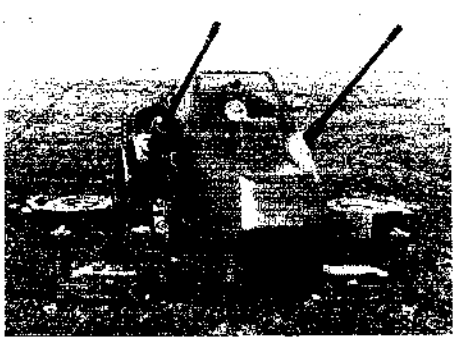
DIANA TWIN 25 mm AA GUN

The Oerlikon 25 mm field AA gun (Diana) is a towed high-performance gun intended primarily for the defence of stationary targets (eg airfields, depots etc) against low-level air attack. It is produced in two versions: GBF-AOA with twin KBA 25 mm cannons and Officine Galileo P75 3-D sight; and the GBF-BOB with two KBB 25 mm cannons and a Contraves Gun-King sight. The former version uses NATO standardised 25 mm ammunition and the Italian sight, otherwise the two Diana versions are very similar, apart from the slightly lower rate of fire of the KBA cannon compared with the KBB.



The Diana system has two externally mounted Oerlikon 25 mm automatic belt-fed cannons, a gunner's cab with a sighting system for 3-D target tracking and an integral power supply. The high rate of fire of the twin cannons, the ammunition performance and the effectiveness of the sight together ensure both high hit and high kill probabilities against all hostile targets.

The gun mounting and carriage arrangement can be seen from the adjacent illustrations of the system. Conversion of the gun from the travelling to the action configuration is rapid: the mounting legs are extended until the two wheels lift clear of the ground and swivel inwards. The location of the gunner's cab in the centre of the rotating structure between the externally mounted cannons enables both the overall length and height of the gun to be minimised, as well as reducing rotational effects on the operator.



Target acquisition and designation is carried out either optically and autonomously or by a remote radar unit such as the Skyguard central fire control system (**2377.181**), but in both cases the target is tracked by the gunner using his 3-D sight. This is normally the new Contraves Gun-King laser computer controlled sight which can be employed for the engagement of both air and ground targets by autonomous gunfire, although the Officine Galileo P75 optical sight may be fitted in the GBF-AOA version. Precise fire control data is automatically determined and updated by a digital microprocessor developed by Contraves, and coupled with a laser rangefinder the computer controls the combat sequence of the entire gun system.

Diana GBF-AOA with P75 sight and two KBA 25 mm cannon

GBF-BOB version of Diana ready for the road

Diana GBF-BOB version with Gun-King sight and twin KBB 25 mm cannon

The system has two 25 mm automatic cannon (KBA or KBB), each with a cyclic rate of fire of 570 or 800 rounds/minute and 250 rounds each of ready-use ammunition. The dual belt feed allows the gunner to select either of two types of ammunition. The mount has an integral power supply for both electric and hydraulic operation and it can also be operated manually if required.

The ammunition employed with the KBB gun has been designed to ensure optimum efficiency against targets of all kinds, and the high muzzle velocities and flat trajectories with short flight times give high hit probabilities. Available ammunition includes four types as follows:

Type	NATO Designation	Round Weight	Round Length	MV
Fragmentation HE incendiary	HEI	625 g	288 mm	1160 m/s
Discarding sabot hard core projectile with tracer	APDS-T	550 g	288 mm	1460 m/s
Practice with tracer	TP-T	625 g	288 mm	1160 m/s
Practice with tracer	APP-T	550 g	288 mm	1355 m/s

The fragmentation HE incendiary shell is primarily for use against soft or lightly armoured targets (such as aircraft, helicopters etc) and is characterised by intense blast and fragmentation effects inside the targets. The discarding sabot ammunition is most suitable for use against armoured targets such as APCs and AFVs

CHARACTERISTICS

Gun: Twin cannon (KBA/KBB)
Calibre: 25 mm
Rate of fire: 2 × 570/800 rounds/minute
Barrel length: 2300 mm (92 calibres)
Ammunition: 250 rounds/gun
Weight: 1725 kg (less ammunition); 2100 kg (ready to fire)
Length: 4·295 m
Width: 2·1 m
Height: 2·13 m
Elevation: −5 to −85°
Traverse: 360°
Traverse speed: 1·4 rad/s (max)
Traverse acceleration: 1 rad/s²
Elevation speed: 0·85 rad/s (max)
Elevation acceleration: 1·3 rad/s²
Sight: Gun-King/Galileo P75
Magnification: ×5
Field of view: 12°
Laser rangefinder
Range: 5 km
Accuracy: ±5 m
PRF: 10 Hz
Max lead angle: ±20°

STATUS

Early production.

UNION OF SOVIET SOCIALIST REPUBLICS

5548.131
23 mm ZSU-23-4 SP AA VEHICLE

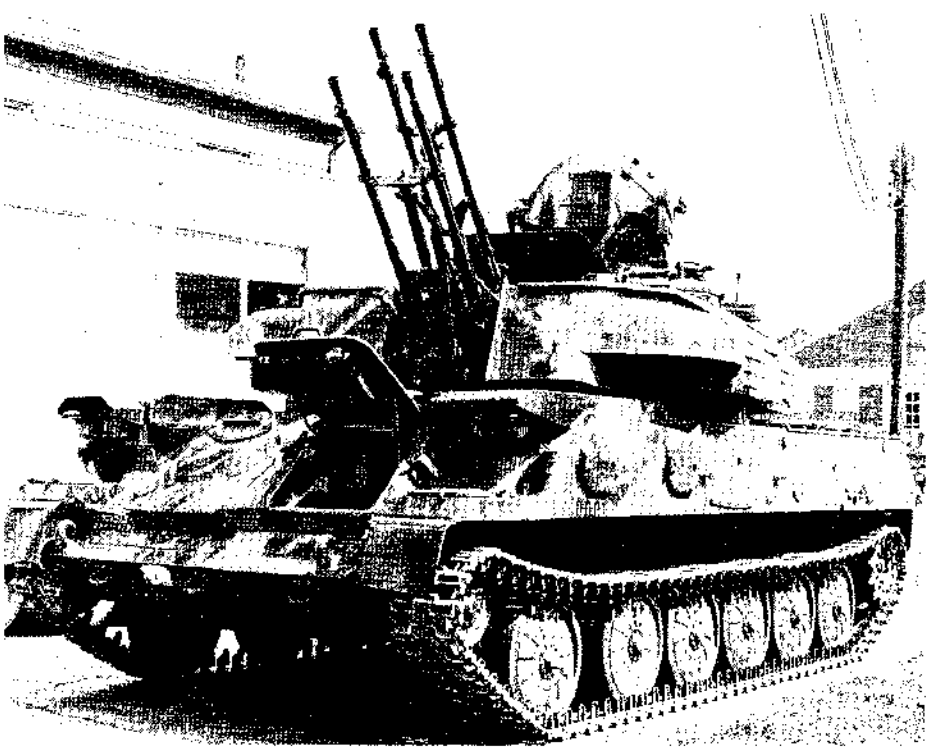
The ZSU-23-4 has been in service with the Soviet Army since 1965, and subsequently has been built in large numbers. It is issued on the scale of four per motor rifle regiment and eight per tank regiment. The ZSU-23-4 saw extensive service in the 1973 Middle East campaign when it proved to be one of the most effective of all the low-level anti-aircraft systems employed.

It has a chassis developed from the PT-76 light tank which is almost identical to that used for the SA-6 (**2930.131**). The four ZU-23 cannons are similar to those used on the ZU-23 twin towed anti-aircraft system (**5581.103** in 1982-83 and earlier editions), but are water-cooled rather than air-cooled.

Each barrel has a cyclic rate of fire of 800/1000 rounds/minute, but their practical rate of fire is 200 rounds/minute, and they normally fire in bursts of 50 rounds/barrel. A total of 2000 rounds of 23 mm ammunition is carried, 500 per barrel. Two types of ammunition are used, the HEI projectile weighs 0·19 kg while the API projectile weighs 0·189 kg; both have a muzzle velocity of 970 metres/second. The guns can be used both against ground and air targets and can be laid and fired while on the move.

The turret has full powered traverse through 360°, elevation limits being from −7 to +80°. The B-76 radar (also known in the West as Gun Dish **2876.153**) is mounted at the rear of the turret and has both target acquisition and fire control capabilities. The radar can pick targets up at a maximum range of 20 km and operates in the J-band. An MTI facility is provided, as is a computer. Optical sights are provided for use in both the ground and air roles. Day and night vision devices are incorporated, and the turret has a TPKU-2 daylight observation periscope plus two BM-190 viewers. The first type, TPKU-2 has an elevation adjustment. For night observation, the TPKU-2 is replaced by a TKN-1T infra-red periscopic sight. A generator is mounted in the forward part of the hull to provide power when the main engine is not being used.

OPERATION



The ZSU-23-4 vehicle is operated by a crew of four: commander, search/surveillance radar operator/gunner, rangefinder, and driver, the first three being housed in the turret. Either of the first two crew members can control gun firing, stowing and erection, and all three crew members stationed in the turret are separated from the guns by a vertical armour bulkhead which provides protection from fragments, propellant gases and flame. During live firing, guns can be positioned automatically by the radar fire control system or manually, by handwheels. Radar directed fire is usual against air targets, radar modes providing for search and detection, after acquisition followed by tracking. A conical scan pattern is employed for tracking and this gives angular error signals relative to the target's position from the radar boresight axis. The latter signals are used to calculate drive signals for the turret to bring stabilised line of sight and the predicted target into coincidence. Two radar CRT displays are provided, one for the search and tracking functions carried out by the radar operator/gunner, and the other for range measurement by the ranging operator. Optical fire direction, with optical target tracking is also possible, possibly allied to radar ranging. To permit firing on the move, stabilisation is provided.

CHARACTERISTICS

Crew: 4
Weight: 14 t
Length: 6·3 m
Width: 2·95 m
Height (radar retracted): 2·25 m
Road speed/range: 44 km/h/260 km
Engine: Model V-6, 6-cylinder water-cooled diesel developing 240 hp at 1800 rpm
Agility
Max step: 1·1 m
Max trench: 2·8 m
Max gradient: 60%
Ground clearance: 0·4 m
Water crossing ability: 1·07 m
Weapon: 4 × 23 mm automatic guns
Rate of fire: 3400 rounds/minute (max combined)
Standard ammunition load: 2000 rounds
Elevation: −4 to +85°
Other equipment: NBC system and infra-red driving lights are provided
Effective anti-aircraft range: 2000/2500 m
Effective ground range: 2000 m

STATUS

In production. In service with Afghanistan, Angola, Bulgaria, Cuba, Czechoslovakia, East Germany, Egypt, Ethiopia, Finland, Hungary, India, Iran, Iraq, Libya, North Korea, Poland, Romania, Somalia, Soviet Union, South Yemen, Syria and Viet-Nam.

ZSU-23-4 self-propelled anti-aircraft quadruple 23mm gun vehicle

UNITED KINGDOM

4588.131
MARKSMAN AA GUN TURRET

The Marksman twin 35 mm anti-aircraft gun turret system has been designed by Marconi Command and Control Systems for installation as a direct replacement for the gun turret normally fitted in a wide range of main battle tanks (MBTs), thereby facilitating retrofitting to a number of vehicles in an existing fleet of MBTs to provide them with the mobile AA defence increasingly being demanded for armoured formations. Marksman is an all weather, day/night system. The new AA turret is mounted onto the hull by means of a combined main bearing and traverse drive rack assembly with a conversion ring to allow the turret to be fitted to tank hulls such as the Soviet T and US M series, AMX, Centurions Challenger, Chieftains and the Vickers Mk 3. Virtually all the equipment is housed within the gun turret itself, compared with other solutions that call for equipment stowage in the vehicle hull.

The turret is fabricated in steel armour plate, giving ballistic immunity against 14·5 mm heavy machine gun armour-piercing rounds and 155 mm airburst shell fragments. Two rapid fire Oerlikon 35 mm AA cannon are mounted, one on each side, by large diameter bearings, through which the guns are fed from two readily replaceable ammunition containers located inboard. Each gun has 230 rounds of anti-aircraft and 20 rounds of anti-tank ammunition.

Turret traverse and weapon elevation are electrically driven with manual controls for emergency use. The commander sits on the left and the gunner on the right with observation periscopes

to their front, sides and rear. Each crew member also has a roof-mounted gyro-stabilised sight with magnifications of ×3 and ×10 for optical engagement of air and ground targets; the gunner's sight also incorporates a laser rangefinder.

A Marconi digital fire control system is provided, with target information supplied by a Marconi 400 Series X band surveillance and tracking radar, and the commander's and gunner's optical sights. The radar has a range of 12 km in the surveillance mode. The commander and gunner sit side-by-side on the approximate centre of rotation, in front of an ergonomically designed console so that both have access to the fire control system.

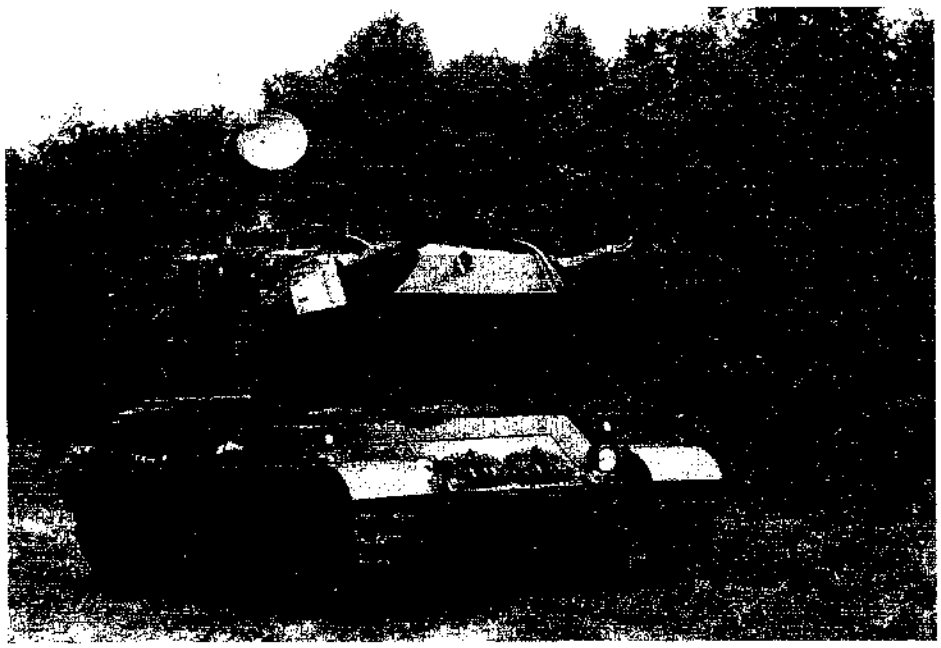
Also within the turret, the solid-state stabilised turret drive system employs an electronic servo control system, with batteries and power amplifiers located on the floor of the turret basket. An auxiliary diesel generator is mounted in a separate compartment at the rear of the turret. As options an NBC pack and air conditioning are available. There is space provision in the turret for radios and other conventional equipment supplied by the user to be installed.

The Series 400 radar uses a single antenna, rotated at 60 rpm, for both surveillance and target tracking, and the modular radar units are mounted inboard within the bustle of the turret. Features of the radar emphasised by the manufacturer include: high resistance to ECM and freedom from the effects of secondary ground reflection (multi-path) signals. It is claimed to be smaller and lighter than comparable radars of the previous generation. A fast reaction is achieved by fully automatic operation from the first surveillance detection of a target, through tracking and aim-off to firing of the gun. Manual operation and optical sighting are available as reversionary modes.

The complete turret, with ammunition stowed weighs approximately 11 tonnes.

STATUS

Development of the Marksman turret was started in 1983 as a private venture by Marconi. It was first shown publicly in 1984, with the first prototype mounted on a Vickers Mk 3 MBT chassis. The second prototype is expected to be completed in late 1985.



Radar trials were held in October 1984 against tactical aircraft flying low-level sorties, and successful proof and endurance trials were held in the following month. Later live firing trails against sleeve targets and remotely controlled target drones took place with a MATS B target being destroyed in a fully automatic radar directed engagement, at a range of 4 km, by direct hits from two rounds from a burst of 16 rounds.

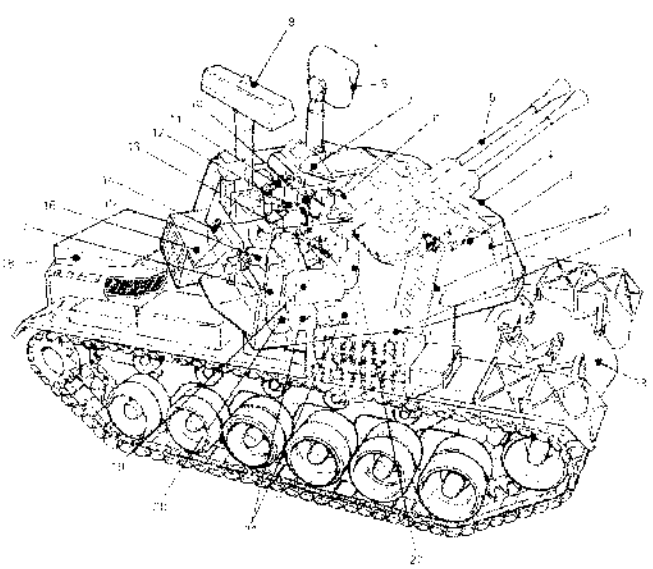
DIVAD SGT YORK GUN SYSTEM

The FACC DIVAD Sgt York system was the successful winner of two designs which competed for the contract to meet the US Army's Division Air Defence (DIVAD) gun system requirement. Sgt York and an alternative proposal submitted by General Dynamics underwent a competitive development programme following the award of contracts to the two groups of companies in January 1978. The system is named after World War 1 hero, Sgt Alvin C York.

The new system will replace the self-propelled Vulcan system (**2850.131**) now in service, and is a successor to the earlier GLAADS (Gun Low-Altitude Air Defence System) programme (**2544.131**) described in previous editions of *Jane's Weapon Systems*. It is designed to provide US Army forward combat forces with an effective defence against armoured helicopters, aircraft, and fixed wing ground targets.



The weapon employed is the widely used Bofors L/70 40 mm gun, two of which are mounted in an armoured turret. Each gun is fitted with two independent magazines allowing near instantaneous selection of either high-explosive point detonating (HEPD) rounds with delay action fuzes, or prefragmented proximity fuzed (PFPX) rounds. A total of 502 ready use rounds are carried in the four magazines. The HEPD rounds are used for close-in aerial targets and ground targets at all ranges. Because of its delayed action fuze and robust construction, the HEPD round is capable of defeating most modern APCs at extended range, obviating the need for an armour-piercing round.

PFPX rounds are used against longer range aircraft. They contain 640 tungsten-alloy pellets. The fuze functions in aircraft, helicopters, large sea-skimming missiles and small anti-tank missiles. Because of its shape and density of the ore-formed tungsten-alloy pellets, they are able to achieve twice the depth of penetration as steel pellets of the same weight, giving a notable increase in lethality. The 40 mm L/70 gun and ammunition are NATO standard, used and produced by ten NATO countries as well as 40 other states world-wide.

The DIVAD system has a digital fire control system, allied to a search and tracking radar system developed by Westinghouse from the AN/APG-66 fire control radar (**3303.353**) for the F-16 aircraft. Other sensors include the vehicle commander's optical periscope, and the gunner's optical sight and laser rangefinder, and these provide a stabilised optical search and tracking capability to supplement the radar system.

The vehicle uses a modified M48A5 tank chassis and has a crew of three. The driver's position is central in the hull, while the commander and gunner have places in the turret. The two combat crew members sit side-by-side with the commander on the right. There is a centrally located combat display, and the controls are accessible to either crew member. Voice communications are handled by an AN/VRC-47 radio set.

Either of the crew members can override the automatic target engagement mode with the direct optical engagement mode. Targets may be acquired optically with either periscope or gun sight. Alternative targets may be designated for radar

engagement, and the gunner can optically aid the automatic radar engagement with precision thumb control tracking and laser rangefinding. For full automatic engagement the search radar detects and the fire control computer classifies and places in order of priority multiple targets. With crew consent, the remaining functions of target tracking, gun pointing, ammunition selection, burst length, and open fire range are also automatic. The resultant system reaction time is consequently very short. The system has an all-round (360°) engagement capability.

The radar's IFF system can interrogate and evaluate multiple targets simultaneously and these are classified as: enemy fixed-wing, enemy helicopter, enemy ground target, or friendly. The tracking radar locks onto the highest priority threat of those presented, while the search radar continues to alert the crew to remaining threats within detection range. The use of coherent pulse doppler radar and specially developed algorithms overcome the problem of discerning a helicopter hovering amidst ground clutter, and multi-path tracking problems are overcome by multiple-beam tracking techniques. The combat situation display is a plasma panel display which presents actual targets, target identity, target priorities and battle status information.

Sgt York DIVAD Division Air Defence gun system

STATUS

The Ford system was chosen for the DIVADs production programme in May 1981 after an extended competitive evaluation by the US Army. The initial production contract for DIVAD was signed in May 1982.

The programme RDT&E phase ended in 1983. Production options 1 and 2, (for 50 and 96 units, respectively) contracts have been awarded. A third production option, for 117 units, is expected on completion of initial production testing (IPT) and follow-on evaluation stages in September 1985. The DIVAD gun will be deployed with air defence artillery batallions of the armoured and mechanised divisions of the US Army, as well as the corps air defence artillery group and armoured cavalry regiments.

Attitude reference unit: Litton Industries, USA.

2850.131

VULCAN AIR DEFENCE SYSTEM

This is an anti-aircraft weapon system based on the Vulcan 20 mm six-barrel gun. The tracked version, M163, comprises the Vulcan gun, a linked ammunition feed sub-system, and a fire control sub-system, all mounted in an electrically-powered turret and carried on a derivative of the M113 APC. The fire control sub-system consists of a range-only radar and a lead-computing gun sight with its associated current generator. The towed VADS system, M167, contains its own batteries and is equipped with a petrol-driven generator for recharging and the whole system is mounted on an M42A1 gun carriage.

GUN

The Vulcan M168 gun, previously used as aircraft armament at rates as high as 6000 rounds per minute, has been modified for the air defence application to provide alternative firing rates of 1000 and 3000 rounds per minute. There is a burst limiting device, controlled by the gunner, which can be set for 10, 30, 60 or 100 rounds. Three muzzle clamps are available that provide different dispersion patterns for air defence and ground engagement modes. In the former a wide-angle or rectangular pattern is used to provide a high hit probability against low-flying aircraft. A concentrated dispersion pattern is used in the ground role.

In the towed system a conventional belt feed is used for ammunition, the belted rounds being fed from a 500-round container. In other systems where more space is available a linkless feed system can be used and this has a capacity of 1100 rounds.

The turret is electrically driven and its drive is controlled by three solid-state servo amplifiers.

FIRE CONTROL

The fire control system consists of an XM61 gyro lead-computing gunsight and a sight current generator. The gunner visually acquires and tracks the target with the gyro lead-computing gunsight. The antenna axis of the radar is servoed to the optical line-of-sight and the radar supplies target range and range-rate data to the sight current generator. These inputs are then processed to provide outputs that are used to control the gunsight.

With inputs of range, range rate, and angular tracking of the optical line-of-sight (measured by a freely gimballed gyro), the sight automatically computes the future target position and adds the required super-elevation to hit the target.

Turret fire control is a disturbed line-of-sight system. The sight case and gun bore are physically fixed in alignment, but the sight reticle, which defines the optical line-of-sight, is positioned by the gyro and is displaced from the gun bore as the gunner tracks the target, thereby establishing the proper lead angle. The amount of optical line-of-sight displacement is dependent on the range and range rate inputs to the sight, and the required tracking time to establish the lead angle is about one second.

The range-only radar, developed by the Lockheed Electronics Company, is a coherent doppler, moving target indicator (MTI) radar. It will acquire targets up to 5000 metres away.

The fire control system may be supplemented by an AN/TVS-2B night vision and an XM134 telescope.

IMPROVED FIRE CONTROL

Lockheed Electronics Company developed an improved fire control system for the Vulcan air defence system which forms the basis of the Product Improved Vulcan Air Defence System (PIVADS), described in entry **4015.131**, below.

M163 self-propelled Vulcan air defence system on modified M113APC (M741)

CHARACTERISTICS (TOWED TYPE)

Type: Land-mobile, air-transportable, light anti-aircraft weapon system

Control: Radar ranging, optical aiming, automatic lead computation

Fire power: 6 × 20 mm guns. 3000 rounds/minute rate of fire. 1000 rounds/minute low rate of fire

Dispersion: 12 mrads; 8 × 18 mrads; or 6 mrads (80% 4 rounds fired)

Radar range: 5000 m

Weapon coverage: Azimuth 360°; elevation -5 to +80°

Turret slewing rate: Azimuth 75°/s; elevation 60°/s

Height on wheels: 2·03 m

Height emplaced: 1·73 m

Wheel track: 1·75 m

Weight: 1406 kg

Standby power requirement: 500 W

STATUS

In production for US and other governments. A towed version without radar is in production for the Belgian Air Force. The US Army's Vulcan inventory in mid-1979 consisted of about 380 tracked Vulcan air defence systems and some 220 towed models.

Future US Army procurement is likely to be in the PIVADS form (**4015.131**), with light divisions having the M167A2 version and heavy divisions the M163A2 self-propelled version, until deployment of the Sergeant York system, when the M163A2 will be passed to the National Guard.

CONTRACTORS

Complete system: Aircraft Equipment Division, General Electric Company, Burlington, Vermont 05402, USA.

Radar: Lockheed Electronics, Plainfield, New Jersey, USA, and American Electronic Laboratory, Philadelphia, Pennsylvania, USA.

Vehicle: FMC Corporation, San Jose, California, USA.

Vulcan air defence system XM167 towed version

4062.131

VULCAN/COMMANDO AIR DEFENCE SYSTEM

The Vulcan/Commando air defence system is a combination of the Commando V-150 wheeled armoured vehicle and the M167A1 20 mm Vulcan air defence turret. The resulting air defence system provides highly effective close-in air defence and defence against light enemy ground armour, in an armoured platform capable of both off-the-road and high-speed highway travel. The versatility of the wheeled platform allows rapid dispersal to practically all types of combat areas, and the high firing rate (1000/3000 rounds/minute) of the 20 mm Vulcan allows both air and ground targets to be engaged.

The system may be operated against targets in any of four firing modes. In the radar mode, which is the most accurate mode for engaging aircraft targets, the radar supplies continuous present range and present range rate information to the analogue computer (the sight current generator) for the computation of magnet current for the gyro lead computing sight. In the manual mode the gunner estimates engagement range and target speed and makes these settings on the control panel. In the external mode a second person, located off-mount, estimates the target's range, making the setting on a hand-held potentiometer connected to the system slip rings by a cable. In the ground mode the sight gyro is not operated and lead angle is not computed. The sight is mechanically caged at zero lead angle and 7 mils of super-elevation.

The M167A1 20 mm Vulcan turret is a 'drop-in' installation, requiring only proper location of mounting holes in the vehicle hull. The turret is totally self-contained, and remains operationally independent of the vehicle. The M167A1 VADS turret may be replaced with the basic VADS turret (without radar) with identical installation requirements.

The Vulcan/Commando air defence system armament is the same turret, weapon and associated feed, power and radar equipment as used in the M167A1 Vulcan air defence system, in production since 1967.

The system is made up of the 20 mm M168 Vulcan gun, a linked ammunition feed system, and a fire control system, all mounted in an electrically powered turret. The system contains its own batteries.

Firing rates for the Vulcan gun with the linked feed system are 3000 and 1000 rounds/minute. The high firing rate provides effective defence against low-flying, subsonic aircraft. The lower firing rate provides effective fire against ground targets such as trucks, boats and lightly armoured vehicles.

Fire control consists of a gyro lead-computing gunsight, a range-only radar, and a sight current generator. The gunner visually acquires and tracks the target. The radar supplies range and range-rate data to the sight current generator. These inputs are converted to proper current for use in the sight. With this current the sight computes the correct gun lead angle and adds the required super-elevation. The system uses the XM61 gyro lead-computing gunsight.

GE/Cadillac-Gage Vulcan/Commando air defence vehicle

CHARACTERISTICS

Gun

Type: 20 mm 6-barrel Gatling
Length: 1864·4 mm
Max diameter: 342·9 mm
Weight: 124·7 kg
Ammunition: M50 Series
Muzzle velocity: 1030 m/s
Rate of fire: 1000/3000 rounds/minute
Dispersion: 12 mils circular; 8 × 18 mils elliptical (80% of rounds fired)

Turret

Weight: with gun 1134 kg
Ammunition capacity: 500 ready; 800 stowed
Slewing rates: Azimuth 75°/s; elevation 60°/s
Weapon coverage: Azimuth 360° continuous; elevation +80°, -5°
Modes of operation: Radar, manual, external, ground

Vehicle

Weight: 9072 kg
Max speed: Land 88 km/h; water 4·8 34 km/h
Engine: Diesel
Transmission: Automatic, 4-speed
Crew: 4 (driver, gunner, commander, radio operator)

STATUS

The only known procurement of this system was an unspecified quantity for Saudi Arabian forces.

4015.131

PIVADS (PRODUCT IMPROVED VULCAN AIR DEFENCE SYSTEM)

PIVADS, which was developed for the US Army, offers two improvements to the basic Vulcan:

(1) effectiveness: improved probability of hit by replacing the fire control system
(2) availability: reduced system 'down time' by utilising built-in test (BITE) to identify and isolate faults.

This cost-effective improvement of the Vulcan extends the useable service life against current threats and permits a higher degree of readiness. The improvement technology is applicable to new gun systems or to upgrading existing systems and uses the following techniques:

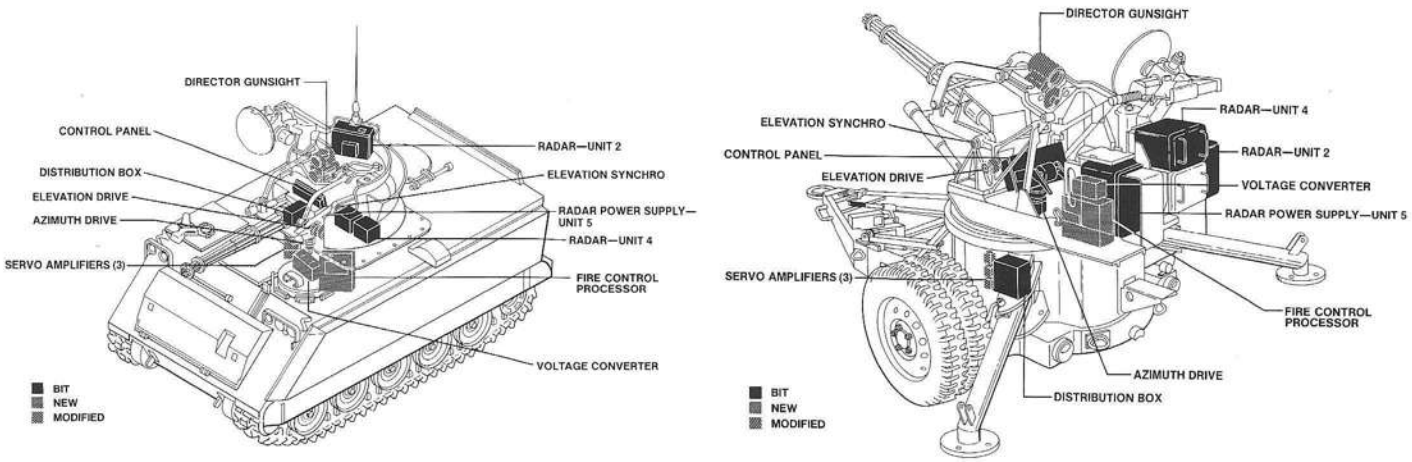
(1) replacement of disturbed line-of-sight (DLOS) gunsight configuration by a stabilised 'director' sight

(2) use of a stabilised optical sight, isolated from turret motion to provide accurate target acquisition and tracking. The tracking reticle is directly controlled by the gunner
(3) computer generated rate-aid signals significantly reduce gunner workload by driving turret to future target position based on historical position data
(4) special servos and turret drive design techniques (rate feed-forward, resonance equalisation, harmonic drives) provide the following characteristics: improved turret stiffness, minimised backlash and high bandwidth turret and sight servos, improved turret transient and steady-state tracking performance
(5) militarised digital microprocessors dramatically reduce size, cost and weight, enhance system reliability, and permit adaptive software modifications.

DEVELOPMENT

Development was undertaken as a private venture by Lockheed Electronics Company to exploit experience accumulated in the design and development of the Mk 86 GFCS (**1241.281**) and small weapon control systems simulation analysis.

STATUS



The US Army awarded research, development, test and evaluation contracts to Lockheed Electronics in September 1982 for the M163A2 self-propelled PIVADS, and a contract for the M167A2 towed PIVADS in November 1983. In fiscal year 1985, the Army awarded a production contract to Lockheed Electronics for 285 M163A2 and M167A2 PIVADS. It is planned to deploy PIVADS with the active Army as soon as possible, primarily with the light divisions.

CONTRACTOR

Lockheed Electronics Company Inc, 1501 US Highway No 22, Plainfield, New Jersey 07061, USA.

The PIVADS modification kit enhances system effectiveness by the use of a director-type sight, a microprocessor and improved turret drives

GEMAG 25 AA GUN SYSTEM

The GEMAG 25 (General Electric Mobile Air Defence Gun) is a 25 mm towed mobile gun system that has been developed as an air-transportable air defence weapon similar in concept to the Vulcan towed anti-aircraft gun, and of similar size and weight but with a new gun. This is the 25 mm GAU-12/U Bushmaster which is allied to improved gun carriage drives and mountings. The 25 mm Bushmaster rotary multi-barrel gun was selected for the improvements in range and time-of-flight that it offers in comparison with the existing 20 mm Vulcan rounds. The GAU-12/U also has dual-feed facilities which permit the use of either HEI (high explosive incendiary) or APDS (armour piercing discarding sabot) rounds to be fired by the gun without altering ammunition feed arrangements. The gun is fired at rates of either 1000 or 2000 rounds per minute. The carriage has provision for a capacity of 530 rounds.

The fire control system is based on the digital system developed for the PIVADS (**4015.131** Product Improved Vulcan Air Defence System), but with provision for a number of additions including a night vision system based on the AN/TAS-6 forward-looking infra-red night observation device (**3826.193**), and a laser rangefinder. The radar provides both search and target tracking facilities and incorporates microprocessor control.

GEMAG 25 multi-barrel anti-aircraft weapon system deployed

CHARACTERISTICS

Weight: 1814 kg (loaded ready for combat)
Height: 2057 mm (travel configuration); 1828 mm (emplaced)
Length: 3683 m (travel configuration); 3589 mm (emplaced)
Gun: 25 mm GAU-12/U
Ammunition system: Linked, dual feed, HEI, APDS
Ammunition capacity: 530 rounds
Feed system: Linked hanging rail type
Firing rates: 2200/1000 rounds/minute
FLIR: AN/TAS-6
Radar: Ku-band search and track
Sight: Optical director
Computer: LSI 11M digital
IFF: AN/PPX-3 Mk XII

EGYPT

4841.131

SAKR EYE PORTABLE ANTI-AIRCRAFT MISSILE

After several years of experience using Soviet-supplied SA-7, Grail man-portable anti-aircraft missile systems, the Egyptian authorities have undertaken production of an indigenous version known as the Sakr Eye. Local series production was expected to begin in early 1985.

The system consists of the missile, housed in a disposable container/launcher, and a grip-stock which includes the sight and firing mechanism. Two complete Sakr Eye rounds are packed into a storage and transport container. The Egyptian version of the SA-7 is understood to be virtually identical to the Soviet item, although better reliability is claimed for the former.

In the absence of an integrated IFF subsystem (French and British add-on IFF equipments are available) a typical engagement follows this sequence: the gunner acquires the target and aligns the weapon using the open sight, and then selects either manual or automatic firing mode. Audio and visual cues are given to the gunner to indicate when the target is within the engagement envelope. The trigger is then squeezed fully and the missile is ejected from the launch tube by a small rocket motor. The booster then accelerates the missile until the sustainer motor is ignited to propel it to the target. If a target is not encountered within 4400 m the Sakr Eye destroys itself.

Homing is by means of a passive infra-red seeker, and the HE warhead is detonated by an impact fuze that provides for graze initiation of the warhead.

CHARACTERISTICS

Calibre: 72 mm
Weight: 15 kg (ready for use)
Max target altitude: 2400 m
Minimum target altitude: 50 m
Max range: 4400 m
Max target speed: 150 m/s (head-on); 280 m/s (pursuit)

STATUS

Qualification tests completed in 1984-5, and initial production planned for early 1985 with series production in late-1985/86.

CONTRACTOR

Sakr Factory for Developed Industries, PO Box 33, Heliopolis, Cairo, Arab Republic of Egypt.

FRANCE

SATCP AIR DEFENCE MISSILE MISTRAL

The Mistral/SATCP (sol-air-très courte portée) missile project is a development programme intended to provide a short-range air defence missile system capable of production in several versions ranging from the simplest man-portable type including a variety of vehicle and AFV installations, to airborne and naval variants. The work has been entrusted to Matra, the winner from about five contractors which submitted proposals for the SATCP requirement.

The Matra Mistral SATCP system comprises, in the portable version (basic), two main elements: the missile and the firing station. The former is, of course, expendable whereas the firing unit is not, and the whole assembly can be carried by two men in separate packages.

The missile uses infra-red homing guidance, employing a passive system that is claimed to be very sensitive and capable of true 'fire-and-forget' operation. Impact and proximity fuzing is provided for the 3 kg warhead, the latter being a laser-based device, and an IFF module is available to prevent engagement of friendly aircraft and to minimise reaction time in the face of enemy targets. The system is for defence against both fixed-wing high-speed aircraft and helicopters. The two packages comprising the man-portable version each weigh less than 20 kg. One pack consists of the missile in its launch/transport container tube, and the other includes the stand, seat and sight unit.

The SAT infra-red homing head, instead of relying on a single-cell IR receiver with consequent risks of

Matra Mistral/SATCP short-range air defence missile system

Mistral is suitable for mounting on a variety of military vehicles for use by different infantry units

unwanted responses from ground objects at low elevation angles etc, employs a multi-element seeker. This and the use of digital signal processing is stated to enhance the Mistral's performance in the face of IR countermeasures, or natural interference from the background. The sensitivity is claimed to be adequate for acquisition of a single jet aircraft target at a range of 6 km or more, or a light helicopter at 4 km, irrespective of the target aspect. Homing-head gyro run-up and head cooling preparatory to launch takes only two seconds, and weapon reaction times of less than five seconds have been achieved in tests without early warning facilities.

The firer has a sighting system that includes a clear collimator and a magnifying telescope. The former allows the display of aiming data enabling the launcher to track the target while following the pre-launch sequence progress and assess azimuth and elevation lead angles. Reload time is quoted as less than 30 seconds.

In addition to the main solid-propellant rocket motor which gives the Mistral a peak speed of about Mach 2·6, there is a solid booster which gives the missile a muzzle velocity of 40 m/s, and this is jettisoned when the main motor ignites about 15 m ahead of the firer.

It is intended to employ the same missile in all versions of the system in the interests of logistic simplicity and economy. The homing head is the responsibility of SAT, and SEP and Manhurin will undertake the propulsion and warhead manufacture respectively.

CHARACTERISTICS

Length: 1·8 m
Diameter: 90 mm
Weight: 17 kg
Warhead: 3 kg
Range: 300 - 6000 m
Peak speed: Mach 2·6

It is proposed to develop thermal sight equipment to provide a night capability for the Mistral weapon system. Five versions are understood to have been considered. The first is meant to fill French Army and Air Force requirements for portable defences for important points in the battle area or near airfields. The French Navy plans to use Mistral for the air defence of small vessels with the SADRAL (Système d'Autodéfense Rapprochée Anti-Aérien Léger), and as a supplement to existing air defence armament of large ships (**4509.231**). The Army envisages its use for air-to-air purposes on anti-tank helicopters (**4510.311**) and it is also seen as suitable for mounting on Jeeps or trucks in the dual missile launcher configuration, and on AFVs (with a six-round turret and radar) for the defence of armoured units and rapid deployment forces.

STATUS

The portable version is being developed for the French Army and Air Force.

JAPAN

4199.131
JAPANESE MAN-PORTABLE SURFACE-TO-AIR MISSILE

A man-portable surface-to-air missile development project was started in fiscal year 1979 by the Japanese Self Defence Force Technical Research Institute. It is understood that the intention is to develop a weapon similar to the existing generation of man-portable SAMs, such as the American Redeye, Soviet SA-7 and the British Blowpipe, but instead of relying on infra-red homing or radar guidance, the Japanese SAM will use an imaging homing system for guidance. This is claimed to be better in that it will have an all-round attack capability and high resistance to jamming. The guidance system will incorporate a CCD (charge-coupled device) to store the target image, and other important factors are the resolution characteristics of CCDs and low cost. It is hoped to achieve a unit cost of less than ten million Yen. Two types of homing head were under evaluation in 1979, and a propellant unit and a wind tunnel test model had been constructed. The former consists of a booster rocket and a sustainer motor. No other details have been made available for publication.

STATUS

Development continuing. No schedule for development or production plans have been released.

CONTRACTOR

JSDF Technical Institute.

SWEDEN

2348.131
RBS 70 RAY RIDER ANTI-AIRCRAFT MISSILE SYSTEM

RBS 70 Ray Rider is a portable surface-to-air missile system operating on the beam-riding principle, and a laser beam is used rather than one of non-coherent light, which gives it substantial immunity to jamming. It has a range of about 5 km and is suitable for use against both fighter-bombers and helicopters even at the lowest levels. The engagement of targets is carried out by one man, but to fire several missiles in rapid succession a loader is needed.

The system is suitable for integration with other surface-to-air weapons or as a separate unit. Unlike many other portable anti-aircraft missile systems, Ray Rider can utilise precision target information from a search radar and it is both possible and desirable to group several Ray Rider units with one or more search radars to form an anti-aircraft battery. Ray Rider is also designed to utilise IFF signals.

A land-mobile G/H-band (former C-band) radar has been developed by LME for use with the RBS 70. It was introduced as the PS-70R but is now known under the name of Giraffe (**1957.153**). Other search radars, such as Signaal's Reporter, can also be integrated with the Ray Rider.

Three packs, stand, sight, and missile in container, make up the complete firing unit which can be assembled and ready to fire in less than 30 seconds. The stand has three legs and forms the suspension device for the telescopic sight which has gyro-stabilised optics and which also contains the guidance laser beam transmitter.

To slew on to the target the operator uses coarse aiming, turning the whole sight housing in the required direction. For tracking, a thumb lever is used to operate the gyro-stabilised optics.

The missile is launched from a container which also serves for both storage and transport, the missile never being removed from the container except at the moment of firing. A starting motor ejects the missile from this launch container and separates from it at the mouth of the tube after which the missile sustainer takes over. The missile carries a receiver for the guidance beam and a small computer for calculation of control signals for the control surfaces. The warhead has both proximity and percussion fuzes but if desired the active optical proximity fuze can be paralysed before the missile is fired

Among the items of test and training equipment supplied for use with the missile is a sight simulator for use in training operators. With this equipment an average AA soldier can be fully trained within 15 to 20 hours, and without a need to fire live rounds. Most of the training can be carried out indoors.

Mobile, vehicle-mounted versions of the RBS 70 Ray Rider are being studied and are described in entry **3617.131**.

In May 1983 it was revealed that an improved version, designated RBS 70X, is being delivered. Design changes to the missile's laser beam receiver give an increase of between 30 and 50 per cent in the engagement envelope. Weight, dimensions and maximum range remain unchanged.

CHARACTERISTICS

Type: Man-portable surface-to-air guided missile system
Guidance: Optical beam-riding on laser beam
Propulsion: Booster plus solid propellant sustainer
Warhead: Fragmentation with impact and proximity fuzes
Weight
Firing unit complete: About 80 kg
Missile in container: 24 kg
Container length: 1·6 m
Container diameter: 15 cm
Missile range: 5 km

STATUS

Development started in 1969 and the system is now in series production. In service with the Swedish and Norwegian armies, and ordered by several other nations believed to include Ireland and Singapore. Demonstrations have been given to about 20 countries, and the Swiss Government contributed to development.

2941.131
SA-7 (GRAIL) MAN-PORTABLE ANTI-AIRCRAFT MISSILE

The SA-7, Grail (once widely known as Strela - arrow) is an extensively deployed man-portable infra-red homing light anti-aircraft missile, very similar in concept to the American Redeye (**2784.131**) but preceding the latter into service. It relies upon a tail pursuit interception to engage low-flying aircraft targets and has proved especially effective against helicopters.

Overall length of the missile is 1·29 metres and the weight is in the region of 9·2 kg. An official UK MoD report issued in April 1976 stated that the range of the SA-7 is approximately 9 to 10 km. Simple optical sighting and tracking are employed, the IR seeker being activated when the operator has acquired the target. An indicator light denotes seeker acquisition and the operator is then free to fire the missile.

Flares were for a time found to provide an effective countermeasure but it is reported that later models are equipped with filters to combat this tactic. The existence of an improved Mk 2 version of SA-7 has been confirmed, the principal difference lying in a boosted propellant charge to increase range and speed of the missile.

Over the years that SA-7 has been in use - well over ten - additional forms of deployment have been evolved, apparently by both the USSR and individual client states. In October 1975, for example, a number of Jeep-type vehicles were seen during an Egyptian military parade with a rudimentary platform and support for an SA-7 gunner at the rear of the vehicle. Four reload rounds were attached to the sides of the vehicle. Various ship fittings of this missile have been noted and the designation given to naval applications is SA-N-5.

The Soviet development is the SA-9, Gaskin, according to the British report mentioned above. In this version four missiles thought to be derived from the SA-7 are housed in rectangular launcher boxes, turret mounted on a BRDM AFV. Some observers claim that the missiles used in this system are larger and heavier, and with correspondingly higher performance, than the SA-7 Grail, but no evidence either way has been obtained. The MoD report, in fact, quotes a slightly lower range value for the SA-9 Gaskin missile than for the basic SA-7.

STATUS

In widespread use with Warsaw Pact nations, Egypt, Syria, Viet-Nam, South Yemen, and probably others including Cuba, China, Morocco and Yugoslavia.

East German troops training in the use of the SA-7 Grail anti-aircraft missile

UNITED KINGDOM

2409.131
BLOWPIPE PORTABLE ANTI-AIRCRAFT MISSILE SYSTEM

Blowpipe is a surface-to-air weapon for unit self defence in forward areas against close-range low-level air attack. To carry out this role effectively the equipment is compact, light, and simple so that it can be both carried and operated by one man.

The weapon is suitable for use in extremes of climate with no maintenance needed during long periods in the field. It can be brought into action very rapidly, and reloading time is a few seconds. Blowpipe can be used against both attacking and receding fast aircraft and helicopter targets.

The Blowpipe weapon system is entirely self-contained with no external power requirements, and consists of two main components: the missile sealed within its launching canister, and the aiming unit. The missile/canister combination is treated as a round of ammunition that can be taken out of store and fired with no preparation or testing. The aiming unit houses all the necessary equipment and controls to launch the missile and guide it towards the target.

OPERATION

To prepare the system for action all that is necessary is to clip the aiming unit to the canister, which requires only a few seconds, and the complete system, which weighs about 20 kg, is lifted to the man's shoulder. The aimer acquires his target in his monocular sight, fires the missile, and controls its flight to the target by means of a thumb-operated flight controller.

Shorts Blowpipe close-range guided missile, although designed for low-level air defence, can also be used against lightly armoured surface targets

The act of pulling the trigger activates thermal batteries for power supplies in both the missile and canister (to supply the aiming unit). When these batteries have reached a sufficiently high voltage (in about one second), the missile first stage motor ejects the missile from the canister. This motor is extinguished before the missile fully emerges and the missile coasts for a safe distance from the aimer before the second stage main motor ignites to boost the missile to supersonic speed.

The missile is fitted with flares which in the early stages of flight are detected by a sensor in the aiming unit to gather the missile to the centre of the aimer's field of view. From then on the aimer guides the missile to the target by means of the controller with up/down and left/right movements. When within lethal distance of the target a proximity fuze in the nose of the missile detonates the warhead.

Commands are transmitted to the missile over a radio link, through the receiver and decoder to the missile control system. This works on 'twist and steer' principles with one pair of nose-mounted control surfaces working differentially to produce roll, and the other pair producing lateral movements.

The missile has a slim, cylindrical body and ogival-nose cone. Cruciform delta-shape canard control surfaces are mounted on the nose cone and a unique type of cruciform delta-shape tail-fin assembly is used. This consists of a sliding ring structure which, in the launching canister, is positioned near the nose of the missile, enabling the diameter of the rear of the canister to be minimised. As the missile is launched, it passes through the tail-fin assembly which finally locks on the rear of the missile. The folded wing tips open to their full span as they emerge from the canister.

CHARACTERISTICS

Type: Man-portable, shoulder-fired surface-to-air (or surface) tactical guided missile
Guidance: Radio command with optical tracking
Guidance method: Twist and steer by nose-mounted control surfaces
Propulsion: 2-stage booster-accelerator solid-propellant rocket motor
Warhead: HE with contact and proximity fuze
Missile length: 1390 mm
Missile diameter: 76 mm
System weight: 20·67 kg

STATUS

In service with the British, Canadian, Omani, Thai, and other, unnamed, forces. Blowpipe is credited with a number of successes during fighting in the Falkland Islands in 1982.

During 1982, in addition to a repeat contract from the Royal Air Force, a multi-million pound order for Blowpipe systems was placed by the Sultanate of Oman. This brought the total number of operators of the system to 16 armed forces in 11 countries. These include the British Army and Royal Marines.

Under UK MoD contract, Shorts are developing a family of Blowpipe variants for use on armoured vehicles and helicopters.

CONTRACTORS

The following manufacturers are known to have been associated with the development and manufacture of the system:

Main contractor: Short Brothers plc, Belfast.
IFF system: Cossor Electronics Ltd.
Fuze: Marconi Space and Defence Systems Ltd.
Ignition, safety and arming unit: Royal Ordnance Factory, Blackburn.
Firing circuits: Pye Dynamics Ltd.
Thermal batteries: Mine Safety Appliances Ltd.

The co-ordinating research and development authority is the Royal Radar Establishment.

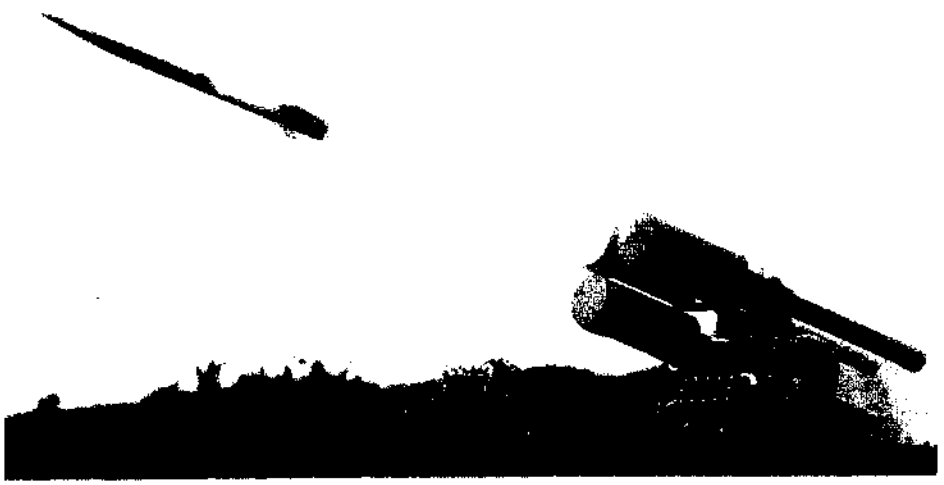
4533.131
JAVELIN/BLOWPIPE PORTABLE ANTI-AIRCRAFT MISSILE

Evolved from the very successful Blowpipe man-portable anti-aircraft missile system (**2409.131**), the Javelin shoulder-launched weapon is a surface-to-air missile system that employs a semi-automatic line-of-sight command guidance technique based on a visual system that means that the operator does not have to steer the missile in flight by means of a thumb-stick. Instead the missile is tracked to its target by keeping the target centred in the launcher sight, command signals being generated automatically.

Javelin is a direct development from the Shorts Blowpipe, but has a higher impulse rocket motor, a new warhead and modified fuze. The warhead is in the centre section with the fuzes in the nose. The forward part of the body contains the guidance equipment and the rear part houses the two solid-propellant rocket motors. There are four delta-shaped aerofoil surfaces in the nose for missile aerodynamic control and four at the tail to improve ballistic stability. A feature of the missile is that the nose section is free to rotate independently of the main body, to which it is attached by a low-friction bearing. Twist and steer commands to the control fins guide the missile, resulting in a fast response rate. The new warhead relies on blast/fragmentation effects rather than penetration to effect a kill, and the improved fuze will allow remote de-activation by the operator to enable the missile to be steered away from an incorrectly engaged target without detonating.

The canister in which the missile is factory sealed is a lightweight environmental container designed to act as a recoilless launcher. The front cap is blown off by gas pressure when the missile gyro is fired, while the laminated rear closure is ejected at launch.

A lightweight multiple launcher (LML) has been developed by the manufacturer to provide a multi-



engagement capability for the Javelin system. It is designed to suit a wide range of potential operational deployments, and several versions have been developed for applications other than the man-portable role. All LML configurations use, as clip-on items of equipment: three Javelin canister-housed missiles, and a standard shoulder-launch aiming unit, which are fixed to a collapsible tubular tripod.

In the free-standing application, the main support tube is held vertically by the tripod legs which pivot from an eccentric support collar. Short screw jacks between the top of the sleeve and the legs are used to level the launcher. For trench deployment, it is possible to have one leg as a vertical support within the trench and the two others arranged horizontally to provide lateral support on the trench side(s). There is a version for use with APCs or similar vehicles, the LML(V), in which a pintle mounting provides 60 degrees of freedom, relative to the turret ring, in traverse. The ring is provided with a handgrip and frictional brake, so that the aimer can slew it to the approximate target bearing and then track the target.

A naval version LML (N) has been developed that incorporates an operator's seat mounted on the pillar of the simple pedestal mounting, which provides for manual training and elevation of the three-round aiming and launching head.

The aiming unit is a self-contained firing and control pack with a pistol grip firing handle on the right-hand side. It contains a stabilised sighting system which provides manual tracking and automatic missile guidance through a solid state TV camera. Digital signals from the camera are fed to a microprocessor and the resultant guidance demands are transmitted to the missile by radio link. Controls on the handle include firing trigger, thumb-controlled joystick and system, fuze mode and super-elevation switches. Other controls are channel selector switches for the transmitter and automatic cross-wind correction switch.

CHARACTERISTICS
Length: 1·4 m
Guidance: SACLOS
Propulsion: 2-stage solid
Speed: Supersonic
Range: >4 km
Aiming unit: Standard Blowpipe type (as clip-on equipment)
Missiles on launcher: 3
Elevation: 10 to +45°
Traverse: Continuous (stop fitted as required)
Lightweight multiple launchers
Weights: 14 kg (traverse head); 16 kg (tripod support)
LML (V)
Traverse head: 35·5 kg
Turret: 78 kg (with hatch and pintle)
LML (N)
Traverse head: 35·5 kg
Fixed pedestal: 13·5 kg
Seat assembly: 16·1 kg
STATUS
In product on for UK and overseas forces.

Shorts LML for Javelin, fitted with Cossor IFF 880L (antenna above missile canisters, transmitter/receiver on support pillar)

UNITED STATES OF AMERICA

2784.131
REDEYE PORTABLE ANTI-AIRCRAFT MISSILE

Redeye is a shoulder-fired guided missile system designed to give a soldier an effective defence against low-flying aircraft. The US designation is FIM-43 and other users have their own nomenclature as follows: Denmark - Hamlet; West Germany - FLF-1 and Fliegerfaust; Sweden - RB69. The missile's infra-red sensing device homes on the heat of an aircraft's engines. The Redeye carries a high-explosive conventional warhead and has a two-stage solid-propellant engine. The light launching tube is also a carrying case and can be borne through brush and over rough terrain. A shipping and storage container holds one missile and three battery/coolant units.

On sighting a hostile aircraft, the gunner tracks it in an optical sight. At the same time, he energises the missile guidance system. A buzzer located in the launch tube gripstock informs the gunner when the missile is ready to fire. Upon firing, the booster charge propels the missile out of the launch tube. When the missile has cleared the launch tube muzzle by a distance sufficient to protect the gunner from blast effect (about 6 m), the main rocket ignites and propels the missile the rest of the way to its target. The missile is stabilised in flight by cruciform tail fins and steered by two movable fins close to its nose.

Redeye has no IFF facility and is limited to pursuit course engagements.

CHARACTERISTICS
Designation: FIM-43A
Type: Man-portable, shoulder-fired, surface-to-air guided missile
Guidance: Optical aiming, infra-red homing
Propulsion: Solid-propellant booster and sustainer

Practice firing of Redeye portable anti-aircraft missile

Warhead: HE
Missile length: 1·22 m
Diameter: 70 mm
Weight: 13 kg
Speed: Supersonic
Range: Not disclosed. Probably about 3 km
Crew: Normally 2

Redeye is employed in the forward battle area to protect combat troops against low-level aircraft. In the US Army the weapon is issued to Redeye teams, each made up of a gunner and assistant gunner. From four to six of these teams are assigned to a Redeye section at infantry battalion level.

STATUS

Procurement of Redeye was completed in fiscal year 1970. It has been issued to the USMC as well as the US Army and has been supplied also to the Australian, Danish, West German and Swedish armed forces. Gradual replacement by the Stinger system (**2805.131**) is in progress by the US forces.

CONTRACTOR

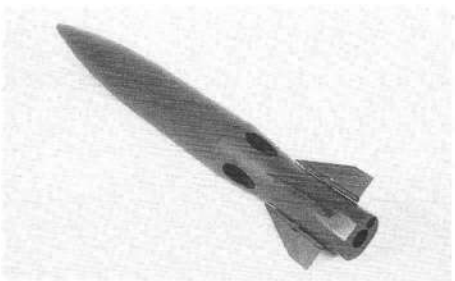
Prime: General Dynamics Corporation, Pomona Division, Pomona, California, USA.
Rocket motor: Atlantic Research Corporation.

4534.131
SABER PORTABLE ANTI-AIRCRAFT MISSILE

Saber is designed to engage all types of subsonic air threats and for deployment by foot soldiers. A dual-purpose shaped charge warhead is intended to provide a useful anti-armour capability also. The system is composed of three elements: the missile, launcher assembly, and a re-usable guidance unit that is easily and rapidly attached to the launcher. The missile is a simple cylindrical body with tail surfaces, and it is stabilised in all three axes. It is ejected from the launcher at low speed to minimise flashback and noise experienced by the operator, and the solid propellant rocket motor is ignited after the missile has travelled some distance from the launcher. Guidance is provided by the guidance unit attached to the launcher, which incorporates a stabilised sight line for target tracking and a guidance beam projector that provides steering signals via the guidance receiver in the missile. There is no separate seeker head in the missile itself, resulting in a very low cost system.

Ford Saber man-portable missile system

CHARACTERISTICS



Length: 1·09 m
Diameter: 120 mm
Missile weight: 11·3 kg
Weight: <18·1 kg (system including launcher)
Guidance: Laser beam riding

STATUS

All phases of an advanced development flight test programme have been completed successfully. The last two flights were conducted against moving aerial targets with a gunner tracking the target and automatically directing the laser guidance beam at the target. Both resulted in direct hits. Since these tests, Ford Aerospace has incorporated various technological advances in the sub-systems that result in increased range and warhead performance for the system.

CONTRACTOR

2805.131
STINGER PORTABLE ANTI-AIRCRAFT MISSILE (FIM-92A)

Stinger, Redeye's successor, was in engineering development from July 1972, and is the current US Army and Marine Corps' man portable air defence system (MANPADS). It is an infra-red seeking missile which enables the soldier to engage effectively low-altitude, high-speed jet, propeller-driven and helicopter aircraft. Designed for the threat beyond the 1980s, Stinger has all-aspect engagement capability, an IFF system, improved range and manoeuvrability and significant countermeasure immunity.

CHARACTERISTICS

Designation: FIM-92A
Type: Man-portable, shoulder-fired, surface-to-air guided missile
Guidance: Passive IR homing
Propulsion: Solid-propellant
Warhead: HE
Length: 1·52 m
Diameter: 70 cm
Weight: 15·8 kg

An airborne application of Stinger has been proposed, employing a two-round launcher for installation on helicopters to provide such aircraft with an air-to-air self-defence capability and an air-to-ground facility for engaging suitable radiating targets. This project has been named Air Launched Stinger (formerly Multi-purpose Lightweight Missile System, MLMS) in the former role, and ADSM (air defence suppression missile) in the air-to-ground application.

Tests have been carried out where Stinger missiles have been carried and fired from Roland surface-to-air missile system (**2218.131**) fire units. Using a special Stinger container developed by Boeing four Stinger missiles can be housed in the space of a single standard Roland launch tube.

Boeing Avenger prototype lightweight air defence system mounted on HMMWV

STATUS

Stinger became operational in West Germany in February 1981, and with the US Army 82nd Airborne Division in April 1982. The improved Stinger-POST version went into production in 1983 for deployment in 1987.

In addition to the US Army and Marine Corps, it is planned for use by the USAF in small quantities for airfield defence. Projected procurement for the three US Forces as detailed in the fiscal year 1986 DoD

budget is as follows, quantities in brackets and funding in $ millions:

Fiscal year	1984	1985	1986	1987
Army	(1295) 137·8	(2360) 207·3	(3439) 304·1	(7130) 585·9
USMC	(691) 40	(700) 58·8	(800) 59·4	(2080) 146·4
USAF	(60) 4·9	(156) 12·9	—	—

The advanced design Stinger-POST version of the weapon entered production in fiscal year 1983 and is planned for deployment in mid-1987. A product improvement, known as Stinger-RMP (Stinger-reprogrammable microprocessor) went into development in September 1984. This improvement is required to retain the ability to up-grade this weapon as the overall threat evolves without having to initiate a costly retrofit programme, and the 1986 budget included $18·6 million to continue Stinger-RMP development. Missiles to be delivered from July 1987 will be RMP equipped.

In April 1985 Atlantic Research Corp received a $22·8 million contract from General Dynamics for the sixth production buy of solid propellant rocket motors for Stinger missiles.

Since its introduction into service in the man-portable role, a number of additional applications of the Stinger weapon system have been designed. Some of these have been developed and tested, others remain proposals; several involve the use of single or multiple Stingers either with novel mountings, or in conjunction with another weapon (gun or missile). The major projects of this nature are summarised briefly in the following paragraphs.

Avenger

Boeing began the Avenger air defence system development as a private venture in mid-1983. The general arrangement of the system is clear from the illustration showing Stinger missile pods and their turret mounted on the Army High Mobility Multi-purpose Wheeled Vehicle (HMMWV). With eight 'ready to fire' missiles, the Avenger requires a crew of two. Operational characteristics include: an ability to shoot on the move (hits have been obtained with the vehicle travelling at 20 mph); autotrack to missile seeker; automatic lead angle superelevation in fire sequence; short reaction time (turret under ten seconds, missile less than three seconds); high rate of fire (less than five seconds between shots); stabilised launch arms; an ability to reload eight rounds in four minutes.

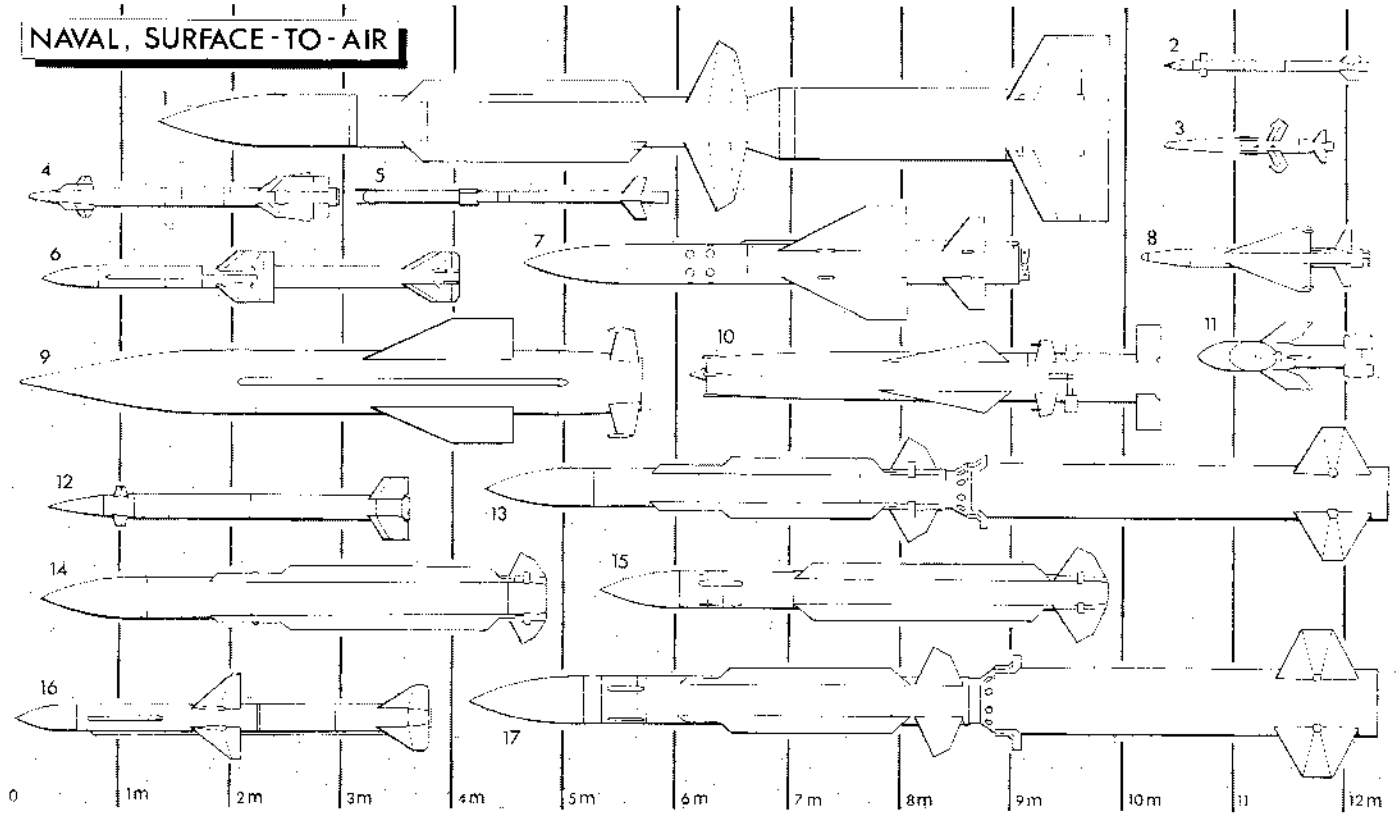
The turret employs azimuth and elevation drive mechanisms as supplied for the M1 Abrams MBT, and in addition to the CAI Inc optical sight there is a Honeywell FLIR and Ferranti laser rangefinder.

Setter

The US Army Missile Command (MICOM) began the Setter programme in 1981 with the design and construction of a multiple Stinger launcher prototype, consisting of a power-operated mount with the gunner seated in the centre, flanked by two × four Stinger missiles in pods. Fire control include a passive RF sensor, day/night vision with TV/FLIR, and the turret is mounted on the HMMWV like Boeing's Avenger. Setter also provides for hypervelocity rockets (HVR) in its armament and a total of 54 HVR launch tubes are carried on the turret. A portable gunner fire control console permits dismounted operation remote from the vehicle.

The Stinger provides long-range capability while the HVRs have an effective range of about 1200 m. Firing demonstrations of the Setter system were planned to begin in 1984.

Stinger AA missile system



Other programmes

The Stinger manufacturers produce as standard items two- and four-round launchers which include system electronics, cooling equipment, and interface, control and display units suitable for use on a variety of platforms. Such launchers feature in numerous other programmes that provide for the application of Stinger to towed systems such as the GEMAG-25 and Vulcan multi-barrel gun systems, powered vehicles such as the LAV, IFV/CFV and deployed with Roland SAM-armed tracked vehicles. Air-to-air use of Stinger has been studied with several types of helicopter, and naval possibilities include the combination of multiple Stinger launchers on the Mk 15 Phalanx CIWS.

SAAM NAVAL AIR DEFENCE SYSTEM

In 1983 the French authorities initiated a feasibility study into a family of new air defence weapons suitable for use aboard naval vessels and by land forces to give protection from attacks by aircraft and missiles in the 1990s and beyond. It is hoped to run the two programmes, known as SAAM (surface-to-air anti-missile) and SAMP (medium range, ground-to-air system) concurrently in the initial stages, and to maintain a considerable degree of commonality between the hardware of the land and naval versions of the system. The land mobile SAMP system is described in the Mobile Surface-to-Air Guided Missile Systems section of this book (**4771.131**) where the common aspects that have been defined to date are summarised.

The threat to be addressed embraces saturation air attacks with aircraft and missiles, at all altitudes and from multiple azimuth angles. The targets may be expected to be capable of very high manoeuvring capabilities, calling for a defensive missile able to defeat attacking missiles capable of up to 15 *g* and speeds of up to Mach 2.5 or more. Dense and varied ECM and other countermeasures are expected, and high resistance to such challenges is essential, as is maximum autonomy of operation against multiple threats.

The ability to intercept several targets simultaneously and provide a short reaction time will be facilitated by use of a new X-band 3-D radar developed by Thomson-CSF. This will simultaneously carry out surveillance, detection, identification, threat evaluation, designation and tracking of targets, in addition to up-dating the missile inertial navigation system. Rotating at 60 rpm, this radar will incorporate frequency agility, and will be compatible with a missile launching rate of up to one per second. It is possible that electro-optical sensors may be added as a radar back-up and to provide for loss of target data as a result of jamming.

The SAN-90 missile will be designed for exceptional manoeuvrability: three times that of potential targets is the estimated requirement, ie about 50 *g*. It will have a hybrid control system incorporating aerodynamic and direct force control elements. Missile guidance will consist of two steps: the initial guidance phase during which the missile heads toward its target under the control of its on-board inertial system, and the terminal phase during which it will use a K-band active radar seeker.

Montage photograph to show appearance of ship fitted with projected SAAM system. Radar at top of lattice mast is new Thomson-CSF 3-D multi-purpose system. Vertical launchers are grouped aft of funnel

SAAM

This version of the system is intended principally for the self-defence of ships, and particularly to

destroy diving and sea-skimming anti-ship missiles. For this the SAN 90 will have a 10 km interception range. It will be fired from a vertical launcher and will have rocket motor propulsion. The guidance system will be optimised to give minimum miss-distance performance to achieve maximum destructive effect from the warhead. The multi-purpose radar antenna will have a stabilised mount and will be located very high on the ship's superstructure to give the best overall performance against both high- and low-flying targets.

STATUS

Feasibility study started in 1983. SAAM (SAN 90) development planned to begin in 1986, with ground based version (SAMP) following in 1987.

1177.231

MASURCA SURFACE-TO-AIR MISSILE SYSTEM

Masurca is the surface-to-air missile system which forms the main anti-aircraft armament of the French frigates *Duquesne* and *Suffren*, whose principal role is that of escort to the aircraft carriers *Foch* and *Clemenceau*. Masurca also has armed the AA cruiser *Colbert* since 1973 when her modernisation was completed. Each of the Masurca ships is equipped with three-dimensional surveillance radar, a weapon direction system, two independent fire control systems, and a twin launcher. Aircraft and missile targets can be intercepted at ranges of 40 km or more.

The main characteristics of the missile are length (with booster) 8·6 m, (without booster) 5·29 m, diameter 41 cm, span of booster fins 150 cm, weight (with booster) 2090 kg, (without booster) 950 kg. A proximity-fuzed high-explosive warhead is carried, and both boosters and sustainer motors are solid-fuel units.

Two types of guidance system have been employed: the Mk 2 Mod 2 uses radio command, and the Mk 2 Mod 3 is equipped with a semi-active radar homing head, but the latter only is currently in service.

In addition to the missiles themselves, the Masurca weapon system contains the following main elements:

(1) a twin launcher
(2) two storage and handling systems
(3) two directors, each with a tracking radar and a target illuminator.

The DRBR 51 tracking radar has two main functions in the Mk 2 Mod 3 role:

(1) it continuously follows the target
(2) it controls the pointing of the target illuminator radar.

OPERATION

The DRBR 51 has two antennas, the main one of which is used for target tracking and as an I/J-band target illuminator radar. The missile is equipped with two antenna systems, one at the front of the vehicle, and two fixed antennas mounted on the missile body. The latter are used to receive the illuminating radar signals direct, to provide a reference signal which can be compared with the signals reflected from the target that are collected by the forward missile antenna. This enables a doppler component to be extracted, which is used in the on-board computation of a proportional navigation intercept-on course to the target.

DEVELOPMENT

The Masurca missile was developed by Etablissement des Constructions et Armes Navales de Ruelle in co-operation with Société des Engins Matra.

Fire control radar, missile homing head and proximity fuze were developed by Thomson-CSF. Solid propellants are manufactured by Société Nationale des Poudres et Explosifs (SNPE). Launch, storage, and handling equipments were designed and developed by Etablissement des Constructions et Armes Navales de Ruelle.

STATUS

The Masurca weapon system is operational in the Mk 2 Mod 3 version aboard the three ships named in the opening paragraph of this entry. In 1985 the onboard Masurca system equipment was in the process of being modernised on all three ships. This includes radars, computers and displays.

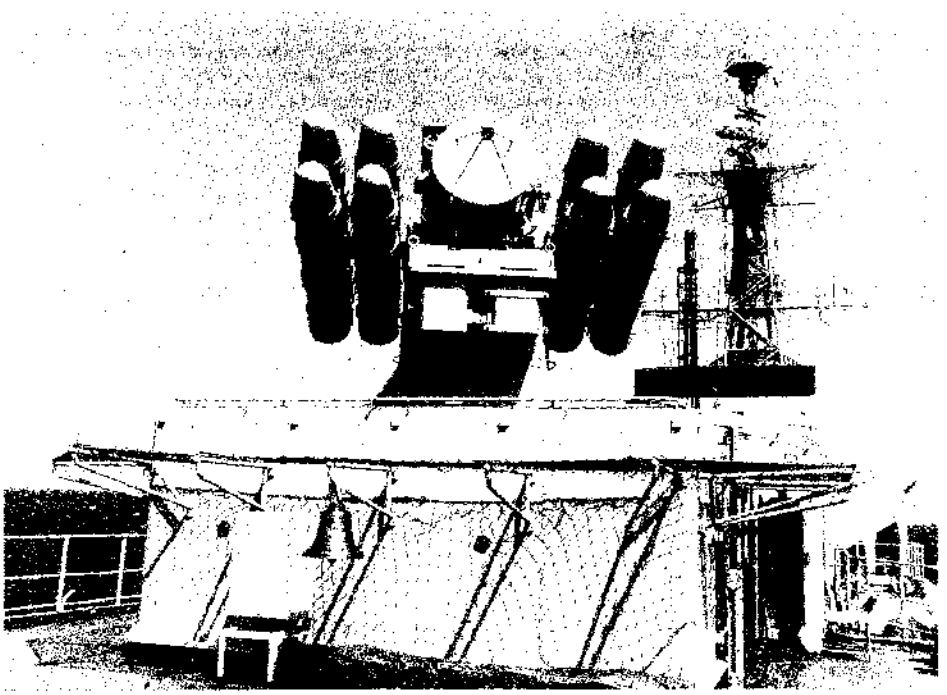
2111.231

NAVAL CROTALE SURFACE-TO-AIR WEAPON SYSTEM (TSE 5500)

Directly derived from the ground version of the Crotale (**2074.131**), the Naval Crotale weapon system is designed for the self-defence of ships against short range air attacks at medium, low and very low altitude, these attacks being conducted by aircraft, helicopters, air launched and sea-skimming missiles. The Naval Crotale may also be used against surface targets and is capable of artillery control.

The Naval Crotale is now operational with the French Navy and has been ordered by the Saudi Arabian Navy (8 S version).



A new version, the Modular Naval Crotale, is now available (8 MS version) for installation on board ships of 200 tons or more.

In its 8 S version, Naval Crotale is composed of:

(1) a turret assembly with two coaxial turrets: the eight-missile turret and the fire director supporting the radar antenna and receiver, the remote control antenna, the IR receiver for localisation of the missile during the first part of its flight (gathering), the differential IR tracker for guidance of the missile at very low altitude and the TV camera
(2) a shelter housing the electronic equipment: data processing, radar and IR processing cabinets, launcher power control cabinet and maintenance unit
(3) an operator console in the combat information centre (CIC) for supervision of the system and sending of firing orders. Operation of the system is fully automatic, pushing the 'Fire' button being the only manual action. In the normal mode, the operator sitting in front of the data processing cabinet has just to start the system, to supervise its working and to depress the 'Fire' button.

Acquisition and tracking of the target on the target designation from the ship (surveillance radar, optical sight, radar detector or another tracking radar) are performed by the radar of the Crotale system.

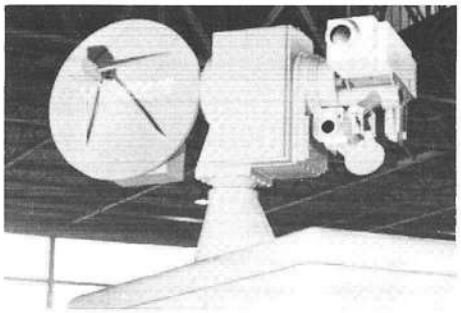
After launching, the missile is gathered by the large field of the IR localiser which locks it within the radar beam. Missile guidance is performed by an improved line-of-sight guidance which optimises the manoeuvrability of the missile. A proportional navigation law is elaborated at the end of the missile flight to reduce the miss-distance in the case of a manoeuvring target. In the case of a target at very low altitude (sea-skimmer), tracking of the target and of the missile is performed by the differential IR tracker, a device developed by SAT and known as SEID (Système d'Ecartométrie Infrarouge Différentiel). The missile is fired and guided as in the radar mode.

Naval Crotale compact version installation aboard the French destroyer Mortcalm

The Crotale missile is boosted by a solid propellant rocket motor. The warhead, weighing about 14 kg, is triggered by an electromagnetic proximity fuze; the delay of explosion is calculated to concentrate the prefragmented splinters in the most vulnerable zone of the target.

The missile is housed inside a sealed container, which is used for transport, storage and launching. A missile inside its container forms a Crotale round. The 8-missile magazine and loading mechanism is manufactured in French Navy yards.

Modular Naval Crotale is composed of the following parts:



(1) the fire director turret, supporting the radar antenna and receiver, the remote control antenna, the IR tracker (for guidance against sea-skimmer targets) and the TV camera
(2) an independent launcher turret, supporting the IR localiser (gathering) and eight rounds
(3) the data processing cabinet, installed in the CIC.
(4) the other electronic equipments (radar, IR and launcher power control cabinets) which are installed in any available compartment(s) of the ship.

Operation of the system does not differ from the Naval Crotale. The fire director of the Modular Naval Crotale, as for the Naval Crotale, can also be used for the direction of naval guns. The Modular Naval Crotale can be installed on ships of 200 tons or more. The light eight-missile loading system is manufactured by the French Navy yards.

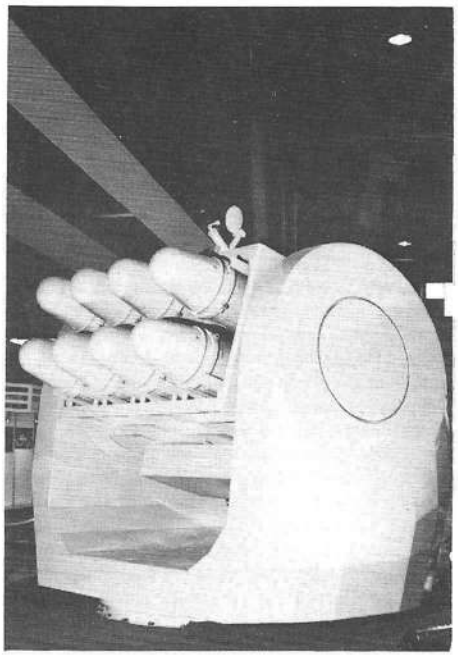
CHARACTERISTICS

Radar frequency: K$_u$-band
Range: 18 km
Differential deviation measurement accuracy: 0·1 mrad
Remote control frequency: X-band

IR tracker: 10 μ band, range 18 km
Differential deviation measurement accuracy: 0·1 mrad
Guidance: Improved line-of-sight command and proportional navigation at end of missile flight
Useful elevation: -15 to +70° (8 S); -15 to +80° (8 MS)
Useful training arc: Unlimited
Missile max speed: 750 m/s after 2·3 s
Targets for which system has been optimised
Aircraft
Speed: Mach 1·2
Altitude: 15 - 5000 m
Radar cross-section: 1 m² fluctuating
Target manoeuvrability: 2 *g* at 10 km
Missiles
Speed: Up to Mach 2
Minimum altitude: 4 m
Radar cross-section: 0·1 m²
Max interception range: 13 km (helicopter or non-manoeuvring target); 10 km (manoeuvring Mach 1·2 aircraft); 6·5 km (sea-skimmer)
Minimum interception range: 700 m
Vertical coverage: From 4-5000 m
Target max speed: Mach 2 (radial attack aircraft/sea skimmer); Mach 1·2 (crossing target)
Reaction time: 4·5 s (between target designation reception and first missile start)
Weight
Naval Crotale
Turret assembly: 8·2 tons with 8 rounds
Shelter + electronic equipment: Approx 10 tons
18-missile storage and loading system: Approx 15 tons with 18 rounds
Modular Naval Crotale
Fire director turret: 800 kg

Fire director of Modular Naval Crotale

8-missile turret: 4·2 tons with 8 rounds
Electronic equipment: 2·8 tons
8-missile loading system: 3·2 tons with 8 rounds



DEVELOPMENT

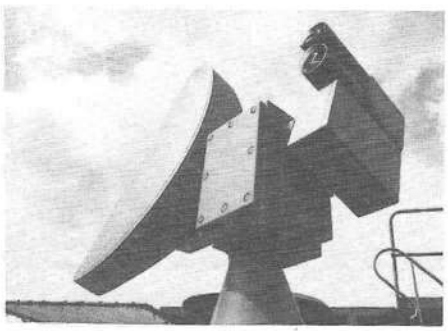
Development of the Naval Crotale was carried out under the responsiblity of DCN and DTEN with Thomson-CSF as systems manager and supplier.

STATUS

The Naval Crotale, in its basic version, is now operational on 'Georges Leygues' class corvettes and 'Tourville' class frigates of the French Navy. These units are about to be retrofitted with the anti-sea-skimmer capability (8 S version) and five more systems were ordered by the French Navy in 1982, bringing the total number of systems ordered by the French Navy to 14.

Five systems were ordered by the Saudi Arabian Navy in 1980 and are now operational. Negotiations are progressing with several other naval forces for Naval Crotale and Modular Naval Crotale.

Modular Crotale will employ new design 8-round launcher



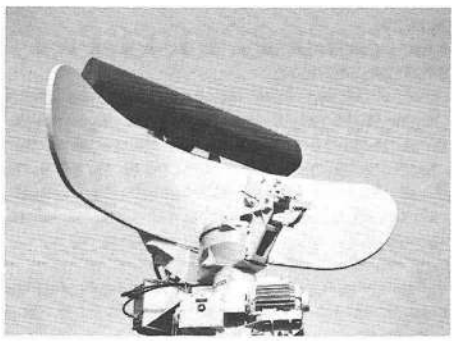
CONTRACTORS

System: Thomson-CSF, Division Systèmes Electroniques, 116 ave Aristide Briand-92222 Bagneux, France.

4776.231
SATAN CLOSE-IN WEAPON SYSTEM

SATAN (Système Autonome Tout temps d'Auto-defense Naval) is a new project for the design and development of an entirely autonomous all-weather close-in defence system for ships to provide protection against aircraft and missiles. The design is intended for fitting in ships which may already be equipped with one or more longer-range missile systems such as the Naval Crotale (**2111.231**), or as the main anti-missile defence in other types of ship. It is completely automatic from detection to firing and has a very short reaction time.

A modular design has been chosen to permit easy installation and rapid changes to accommodate developments in the threats anticipated, and advancing technology. The main elements are:



Castor II J director is main sensor for new SATAN autonomous naval CIWS

(1) a doppler frequency-agile surveillance radar (Sea Tiger or Triton G) which is capable of automatic detection of missile targets in sea or rain clutter and in a heavy jamming environment. An automatic extraction system is associated with an automatic plot tracking device
(2) a data processing system with a VDU for threat evaluation, co-ordination with other weapon systems, electronic warfare and target designation
(3) a Castor II J Ku-band director radar, with an added continuous target-to-shell radar angle tracking facility. An associated digital computer generates the firing data and uses the target-to-shell angle tracking information to produce an efficient automatic firing correction closed control loop. (In many cases this IR tracking facility will be provided by a ship's Crotale system, but where this is not the case, separate E-O sensors are provided for TV or IR target tracking)
(4) one or more 30 mm Gatling EX 33 multi-barrel guns by General Electric.

By adopting an off-mounted solution for the surveillance radar and the Castor II J fire control radar, it is possible to site the various sensors aboard the ships in the optimum fashion for accurate detection and tracking. The surveillance antenna can be placed at a height that offers maximum sea-skimmer detection range, given the problems posed by geographical range and particularly the interference fringes. (Against a 500 m/s target, every kilometre gained in early detection gives three seconds more for use of defensive weapons.)

As the fire control radar is separate from the gun, it is free from problems such as vibration and debris associated with firing, and may be installed above the gun to improve the field of view or to provide autonomous search facilities. The additional errors introduced by platform movements between the mounting and the radar aiming system are corrected in the firing control loop, and the computer system integrates all platform movements by measuring the various parameters, positions and speeds.

Triton (above) or Sea Tiger doppler surveillance radar, with IFF and an automatic extractor is main detection sensor for SATAN system

STATUS

Development project.

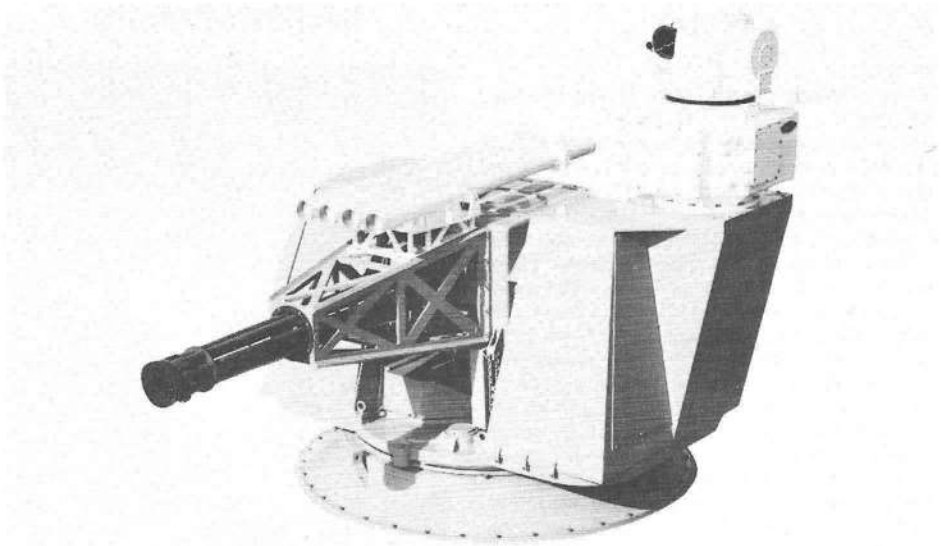
Thomson-CSF, Division Systèmes Electroniques, 1 rue des Mathurins, Bagneux 92222, France.

4861.231
SAMOS NAVAL AIR DEFENCE SYSTEM

SAMOS, the SAGEM Optronic Anti-Missile System, is intended to provide a defence against sea-skimming anti-ship missiles and short-range defence against aerial targets. It would appear to have been designed in response to a similar naval close-in weapon system requirement as those covering French projects such as SATAN (**4776.231**) and SADRAL (**4509.231**) in this section.

The SAMOS concept consists of a combination on a single integrated naval mount of a SAGEM Volcan (Viseur optronique leger pour conduite d'arme navale) electro-optical fire control system (**3064.293**), a General Electric Sea Vulcan 30 mm gun mount and ground-to-air missiles such as the Matra Mistral used in the SADRAL system mentioned above. This combination promises high effectiveness through accurate stabilisation of the fire control system line-of-sight (LOS), associated with a strap-down inertial reference unit and the low dispersion, high rate of fire (4200 rounds/minute) of the Sea Vulcan multiple barrel 30 mm gun.



The Volcan FCS includes a lightweight electro-optical sight, the lower section of which accommodates TV, IR and laser rangefinder sensors, while the upper, moving section houses a two-axis gyroscope which ensures an accurate stabilised LOS. A control and display console is provided for operation of the system and its associated electronics.

The inclusion of four launch tubes for short-range surface-to-air missiles on the top of the Sea Vulcan mount is optional. Typically these missiles would be expected to provide a range extension out to 6000 metres using IR homing weapons capable of engaging attacking aircraft or anti-ship missiles during a diving attack.

By using a target designation from the ship's surveillance radar and/or a passive IR sensor, SAMOS will provide for acquisition and automatic tracking of the target, by either TV or IR, measurement of target range by the laser rangefinder, an automatic computation of target parameters and weapon control.

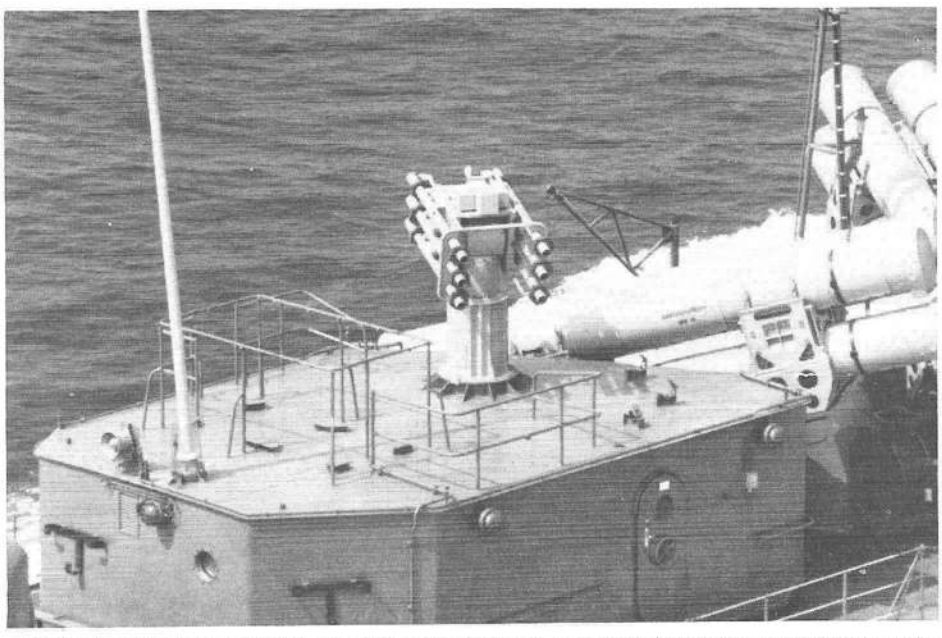
General Electric, Armament and Electric Systems Dept, Lakeside Avenue, Burlington, Vermont 05402, USA.

SAMOS combines GE Sea Vulcan 30 mm gun mount with SAGEM Volcan optronic fire control, and optional IR homing SAMs provide for compact naval close-in air defence system

4509.231
SADRAL NAVAL AIR DEFENCE SYSTEM

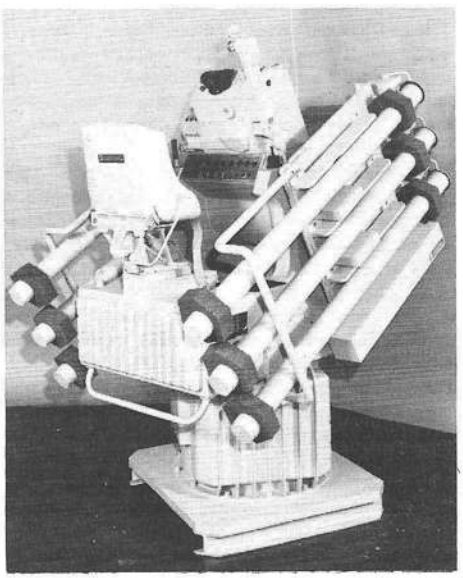
SADRAL (Système d'Autodéfense Rapprochée Anti-aérienne Léger) is an air defence system based on the Matra Mistral land-based SATCP missile system, modified for naval applications and proposed for the French Navy. The Mistral itself is described in entry **4198.131** and the following entry is concerned with its application to 'close-in' defence of ships from aircraft or anti-ship missiles.

The equipment consists of a remotely operated stabilised mount which carries six Mistral rounds and a closed circuit TV camera. The mount can be trained in azimuth and elevation under the control of the operator who mans a simple control desk below deck. The TV camera is used for target acquisition, and this component can be supplemented by an IR thermal imaging camera for night operations.



For the majority of its components, the SADRAL system uses equipment already certified for marine environments and in use for Otomat systems or those derived from the Totem remote-aiming system. The mass of the carriage fitted with its six rounds of ammunition is approximately 900 kg. Total mass of the SADRAL system (carriage, servos and control desk) is about 1500 kg. It is thus possible to mount two SADRAL systems on low-tonnage vessels, with a mass which is still more than 50 per cent less than that, for example, of a single Phalanx system, according to the manufacturer.

Due to missile accuracy and the penetrating power of the fragments of its charge, SADRAL's efficiency is claimed as superior to that of a gun-based system. In addition, the SADRAL system permits interception of targets at distances much greater than those of gun-based systems, thus offering greater safety for ships. Finally, the time required to pass through the firing envelope being much greater, SADRAL permits engaging several missiles against the same target, or against a wave of aircraft, which a gun-based system does not permit.



Although the priority mission assigned to SADRAL by the French Navy is anti-aircraft defence of small vessels (patrol-boats, mine-sweepers, etc) it will also be mounted on logistic backup and transport ships. It may also be mounted in ships already equipped with a surface-to-air system, such as anti-aircraft corvettes, where its firepower would extend the threshold of saturation of the threat. In addition to defence against helicopters or airplanes, the Mistral could be used to engage sea-skimmer-type missiles flying at low altitude above the sea surface.

Target designation may be performed, according to circumstances, by using the ship's surveillance radar or an electro-optical surveillance system (IR or optical), or, if necessary, simpler designation systems (navigation radar or the ELDO (*equipement leger de designation d'objectif*) a lightweight optical sighting system now under study).

CHARACTERISTICS
Mount: 6-round, stabilised
Weight: Approx 900 kg (with 6 rounds)
System weight: Approx 1500 kg
Missile: SATCP (Mistral)

SADRAL launcher on top of deck house on French trials ship. Note eight MM40 anti-ship missile launcher tubes on right

LAMA self-contained optical director/launcher under development for use with Matra Mistral by CSEE can also be used for other weapon/sensor combinations

Length: 1·8 m
Diameter: 90 mm
Weight: 17 kg
Warhead: 3 kg
Fuze: Impact, laser proximity
Guidance: IR homing (2-colour)
Range: 300–6000 m
Peak speed: Mach 2·6
STATUS
Development began in 1981. The French Navy is reported to have plans to procure several dozen systems for its vessels with entry into service planned for 1987.

LAMA

A naval self-defence missile launcher is under development by CSEE. Called LAMA the new fire director consists of an optical director for surveillance and target designation, to the sides of which are attached up to six missile launching ramps. Designed for very short range surface-to-air naval missiles such as the Matra Mistral, other types (eg. Stinger, RBS 70, etc) can be accomodated and it is also possible to mount different sensor/missile combinations on the LAMA director. Weight is 1000 kg.

NATO SEASPARROW SURFACE-TO-AIR MISSILE SYSTEM

The NATO Seasparrow Surface Missile System (NSSMS), originally known as the Point Defence Missile System, is a shipboard air defence system employing the Sparrow family of missiles. The system is designed to counter the threat of anti-ship cruise missiles and aircraft. The original shipboard use of the Sparrow missile was in the Basic Point Defense Missile System (BPDMS) which became operational aboard US ships in 1969 and in 1984 was being phased out of service. The NATO Seasparrow Surface Missile System (NSSMS) became operational in 1973 using RIM-7H missiles. Modifications to the NATO Seasparrow missile systems to accommodate the improved Sparrow AIM/RIM-7M monopulse missile began in 1983. In 1981 Seasparrows were successfully fired from Vertical Launchers aboard a Canadian destroyer. This Seasparrow Vertical Launch System will be operational aboard the new Canadian Patrol Frigates.

Basic Point Defence Missile System

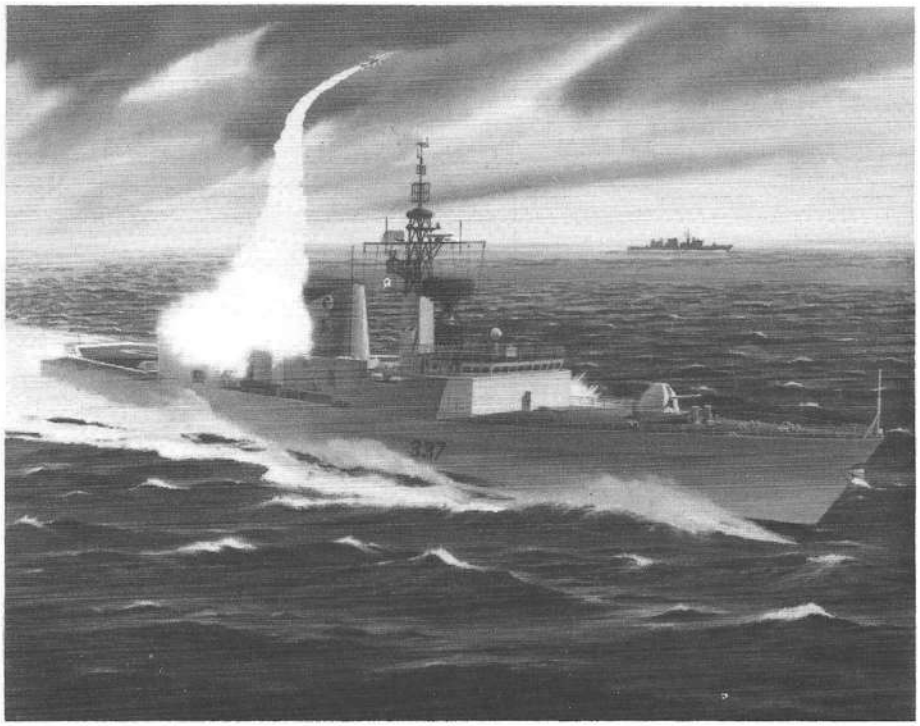
The BPDMS was assembled urgently from existing hardware. It features the Sparrow AIM-7E missile launched from a modified eight-tube ASROC missile launcher. The launcher is housed on a modified 3-inch 50 calibre automatic gun carriage. Total weight of the system is 17 690 kg.

A CW semi-active radar homing system is used. Target data from the combat information centre is supplied to the manually operated Mk 115 fire control system and the target is acquired and illuminated for homing guidance by a Mk 51 director/illuminator radar.

STATUS

BPDMS development began in 1964. In March 1983 USN ships with BPDMSs total 46: (31 in 'Knox' class ships (one system each); two LCCs with two systems each; seven LPHs (two each); five LHAs (two each); and one CV (two systems)).

CONTRACTOR



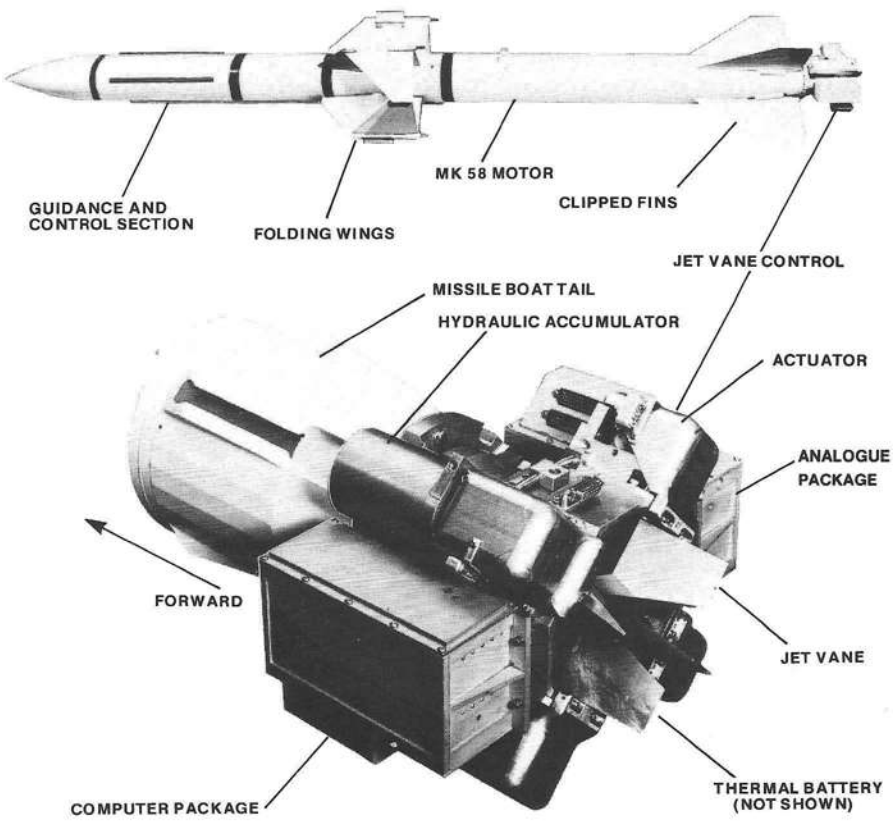
Sparrow missile: Raytheon Company.

Solid-state power drive for fire control system: General Electric.

Fire control system: Frequency Engineering Laboratories.

NATO Seasparrow Surface Missile System (NSSMS), Mk 57

The NSSMS incorporates a lightweight eight-cell launcher (Mk 29), and a fire control system (Mk 91) utilising digital computers, and powered director/illuminator(s). The RIM-7H and AIM/RIM-7M Sparrow missile family is used in a modified form with folding wings that enable them to fit into the smaller, lighter launcher. NSSMS possesses a range of operational modes from manual to fully automatic with operator intervention.



Artist's impression of the new Canadian Patrol Frigate fitted with Vertical Launch Seasparrow

The new digital Sparrow (AIM/RIM-7M) medium range missile features all-aspects, all-weather, crossing target capability. The 7M Sparrow incorporates an advanced inverse monopulse seeker and a digital computer. This provides substantial performance improvements in seeker sensitivity and enhances target discrimination in heavy clutter, ECM conditions, and extreme low altitude intercepts.

The onboard digital computer, besides being reprogrammable, gives greater immunity in the changing ECM threats, while providing for proportional navigation. Proportional navigation directs the missile to fly a lead angle course to the intercept point, which provides NSSMS equipped ships with the ability to protect other ships in the vicinity. The AIM/RIM-7M also includes a larger boost sustain rocket motor and blast fragmentation warhead.

The NATO Seasparrow programme was established by a Memorandum of Understanding in 1968 between Denmark, Italy, Norway and the US. Belgium and The Netherlands joined in 1970, the Federal Republic of Germany in 1977, and Canada and Greece acceded in 1982.

The contract definition phase began in 1968 and in 1969 Raytheon Company was awarded a $23 million prime contract for engineering and development, requiring the production of three engineering and development systems. One system was to be tested by the US Navy, one sent to Norway for operational

JVC package is attached to tail of AIM/RIM-7M Seasparrow missile to provide for initial tip-over after vertical launch. 15·8 kg package contains strapdown inertial reference system, digital microprocessor, independently operated vanes and self-contained actuator system

Vertical Launch of Seasparrow from HMCS Huron

environment testing, and one remained at Raytheon for systems evaluation.

The first successful shipborne launch took place in March 1972 when a NSSMS on the frigate USS Downes (FF 1070) acquired and tracked an incoming target and successfully fired its missile. Another prototype Seasparrow System was installed on the Royal Norwegian Navy ship KNM Bergen (F-301) in 1973.

NSSMS entered full scale production in 1973 as a co-operative effort by the US and other NATO countries – Belgium, Denmark, Italy, The Netherlands and Norway. The US is expected to purchase approximately half of all systems produced. At autumn 1983, 111 systems had been installed with a total of 143 systems being ordered worldwide. Of this total, 87 systems are for the US aboard CV/CVN, DD, AOE and AOR class ships.

All NATO ships which will have NSSMS installations are frigates. Three NATO countries use the full system similar to the US configuration. Denmark has dual director systems in five frigates and a single director system at a land-based site. Italy has single director systems in four frigates. Norway has a single director in five frigates and one land-based site.

Five other NATO countries use the NSSMS launcher, transmitter and Seasparrow missile, but with their own fire control systems: Belgium has four. Greece with two, The Netherlands will have 14 plus one land-based site. The Federal Republic of Germany will have six plus two land-based sites, and Turkey will have four.

Japan (five systems) and Spain (four systems) have also purchased NSSMS.

Seasparrow, Guided Missile Vertical Launch System (GMVLS)

The Raytheon Company was awarded a contract in 1983 to supply the Seasparrow Vertical Launch Missile Systems for the Canadian Patrol Frigates programme. The first ship of this new class, which is scheduled for delivery in 1988, will carry 16 Vertical Launch Seasparrow cells.

Vertical Launch Seasparrow was demonstrated aboard the Canadian destroyer HMCS Huron with the successful interception of missile targets during a joint at-sea test in 1981 (**2036.231** in the 1983-84 Edition).

The vertically launched AIM/RIM-7M Seasparrow missile is modified with the addition of a Jet Vane Control (JVC) unit. The JVC provides for initial missile tip-over, orientation, and course control after vertical launch prior to the normal Sparrow guidance control. The GMVLS vertically mounted missile launching canisters are designed to function as the transport and storage units as well as the launch cells.

STATUS

In production.

The AIM/RIM-7M, developed by Raytheon Company, completed a full-scale development test in 1982 and is now in full rate production, with total production awards of 3400 missiles. This missile system entered the US Navy inventory in 1983. RIM-7M deliveries to NATO countries also began in 1983.

In 1982 General Dynamics was awarded a second source contract for the production of 690 AIM/RIM-7M missiles. General Dynamics missile deliveries are expected to begin during mid 1984.

Under a $76 million contract awarded to Raytheon in early 1984 the company is to supply Seasparrow VLS missile systems and AN/SPS-49 long range surveillance radars for the Canadian Patrol Frigate programme. In addition Raytheon is to receive a $16 million contract for modifications to the RIM-7M Seasparrow missile. Both contracts were issued by Paramax Electronics Inc, of Canada, a division of Sperry responsible for integrating the combat systems aboard the Canadian vessels. First ship of the new class is due for delivery in 1988.

3616.231

GOALKEEPER NAVAL AIR DEFENCE SYSTEM

The Goalkeeper naval air defence system is an autonomous ('stand alone') radar-directed automatic weapon system developed for use aboard the Royal Netherlands Navy's 'Kortenaer' class frigates for their defence at short range against high speed missiles and aircraft. The system has been developed under contract to the Royal Netherlands Navy by Hollandse Signaalapparaten BV (Signaal) in the Netherlands and the General Electric Company (GE) in the United States.

The system has all its elements integrated on a single mount and consists of a surveillance radar, a dual-frequency tracking radar, fire control and a high rate-of-fire seven-barrel GAU-8/A 30 mm Gatling gun. Operation of the Goalkeeper system is completely automatic from target detection to target destruction, termination of firing and engagement of the next target.

For the surveillance radar Goalkeeper uses an X-band (3 cm) high power, pulse-to-pulse coherent search radar to provide a high detection probability of small targets in all weather conditions and under ECM conditions. A synthesizer-driven travelling wave tube transmitter is used to provide high power for burn-through and to permit flexibility in frequency and PRF to counteract jamming. A 30 or 60° vertical beamwidth antenna is fully stabilised in two modes to ensure detection and track information is obtained independent of the ship's movements. The antenna has a rotation rate of 60 rpm. Detection probability is further enhanced by the application of processing techniques such as digital pulse compression and fast Fourier transformation. Digital moving target detection is used to cope with clutter conditions and further ECCM features include PRF stagger and frequency diversity. Dual receiver channels are used to speed processing, plot extraction, track build-up, threat evaluation and target selection, followed immediately by priority target designation indication for the tracking radar and weapon. Continuous search allows rapid engagement of any subsequent targets.

Goalkeeper naval air defence system with GE 30 mm GAU-8/A Gatling gun and Signaal radars combined on a single mounting

After target designation the target is acquired by the dual frequency (X- and Ka-band) tracking radar. The broad X-band beam provides fast target acquisition. The narrow Ka-band beam provides accurate and continuous track data down to very low altitudes and continuous automatic comparison is made of the signal to noise ratios of the X- and Ka-band returns to maintain tracking in clutter or degraded conditions. This system has been tested against missile targets flying as low as 5 m. Digital processing including curved path prediction, is used to predict the hit point and automatic calibration and closed-loop hit point correction are used to compensate for bias errors and inaccurate ballistic data. There is an automatic kill assessment subsystem for use in multiple attacks and the tracking radar has the ability to engage high-elevation targets.

The 30 mm GAU-8/A gun has a rate of fire of 4200 rounds per minute. It and the prototype EX-83 naval mounting are described in entry **4042.203** in the Naval Guns section. The Goalkeeper mount has an ammunition capacity of 1190 rounds carried in a linkless system using a feed and storage drum. To reload the gun system a bulk loading system is employed but manual loading is possible using a manual loading tray. Spent cases are returned to the drum to prevent deck debris after firing. The ammunition capacity is stated to be sufficient for several target engagements before reloading is necessary. The feed drum and much of the ammunition feed system is protected below deck. Produced by NWM de Kruithoorn in collaboration with Armatechnica Corporation of Santa Barbara, California, is an APDS round for use with Goalkeeper. For soft targets HEI will be used and a TP round is available. The APDS round has a high density tunsten alloy penetrator.

Using computer modelling, extensive simulations of Goalkeeper performance will be carried out by Signaal, using simulated targets with armour-protected warheads. Based on the results of these simulations supersonic targets have been destroyed at a range of 500 m with the immediately following target being destroyed at a range of 400 m.

CHARACTERISTICS

Gun type: 30 mm Gatling-type GAU-8/A, seven barrels
Muzzle velocity: 1021 m/s TP, HEI; 1150 m/s APDS
Rate of fire: 4200 rounds/minute
Feed system: Linkless, 1190 rounds capacity
Ammunition: APDS, HEI, TP
Weight: 6730 kg (all-up with 1190 rounds)
Elevation/depression: +85/-25°
Radar (search): X-band
Antenna: Slotted waveguide, 2050 × 250 mm
Beamwidth: 1·5° (horizontal); 30 or 60° (vertical)
Stabilisation: 2-axis
Rotation speed: 60 rpm
SLS antenna: Omni-directional
Radar (tracking): Dual frequency, X-/Ka-band
Antenna, Cassegrain: 1000 mm diameter
TV camera: Compatible with CCIR Type B

STATUS

Demonstrations of the GE EX-83 prototype gun and mount for the Goalkeeper were carried out in the Netherlands at Erfprins Naval Base, at least 80 NATO observers attending firings against sleeve targets in November 1979. In December 1980 the Royal Netherlands Navy and Signaal signed a contract for one prototype and two pre-production systems. Further Goalkeeper fittings are planned for both the 'S' and 'M' frigates of the Royal Netherlands Navy.

Ordered for Royal Navy in early 1984.

CONTRACTORS

General Electric Company, Armament Systems Department, Lakeside Avenue, Burlington, Vermont 05402, USA.

Hollandse Signaalapparaten BV, PO Box 42, 7750 GD Hengelo, Netherlands.

4016.231

SEAGUARD CIWS

Seaguard CIWS (close-in weapon system) is one configuration of the modular Seaguard naval equipment range (**3509.281**) and consists essentially of a dedicated search radar (**4004.253** in 1982-83 and earlier edition) and fire control modules integrated with the Sea Zenith 25 mm multiple-barrelled gun module (**4017.203**). The main elements are an above-deck search radar antenna, an above-deck sensor mount, a gun mount with below-deck ammunition feed, below-deck operator console and associated below-deck electronic cabinets.

The search radar element of the CIWS is the Plessey Dolphin dual beam, C band radar (**4004.253** in 1982-83 and earlier edition) designed to provide target indication of sea-skimming and high diving missiles in severe environmental and ECM conditions. The 'fire control' element of the CIWS, the tracker module (CIWS-TM), uses a three-axis tracker mount having Ku-band radar, forward looking infra-

red (FLIR) and laser sensors for the acquisition and tracking of missile targets. The Ku-band radar includes a patented mirror effect suppression technique. This radar together with the FLIR and laser are intimately combined with specialised and innovative signal processing and advanced control algorithms into a missile target tracking system which can adaptively counteract the disturbances of the mirror effect and the effects of bad weather as well as those arising from severe ECM. The naval three-axis sensor and gun mounts each have a wide dynamic performance range appropriate for defence systems intended to defeat sea-skimming and diving anti-ship missiles. A valuable feature of the three-axis mounting technique is its ability to provide hemispherical cover which includes the 'zenith cone'.

The gun element of the CIWS, the gun module (CIWS-GM) is a four-barrelled 25 mm gun mount (**4017.203**). Each gun is independently fed from below decks where sufficient on-mount ammunition is available to engage 18 targets without reloading. A unique feature of the reload system is that of on-line replenishment of ammunition which can take place without interfering with the gun module availability for firing, and indeed it may be replenished during firing. The axis configuration of the gun mount allows an elevation range of −15 to +127° for hemispherical engagement coverage.

The kill-mechanism relied upon is based on a single hit detonating the warhead and resulting in a single-round kill. This is achieved by the use of AMDS with a non-exotic material as the sub-calibre penetrator. The high energy level required to achieve this ultimate kill mechanism results from an ammunition development programme by Oerlikon where the boundaries of ordnance technology have been considerably advanced. A full range of other ammunition types may be used according to target or usage requirements. The overall kill probability of the Seaguard CIWS has been assessed as greater than 90 per cent against a single missile whose terminal trajectory may be from 0° (sea-skimmer) to 90° (zenith threat) with a speed of up to Mach 3. Additionally this performance is valid when evasive or pre-programmed manoeuvres are superimposed upon the basic terminal approach, and engagements can be continued at extremely close-in ranges against targets with speeds of up to 900 m/s by both the tracking and gun mount modules.

DEVELOPMENT

Development was initiated in 1978 as a joint private venture by Contraves and Oerlikon, with co-operation from other manufacturers in Switzerland, Italy, the UK and USA.

STATUS

In full series production following a contract from a West German shipyard for Seaguard systems to be fitted in four frigates under construction for the Turkish Navy. Other contracts were under negotiation in May 1985.

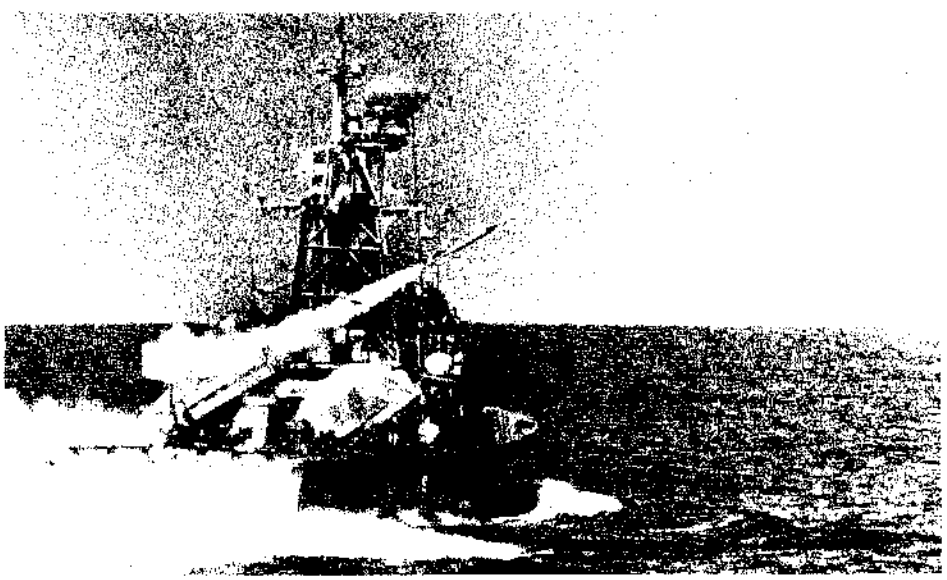
ISRAEL



4200.231

BARAK SHIP POINT DEFENCE SYSTEM

This is a joint development venture by Israel Aircraft Industries Ltd and Rafael Armament Development Authority for the Israel Defence Forces (IDF) to counter aircraft and missile attacks, including sea skimmers. Described as a compact modular lightweight system, Barak is capable of multiple target engagement under all weather conditions by day or night. It is comprised of a vertical launch unit above deck; search track and guidance radar on the mast and control units below deck.

The early development system comprised three main units: a deck launcher containing eight Rafael (the Israeli state armament development authority) point defence missiles (PDMs) on which was mounted an autonomous radar, a fire control console mounted below decks in the ship's combat information centre, and a processing unit. The radar on the launcher unit, in addition to pointing with the launcher, had its own rapid scanning capability. It was a dual-band radar with a single antenna providing both monopulse tracking and target illumination facilities. Eight missiles were carried on the launcher unit, each of these being supersonic and highly manoeuvrable and carrying a blast fragmentation warhead equipped with contact and proximity fuzes. Missile propulsion is by a solid-propellant rocket motor, and semi-active radar homing was used. The missile configuration incorporates cruciform wings and tail control surfaces, the former being positioned in the rear portion of the missile body, close to the tail fin leading edges. The eight-round launcher was provided with training and elevation facilities, and the radar moved in azimuth with the missile mount but had its own search scan pattern also.

This configuration was apparently dropped after sea trials which confirmed many of the design parameters, in favour of the current arrangement which is based on the use of vertical launch magazines and separate search and fire control sensors.

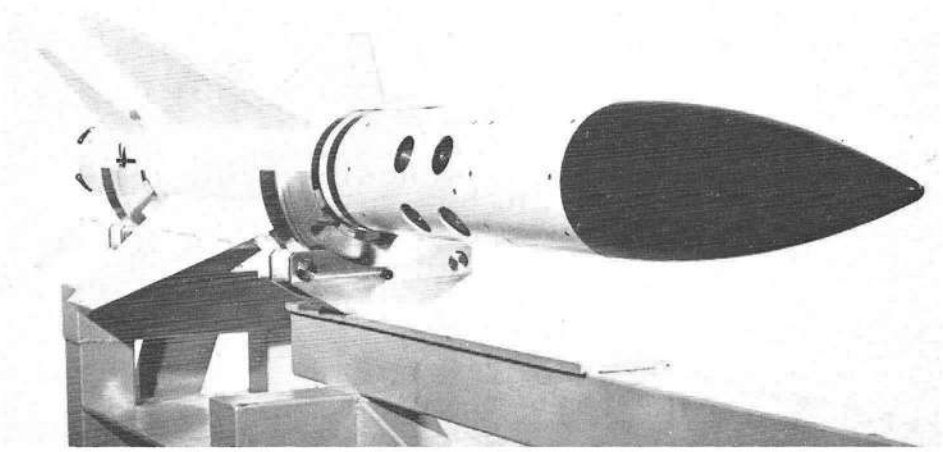
Barak point defence missile launch from early development model of the system aboard an Israeli ship. Current Barak uses vertical launch magazine(s)

Barak 1 is the latest version of this system and was publicly revealed for the first time at the 1983 Paris Air Show. It differs in configuration from the original Barak where target tracking and illuminating radar and missile launchers were combined on one mount, by adopting the latest vertical launch technique for the missiles and siting the guidance radars higher up on the ship's superstructure. Apparently, the PDM is virtually unchanged, apart from modifications to produce the necessary pitch-over movement when clear of the launching ship toward the target.

Vertical launch units (VLUs) containing up to eight missiles each can be fitted anywhere on the vessel to provide a total of 32 missiles per Barak 1 system, operated from a single below-deck console.

Missile range is about 10 km and both aircraft and anti-ship missile targets can be engaged within 360° in azimuth and between −25 and +85° elevation.

A large warhead (about 22 kg) is fitted, complemented by a sophisticated adaptive proximity fuze system. Flight control of the missile appears to be by a combination of moving tail surfaces which operate aerodynamically and four vanes mounted internally in the rocket motor efflux, the latter probably being necessary to accomplish the initial pitch-over movement as well as assisting in missile manoeuvrability overall. The aerodynamic tail controls are probably necessary to ensure missile control after rocket motor burn while the missile is 'coasting'. A complete PDM round weighs about



85 kg. One VLU with eight missiles weighs 1300 kg and the radar and fire control gear accounts for a similar weight.

STATUS

By May 1984 there had been several successful firings of the vertical launch system and it was understood that presentations had been made to a number of potential users of Barak. A land-based version of the system is under study, known as ADAMS (Air Defence Advanced Missile System.)

4563.231

TCM 30 NAVAL AIR DEFENCE SYSTEM

The MBT Weapon System plant, part of the Electronics Division, Israel Aircraft Industries Ltd include among its range of air defence products a version of the Spider AA gun-based air defence system that is intended for use aboard ships of all sizes. The principal weapon employed is the TCM-30G twin 30 mm gun mount (**3729.203**), and up to six of these mounts are combined with a search radar, an optical sight, a tracker-director unit, and control consoles to consititute a flexible autonomous naval version of the Spider II land-based air defence system (**4508.131**). The twin 30 mm gun mount is incorporated in an electrically driven turret, the two automatic cannon and their feed systems being carried on a high angular acceleration slewing and elevating mounting.

Twin 30 mm automatic cannon on TCM-30G mount as used in naval air defence system

It is probable that combined installations have been designed in which both TCM-30G turrets and Barak point defence missiles (**4200.231**) are integrated to form a single ship's air defence system. It is also likely that the recently introduced Elta automatic missile detection radar (AMDR) will make an appearance in combination with either or both the gun and missile naval point defence systems. The AMDR is a shipborne radar designed to automatically detect incoming sea-skimming missiles in addition to the normal function of air surveillance with automatic detection and track-while-scan facilities. This will provide rapid and reliable automatic alarm of incoming missiles; automatic detection and tracking of all high speed targets; threat evaluation, designation and data transmission to other defensive systems, such as a ship's ESM and command and control.

STATUS

No firm information on fittings has been received, but it is believed that certain vessels of the 'Saar 4·5' and 'Saar 5' classes and the 'Flagstaff 2' class hydrofoils are fitted with the TCM-30G twin 30 mm guns. No details of export sales have been disclosed.

ALBATROS NAVAL DEFENCE SYSTEM

The Albatros weapon system design is based on the concept of combining the air defence potential of a medium range surface-to-air missile with the fire power of conventional gun armaments. The Albatros system makes use of the Aspide missile (**1656.331**) and can be fitted to integrate with various gunfire control systems. The resultant ship's anti-air defence capability is greatly enhanced owing to the wide coverage envelope and high kill probability of the missile, while retaining all conventional gunfire roles. Missile performance contributes to an all-weather capability against anti-ship missiles of either sea-skimming or 'diving' types.

The Albatros missile system consists of:

(a) Missile guidance
(b) Missile launching
(c) Missile magazine
(d) Aspide missiles.

Riva-Calzoni 16-cell missile magazine for Albatros system

Details of inter-relationships with the gunfire control section are illustrated in **1551.281** under the Naval Fire Control and Action Data Automation section. Missile guidance is by semi-active radar homing and the missile path to the target is a collision course with proportional navigation. Target illumination for missile homing is provided by the missile guidance section.

The missile launching section comprises either the standard eight-cell or a four-cell launcher so as to meet different operational and installation requirements. The eight-cell missile launcher is a self-contained mount manufactured by OTO-Melara and utilising the same power driver as the 76/62 compact gun mount. The four-cell launcher is a compact unit on which four separate canisters are mounted. Each canister is used both as container, for missile handling, and as a launching cell. A missile magazine, allowing for storage and reloading at sea, is associated with the eight-cell launcher on request. Storage and reload of canisters for the four-cell launcher is implemented by means of standard shipborne facilities.

A missile magazine, allowing for storage and reloading at sea, is associated with the eight-cell launcher on request. This magazine (manufactured by Riva Calzoni) is a 16-cell unit and can be installed below or behind the Albatros launcher; the magazine is hydraulically operated and allows for fast loading and unloading of missiles even in a severe sea environment.

The missile launching section can be associated with either a single or a double missile guidance section (Type 1/1/ or Type 2/1 respectively). The latter configuration involves the use of two directors and enables launcher sequential assignment to either director so that two distinct targets, respectively

Albatros 4-cell canister launcher on corvette

tracked by the relevant director, can be simultaneously engaged by missiles.

STATUS

The Albatros missile system was designed and developed by Selenia under contract from the Italian MoD (Navy) in the early 1970s. The first of class Albatros Mk 1 Mod 1 system, for which the missile section was fitted to integrate with an Elsag GFCS, underwent an extensive series of operational trials aboard the Italian Navy ship *Aviere*, successfully completed in 1973.

The latest version of the system, Albatros Mk 2 is now in series production and first trials, in an Italian Navy 'Maestrale' frigate, were successfully carried out in October-November, 1983. This series of trials were to verify missile intercept capability at the extremes of the missile performance envelope, and overall capability was demonstrated against a Rushton sea-skimming target. To date, 15 countries have adopted the Albatros weapon system and it was revealed that the Japanese Navy had signed a contract with Selenia for the supply of equipment and manufacturing know-how for licence production in Japan of the complete missile launching system.

In January 1985 it was stated that Thailand had decided to procure Aspide missiles to arm two new corvettes to enter service in 1986.

DARDO CLOSE-IN WEAPON SYSTEM

The Dardo system, specifically dedicated to close range anti-missile defence, has been designed and developed by Elettronica San Giorgio - ELSAG, in collaboration with Selenia. Its prime purpose is to counter effectively high speed, late detection attacks requiring very rapid response, and especially attacks by sea skimming missiles, missiles with a diving attack profile, and aircraft launching rockets and missiles.

Typical Dardo CIWS shipboard installation with 4OL70 gun and Orion 20X fire control radar with on-mounted TV camera

Thanks to a direct electronic link with the ship's own main surveillance radar, the Dardo system can operate without human intervention as soon as it is triggered by the detection of a fast low flying target. Manual operation, as a conventional FCS, is also possible. Specifically, the Dardo system carries out automatically the following functions:

(1) correlation of successive target echoes to plot the flight trajectories
(2) assignation of a priority index, continuously updated, based on time remaining to reach own ship, of a significant number of threatening targets
(3) selection of the most threatening target
(4) auto-designation of the target to the system tracking radar
(5) automatic acquisition and tracking initiation
(6) automatic opening of fire at the maximum effective firing range permitted by the tactical situation
(7) auto-spotting on the burst of rounds fired.

The tracking radar, a Selenia Orion RTN 20X (**1935.253**), has an X-band monopulse antenna, employing a coherent MTI, with frequency agility and staggered PRF. A TV camera is mounted on the same tracker pedestal, which is normally installed in a location remote from the gun.

The Selenia Orion RTN 20X is a modern X-band radar mounted separately from the gun and performs the following functions: automatic acquisition of very low flying and fast targets; autonomous detection of targets at low elevation with a 'guard ring' for target lock-on; automatic target tracking; effective reduction of the 'image effect'; auto-spotting of the burst of rounds fired.

These functions are performed despite clutter and or a hostile ECM environment thanks to: an X-band monopulse antenna system; employment of a coherent MTI for fixed echo cancellation; high PRF; frequency agility and staggered PRF; digital processing of the video inputs.

The data processing and interfacing unit includes a digital computer, specially adapted to fire control problems with special fixed routines; an interfacing electronic module assembly to link the processing section to the peripherals; and a full range of system ON/OFF line test facilities.

This unit is directly connected to the ship's surveillance radar, processes the information received, evaluates the threats and performs a decision on which target is to be engaged.

A supervision console, which also allows the operator to carry out a manually assisted firing, is associated with the system for control and supervision of correct operation.

STATUS

In series production and operational with the Italian and several other Navies.

CONTRACTOR

Selenia-Elsag Consortium for Naval Systems, Via Panama 52, 00198 Rome, Italy.

SPAIN

4564.231

MEROKA NAVAL CIWS

Meroka is the name of a novel type of close-in air defence weapon system that has been under development for a number of years by the Spanish authorities. Both land-based and naval versions have been designed; the former is described in entry **3208.131** in the mobile guns and rocket systems section of this volume. Some of the background to the programme has appeared under that entry number in previous editions.

The weapon used in both versions is a twelve-barrelled arrangement of 20 mm/120 calibre Oerlikon machine cannons, grouped together in two horizontal rows of six. A salvo of 12 rounds can be fired in a time of 0·08 seconds, which amounts to a theoretical rate of fire of 9000 rounds/minute. The main purpose of this high rate is less the delivery of a large total of projectiles on to a target but more to meet a need for maximum density of fire when engaging certain categories of air targets such as low-flying ground attack aircraft and sea-skimming anti-ship missiles in the naval application. The normal practice is for each salvo to be fired as four groups of three rounds, minimising the total recoil force applied to the mount as well as having other beneficial operating characteristics.

The group of 12 barrels forms a single rigid unit which is traversed and elevated as a conventional gun, mechanical rigidity being aided by a number of steel bands (two in the army version, four in the naval version) that determine the spacing between the individual barrels. This feature is also used to adjust the dispersion of fire and fire pattern. Ammunition is brought to the 12 guns by two belt feeds which are supplied from an hydraulically powered rotating magazine with a capacity of 720 rounds. Elevation limits are -20 to +85 degrees, and the gun can be traversed in azimuth through 360 degrees at a rate of 90 degrees/second.

The radar selected for target detection was the Selenia RAN-12L L-band search radar, a frequency-agile equipment with a range of about 15 km. Target assessment, threat evaluation and related functions are aided by a 16-bit miroprocessor, which can handle data for up to four Meroka turrets. Individual targets are designated to weapons which are automatically laid-on by direct links between the computer and the guns control systems.

The digital fire control system was designed by Lockheed Electronics who have been associated with the Meroka programme from a very early stage, and the antenna of that company's AN/PVS-2 doppler tracker radar (as used in land-based Phalanx air defence gun system) is mounted on top of the Meroka turret. This X-band radar will automatically track targets from a range of just over five km. A secondary line-of-sight for target tracking is provided by a General Electric low-light TV camera, boresighted to the gun axis. The latter can be used by an operator

using a joy-stick control for manual target tracking in an emergency.

CHARACTERISTICS

Search radar: RAN-12L
Tracking radar: AN/VPS-2
Optical system: GE low-light TV
Weapon: 12-barrel 20 mm Oerlikon
Barrel length: 2·4 m (120 cal)
Recoiling mass: 300 kg
Theoretical rate of fire: 9000 rounds/minute
Magazine capacity: 720 rounds
Elevation: -20 to +85°
Traverse: Unlimited 360°
Effective range: 3000+ m
Turret weight: 4·5 t

STATUS

In June 1985 it was reported that seven Meroka systems were in production, with a further 13 on order for 'Descubierta' and 'Baleares' class frigates. Of the first production batch of seven systems, three are for the new 'Santa Maria' class frigates, and four for the support carrier *Principe de Asturias*.

4546.231
RBS 70 SHIP LAUNCHED MISSILE SYSTEM (SLM)

The RBS 70 ship launched missile system is a recent proposal to adapt the well-established RBS 70 missile system for use on naval vessels. RBS 70 SLM is capable of combatting incoming aircraft at long range. The sight as used on the land-based RBS 70 (**2348.131**) has been retained, and gyro-stabilised optics have been added. The low weight and small dimensions of the system allow it to be fitted on very small vessels eg patrol boats and minesweepers.

During 1983, tests, arranged by the Swedish navy in collaboration with Bofors Ordnance Division, were carried out on a Swedish coastal minesweeper under varying weather conditions and included live firings. The firings took place with the vessel, an 'Arko' class coastal minesweeper, under way at normal speed. A prototype of the RBS 70 SLM installation was mounted on a platform above the large sweeping winches on the after deck.

The stand for the army version of RBS 70 has been replaced by one specially designed for naval use, and this is fitted directly to the deck. SLM can also be fitted on a fixed, or gyro-stabilised platform. Compared with the army version, SLM has a greatly increased resistance to cross-winds during the initial launching stage.

The system has been provided with firing limits which prevent the missile being launched on a course which would endanger the vessel or its crew. SLM is operated by one man who sits on the stand seat and operates the sight in exactly the same way as the army version. Reloading can be carried out either by the operator or a member of the ship's crew. The operator receives information on incoming targets from a suitably placed look-out.

CHARACTERISTICS

Range: 5 000 m
Height coverage: 3 000 m

A recent test firing by the Swedish Navy of the RBS Ray Rider missile

Reloading time: Up to 20 s
Time from target detection to launch: From 5 s
IFF: Optional

STATUS

Prototype tested and ready for production by early 1984.

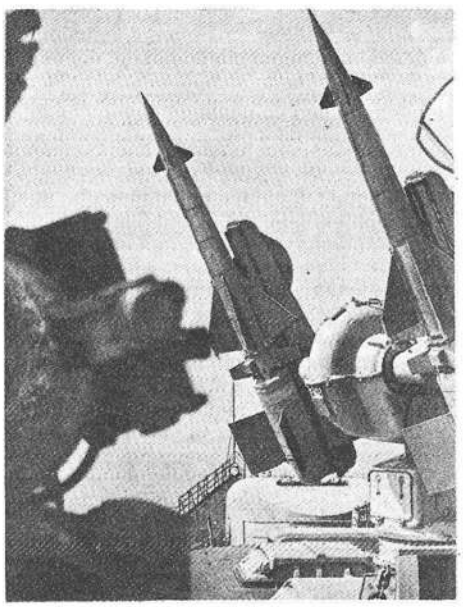
UNION OF SOVIET SOCIALIST REPUBLICS

2939.231
GOA SHIPBORNE SURFACE-TO-AIR MISSILE (SA-N-1)

Known also by the US alpha-numeric code SA-N-1, the missile, whose NATO code-name is Goa, was for many years the principal surface-to-air missile of the Soviet Navy. It is fitted to the 'Kanin', 'Kashin', 'Kotlin', 'Kresta', and 'Kynda' classes on scales ranging from one to four twin launchers.

The shipborne Goa missile is assumed to be identical with the ground-to-air missile (**2938.131**) but the equipment associated with it is very different. The standard launcher is clearly roll-stabilised as can be seen from the accompanying illustration. Rather different, and not obviously stabilised, launchers have also been observed, but these are most probably not for Goa. The launcher is mounted on top of the missile magazine and is reloaded vertically through small hatches.

Associated with the missile in all installations is a compound radar system known by the NATO code-name Peel Group (**1323.253**) and described in the Naval Radar section. Guidance is probably by radio command.

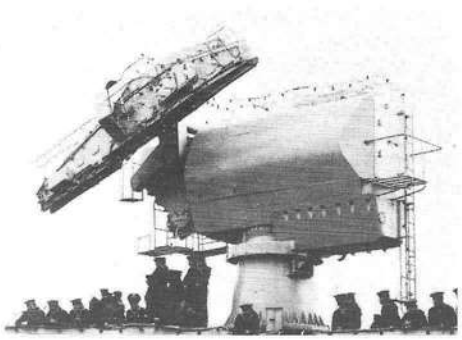


There is, of course, no definite information on Goa's performance but it is generally taken to have a maximum slant range of about 15 km and a ceiling of some 12 000 m. Length is estimated at about 5·9 m and the maximum span at 1·2 m. A moderately sized HE warhead of about 70 kg is thought to be carried.

STATUS

Entry into service with the Soviet Fleet was in 1961-62. There are single systems on each of eight SAM 'Kotlin' class, eight 'Kanin' class, and four 'Kynda' class ships, while 19 'Kashin' class, and four 'Kresta I' class vessels each have two twin launcher installations. One Polish, ex-Soviet 'Kotlin' class, ship is fitted with Goa.

Twin launcher for SA-N-1 Goa on 'Kotlin'-class ship (G. Jacobs)



Goa naval air defence missiles in firing position

2943.231
GUIDELINE SHIPBORNE SURFACE-TO-AIR MISSILE (SA-N-2)

Guideline, also known, in its shipborne application, by the US alpha-numeric code SA-N-2, has been installed in only one Soviet ship, so far as is known at present, the cruiser *Dzerzhinski*.

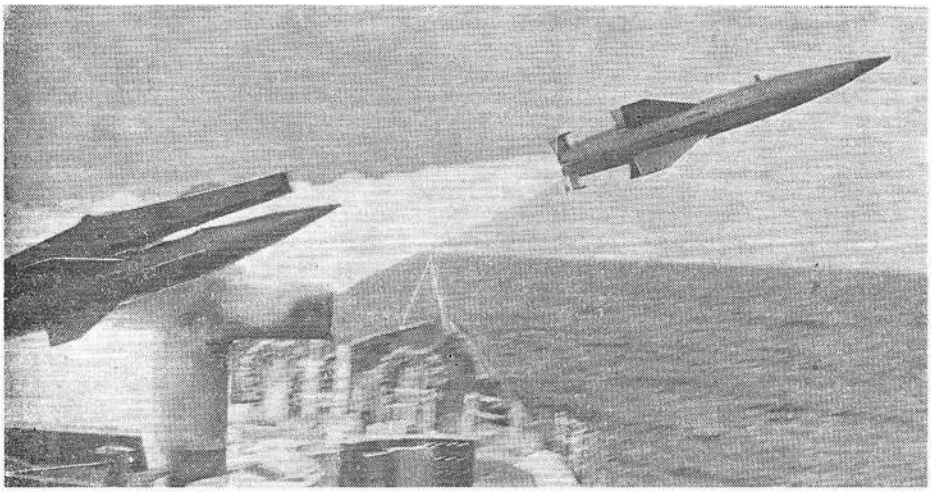
It has been suggested that one reason for this is the difficulty of providing suitable stable platforms on smaller vessels for the flapping Fan Song (**2866.153**) radars used to guide these missiles. It could also be that the relative difficulty that there appears to be in gathering these missiles to the required flight path presents even more of a problem in shipborne installations than it does on the ground.

So far as is known the general performance of Guideline as a shipborne missile is substantially the same as that described in the entry for the ground-based version.

Close-up of the massive twin launcher for SA-N-2 Guideline on Dzerzhinski (G. Jacobs)

2947.231
GOBLET SHIPBORNE SURFACE-TO-AIR MISSILE (SA-N-3)

The helicopter-carrier *Moskva* and the 'Kresta II' class cruisers were the first ships of the Soviet Navy to be seen equipped with a new surface-to-air missile that is similar in size to Goa (**2939.231**) but possibly larger and certainly launched from a different launcher and directed by a different radar complex. It has since appeared on other classes.



Although there was confusion concerning this missile it now seems to be agreed that it is that classified in the American code as SA-N-3; it is also widely believed – without, of course, any official confirmation – that its NATO code-name is Goblet.

The launcher, illustrated here, does not appear to be roll-stabilised – suggesting that the missile gathering is efficient. The missile is of conventional configuration (see photograph) and is about six metres long, weighing approximately 540 kg. A conventional high explosive warhead of about 40 kg (other estimates, however, suggest a figure of over 200 kg) is carried and the missile is powered by a two-stage solid-propellant rocket motor. Command guidance is employed, and the associated radar fire control group has the NATO code 'Head Light' (**1328.253**). The early version, aboard 'Moskva', 'Kresta III' and 'Kara' classes, has a range of 30 km and can intercept targets at between 150 and 25 000 m. The SA-N-3 missile has been credited with a maximum speed of over Mach 3.

The four reload hatches associated with the Goblet launcher are generally accepted as indicating that the launcher is a dual-purpose device and that the magazine below deck contains both Goblet, SA-N-3, anti-aircraft missiles and possibly SS-N-14 anti-submarine weapons also.

STATUS

The SA-N-3 Goblet air defence missile system entered service in 1967, and it is fitted in ships of the 'Kiev' and 'Moskva' classes of aircraft carrier, and 'Kara' and 'Kresta II' classes of cruiser.

SA-N-3 Goblet air defence missile firing, with another round on the ramp

2954.231
SA-N-4 SHIPBORNE SURFACE-TO-AIR-MISSILE

Since its appearance and entry into operational service in the 1970s, the SA-N-4 naval surface-to-air system has generally become accepted as the Red Fleet's standard close-in air defence weapon system, fitted as it is to about 120 ships of various classes.

The system quickly became noted for its drum-shaped container magazine/launcher mounting with its 'pop-up' twin ramp launcher, and the associated radar group that earned itself the NATO reporting name Pop Group (**1897.253**). Later analysis of the container credits it with a capacity of 20 reload missiles disposed circularly around the periphery of the inner wall of the silo, from whence they are fed to the arms of the retracted launcher ramp which descends into the silo for reloading during an engagement, and stowage at other times.

The estimated dimensions of the silo are height five metres and the diameter about 2·9 metres. At its centre is assumed to be a hydraulic ramp with the two-ramp launcher at its upper end, the arms of which can be elevated through an elevation arc that allows them to be locked in a vertical position for lowering into the silo for stowage or reloading. The traverse arc of the launcher is a full 360 degrees, and this also is assumed to be hydraulically driven. The silo is provided with a flat cover plate in two sections that slide apart to allow the launcher to rise to the firing position. The cover plates close before firing takes place.

The SA-N-4 missile itself is estimated to be about 3·2 metres long with cruciform guidance fins near the nose and four stub stabiliser/wings near the rear. Propulsion is by solid fuel rocket motor, which gives an estimated maximum speed of around Mach 2·5 and a probable maximum range of between 9 and 12 km. Launch weight is assumed to be in the region of 185 kg. The similarities between the SA-N-4 and the SA-8 Gecko land-based SAM have been noted by western observers from an early stage in the history of

SA-N-4 launcher in ready to fire position with missiles on ramp

the naval weapon, and it is now generally accepted that in all probability the land-based and naval weapons are two versions of the same system. The similarity extends to the associated radar groups of the SA-N-4 and Gecko versions which tends to corroborate the supposition that the two systems have common origins.

STATUS

Operational since the early 1970s and fitted in a wide variety of ship classes over a relatively long period. Major classes, such as the 'Kiev', 'Kirov', 'Slava' and 'Kara' aircraft carrier and cruiser classes are each fitted with two SA-N-4 silos equipped with a total of 40 rounds per ship, and the numerous 'Krivak' destroyers have the same size of SA-N-4 installation. Still more numerous are the 'Grisha' I and II and 'Nanuchka' light missile craft all of which have single silos with 20 rounds. The system is also used to provide air defence for certain important vessels such as the replenishment ship 'Berezina', and the two amphibious warfare ships of the 'Ivan Rogov' class.

Soviet 'Kara'-class cruiser, Petropavlovsk *is seen here with the starboard twin-ramp SA-N-4 surface-to-air missile launcher raised from its silo abreast of the main-mast structure. Associated Pop Group radar is immediately aft of SA-N-4 launcher: note shield to protect radar from blast from missile exhaust at launch. Picture also shows aft SA-N-3 SAM system for longer range air defence, anti-submarine helicopter landing pad and hangar, two quintuple torpedo tubes, and two of the four 30 mm gatling-type guns for close-in air defence.* (G. Jacobs)

4201.231

SA-N-5 SURFACE-TO-AIR MISSILE

SA-N-5 is the designation allocated to the naval version of the man-portable anti-aircraft missile SA-7, Grail, (**2941.131**). For use aboard ships the four-round multiple version, which has been seen also on certain vehicles of the Warsaw Pact states, is employed. It is a relatively simple conversion of the original man-portable battlefield weapon, basically consisting of a framework on which four Grail rocket launcher tubes can be fixed side-by-side and supported on a central pedestal which permits the gunner to slew and train the missiles manually. Performance of the missile is likely to be substantially the same as in land-based use, although the task of manually acquiring the target and aiming the weapon cannot have been made any easier for the operator by being mounted on a platform subject to sea motion as well as the ship's own course changes during any engagement.

Nevertheless its potential as a deterrent to close investigation by hostile air forces (especially helicopters), is probably well worth the modest cost of such fittings.

STATUS

Now very extensively fitted in a wide variety of ship classes. Our companion volume *Jane's Fighting Ships* reports at least 169 Soviet vessels fitted with SA-N-5 installations that consist of one, two, three or four quadruple launchers for the system, although fittings of two quadruple launchers per ship are most common.

The most numerous classes of vessel fitted with this system are those built for amphibious operations, such as the 'Ropucha' class (17 ships) some of which have four quadruple mountings, the 'Alligator' class (14) with two or three twin mountings, 'Polnochny' ships (14) with two or four quad mountings, and the two 'Ivan Rogov' ships which each have two quad SA-N-5 mountings in addition to their SA-N-4 missile silos. Intelligence gathering vessels of many types have been given SA-N-5 installations for their protection; such ships include those of the 'Balzam', 'Primorye', 'Nikolay Zubov', modified 'Pamir', 'Moma', 'Mirny', 'Mayak', and 'Okean' classes. Most of these have two quadruple mountings and between them these classes amount to a total of between 40 and 50 ships.

Other important vessels with SA-N-5 systems are seven 'Ugra' submarine support ships (some with two quad mountings) and 'Lama' class (seven vessels) missile support ships with either four or two quad mountings. Certain light missile craft, such as the 'Tarantul' and 'Pauk' classes are equipped with SA-N-5 mountings also.

Soviet battle cruiser Kirov *shows the varied range of sensors available for use in detecting targets for the SA-N-6 air defence missile system. Top Pair and Top Steer radar groups high on the superstructure give early warning of air targets, while the Top Dome radar director groups (fore and aft) track both target and missile* (Royal Navy)

4206.231

SA-N-6 SURFACE-TO-AIR MISSILE SYSTEM

SA-N-6 is the designation assigned to the vertically launched naval air defence missile system first reported aboard the Soviet cruiser *Kirov*, commissioned in July 1980, and since noted in the cruiser *Frunze* of the same class and the smaller 'Slava' class cruisers. There are no known photographs of the actual missile but it is generally

supposed to be a naval version of the land-based SA-10 air defence system (**3620.131**), in which case a length in the region of seven metres overall is likely. In the land-based role this missile is reported to be deployed in both semi-permanent and mobile versions. Official US drawings of the latter model suggest that the SA-10 is launched from tubular canisters carried on a transporter/erector/launcher vehicle.

From photographs that have been obtained of the SA-N-6-fitted ships mentioned above, it appears that two kinds of launching arrangements have been devised: The original *Kirov* installation was noted for its array of 12 hatches covering the vertical launchers on the ship's foredeck, immediately forward of the broadly similar (but larger) set of 20 hatches for the SS-N-19 surface-to-surface missiles that arm *Kirov*. The SA-N-6 hatch covers are rectangular in shape and give little indication of the arrangements for firing, loading, replenishing and reloading below deck. However, the 'Slava'-class ships which made their appearance somewhat later have a different arrangement for the eight SA-N-6 launcher units that are located abaft the funnels of these ships. In two rows of four running fore-and-aft, these have the appearance of eight sets of eight vertical tubes arranged in a circle, with each set having what could be an external hatch lifting mechanism, pivoted in the centre of the eight tubes and able to be located over each tube. This mechanism might also be connected with replenishing the magazine of each group of eight tubes.

The 'Kirov'-class ships are also assumed to have eight rounds per launcher, so that the scale of deployment on this basis gives the larger (Kirov) class 96 missiles per ship, and 'Slava'-class vessels 64.

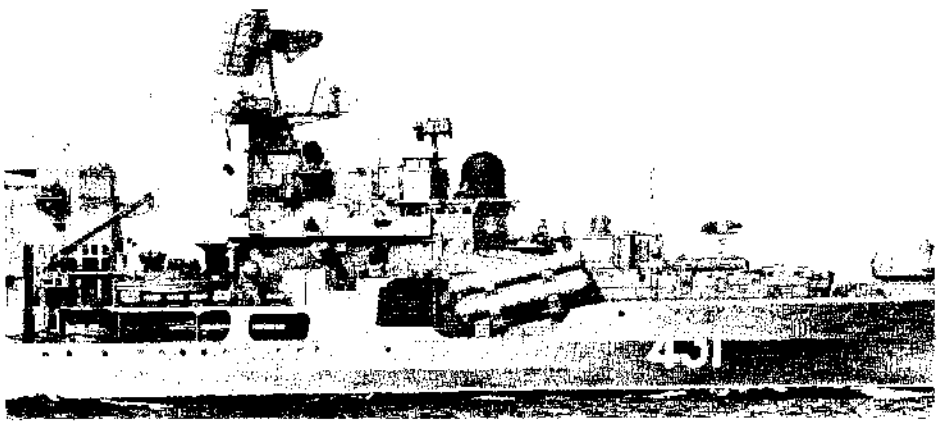
Other external evidence that presents itself in photographs of ships with this system are the Top Dome radar director group (**4088.253**) (two in 'Kirov' class ships, one in 'Slava' class) and various other types of sensor that may play a part in the operational use of the SA-N-6 system. The latter include both passive and active types, some of which undoubtedly provide target detection and designation services for the air defence fire control system. Interpretation of such details is assisted if some assumptions are made concerning the likely operational role of the SA-N-6 system. While by no means necessarily inspired by the American Aegis naval area air defence system (**2507.231**), it is a reasonable guess that the Soviet requirement was for a system to meet a very similar potential threat environment. This envisages aircraft, aircraft-launched anti-ship missiles, stand-off jamming aircraft, reconnaissance aircraft, and anti-ship missiles launched by both surface vessels and submarines. All-round hemispherical cover is required out to long ranges with a multiple target detection and tracking capability, coupled with high resistance to ECM and jamming. In the Aegis system, the missiles are equipped with mid-course guidance and terminal homing facilities, and these may be expected in the Soviet SA-N-6. Other characteristics of the latter which have been estimated include an operating ceiling of at least 30 000 m, a range of up to 60 km at a speed of Mach 6, carrying a 90 kg warhead, and a missile length of about 7 m. We have received no information which causes us to disagree violently with these estimates at present, with the single proviso that the range claimed seems on the low side and may well prove to be appreciably greater when more is known of the SA-N-6. Also, at least one respected authority has revised the estimated maximum missile speed downwards to Mach 3.

Certain aspects of the numerous sensors fitted on the *Kirov*'s superstructure suggest various other possibilities relating to the SA-N-6. Target detection is technically possible by a wide selection of sensors: the Top Pair (**4087.253**) and Top Steer (**4086.253**) air search radar groups are capable of long range air target detection and position fixing and enjoy high placings on the ship, thereby maximising their range potential; also located high on the ship's structure there are dual installations of Round House and Rum Tub passive ESM antenna arrays which obviously provide 360° detection facilities. Lower down on various parts of the upperworks are numerous other shorter-range sensors of different types which could serve for target detection and/or tracking at closer ranges and lower elevation angles. The two Top Dome director radar groups (**4088.253**) are complex systems incorporating a number of different antenna elements, clearly denoting multipurpose operation. The largest of these is that which is concealed behind the large dome from which the group derives its NATO code-name and this probably serves to track both targets and outgoing missiles. Carried on the same, trainable, pedestal is a group of three hemi-cylindrical antennas, the precise function of which is not clear, and above these is a small 'thimble'-shaped unit which might house a command antenna.

STATUS

Operational in 1979. Fitted in 'Kirov' and 'Slava' class ships.

4473.231



SA-N-7 SURFACE-TO-AIR MISSILE SYSTEM

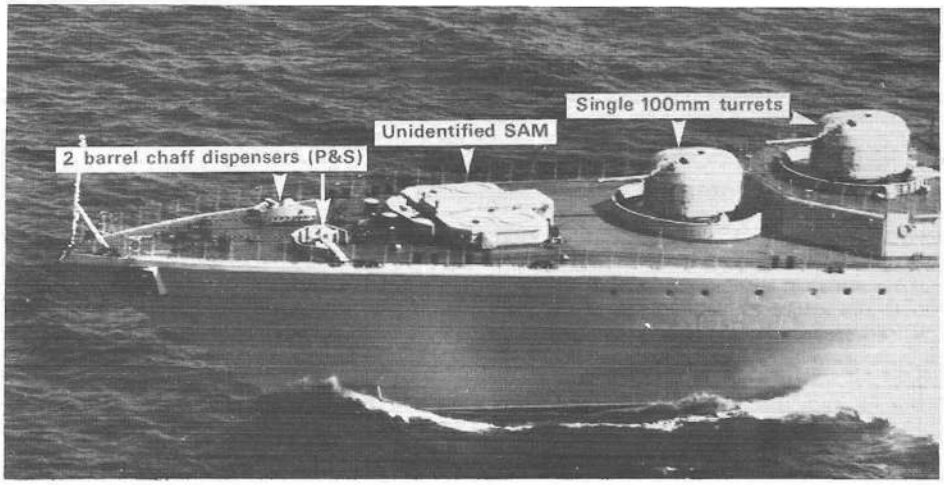
SA-N-7 is the number assigned to the recently introduced naval air defence weapon system associated with the new type of launcher ramp that was first noted in the trials ship *Provorny* (a modified 'Kashin'-class destroyer) and subsequently deployed in 'Sovremennyi'-class vessels. To date, the launcher is all that has been revealed publicly in the West of this new system although official US sources have claimed that the SA-N-7 missile is probably a naval version of the land-based SA-11 air defence weapon (**4470.131**), with a range of about 28 km and possibly a maximum speed of Mach 3.

Aboard the *Sovremennyi* there are fore and aft SA-N-7 launchers, which appear to be single round units, although until photographs of one loaded are obtained it is not possible to be definite on this point. Reportedly associated with the SA-N-7 is what is assumed to be a target tracking/illuminating radar said to bear the NATO reporting name of Front Dome. During Black Sea trials in the *Provorny*, this ship was sighted with no less than eight of these radars, while the *Sovremennyi* is fitted with six of them, according to the latest available photographs. Target designation to these individual radars is probably by one or more of the several air surveillance radars fitted in the ship, ie, either or both of the Top Steer pair located at the highest point of the superstructure. It has been conjectured that to date the *Sovremennyi* has not been seen in its final form, and it is true that there are several possible sites for additional radar antennas to be located.

These provisional details suggest that the SA-N-7 is intended to deal with multiple targets, with a high degree of autonomy after assignment of individual missiles and lock-on to their respective targets. Command guidance is probable and there is also a possibility that the system incorporates provision for a back-up optically-guided CLOS mode to cope with 'saturation' air attacks where there could be more targets than there are tracking radars to deal with them. Such a mode of operation would also be a useful countermeasure against the attacker's ECM, or in the event of loss of own radar for any reason. Official US sources estimate that each ship of the 'Sovremennyi'-class has a capacity of 44 missiles for its SA-N-7 air defence system.

If the belief that SA-N-7 launcher ramps are single rail units, and that the system is designed to deal with multiple air threats at short to medium ranges, are correct, this implies that each launcher must be capable of rapid firing and reloading. A further reasonable conjecture might be that the overall fire control system has a high level of sophistication, possibly based on digital computers, to ensure optimum co-ordination of such aspects as target designation, threat evaluation, radar assignment, launcher pointing, reloading etc. If, as the above would seem to suggest, a number of simultaneous target engagements are contemplated, by means of a launcher system able to fire several missiles in quick succession, it is therefore likely that tracking radars are assigned to targets individually and the missiles home by semi-active radar, operating virtually autonomously after launch

Beam view of 'Sovremennyi'-class ship Otchyannyy, *in addition to starboard group of SS-N-22 anti-ship missile launcher/containers, reveals the new style launcher for the SA-N-7 air defence missile system. Also visible are Top Steer air surveillance radar group, Band Stand SSM guidance radar, Kite Screech gun FC radar, several of the Front Dome SA-N-7 radars, and various E-C director equipments and EW/ESM antennas* (G. Jacobs)



4565.231

SA-N-8 NAVAL SURFACE-TO-AIR MISSILE

SA-N-8 is the number assigned to the as yet unseen new missile system associated with equipment noted aboard the recently revealed 'Udaloy' class of large anti-submarine ships. External visible evidence is so far confined to vertical launching silo hatches located on the forecheck near the bow and aft inboard of the port and starboard multiple torpedo tube mountings. The forward launcher installation appears to consist of four silos grouped together, apparently all of the same size (about 2 m diameter lids), but closer scrutiny of photographs shows that the aft pair of this group of four lack the central protuberance that can be discerned on the others. The reason for this discrepancy is not known.

Also noted in pictures that have so far been obtained, of the incompletely fitted out *Udaloy* and thought in some quarters to be associated with the SA-N-8 system, are platforms forward and aft that are believed to be the future sites of radar installations that may eventually be housed within protective radomes. At this stage there is no way of confirming or denying this suggestion, and the available evidence for further speculation on such aspects as the precise role of the missile, its operation, performance and other characteristics remains extremely slender. The *Udaloy* is fitted with a CIWS installation amidships consisting of four 30 mm Gatling-type gun barbettes directed by port and starboard Bass Tilt radars. The ship's main armament comprises two quadruple SS-N-14 missile launchers for anti-submarine operations and these are

associated with two Eye Bowl director/guidance radars mounted on top of the bridge house. Two single 100 mm guns controlled by a Kite Screech radar mounted forward comprise the surface engagement armament. Two Helix helipcopters are embarked, and with an estimated displacement of 8 500 tons (full load), this class of vessel clearly constitutes a 'high value' target for opposing aircraft and so it would be reasonable to assume a correspondingly elaborate and effective air defence system for its protection. On the basis of this information and with, at first glance, an apparently limited scope for fitting more than one radar group each for the forward and aft SA-N-8 installations, together with the knowledge of the vertical launch technique that has been assumed from the layout of the missile launcher silos, a short- to medium-range performance with high speed missiles using a sophisticated semi-active or active radar plus IR homing guidance technique might be a reasonable basis for further speculation on the system's operation.

Bow view of Udaloy *shows forward SA-N-8 missile installation with four VLS hatch covers and the two 100 mm gun turrets*

4885.231
SA-NX-9 NAVAL SURFACE-TO-AIR MISSILE SYSTEM

SA-NX-9 is the number assigned by an official US source to an as yet unseen naval surface-to-air missile system that is believed to be in preparation for fitting in the second ship of the 'Kirov' class of missile cruisers, the *Frunze* which made her first public appearance in the latter half of 1984.

It was subsequently noted that the second ship of the class differed from *Kirov* (the first of class) in its weapons and equipment fits. Notably, the *Kirov's* SS-N-14 anti-submarine missile containers and the after 30 mm Gatling air defence guns have been removed, and in their stead there are four hatch covers that are believed to protect the launcher sites for a new short/medium-range vertical launch air defence missile system. This will presumably cover any gap in the range coverage between the SA-N-4 and the SA-N-6 systems, which *Frunze* retains of the original *Kirov* SAM fit. According to US estimates *Frunze* will have a capacity of 128 SA-NX-9 missiles.

These will be shared between the two rows of four vertical launch tubes aft, on either side of the helicopter handling area, and two rectangular groups of four on the forecastle. No other clues as to the nature or identity of the missiles that will be used in this role have been obtained at the time of going to print, and although some observers have postulated sites for the guidance radars that it is assumed will be fitted, to date no photographs of any such radars have appeared.

It has also been suggested that the vacant missile silos will house the SA-N-8 system, above, (itself still largely a mystery), but an official US DoD publication (*Soviet Military Power 1985*) has assigned the number SA-NX-9 to the new *Frunze* installation, and in any case photographs of the SA-N-8 launcher installation in 'Udaloy'-class ships does not readily fit with the sites assigned to the new weapon system in the *Frunze*. If this assumption should be confirmed, it still leaves the question of whether or not *Frunze* is to have a completely new air defence missile system or if it will merely be a new form of launch arrangement for an existing weapon, such as the SA-N-7, itself another new Soviet missile as yet imperfectly understood among open sources in the West.

Forecastle of the new missile cruiser Frunze *showing the two square hatch covers that are thought to mark the site of the future SA-NX-9 air defence missile launchers, immediately aft of another hatch cover for an unknown purpose and forward of the ship's SA-N-6 surface-to-air missile launcher tube covers on the foredeck* (Jane's Defence Weekly)

Frunze's quarter deck showing the two covers on either side of the helicopter handling area that are expected to be occupied by vertical launchers for the SA-NX-9 air defence missile when fitting out is completed. In the first of class, Kirov, *these sites are occupied by two 30 mm Gatling gun barbettes* (Jane's Defence Weekly)

UNITED KINGDOM

1019.231
SEACAT SHIPBORNE SURFACE-TO-AIR MISSILE

Seacat is a close range, shipborne, guided missile system for anti-aircraft defence which may also be used against surface targets within visual range. The system has been designed to provide a simple and low-cost anti-aircraft capability, and represents a very cost-effective system. The guidance system is based on the use of optical tracking and a radio command link, but the system is capable of various degrees of sophistication and this has in fact been undertaken in a number of instances. Generally, such improvements take the form of integrating Seacat with ships' fire control systems. An advantage of this is that disablement of the fire control radars, or other part of that system, still leaves the option of the optically guided mode.

OPERATION

The basic form of the system, introduced into the Royal Navy as Guided Weapons System Mk 20 (GWS 20), consists of separate launcher and operator mounts, the latter carrying sighting binoculars with which the aimer first 'gathers' the missile after launch and subsequently tracks it to the target. A thumb joystick control is provided for missile guidance. Movements of the joystick are converted into command signals which are transmitted to the missile from an antenna unit on the launcher mounting to maintain the missile on the line of sight to the target.

Seacat has since been deployed with the RN GWS 22 (**1242.281** and **1563.253**) fire control system in which a lock and follow tracking radar is linked to the aimer's binocular sight. Subsequent operation is the same as for the GWS 20 system. It has also been combined with Contraves Sea Hunter, San Giorgio NA9, and Signaal M 40 series fire control systems. A

later development is a system that replaces the optical sighting binocular with a closed circuit television (CCTV) system produced by Marconi-Elliot Avionic Systems as the 323 Series (**1021.293**). This enables the aimer to be placed in a much less vulnerable position and also results in important improvements in efficiency. The missile gathering phase has been reduced from about seven seconds (conventional optical technique) to six seconds or less with the aid of CCTV.

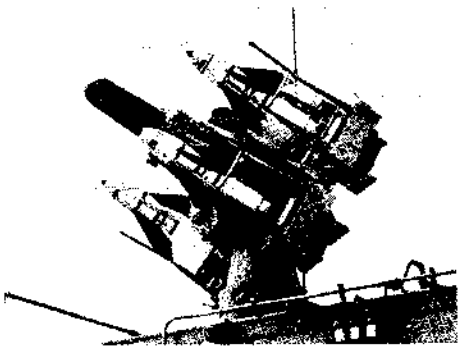
A lightweight version of Seacat has been developed for installation in such vessels as 30 m fast patrol boats and inshore minesweepers, giving them guided-weapon defence against low-flying aircraft. It is in service with the Brazilian Navy and the Iranian Navy, and has attracted interest from other navies, some of which already have the standard Seacat system.

It employs a new three-round launcher (based on the Short Tigercat launcher) which weighs only 2007 kg with all its ancillaries instead of the 4700 kg of the standard four-round Mk 20 launcher. Binoculars mounted on the head of a single manually operated pedestal director form a combined director and missile aiming sight.

The latest Seacat improvement is the introduction of a height control capability which enables the missile to be flown at heights down to 4 m above the sea against surface or sea skimming targets without danger of ditching. This modification provides a 'cushion' between missile and sea, the clearance distance being automatically adjusted according to the sea state encountered. The height control facility is incorporated in one of the missile's four guidance wings and can be readily fitted to existing Seacat installations. The missile's proximity fuze is not disturbed by being close to sea or land surfaces, and its fuzing system – both proximity and contact – in conjunction with its highly potent warhead provide a most effective counter to low level missile attack, and also permit ship or shore targets to be successfully engaged at all ranges up to maximum.

The surface skimming modification can be easily introduced to existing Seacat installations with virtually no disturbance of components, providing a highly flexible close-range defence system with the ability to engage air, shore and surface targets.

CHARACTERISTICS



Max effective range: Approx 5500 m
Warhead: HE
Solid fuel motor
Length: 1·48 m
Max span: 65 cm
Estimated weight: 63 kg

DEVELOPMENT

Development work started in the late 1950s and the first sea trials took place on HMS *Decoy* in 1962. The basic system has proved itself adaptable to other roles and a land-based version has been developed as the Tigercat (**2465.131**).

STATUS

In addition to the RN, Seacat has been ordered by 15 other navies including: Argentina, Australia, Brazil, Chile, West Germany, India, Iran, Libya, Malaysia, Netherlands, New Zealand, Sweden, Thailand and Venezuela. A fresh multi-million pound contract was awarded in 1982 for additional Seacat equipment for the RN.

Shorts Seacat installed on an RN ship. The system is scheduled for service well into the 1990s

A number of Argentinian aircraft were believed to have been shot down by Royal Navy Seacat missiles in the Falklands conflict of 1982, and the land-based version of the system, Tigercat, operated by Argentinian forces are reported to have claimed some British aircraft attacking Port Stanley airport in the same campaign.

CONTRACTOR

Short Brothers plc., Castlereagh, Belfast BT6 9HN, Northern Ireland.

6004.231

SEA DART SURFACE-TO-AIR MISSILE

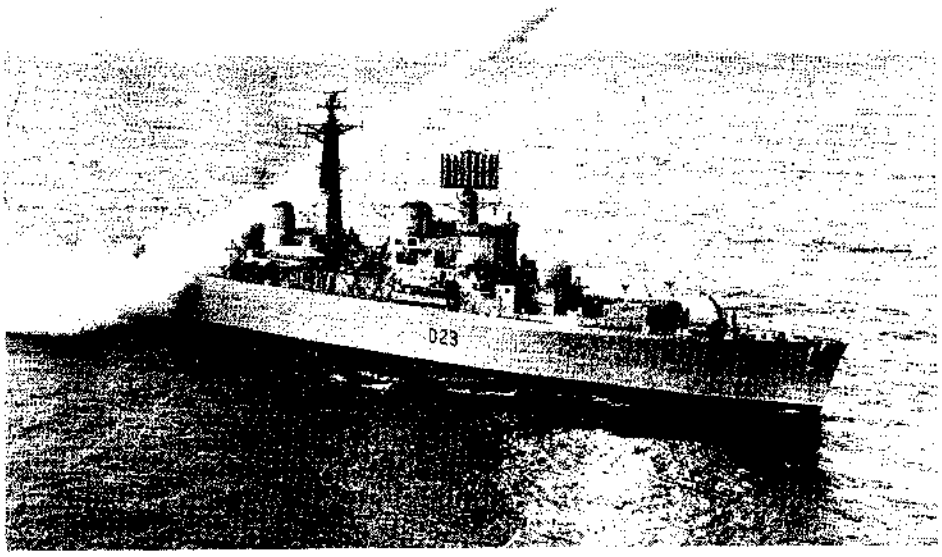
Sea Dart (GWS 30) is a third-generation area defence weapon system, capable of intercepting aircraft, at both very high and extremely low altitudes, and air and surface launch missiles. It is also effective against surface vessels thus giving it a triple-role capability. Launch rate is rapid and the weapon system is capable of dealing simultaneously with many targets. Despite all this the system can be installed in a variety of fighting ships from small frigates upwards, including some vessels that would be too small to accept, for example, Seaslug (**6003.231**).

The missile is launched from a twin launcher. Performance data is classified and only the linear dimensions have been released for publication, other data in the accompanying table is taken from published unofficial estimates.

The missile is virtually a thick-walled cylinder built around the Rolls-Royce (1971) Ltd Odin ramjet engine. The guidance equipment (Marconi Space and Defence Systems), the proximity fuze (EMI), the control system (BAe Bracknell division), and the fuel tanks and engine controls are all wrapped around the central air duct and ramjet in the annular space between them and the missile's outer skin.

The guidance system is one of a semi-active 'homing all-the-way' nature. It uses a proportional navigation law. The ramjet engine enables the missile to fly at controlled speeds throughout its flight envelope. The guidance system will detect very small changes in target movement. This capability, combined with very fast control responses, enables very small miss distances to be achieved.

CHARACTERISTICS



Designation: GWS 30
Type: Shipborne area defence, surface-to-air, surface-to-surface, and anti-missile guided weapon system
Guidance principle: Radar guidance and semi-active homing using tracker illuminator radar Type 909
Guidance method: By control of movable tail surfaces
Propulsion: Solid-propellant booster and ramjet sustainer
Warhead: Presumably HE
Length: 4·36 m
Body diameter: 42 cm
Span: 91 cm
Launch weight: 550 kg
Range: At least 30 km

OPERATION

A fully automatic below decks magazine is provided. Missiles are stowed vertically and are hoisted through an intermediate position onto the electrically driven twin beam launcher. Targets are designated to the system in three co-ordinates by radar. The system automatically tracks the target and points the launcher. Radar illuminates the target to provide the missile with the RF signal for self-guidance on to the target. The Type 909 target tracking and illuminating radar (**1559.253**) produced by Marconi Radar Systems has been developed from the equipment used with certain Bloodhound and Thunderbird missile systems. The missile is boosted to speed by a solid fuel tandem boost and speed is sustained by an Odin ramjet burning a liquid fuel.

Lightweight Sea Dart

In 1978 British Aerospace announced the Lightweight Sea Dart system, intended for ships down to 300 tons in size. In place of the GWS 30 missile launcher and missile magazine, the lightweight system employs fixed deck-mounted launchers, each carrying four missiles in sealed launch boxes. The boxes also serve to protect the missile during all stages of transportation and handling. The number and siting of these units depends on particular ship configurations and customer/operational requirements, but typically a small craft might fit two groups of four missiles. A trainable version of the four-box launcher was introduced by British Aerospace in 1984. This version is more suitable for larger warships and offers improved firing arcs and simplified launcher management in action condidtions. A firing equipment cabinet provides the interface between the missiles and a 1412AL digital computer which is dedicated to the Sea Dart system. The computer and control panels form a single equipment console requiring only one operator. The Marconi 805 SD (**4302.253**) is in production as the system fire control radar. It provides target tracking and illuminating channels, with the signals being radiated by a single antenna. The ship's surveillance radar is used to provide initial target detection and to 'lay on' the tracker. The performance of Lightweight Sea Dart is dependent on the capabilities of the surveillance and tracking radars fitted. Studies of modern naval radars in combination with the 805 SD have shown that in the surface-to-surface role Sea Dart will match other missiles while providing better performance in the air defence role. The system retains the original triple-

Launch of a Sea Dart missile from the British Type 82 destroyer HMS Bristol. *Sea Dart is an area defence system against high and low flying aircraft, with an anti-missile and surface-to-surface capability. A lightweight Sea Dart system has been developed using the existing missile with lighter and simpler ship equipment. Deck mounted boxes which both protect the missile during its life on board ship and act as the missile launcher enable Lightweight Sea Dart to be fitted in ships down to 300 tons*

role capability of the Sea Dart GWS 30 and is intended to eliminate the need to fit a number of alternative systems in a warship to gain a similar capability.

DEVELOPMENT

Development started August 1962. Test firings began in 1965 and the first production order was announced in November 1967.

In mid-1982 BAe revealed a proposed long-range land-based air defence system designed around Sea Dart missiles and called Guardian (**4524.131**).

STATUS

Development is complete and the system is at sea in HMS *Bristol* and all RN Type 42 destroyers. It is also in service with the Argentinian Navy in ARA *Hercules* and ARA *Santisima Trinidad* Type 42 ships. Sea Dart also provides area defence for the new class of anti-submarine cruisers, HMS *Invincible*, HMS *Illustrious* and HMS *Ark Royal*. In the course of the fighting for the Falkland Islands, Sea Dart missiles fired from British ships claimed eight Argentinian aircraft.

CONTRACTORS

System contractor: British Aerospace Dynamics Group, Bristol Division, PO Box 5, Filton, Bristol BS12 7QW, England.

Other contractors associated with the system include:

Marconi Space and Defence Systems Ltd - guidance; Rolls-Royce (1971) Ltd - Odin ramjet; EMI - fuze; Vickers Shipbuilding and Engineering Ltd - launcher magazine and handling equipment; Marconi Radar Systems, Ltd - Type 909 tracker illuminator radar; Ferranti Ltd - computer and data handling; Plessey Radar Ltd - operations room equipment.

6003.231

SEASLUG SURFACE-TO-AIR MISSILE

Seaslug is a long-range beam-riding shipborne surface-to-air guided missile system.

Targets are detected at long range by radar (3-D or surveillance plus heightfinder) and their co-ordinates are supplied to the missile system control which commands the launcher. A twin ramp launcher is used and is reloaded from a between-decks magazine.

There are two versions of the missile, the Mk 2 having a rather longer range and better performance against low-flying aircraft. Both missiles have a surface-to-surface capability, but again that of the Mk 2 is better than that of the Mk 1.

CHARACTERISTICS

Type: Shipborne surface-to-air tactical guided missile. Surface-to-surface capability

Guidance principle: Beam-riding using Type 901 M shipborne radar with coded transmissions

Guidance method: By control of tail surfaces

Propulsion: Solid-propellant sustainer with 4 wrap-round solid-propellant boosters

Warhead: HE with proximity fuze

Missile length: 6 m

Missile diameter: 41 cm

Range: Probably better than 45 km. Targets engaged at heights above 15 000 m in trials

OPERATION

Fully automatic magazine handling and loading arrangements. Electrically driven twin launcher. Targets are designated to the system in three co-ordinates by radar. The system automatically tracks the target and points the launcher. When the target comes within range the missile is fired and intercepts the target using beam-riding guidance techniques. Typical radars are the RN Type 965 (**1560.253**) for primary long-range surveillance, Type 277 for height-finding, and the Type 901 which is the Seaslug tracking and illuminating radar. It has an HE warhead with DA and proximity fuzes and four wrap-round boosters.

Seaslug surface-to-air missile launch

DEVELOPMENT

Development started in the early 1950s. Prototype trials carried out in HMS *Girdleness* during late 1950s. First fitted in 'County' class destroyers in 1961.

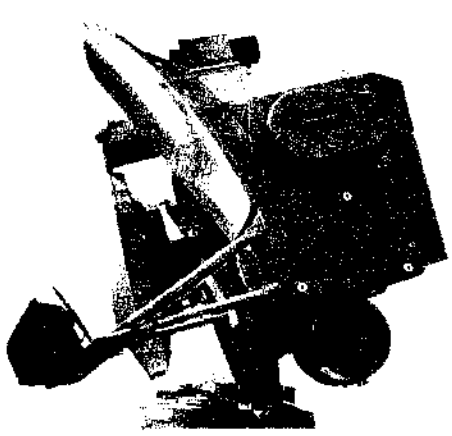
STATUS

Mk 2 systems remain in RN ships *Glamorgan* and *Fife*, in the Chilean ships *Prat* and *Almirante Cochran* (the former RN *Norfolk* and *Antrim*). The former HMS *London*, now serving with the Pakistan Navy as PNS *Babur* retains its Mk 1 Seaslug although it is thought there are plans to remove it.

CONTRACTORS

British Aerospace Dynamics Group, Bristol Division, Filton House, Bristol BS99 7AR, England.

Sub-contractors include:



Marconi Space and Defence Systems - missile guidance; Vickers Shipbuilding and Engineering Ltd - magazine handling gear and launcher.

2442.231

SEAWOLF SURFACE-TO-AIR MISSILE

Seawolf is the missile used in the RN's short range point defence guided weapon system, GWS 25 Mod 0. The system is currently installed in all Type 22 and some Leander class frigates. A complete single-headed system comprises surveillance radars, tracking and guidance radar and fire control, six-barrel trainable launcher and missiles. It is capable of being installed in vessels down to about 3000 tons. A derivative of this system, designated GWS 25 Mod 3, employs a new lightweight dual frequency tracker designated Type 911. Developed by Marconi Radar Systems in order to give improved performance down to sea level, it will be retrofitted to ships of the Type 22 Broadsword class.

Development of the Seawolf system has produced a family of subsystem options known as Lightweight Seawolf, enabling installation in ships down to a few hundred tons. The tracking and guidance functions is provided by the Marconi 805 SW radar, derived from the Type 911. The launching system can comprise either a low mass, trainable 4-barrel launcher, based on the Seacat mounting, or the new Vertical Launching System. The latter employs the existing Seawolf missile fitted with a tandem boost motor which is jettisoned after turnover.

Seawolf tracker/director group in addition to radar features GEC Avionics TV tracker

The Seawolf missile employs line-of-sight guidance with radar differential tracking or TV, both with radio command. Speed and manoeuvrability characteristics are suitable for the engagement of small Mach 2 missile and aircraft targets under severe weather conditions and sea states.

Seawolf GWS 25 Mod 0

The complete system comprises the following units:

(1) air and low-air surveillance radars, Type 967 and 968
(2) radar trackers, Type 910, and TV trackers (GWS 25 Mod 0); radar trackers, Type 911 (GWS 25 Mod 3)
(3) command transmitter
(4) launcher and firing system
(5) missile and handling frame
(6) data handling
(7) guidance shaping unit
(8) operations consoles
(9) magazines.

The Type 910 tracking radar is produced by Marconi and is described more fully in the Equipment Section (**1562.253**). The TV system is produced by GEC Avionics. The Type 911 tracking radar is described more fully in entries **1508.253** and **2439.153** in the Equipment Section. The Type 967 and Type 968 surveillance radars provide both high and low cover, and are also produced by Marconi (**1561.253**). They are of modern design and incorporate features for air target detection up to high elevation angles as well as high performance against low-level and surface targets. Comprehensive precautions against sea and land clutter, as well as natural and man-made interference are incorporated, as is IFF.

The line of sight to a target is established by either the tracking radar or the TV system. Error signals proportional to Seawolf missile deviations from this datum are derived from the differential tracking radar or the TV system, and these signals are processed by a guidance shaping unit. Coded correction signals for missile guidance are produced and transmitted by microwave command link to bring the missile to the required flight path. In the GWS 25 system the data processing required to interpret the tracking data and calculate the correction demand signals is based on the use of a Ferranti FM 1600B computer (**1433.063**), which has been adopted as a standard.

A multiple launcher developed by VSEL is common to both standards and consists of six rectangular launch-tubes disposed in two banks of three, one on each side of an azimuth/elevation mounting. Reloading is manual, presumably to avoid the complexity and, particularly, the weight of an automatic system which might undesirably limit the number of ships which can carry the full Seawolf system. The launcher is separate from the tracking radar. High slewing rate and pointing accuracy are important features of the Seawolf launcher which is equipped for fully automatic firing sequence, with command override.

The Seawolf missile weighs approximately 80 kg at launch, is about 2 m in length, and has four fixed wings and four moving tail fins. A solid booster motor is designed to give minimal launch drop and speed is quoted as being in excess of Mach 2. Successful techniques employed in Rapier (**2424.131**) have been incorporated, and no on-board test or repair facilities for missiles are called for. The HE warhead is provided with both proximity and contact fuzing.

OPERATION

For the successful interception of an incoming anti-ship missile great accuracy and an extremely short reaction time are required of the system. To achieve this it is arranged that, once a target has been certified as hostile, all subsequent phases of the launch and guidance operation will be carried out automatically and without further manual control.

Other relevant features include the ability to fire salvoes, immediate readiness capability maintained over long periods, and extremely fast data handling facilities in all parts of the system.

Automatic radar guidance is the normal operating mode, with TV tracking by an aimer for low angle of sight and surface target engagement in GWS 25 Mod 0.

VARIANTS

Seawolf GWS 25 Mod 3

The most recent lightweight Seawolf system to be devised uses a Marconi 805SW tracking radar director to produce a Seawolf system suitable for fitting in ships with displacements of less than 1000 tonnes. The 805SW, designated Type 911 in RN service, is a lightweight dual frequency differential tracker that can be used in single or multifire channel installations. The major components are taken from the basic Marconi 805 range of radars (**1508.253**) to which is added the millimetric wavelength DN181 Rapier Blindfire radar (**2439.153**) and elements of the original RN GWS 25 system. The millimetric radar provides accurate tracking at low elevations, and in a series of live firings of Seawolf against small and large targets close to the sea surface in trials at a RN range, a high rate of successes was recorded.

The Mod 3 system incorporates a number of simplifications based on the experience gained in the long proving trials of GWS 25, and the opportunity was taken of modernising the data processing equipment to take advantage of the RN Crocodile and CACS projects while retaining the basic proven software and adding improvements to give a full low-level blindfire capability. Such simplifications were carefully considered to ensure they did not impair the target kill probability. Tracking a missile at I-band would simplify the receiving system, but data gathered during firing trials indicated that the risk of seriously reduced signal returns during the motor burn did not warrant this approach, particularly when salvo firings are contemplated, and so the fully proven tracking of the missile by beacon has been retained.

Two complete differential tracking radars are included, with one operating in the I-band and the other in the millimetric band, both antennas being carried on the same mounting. The J-band command data link also uses the millimetric tracking antenna. Height diversity for the command link transmissions to ensure good guidance data to the missile when flying at low level is achieved by independently illuminating the upper and lower parts of the main tracking antenna. The I-band signal processing uses Fast Fourier Transform techniques to ensure effective operation in the face of severe clutter.

The system operates with the six-round launcher of GWS 25 Mod 0, as used in the RN Type 22 frigates, and will be retrofitted to this class.

Containerised Seawolf

In 1981 British Aerospace Dynamics Group announced the introduction of a containerised version of the Lightweight Seawolf system, intended for rapid installation either on warships, or normally non-combatant vessels such as containerships or auxiliaries. A complete Seawolf installation is configured for housing within standard ISO 6 m containers.

Lightweight Seawolf

The evolution of the system has resulted in a family of lightweight subsystem options to suit different customer applications. The subsystems comprise:

(1) Tracking and Guidance System. Marconi 805 SW, offering the following features:

(a) A computer which interfaces directly with the ship's action information system, automatically controls the acquisition of the target by the tracker, lays on the launching system, decides when a missile should be launched and gathers and guides the missile to the target.

(b) A dual frequency band tracking radar with narrow beams which virtually eliminates multi-path effects, provides excellent tracking accuracy, reduces jamming sensitivity and enables low-level target engagement. Modern techniques allow rejection of clutter effects giving good separation of incoming target and intercepting Seawolf missile.

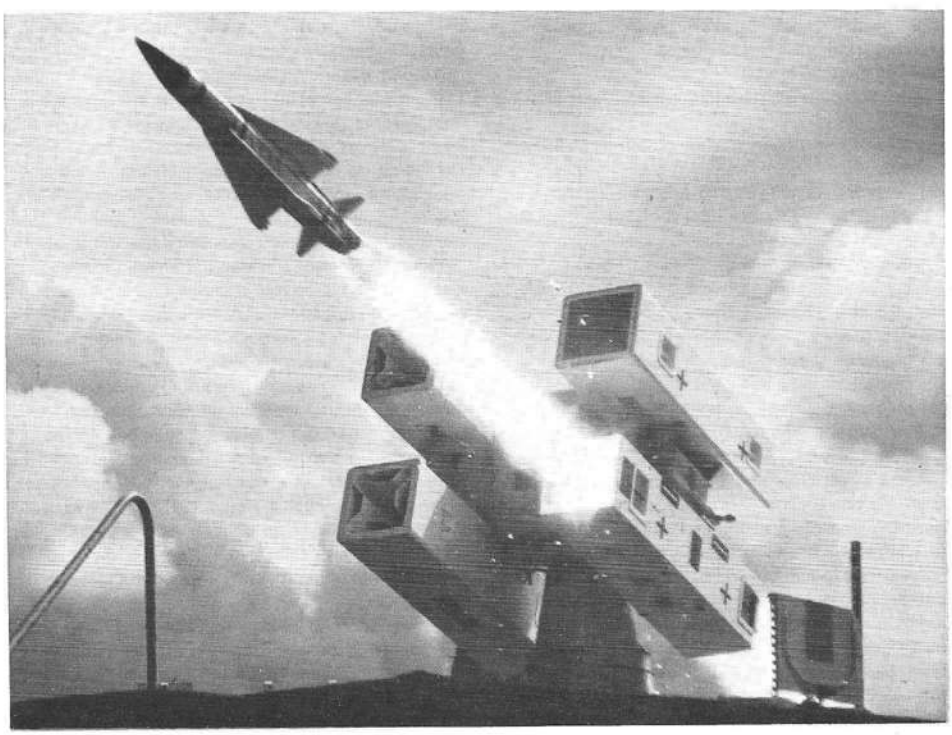
(2) Launching System

(a) 4-barrel Launcher. The lightweight 4-barrel launcher has been developed using the rotating and elevating structure of the well proven Seacat launcher. The launcher carries four Seawolf missiles contained in light alloy barrels which are designed to be semi-permanent, being able to fire many missiles before needing replacement. They are retained using a mechanism similar to an aircraft bomb mount. When reloading, Seawolf missiles are moved singly from a nearby ready-use magazine using a handling frame, and are inserted into the barrel with a loading aid. Protective end covers ensure that the missile can remain on the launcher for extended periods. An associated launcher control console derived from the Seacat equipment controls launcher movement and contains the missile firing unit. A crew safety and load panel is situated close to the launcher to inhibit it in the loading position.

(b) Vertical Launching System. Development of a vertical launch version of Seawolf in which missiles will be loaded aboard the ship in individual launch/containers was confirmed in early 1982. The container is also employed for transport and is fitted with a frangible cover and integral vertical exhaust ducting. For ship fitting, canisters can be installed singly, in groups, or in silos, above or below deck. Modifications to the Seawolf missile for vertical launch are minimal and include the addition of a tandem boost motor with integral thrust vector control to perform the pitch-over manoeuvre, and possibly the inclusion of a microprocessor in the missile itself.

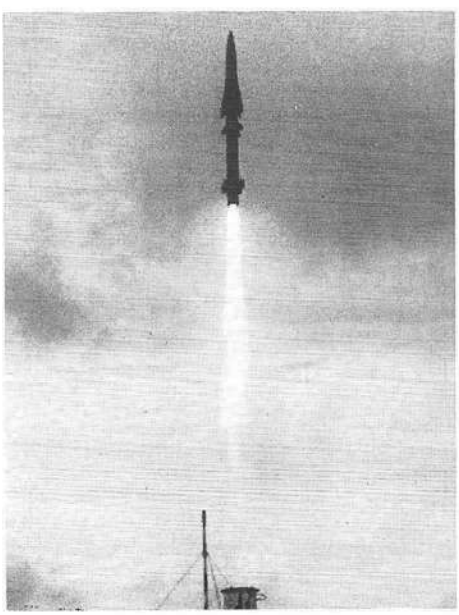
The VL concept was demonstrated in 1968 and it promises faster reaction, much lower installed weights, no on-board handling and the ability to react to multiple targets from all aspects.

Target indication data for all versions of Lightweight Seawolf is supplied from a suitable surveillance radar/action information organistion source, which does not usually form part of the Seawolf system.



Seawolf GWS 26

The current production version of Lightweight Seawolf (GWS 26), for the RN Type 23 frigates is a vertical launch system, as mentioned above. Under a £1 million contract BAe Dynamics Group is developing a strapdown inertial measuring unit (IMU) for this version. This provides digital and analogue signal outputs indicating incremental angle and angular rates about the pitch, yaw and roll axes, plus accelerations and incremental velocities along the missile's axes.



Vertical Launch Seawolf is designed to eliminate blind engagement arcs and, with its high rate of fire defeat saturation attacks, as well as having an extended interception range. Vertical Launch Seawolf is fitted with a tandem booster motor and is fired from a vertical launch tube. Immediately following launch, when clear of the ship's superstructure, the missile/booster assembly has to perform a turnover manoeuvre onto the heading of the approaching target, after which the booster is discarded. This turnover onto the correct heading has to be performed rapidly with great precision. The IMU is required to supply the attitude and motion data needed to perform this complex manoeuvre successfully during this, the most critical phase of the missile's flight. The IMU also provides data to control the missile during the remaining flight to the target.

The IMU uses inertial sensors developed by BAe. Twin-axis dynamically tuned gyros and linear accelerometers, together with their supporting electronics, form the inertial assembly of the IMU. The design uses the strapdown concept and hence provides a compact, rugged and reliable module which is suitable for numerous applications. The supporting electronics includes the analogue-to-digital conversion for the inertial sensors, the gyro rebalance loops and the power supplies required for the module. The analogue-to-digital conversion is a critical element in the design of a strapdown system.

The IMU features a powerful microprocessor used to carry out the systematic error compensation of the

New four-round lightweight Seawolf launcher is based on the Seacat pedestal and weighs about 2·1 tons

Development standard Seawolf missile launched vertically from a simple launch canister during Royal Aircraft Establishment trials

inertial sensors usually required for a strapdown system. The presence of the microprocessor brings the ability to monitor the performance of each sensor within the IMU, and to achieve a higher level of BITE, previously unobtainable, whilst removing much of the overhead from the external system. Full status and telemetry information is constantly available to the guidance system.

A 12 000 tonne ocean-going barge *Dynamic Servant* has been converted into a self-contained trials platform and re-named *Longbow* for Seawolf vertical launcher tests. The fitting out includes installation of two three-barrel vertical Seawolf launchers for salvo firings, a Type 911 radar, accommodation for a crew of eight and 16 trials personnel, and a helicopter landing deck able to accommodate helicopters up to Sea King size.

STATUS

Seawolf GWS 25 entered RN service in 1979 aboard HMS *Broadsword*, first of the Type 22 class of frigates. The system has been installed on 'Leander' class frigates, as well as subsequent Type 22 ships. RN firing trials using the BAe Seawolf anti-missile system have been successfully completed off Aberporth, Cardigan Bay, West Wales. Two Seawolf firings were made from HMS *Broadsword*. In the first trial a shell fired from the Royal Aircraft Establishment, Aberporth, by RN crewmen was aimed to narrowly miss HMS *Broadsword*. Seawolf was fired and scored a direct hit on the shell which was intercepted at the top of its trajectory some 2000 ft above the sea.

In late 1982 a standard operational Seawolf missile was successfully launched vertically from a simple launcher/container during trials at the Royal Aircraft Establishment, Larkhill. This trial satisfied the Seawolf VL operational specification, which includes vertical launch and turn-over onto interception path when well clear of ship's superstructure. This system, designated GWS 26 Mod 1 and including Type 911 trackers, will be operationally available for the first of the RN Type 23 frigates. The launching system could take the form of a 32-missile silo mounted forward of the bridge.

A MoD contract awarded to BAe Dynamics Group Bristol in mid-1983 covers a feasibility study of the possibility of fitting the Seawolf system in the RN's Type 42 destroyers to give these ships the best possible self-defence while retaining the Sea Dart area defence system. Ferranti and Marconi Radar are collaborating with BAe in this study, which may make use of the lightweight 4-barrel launcher.

In late 1983, a Seawolf missile fired from a Type 22 frigate, *HMS Brilliant*, successfully destroyed an MM 38 Exocet anti-ship sea-skimmer missile in a trial designed to prove Seawolf's performance at near maximum crossing range.

A UK Government contract has been awarded for final development and production of Vertical Launch Seawolf for the RN Type 23 frigates. Estimated value of the GWS 26 Mod 1 contract is in excess of £130 million.

In early 1985 British Aerospace Dynamics Group announced the award of a UK MoD contract for the evolution of a Seawolf system designated GWS 27. This will provide the facility for easy up-grading of existing VL Seawolf fitted ships to keep ahead of the anti-ship missile threat in the late 1990s and beyond.

2507.231

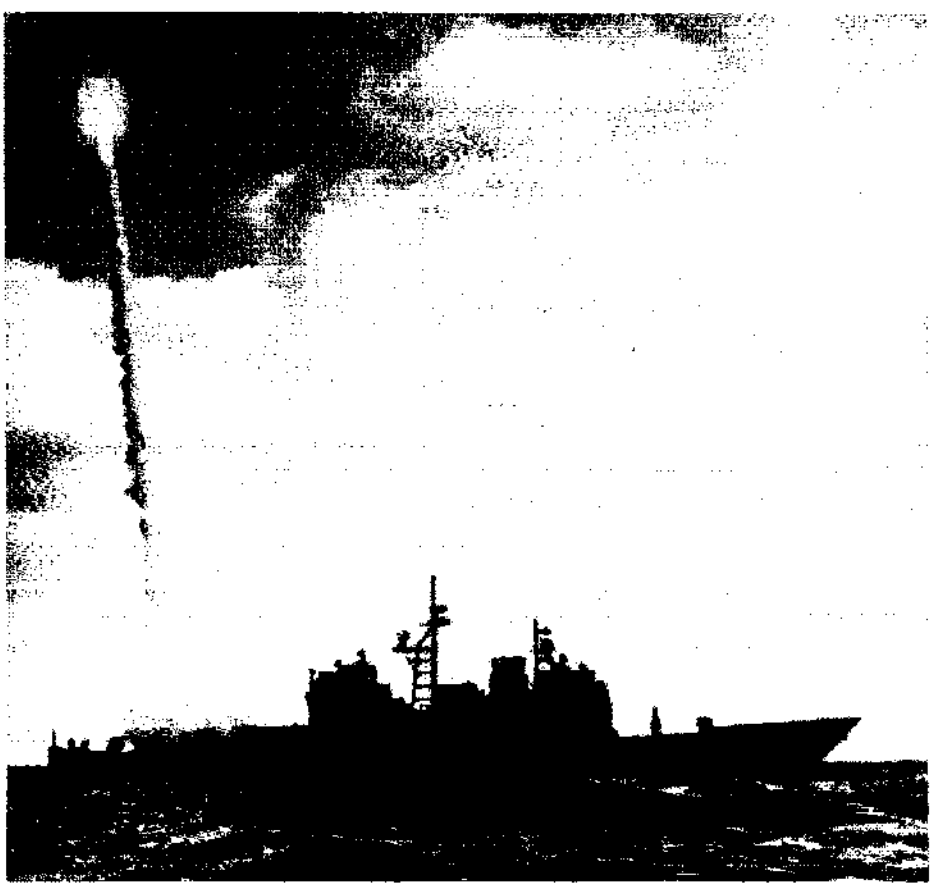
AEGIS SURFACE-TO-AIR WEAPON SYSTEM

Aegis is a surface-to-air weapon system primarily designed to defend against anti-ship cruise missiles and missile launcher platforms. It is the USN's primary defensive missile system for the late-1980s and beyond. Present plans call for its installation aboard a new class of guided missile cruiser (CG-47 class) and DDG-51 destroyers. Aegis is designed to destroy small, fast targets in hostile environments such as severe weather or countermeasure conditions. As an area defence system, Aegis will be capable of defending a task force which includes a carrier and several other types of ship. The system complements the Tartar (**6006.231**) and Terrier (**6005.131**) missile systems.

Major components of the Aegis system are the missile, its launching system, the fire control, and weapon control systems, the multi-function array radar with its computer control, the system command and control, and the operational readiness test system.

The missile used is the SM-2 version of the Standard (**1122.231**), which uses the same airframe and propulsion system developed for the SM-1 but incorporates significant additional facilities. The SM-2 has a command guidance capability, a self-contained navigation capability provided by an inertial reference unit, and a new terminal homing receiver.

This particular combination of guidance techniques imparts considerable operational benefits. The ability to navigate the SM-2 missile to the target area by means of inertial navigation, plus command corrections, followed by terminal homing, results in a much more efficient trajectory which effectively doubles the range. It also means that the demands on the ship-based fire control/guidance system are appreciably reduced. For example, the target illuminating radar needs to be directed at the target for the homing phase only, leaving it free to engage other targets at other times. Similarly, the command guidance system can be shared between a number of SM-2/targets because the inertial reference unit permits the missile to perform its own mid-course navigation and the telemetry link is used to report missile position back to the ship.



The SM-2 is available in MR and ER models, but the current SM-1 Standard is available in the MR version only.

It is launched from the Mk 26 fully automatic dual-purpose launcher which can be used to launch Asroc (**6001.241**) anti-submarine missiles, but as Aegis fittings increase in the US Fleet more ships will be equipped with the Mk 41 vertical launcher system (**4204.231**).

The MK 26 launcher has a digital interface with the Mk 1 weapons control system. One of the three computerised sub-systems of Aegis, all of which use the AN/UYK-7 digital computer, the Mk 1 system accepts weapon assignment commands and special threat criteria from the Mk 1 command and decision system and tracking data from the multi-function radar. These inputs are processed to determine the possibility of engaging the target and then to generate commands for the Mk 26 launcher and pre-launch orders for the missile, commands for the Mk 99 fire control system for target illumination, commands to the multi-function radar, if mid-course guidance is required, and reports to the Mk 1 command and decision system.

The function of the Mk 99 fire control system is to illuminate the target. To do this it uses the AN/SPG-62 (slaved) radar. Inputs to the system come from the Mk 1 weapons control system which, in the case of slaved radar operation is passing on data from the multi-function radar system.

The multi-function phased-array radar, the AN/SPY-1A (described in **1570.253**) is high-performance electronically-scanned equipment capable of surveillance and the simultaneous detection and tracking of multiple targets; it has been described as the heart of the Aegis system. Associated with it are four AN/UYK-7 computers. The primary function is to search for and acquire targets and track them to whatever extent may be necessary. Beam scheduling for this and other tasks is organised by the computer. The system also handles the two-way link with the missile for mid-course guidance when requested by the Mk 1 weapons control system. Certain special facilities can be provided such as 'burn-through' facility for use in ECM conditions or passive angle tracking. The system accepts general operational commands from the Mk 1 Aegis command and decision system and mid-course guidance commands from the Mk 1 weapons control system; its operational outputs are processed signals giving target detection data to the Mk 1 command system and target and missile track data to the Mk 1 control plus mid-course guidance commands to one

US Navy's second Aegis cruiser, Yorktown, *at sea during builder's trials. Ship was commissioned on 4 July 1984*

or more missiles. Like all other operational sub-systems in the Aegis system the radar control system is also connected to the Mk 1 operational readiness test system.

Together with the AN/SPY-1A radar system and the Mk 1 weapons control, the Mk 1 command and decision system make up the detection and decision loops of the Aegis system. The Mk 1 system is the ship's command and control centre, and targets enter the detection and decision loop from the AN/SPY-1A radar, from other ship's own sensors or from data supplied by other ships or aircraft. What happens next depends on which of the four Aegis operating modes has been selected. The modes are automatic special, automatic, semi-automatic, and casualty. In the automatic special mode targets meeting certain predetermined threat criteria are automatically fired upon unless manual override is invoked; in all other modes positive human action to initiate firing is needed.

In these three modes the Mk 1 weapons control system inserts targets into the engagement queue and schedules equipment for launching and terminal illumination. Trial intercepts are computed and a time to fire predicted. Resulting data are fed back to the Mk 1 command and decision centre which is also receiving target detection data from the radar control system, operational readiness data from the Mk 1 operational readiness test system, and electronic warfare and other data from the ship's command and control centre. Incorporated in the Mk 1 command system is another four-bay AN/UYK-7 computer and a comprehensive display system, the AN/UYA-4. On the basis of all these data, threat evaluation and weapon assignment processes are carried out so that the engagement decision can be taken.

The final major element of Aegis is the Mk 1 operational readiness test system (ORTS). This is linked to all the other major elements of the system and has the functions of monitoring actively and continuously the state of readiness of each, and of reporting the results of this process to the Mk 1 command and decision centre.

DEVELOPMENT

Initial planning for Aegis began in 1964 and RCA was awarded the engineering development contract for $252 930 400 in December 1969.

STATUS

At the end of April 1972 the USN and RCA jointly announced completion of the system design phase. At sea, flight tests using the Standard SM-2 were successfully completed in mid-1977. This also marked the completion of the SM-2 development programme.

In mid-1978 a USN contract valued at $224 million was awarded to RCA to build, integrate and test the first Aegis weapon system which became operational aboard the lead ship of the 'Ticonderoga' CG-47 class Aegis cruisers.

In 1983, after completing sea trials and operational tests of Aegis in USS *Ticonderoga*, this ship began operations with the fleet. Present planned construction of CG-47 guided missile cruisers will result in an eventual total of 27 of these ships. In 1984 Congress authorised construction of the first DDG-51 guided missile destroyer lead ship of a new class of 8300 ton Aegis-fitted ships. It is planned to procure 17 DDG-51s over the next five years. In April 1984 RCA announced the receipt of a $233 million contract for the design and development of an Aegis system for the DDG-51 class. The lead ship, *Arleigh Burke*, is due for commissioning in 1989. These ships' Aegis will incorporate the AN/SPY-1D radar and the new AN/UYK-43 computers.

In July 1984 USS *Yorktown*, the second ship of the 'Ticonderoga' class of Aegis ships was commissioned, while the third of the class, *Vincennes*, had been christened in April 1984. The fourth ship, *Valley Forge*, was launched in June 1984.

CONTRACTORS

Prime contractor: RCA Government Systems Division, Moorestown, New Jersey, USA. (Three major RCA divisions are engaged in the project.)

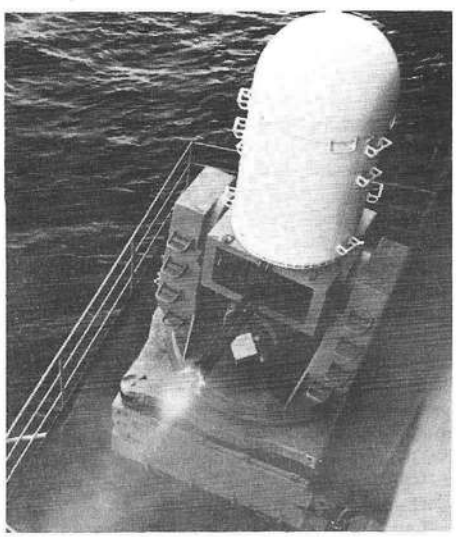
FCS Mk 99, radar and SPY-1A high-power transmitter: Raytheon Company.

AN/UYK-7 computers: Univac Division of Sperry Rand.

Mk 26 launcher: Northern Ordnance Division, FMC Corporation.

SM-2 missile: General Dynamics Corporation, Pomona Division.

Computer software: Computer Sciences Corporation.



Technical advice to USN: The Johns Hopkins University, Applied Physics Laboratory.

Also more than 600 other suppliers.

2543.231

Mk 15 CLOSE-IN WEAPON SYSTEM (PHALANX)

The purpose of Phalanx is to provide last ditch defence against anti-ship missiles. In its primary mode Phalanx provides continuous surveillance and defence within its engagement envelope independent of other ship systems. Phalanx is an automatic gun fire control system that uses projectile spotting coupled with closed-loop aiming to provide multiple target hits and subsequent target destruction. The principal technical feature of the Phalanx system is the closed-loop electronic spotting technique. Aim correction is based on the ability to track both the incoming missile and the outgoing projectile in the vicinity of the missile, and to eliminate the error. The system uses a pulse doppler radar which shares a single transmitter to accomplish the search, acquisition, track and electronic spotting functions.

Phalanx naval close-in weapon system combines on a single mount a six-barrel gatling gun and fire control radars

Incorporating the widely used and service-proven M61A1 Gatling gun used in the Vulcan land mobile system (**2850.131**), Phalanx provides a high fire rate of 3000 rounds per minute. During firing, the ammunition feed system removes rounds from the front of the magazine drum, located under the gun, and feeds them through the chute conveyer system to the gun breech bolt assembly. After each round is fired, the empty case is extracted from the breech and conveyed back into the rear of the magazine. The gun can fire continuously under the control of the system's computer against air targets, or in the operator controlled burst mode against surface targets.

Phalanx is a total weapon system, and as a single modular package, automatically carries out search detection, threat evaluation, tracking, firing, and kill assessment. The system consists of six major assemblies and components: radar-servo assembly, gun assembly, mount and train drive platform, barbette equipment assembly, electronics enclosure and a pair of control panels. Supported by a high-speed digital computer, the fire control assembly performs these functions: target search, detection and declaration, target acquisition, target track and measurement of range, velocity and angle, projectile tracking, and measurement of projectile velocity and angle.

The gun assembly is composed of five major sub-assemblies. The gun, electrically controlled and hydraulically driven, consists of a rotating cluster of six barrels with a breech bolt for each barrel. The ammunition sub-system includes components that store, and transport rounds within the system. The gun's effectiveness is due to its firing a high kinetic energy penetrator made of high density metal. Destruction is caused by penetration of the 20 mm projectile into the warhead (of the incoming missile) and the imparting of kinetic energy into it, causing it to blow up before striking the ship.

The dual motor mount drives are torque biased to reduce system backlash, and friction is minimal. The lightweight structure has high stiffness-to-weight ratio in order to minimise impact of vibration on servo performance. The structural design will withstand all shipboard environments, including wave impact and blast forces from adjacent guns.

STATUS

In production for the USN and the naval forces of Australia, Japan, Saudi Arabia and UK. Since completion of the first Phalanx system in 1979, production contracts amounting to 249 units have been awarded and by December 1983, more than 249 systems were delivered. In November 1983 the manufacturer announced that the 135th USN Phalanx had just been declared operational. It was also reported that the battleship *New Jersey* has four systems fitted and the 'Aegis' class cruiser *Ticonderoga* has two systems. Fittings will be made in 39 classes of ship and the USN plans to install it in over 360 ships ranging from aircraft carriers to frigates. Actual and projected funding for Phalanx systems in the fiscal year 1986 Annual Report to Congress by the US Sectretary of Defence for the years 1984-87, with amounts in millions of dollars and quantities in brackets, was as follows: 1984 - $136·5(40); 1985 - $172·4(49); 1986 - $151·6(39); and 1987 - $134·1(32).

CONTRACTORS

CIWS system contractor: General Dynamics Corporation, Pomona Division, PO Box 2507, Pomona, California 91769, USA.

Vulcan gun: General Electric.

3983.231

SEA CHAPARRAL SURFACE-TO-AIR MISSILE SYSTEM

The Sea Chaparral surface-to-air missile system is an adaptation of the Chaparral land-based mobile air defence missile system (**2542.131**), which uses a version of the Sidewinder, AIM-9 (**1103.331** etc) air-to-air missile.

The launcher is a modification of that used in Chaparral in the self-propelled (M48) and ground emplaced (M54) land-based systems, but with provisions for operation either with the gunner in the mount, or with control by a remote gunner in the ship's operations room or other fire control facility.

As with the standard Land Chaparral, the Sea Chaparral system can be enhanced by the addition of forward looking infra-red sensors to provide a night engagement capability, and provisions can be made for target designation to be carried out by other ship's sensors, such as radar or optical target acquisition sights etc.

Details of the missile and its performance will be found in the above-noted entries in this volume.

STATUS

Few details have been released of fitting programmes for the Sea Chaparral system, but in February 1980 the US DoD was proposing the sale of 284 Sea Chaparral missiles and the necessary supporting and associated hardware to Taiwan at a cost of about $35 million.

In July 1983 it was proposed to supply Taiwan with 120 MIM-72F Sea Chaparral missiles.

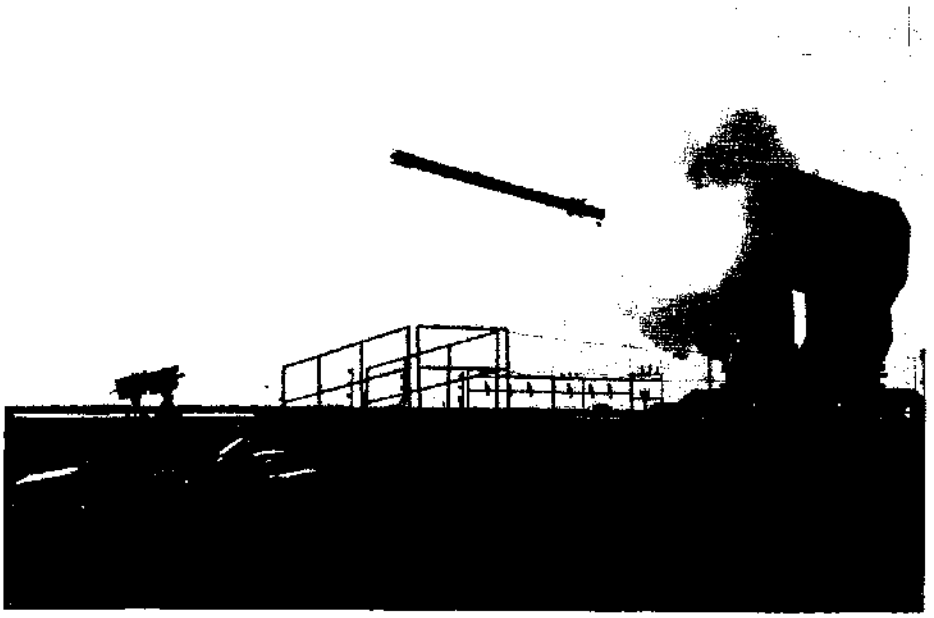
ASMD RAM SYSTEM



The RAM (rolling airframe missile) programme is a joint development programme carried out under a memorandum of understanding (MOU) signed by the United States, Denmark and the Federal Republic of Germany in 1979, with the intention of producing a lightweight, high rate of fire missile which will provide a system for anti-ship missile defence (ASMD).

There is a possibility of wider NATO participation, or of an eventual merging of this effort with a new NATO requirement for a supersonic anti-ship missile defence weapon. It is intended to supplement the anti-missile capabilities of other systems such as CIWS/Phalanx (**2543.231**), the various point defence missile systems based on the Sparrow (**2770.231**), and the longer-range capabilities of the US Fleet's other anti-air missiles. The prime threat which is to be countered by the overall ASMD weapon programme is the cruise missile. Seasparrow is cited as the ship's main battery for point defence, soon to be complemented by the ASMD RAM system, with the CIWS/Phalanx forming the secondary battery.

For those systems without a Sea Sparrow launcher, an ASMD autonomous launcher has been developed which is designated EX-31 GMWS. This consists of a two-axis yoke mount with geared motor drive, based on the CIWS/Phalanx system. The launcher is a bolt-down item which requires connection only of power, launcher train, and elevation orders and missile orders. It has about 80 per cent of the weight of the NATO Sea Sparrow (NSS) launcher.

Those ships already fitted with NSS launchers for ASMD missiles will use insert racks which fit into the NSS cells and hold the ASMD missile canisters which act as launch tubes. The racks will be attached to hard points in the cell and will distribute missile electrical signals from the launcher to the launch tubes. Five of the new ASMD missiles will be housed in each NSS cell. Two of the eight cells in each launcher will be used for ASMD missiles, thereby doubling magazine capacity. This configuration of the system is known as RAM ORDALT, and it is planned to carry ten RAMs in the two lower centre cells of the Sea Sparrow launcher.

The RAM EX-31 version of the system employs a launcher consisting of a production Phalanx mount and elevation and train drive assemblies (see **2543.231** above) carrying a launcher guide assembly which holds 21 missiles. An alternative mode has been designed with a capacity of 8 rounds, called the Very Lightweight RAM launcher and intended for fitting on smaller vessels.

Test firing of ASMD RAM from an EX-31 launcher at a land-based test site

It is planned to use existing command and control systems wherever possible. Ships fitted with tactical data systems will need modifications to digital programs similar to those for other anti-surface missile defence equipment such as Chaff roc. Additional conversion equipment will be required for transmission of ESM data and launcher orders, and receipt of missile and launcher data.

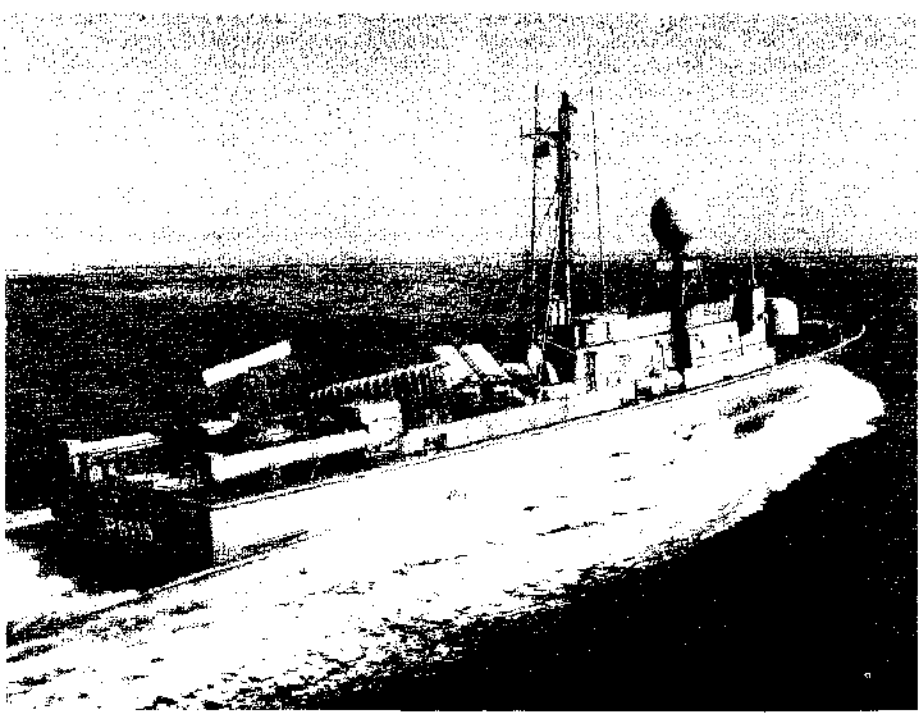
The ASMD missile in its initial configuration consists of a 5 inch rolling airframe with dual-mode passive radio frequency mid-course and IR terminal homing. In this version the Stinger IR seeker, the AIM-9L fuze (Mk 20) and warhead (WDU-17B), and the Chaparral/Sidewinder propulsion motor are used. This guidance technique is target dependent in that it requires both active radar and IR signals from the attacking missile to function. However, a significant proportion of the Soviet inventory is of such a type and is thought likely to be so for some time to come.

CHARACTERISTICS

Length: 2·79 m
Diameter: 127 mm
Weight: 70 kg
Speed: Supersonic
Guidance: Proportional navigation. Dual-mode, passive RF, IR homing
Launcher: RAM EX-31
Weight: 5736 kg (above deck); 726 kg (below deck)
Elevation: -25 to +80°
Train: 360°
Capacity: 21 rounds

STATUS

Two engineering development models of the RAM EX-31 launch system successfully completed proof of performance testing in Europe in March 1982. Two more of these mounts are being used in the USA, one at White Sands Missile Range for firing tests and the other for environmental qualification tests and at-sea firing trials in early 1983.



A series of flight tests is continuing at White Sands Missile Range, New Mexico. In October 1982 a RAM missile successfully intercepted a remotely controlled drone representing an anti-ship missile. This test verified performance in poor visibility. The first of a series of over-water tests took place at the Pacific Missile Range later that month and by February 1983 there had been three consecutive successful interceptions of remotely controlled drone targets that represented anti-ship missiles. In February 1983 it was announced that a RAM had successfully intercepted a remotely controlled supersonic, low-altitude Vandal missile target drone (**3240.391**). The Vandal is a converted Talos naval air defence missile designed to represent typical anti-ship missiles. Additional tests are planned to continue into 1985 when a full-scale production decision is due.

In his Report to Congress in February 1985, the US Secretary of Defense indicated procurement of 30 RAM systems in fiscal year 1985 at a cost of $20·4 million, 117 sets in fiscal year 1986 costing $45·1 million, and 400 systems in 1987 for a cost of $113·8 million. Some of these are expected to be filled retrospectively in selected Seasparrow installations.

It is expected that the US funding plan for this system will be matched proportionately by Denmark and Germany for their procurement shares. Development of RAM is funded equally by the US Navy and the German Navy with the Royal Danish Navy contributing two per cent. Series production deliveries of the first RAM systems to the German Navy are scheduled for 1987 where it is proposed to fit Type 143A fast patrol boats with one stern launcher each, and F122 'Bremen'-class frigates with two launchers each on the hangar deck.

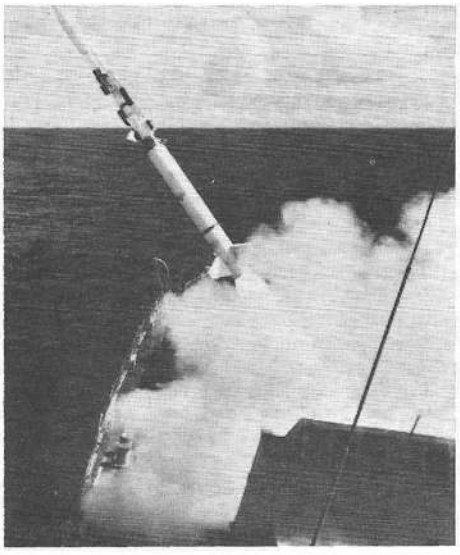
1122.231
STANDARD (RIM-66 AND RIM-67) SURFACE-TO-AIR MISSILE

The Standard shipborne surface-to-air missile began life as a two-model range of anti-aircraft weapons, intended to replace gradually Terrier and Tartar with the US fleet. The original two versions are the medium-range RIM-66A, and the extended-range RIM-67A. It was the first to be solid-state and is all electric with no pneumatic or hydraulically powered controls. Power for guidance and control is derived from a 'one-shot' battery which is activated just prior to missile launch.

For both types, fully automatic magazine and loading facilities are provided for twin electrically driven launchers. The RIM-66A had a dual-thrust solid-propellant motor, and the RIM-67A used solid-propellant booster and sustainer rockets. Both versions are equipped with conventional high explosive warheads, with direct action or proximity fuzing.

CHARACTERISTICS

	RIM-66A	RIM-67A
Speed	>Mach 2	>Mach 2·5
Ceiling	>20 000 m	>20 000 m
Range	>18 km	>55 km
Length	4·47 m	8·23 m
Diameter	34·3 cm	34·3 cm
Weight	Approx 610 kg	Approx 1360 kg



Subsequent developments have somewhat altered the original plan and versions of Standard have been, or are, in the process of development for surface-to-surface, air-to-surface, and new surface-to-air applications. The following list is arranged in logical rather than chronological order.

(1) Medium-range and extended range

All existing and most contemplated variants of the original missile can be made in either MR or ER versions. This possibility should therefore be borne in mind when examining the variants listed below.

(2) Standard 1 Missile (SM-1)

This is the original missile. Its principal advantage over the earlier Terrier or Tartar is that it has a (horizon-limited) surface-to-surface capability. It was expected to remain in production until 1975, but was still being procured in 1978 and is operational in over 70 missile ships and attack carriers.

Standard 2 missile firing from USS Wainwright *near San Juan, Puerto Rico*

Fiscal year:	1984	1985	1986	1987
SM-1 MR	(700) 209·2	(600) 199·3	26·4	(300) 143·5
SM-2 MR	(390) 289·7	(529) 355	(846) 509·7	(900) 527
SM-2 ER	(100) 103	(255) 186·7	(470) 312·2	(600) 365·9
Standard mods	5·1	6·2	17·1	9·3

(3) Standard 2 Missile (SM-2)

This missile completed development in 1977 and has entered the initial phase of production. The SM-2 approximately doubles the range of SM-1 in both MR and ER versions. Lengths of the two versions are 4·47 and 8·23 m. An inertial reference is provided, and to satisfy the requirements of the Aegis system the missile-borne equipment is augmented by a two-way link for the mid-course command guidance. Other improvements include a new semi-active terminal guidance receiver with greater resistance to ECM.

The most important changes embodied in the SM-2 are: the replacement of the SM-1 conical-scan semi-active radar homing receiver by a monopulse receiver; the provision of an inertial reference unit for mid-course guidance; a communications link for mid-course guidance correction/target position data updating and missile position reporting; and a digital guidance computer instead of the SM-1's analogue computer. These improvements make possible a far more efficient trajectory to the target, resulting in an effective 60 per cent increase in range for the MR model and more than 100 per cent increase in that of the ER model.

In the late 1970s, it was decided to expand the number of USN ships capable of employing the added capability of the SM-2 missile, beyond the 'Aegis' class vessels for which it was initially intended. This led to the CG/SM-2 weapon system programme under which it was planned to replace Terrier missiles (**6005.231**) on board 20 ships of the CG-16 and CG-26 classes (33 ships were equipped with Terrier, others being the DDG-37 class of ten vessels, one CG(N)-9 and 2 CV class carriers) with SM-2 Extended Range missiles. This programme entailed modifications to the ships' weapons control systems and radar etc, and computer software and is now largely complete.

By means of the inertial reference unit in the SM-2 missile it flies a mid-course phase wherein the missile navigates itself to the vicinity of the target. Semi-active terminal guidance, supported by the target illumination from the original Terrier fire control system, is used to complete the engagement.

The inertial reference unit and guidance computer in the SM-2 are initialised by the new weapon direction system Mk 14. Target data are derived from the modified AN/SPS-48 radar (**1252.253**) and ship attitude and velocity are provided by new shipboard gyro-compass equipment. The Navy Tactical Data System is modified to accommodate the command and control interface facilities required.

This system results in significantly decreased target processing time. Originally, a series of sequential and manual operations was involved between target detection and missile launch, and this can occupy several minutes. With the CG/SM-2 system, all target detections are passed to NTDS and those selected for engagement by the Terrier systems are automatically passed to the weapon direction system. Subsequent to launch, the fire control radar is assigned to provide target illumination for the terminal phase of flight.

The SM-2 monopulse homing receiver is also to be fitted to SM-1 MR missiles intended to be used in upgrading existing Tartar-fitted ships (see **6006.231**) in a broadly similar fashion to the CG/SM-2 programme. Additional information on the Terrier missile system will be found in **6005.231**.

(4) Standard ARM

Essentially an airborne version (see **1123.331**) this has also been adapted for use in a surface-to-surface role as part of the Interim Surface-to-Surface Missile System (**2669.221** and **2808.221**).

(5) Standard Active

The original intention was for this missile to serve as an interim anti-ship weapon until completion of Harpoon development, but delays with Active Standard made both missiles more or less contemporaries. The position at mid-1974 was that Active Standard would be maintained in development only until it was confirmed that it would no longer be required as a back-up to Harpoon. Progress with Harpoon development has led to cancellation of Standard Active.

Brief details of various Standard models and their US Service designations are given in the following list:

YRIM-66A: Standard-1 (MR). Basic development model to replace Improved Tartar. Mk 27 Mod 0 motor

RIM-66B: Standard-1 (MR). Similar to RIM-66A but with improved motor, Mk 56 Mod 0, for better performance

RIM-66C: Standard-2 (MR). Similar to RIM-66B but adapted for Aegis system

RGM-66D: Standard SSM (ARM). Similar to RIM-66B but modified for surface-to-surface anti-radiation roles

RGM-66E: Standard SSM (ARM). Similar to RGM-66D but adapted for use with Asroc launcher

(Y)RIM-67A: Standard (ER). Replacement for Terrier. Uses Mk 30 Mod 1 sustainer to give extended range

RIM-67B: Standard-2 (ER). Similar to RIM-67A but used with CG/SM-2 weapon system

STATUS

Since the Standard missile entered service in the late 1960s more than 10 000 have been delivered by General Dynamics to the USN and other navies.

In his Report to Congress of February 1985 the US Secretary of Defence stated that to improve the US Navy's area air defences, large quantities of Standard surface-to-air missiles are to be procured, both SM-1 and SM-2 versions, for anti-air warfare (AAW) cruisers, destroyers, and frigates. The five-year programme funds about 11 000 of these missiles. Details of some of the specific funding items that have been identified from the fiscal year 1986 procurement programme are tabulated above (quantities in brackets and funding in millions of dollars):

The Defence Secretary also reported the introduction of major improvements to the Standard system. A 'Block 2' version of the SM-2 in current production will give improved intercept capabilities against sophisticated anti-ship missiles such as the Soviet AS-4. New warhead fuzes, with better capabilities against sea-skimming missiles, are being developed, and an "outer air battle missile" programme is investigating the feasibility of intercepting enemy bombers before they can launch their weapons.

CONTRACTOR

6006.231
TARTAR SURFACE-TO-AIR MISSILE (RIM-24)

Tartar is a medium-range, supersonic surface-to-air shipboard guided missile system. It provides primary air defence for USN destroyers and destroyer escorts and secondary air defence for cruisers. The missile booster and sustainer rockets are combined in a single solid-propellant motor, thus facilitating installation on smaller ships.

OPERATION

Tartar employs a fully automatic magazine handling and loading system. Targets are designated to the system in two or three co-ordinates by radar. The tracker/illuminator radars automatically follow the targets and a computer provides missile launcher pointing orders. Guidance is semi-active homing, probably operating in I/J-band. The missile carries a high explosive warhead with DA and proximity fuzes.

The rocket motor has two levels of thrust to achieve rapid acceleration. The guidance system computes a collision course, then steers to intercept by means of four hydraulically actuated tail fins.

CHARACTERISTICS

Range: >16 km
Speed: Mach 2
Length: 4·6 m
Diameter: 34·3 cm
Weight: 680 kg
Motor: Dual-thrust solid-propellant
Guidance: Semi-active homing

DEVELOPMENT

Developed shortly after Terrier system and first entered USN service in 1961.

At mid-1977 there were 49 USN ships deployed with the Tartar weapons system and with Standard SM-1 (medium range) missiles. This includes nuclear-powered cruisers, guided missile destroyers, and guided missile frigates. This fleet could grow to more than 100 vessels in the 1980s with the introduction of the FFG-7 class. This factor and the evolving threat seen in such Soviet weapons as the Backfire bomber/AS-6 air-to-surface missile combination,

require a continuing programme of ship system and missile improvements. This is applicable in principle to the considerable number of non-US ships fitted with the Tartar/Standard missile system, at present some 29 ships with 11 more planned.

The improvement plan being implemented is similar to that adopted for Terrier-fitted ships and described in the entry for the Standard missile system (**1122.231**), and officially known as the CG/SM-2 (ER) programme. In the case of Tartar ships, such as the DDG-2 class, improvements in the ship's system will entail addition of the AN/SPS-52 three-dimensional radar (**1248.253**), the AN/SPS-65 radar, modifications to the AN/SPS-40 radar (**1746.253**), and integrated automatic detection and tracking of all radar targets by the SYS-1 plot extraction equipment. Control improvements will be provided by the weapons direction system Mk 13 and the DDG tactical data system, which are based on already deployed systems. Engagement from the ship's system aspect is improved by modification to the basic Tartar Mk 74 missile fire control system and addition of the Mk 86 FCS (**1241.281**) with gun and missile capability.

A similar updating and improvement programme will be applied to the SM-1 MR missiles employed. Some of these changes have been implemented and already SM-1 rounds have been deployed incorporating the new, improved Mk 45 fuze and the Mk 90 warhead. Other projected missile improvements include substitution of the SM-2 monopulse seeker receiver for the original conical scan seeker of the SM-1.

Additional details on the Standard Missile programme will be found in **1122.231**, above.

STATUS

Tartar is no longer in production but is still operational in a large number of USN ships and in the Australian, French, Iranian, Italian, Japanese, Netherlands, Spanish and West German navies. Replacement by the Standard missile (**1122.231**) has begun. The fiscal year 1986 Defence budget showed sums of $60·4 million, $113·6 million, $106·8 million and $23·7 million for Tartar support in the years 1984/85/86/87.

CONTRACTOR

Prime contractor: General Dynamics Corporation, Pomona Division, PO Box 2507, Pomona, California 91766, USA.

RIM-24 Tartar surface-to-air missile on Mk 13 GMLS of nuclear-powered cruiser USS California (USN Photo)

6005.231

TERRIER SURFACE-TO-AIR MISSILE (RIM-2)

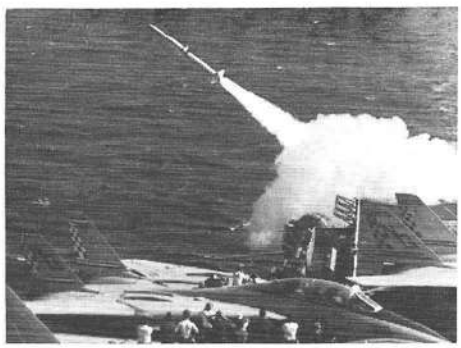
This is a surface-to-air anti-aircraft missile for shipboard use. The Terrier series of missiles has been operational since 1956 and since then it has been the subject of continued development and improvement. The US military designation is RIM-2 and successive models have been denoted by letter suffixes running from RIM-2A to the latest version, the RIM-2F. The latter is also known as the Advanced Terrier.

CHARACTERISTICS

Range: >35 km
Ceiling: >20 000 m
Speed: Mach 2·5
Overall length: 8 m
Length without booster: 4·6 m
Body diameter: 34·3 cm
Weight: 1400 kg (approx)

OPERATION

Beam-rider guidance is employed to direct the missile against a target designated by the ship's tactical data system. A twin launcher is supported by automatic magazine and loading arrangements. Terrier is launched by a solid fuel rocket booster and propelled by a solid fuel sustainer.



The normal warhead is of the HE type with direct action or proximity fuze, but one version of Terrier (RIM-2D) has been produced with a nuclear head.

DEVELOPMENT

Development started about 1951, under the former military designation SAM-N-7, and Terrier was based upon the experimental LARK vehicle. First Terrier became operational in 1956.

STATUS

Advanced Terrier (RIM-2F) became operational in 1963 and is carried by USN cruisers, frigates, and attack carriers. It has also been purchased by the Italian Navy. The system is progressively being replaced by the Standard missile system (**1122.231**). See this entry also for additional details of Terrier weapon system status, in particular in regard to the CG/SM-2 (ER) programme. The 1986 fiscal year Defence budget contained amounts of $83 million, $67·3 million, $112·1 million and $51·0 million for continuing Terrier support in fiscal years 1984/85/86/87.

Launch of Terrier surface-to-air missile from aircraft carrier USS Constellation (USN)

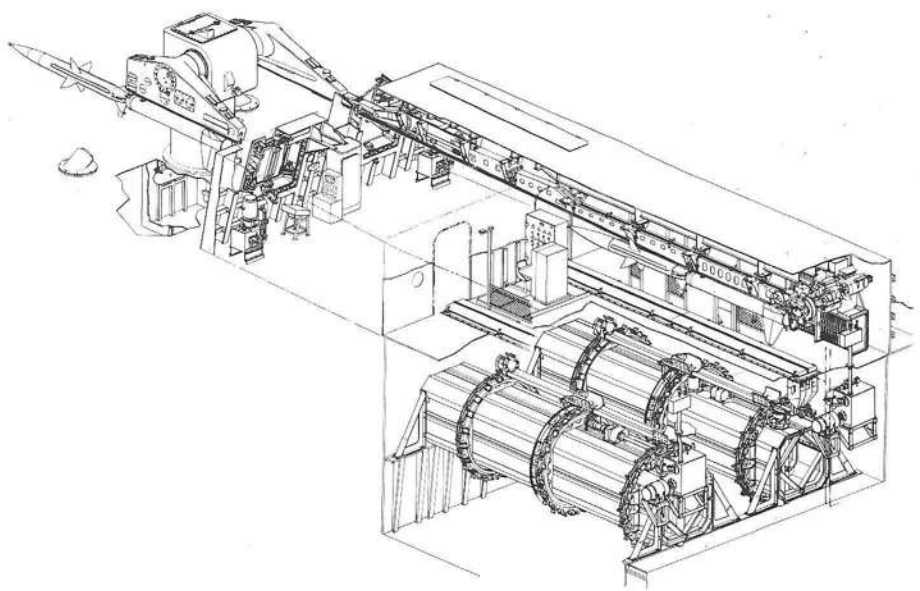
US MISSILE LAUNCHER SYSTEMS

The Northern Ordnance Division of the FMC Corporation, as well as providing most of the naval tubed ordnance requirements of the USN and many friendly navies elsewhere, supplies the launcher systems for most of the guided missiles employed by the USN. Guided missile launching systems (GMLS) are fully automatic systems comprising the missile launcher arms complete with slewing and elevation mechanisms, and reloading facilities appropriate to the missile types carried by the ship. FMC believe the GMLS Mk 4, produced about 25 years ago for the USN, to have been the first entirely automatic missile launching system in the world. Since that date the company has designed and produced six different marks of GMLS, each of them in several models, and the main details are outlined in the following paragraphs.



GMLS Mk 4

This system was produced for ships fitted with the Terrier surface-to-air missile system. The GMLS Mk 4 Mods 0 and 1 were fitted in the USS *Boston* and *Canberra* (both now withdrawn) while the Mk 4 Mod 4 was fitted in the Italian cruiser *Nave Garibaldi* (also decommissioned). Twin-ramp launchers were reloaded vertically through two hatches from a magazine below deck, in which the missiles were also stored vertically.

No Mk 4 Terrier missile systems remain in active service although a few are used on missile test ranges.

General arrangement drawings of FMC Mk 4 Mod 4 GMLS

Mk 10 Mod 0 GMLS with two horizontal magazine drums for reload missiles. Other models have more drums

GMLS Mk 7

Also developed for large ship installation, the Mk 7 missile launcher system is now retired from active service, with a few systems in use on missile test ranges. The Mk 7 was designed for use with the heavy long-range Talos surface-to-air missile system. Missiles were stored horizontally in the magazine and the twin launch ramps were reloaded in a horizontal, or near horizontal position. Obsolete.

GMLS Mk 10

There are numerous models of the GMLS Mk 10, a twin-ramp launcher system designed for use with Terrier and Standard (ER) surface-to-air missile systems. This design continues the horizontal storage and reloading pattern set by the GMLS Mk 7, although certain installations differ by the amount the conveyor track deviates from the true horizontal along the route from the magazine to the missile launch ramp. Mods 2, 5, and 7 are those models which most exhibit this characteristic. Various models of the system are found on numerous ships of lesser tonnage and the capacity of the magazines for reload missiles also varies between models, although all employ a similar form of horizontal drum storage for the rounds to permit mixed salvoes.

Substantial control system and performance improvements are in progress for the Mods 0, 1, 2, 5, 6, 7 and 8. When these are complete the Model designations of these systems will be changed to Mk 10 Mods 10, 11, 12, 13, 14, 15 and 16.

The Mk 10 models 3 and 4 systems originally installed aboard CVAs have been retired from active service.

CHARACTERISTICS

Launcher type: Mk 10 Mods 0-8 (except where otherwise indicated)

Missile(s): Terrier, Standard SM-1 (ER), Standard SM-2 (ER), ASROC (Mods 7 & 8 only)

Ready-use rounds: 40; 80 (Mod 2); 60 including up to 20 ASROC (Mods 7 & 8 only)

Target capability: Air and surface; air, surface, u/water (Mods 7 & 8 only)

System weight (without missiles): 1·251 t (Mod 0); 1·258 t (Mod 1); 2·416 t (Mod 2); 1·291 t (Mods 3 & 4); 1·304 t (Mod 5); 1·247 t (Mod 6); 1·641 t (Mod 7); 1·652 t (Mod 8)

System weight (full missile load): 1·816 t (Mod 0); 1·823 t (Mod 1); 3·154 t (Mod 2); 1·856 t (Mods 3 & 4); 1·869 t (Mod 5); 1·812 t (Mod 6); 2·479 t (Mod 7); 2·491 t (Mod 8). (Missiles assumed 1360 kg each and launcher complete with all fluids.)

Training limits: Unlimited; 180° due to ship's structure (Mod 3)

Training velocity/acceleration: 30°/s; 60°/s²

Elevation limits: –10 to +90°; –3 to +90°, Mods 3 & 4

Elevation velocity/acceleration: 20°/s; 40°/s²

Total crew: 12 (3 panel operators, 8 assembly men, 1 safety observer)

Ship fittings

Mod 0, 'Farragut' class, aft
Mod 1, CG(N)-9 *Long Beach*, forward
Mod 2, CG(N)-9 *Long Beach*, forward
Mod 5, 'Leahy' class, forward
Mod 6, 'Leahy' class destroyers, aft
Mod 7, 'Belknap' class destroyers, forward
Mod 8, CG(N)-35 *Truxtun*

System interface: WDS Mk 14, GMFCS Mk 76, UBFCS 114 or 116 (Mods 7 and 8 only)

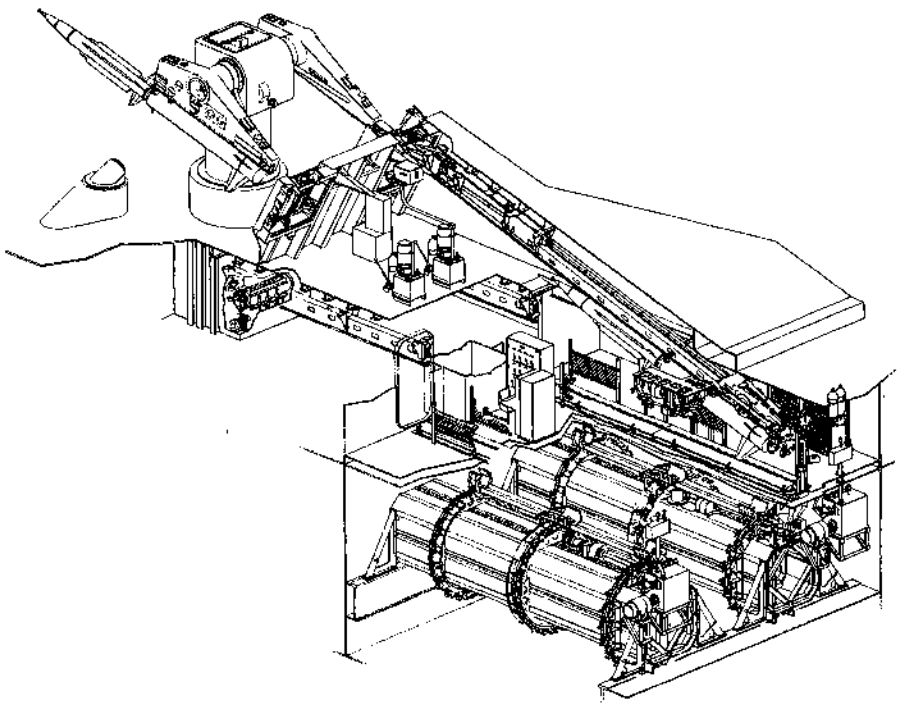
Misfire removal: Automatic jettison, air actuation

Anti-icing system: Steam

Power requirements: 440 V, 60 Hz, 3-ph

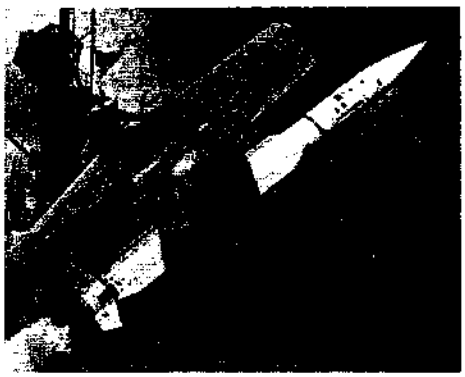
Average standby load: 52·6 kW

Average continuous operation load: 124·9 kW



Peak continuous operation load: 202·7 kW

In addition to the USN fittings of the Mk 10 GMLS listed above, the Italian Navy aircraft carrier *Vittorio Veneto* is fitted with a Mk 10 Mod 9 GMLS forward, and the Italian cruisers *Andrea Doria* and *Caio Dilio* were fitted with the Mk 10 Mod 0. The Peruvian ship *Aquirre* was fitted with a Mk 10 Mod 5, but this was removed and returned to the USA.



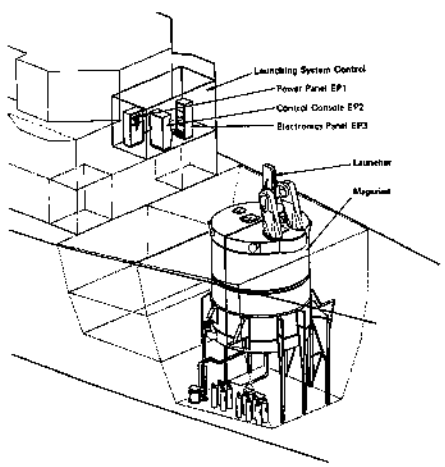
GMLS Mk 13

The GMLS Mk 13 series marks a return to vertical stowage and reloading of missiles, as well as representing a changeover to single-ramp launcher, embodied in a modular design which combines the launcher, reloading mechanism and magazine in a single unit which can be installed in the ship as an entity. This system has been used by the USN since 1962 in various models (from Mod 0 to 3) and a total of 41 had been supplied to the USN and the navies of six friendly countries by 1979, when the Mk 13 Mod 4 was introduced. This version incorporated improvements in all elements of the electrical control system while retaining the basic Mk 13 mechanical and hydraulic design. Among the benefits from these improvements were reduced reaction time because of remote start and fire capabilities that permit remote operation; reduced manning requirements; ability to fire a wide range of missiles; and ability to withstand inadvertant ignition of the 'hotter' Mk 56 rocket motor by virtue of the addition of ablative material in the magazine plenum chamber. The Mk 13 Mods 0 to 3 were designed to accommodate RIM-24 Tartar and Standard 1 (MR) missiles, but the Mod 4 version handles the later Standard 2 (MR) and Harpoon surface-to-surface missiles also.

Three main groups of components comprise the Mk 13 Mod 4 GMLS; the launching system control Mk 162 Mod 0, the launcher Mk 126 Mod 4, and the magazine Mk 109 Mod 0, plus certain ancillary units. The first of these electronically directs and monitors operation of the overall GMLS and includes the power panel (EP1), control console (EP2) and electronics panel (EP3). Control of the GMLS normally takes place remotely from the ship's fire control system, but local loading and pointing are possible from EP2,

FMC Mk 10 Mod 5 missile launcher and magazine. More rotary horizontal magazine drums are provided in other models for different classes of ship

FMC Mk 13 single-ramp launcher in use



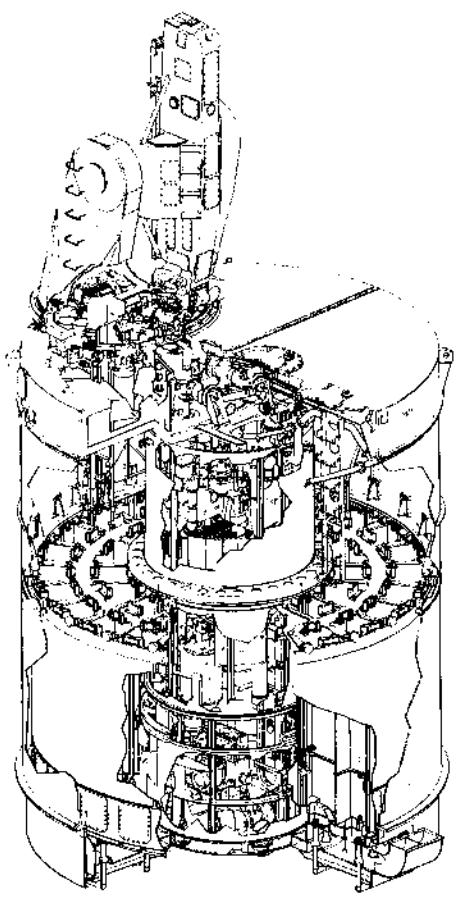


Diagram showing typical location of GMLS Mk 13 Mod 4 components

FMC Mk 13 Mod 1 GMLS employs vertical storage and launcher reloading. This mark permits modular ship fitting of missile launcher and magazine

permitting various reversionary modes of operation and exercise functions. The Mk 126 single-ramp launcher receives missiles from the ready service ring (RSR), part of the Mk 109 magazine that rotates to present missiles from the magazine via inner and outer rings which provide a total of 40 missiles. A single electric motor and hydraulic pump provide the power to drive either the RSR or the hoist used to position missiles in the magazine or offer them to the launcher ramp. Electric motors and hydraulic power transmission trains are used for actuation of the launcher in train and elevation.

CHARACTERISTICS

Launcher type: Mk 13 Mods 0-7 (except where otherwise indicated)

Missile(s): Tartar Standard 1 (MR), Standard 2 (MR), Harpoon (Mods 4-7)

Ready-use rounds: 40, any mixture

Target capability: Air or surface

System weight (without missiles or fluids): 6·022 t (Mod 0); 6·137 t (Mods 1 & 2); 6·133 t (Mod 3); 6·110 t (Mod 4)

System weight (with missiles and fluids): 8·432 t (Mod 0); 8·547 t (Mods 1 & 2); 8·543 t (Mod 3)

Training limits: Unlimited

Training velocity/acceleration: 90°/s, 200°/s²

Elevation limits: −15 to +85°

Elevation velocity/acceleration: 45°/s; 120°/s²

Tactical crew: 2 (1 panel operator, 1 safety observer)

Ship fittings

Mod 5/Mod 0: USN missile destroyers, DDG 15-24; 9 foreign ships

Mod 6/Mod 1: 4 USN (DDG 31-34) and 8 foreign missile destroyers

Mod 7: 2 USN cruisers, CGN 36 & 37

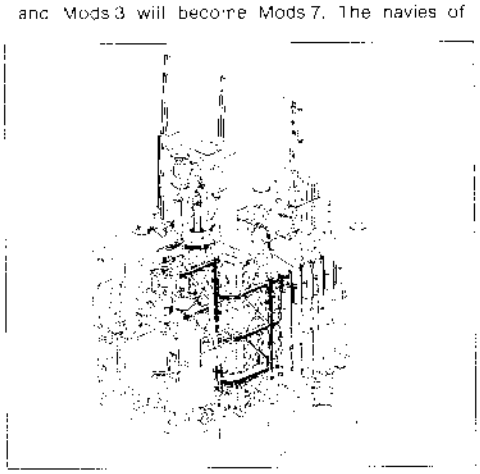
Mod 4: 50+ Oliver Hazard Perry class frigates

System interface: GMFCS Mk 74; GMFCS Mk 92 (Mod 4)

Misfire removal: Automatic jettison

Anti-icing system: Dry steam; electric (Mod 4)

Power requirements: 440 V, 60 Hz, 3-ph



Average standby load: 22·9 kW; 25·7 kW (Mod 4)

Average continuous operation load: 43·9 kW; 46·7 kW (Mod 4)

Peak continuous operation load: 210·7 kW; 209·2 kW (Mod 4)

By 1981, 41 GMLS Mk 13 Mods 0 to 3 had been built and installed for the USN and the navies of six other countries, Australia, France, Italy, Japan, Netherlands, and West Germany. By 1985, 59 GMLS Mk 13 Mod 4 had been built and installed for the USN and the navies of four other countries: Australia, Japan, Netherlands and Spain. Twelve more are planned for delivery between 1985 and 1987 for the USN, Australia, Japan, Italy, Netherlands and Spain.

The USN Mk 13 Conversion Programme is currently upgrading Mods 0, 1, 2 and 3 systems to include features found on the Mk 13 Mod 4. The refurbishment programme adds ablative materials to the magazine plenum chamber, improves sprinkling characteristics, provides a solid state control system with built-in test equipment, and alters the power system from high to low voltage. When the programme is completed, the Mods 0 and 2 GMLS will be designated Mod 5; Mods 1 will become Mods 6 and Mods 3 will become Mods 7. The navies of Australia and France are also currently planning to upgrade GMLS Mk 13.

FMC Mk 26 Mod 1 GMLS is a modular system which can be configured with magazine capacities of 24, 44 or 64 missiles

GMLS Mk 22

The GMLS Mk 22 is a lightweight version of the Mk 13, above, and is designed on an identical concept having much the same performance and configuration. Only the magazine size has been reduced, primarily to facilitate fitting in smaller vessels. Operated from a remote fire control station, the Mk 22 will direct and launch a ready-use complement of 16 Tartar or Standard missiles for surface-to-air applications and can be modified to launch the surface-to-air Standard 2 (MR) and Harpoon missiles for surface-to-surface engagements.

CHARACTERISTICS

Launcher type: Mk 22 Mod 0

Missile(s): RIM-24 Tartar, Standard (MR), Standard 2 and Harpoon with modification

Ready-use rounds: 16, any mixture

Target capability: Surface or air

System weight (without missiles and fluids): 4·190 t

System weight (with missiles and fluids): 5·193 t

Training limits: Unlimited

Training velocity/acceleration: 88·5°/s; 132°/s²

Elevation limits: −15 to +95°

Elevation velocity/acceleration: 49°/s; 135°/s²

Tactical crew: 2 (1 panel operator, 1 safety observer)

Ship fittings

6 USN 'Brooke' class missile frigates

5 Spanish F-70 'Baleares' class frigates

System interface: GMFCS Mk 74

Misfire removal: Automatic jettison

Anti-icing system: Dry steam

Power requirements: 440 V, 60 Hz, 3-ph

Average standby load: 20·6 kW

Average operation load: 39 kW

Peak operation load: 164 kW

GMLS Mk 26

The Mk 26 GMLS is the latest and most versatile launching system in operational use by the US fleet and is capable of automatic handling and launching a mixed complement of Standard surface-to-air and ASROC anti-submarine missiles. Modular design and construction enables installations with magazine capacities of 24, 44 or 64 rounds to be fitted. The Mk 26 is credited with the shortest reaction time and fastest weapon launch rate of any existing US area defence shipboard launching system. The Mk 26 Mod 5 is the main launching system on the USN's new CG-47 Aegis class cruisers.

CHARACTERISTICS

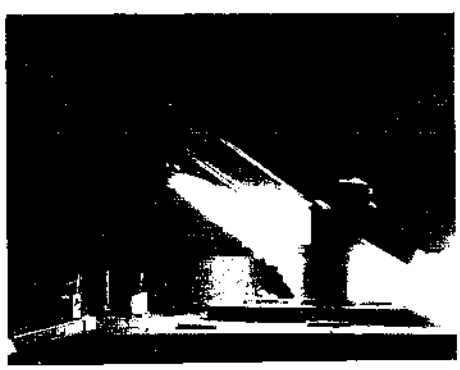
Launcher type: Mk 26 Mods 0-5 (except where otherwise indicated)

Missile(s): Standard (MR), RUR-5A ASROC

Ready-use rounds: 24 (Mods 0 & 3); 44 (Mods 1, 4, 5); 64 (Mod 2), any mixture

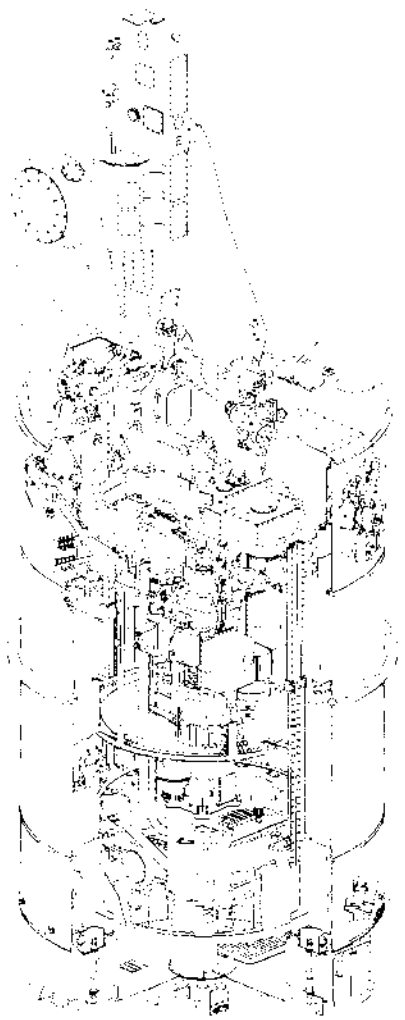
Target capability: Air, surface, u/water

System weight (without missiles and fluids): 7·303 t (Mod 0); 9·385 t (Mod 1); 12·056 t (Mod 2); 7·210 t (Mod 3); 9·237 t (Mods 4 & 5)



System weight (with missiles and fluids): 8·685 t (Mod 0); 11·920 t (Mod 1); 12·056 t (Mod 2); 8·604 t (Mod 3); 11·792 t (Mods 4 & 5) (Missiles assumed average weight 580 kg each.)

Training limits: Unlimited



Training velocity/acceleration: 90°/s, 180°/s²

Elevation limits: 10 to −90°

Elevation velocity/acceleration: 50°/s; 100°/s²

Standard missile launch from GMLS Mk 26 aboard USS Norton Sound

Mk 22 Mod 0 GMLS offers the same modular ship fitting possibilities as the Mk 13, for smaller vessels

Tactical crew: 3 (control console operator, 2 fin assembler/loaders)

Ship fittings

Mod 0: USS *Norton Sound*, 4 USN cruisers

Mod 1: 4 USN nuclear cruisers

Mod 2: Land based test unit

Mod 3: 4 USN 993 class destroyers

Mod 4: 4 USN 993 class destroyers

Mod 5: USN Aegis cruisers 47-51

System interface: GMFCS Mk 74 Mod 5; Mk 116 underwater FCS

Misfire removal: Automatic jettison

Anti-icing system: Steam

Power requirements: 440 V, 60 Hz, 3-ph

Peak standby load: 105 kW

Peak running load: 480 kW

STATUS

The GMLS Mk 4 is now obsolete and few installations remain in service. The situation with the Mk 7 employed for the large Talos air defence missile is also related to the obsolescence of that weapon system. The many existing installations of the various models of the Mk 10 GMLS are likely to remain in service for a considerable period to come, with the systems being updated to accommodate the Standard SM-2 (ER) surface-to-air missile as part of the USN's CGN/New Threat Upgrade programme. FMC was awarded a $36·6 million USN contract in 1983 for continued Mk 13 Mod 4 system production, including two more launchers for FFG-7 class frigates and one launcher for Japan, and with these FMC will have supplied 107 Mk 13 systems since the early 1960s. Deliveries are scheduled to January 1986. The Mk 22 is no longer in production, but is being considered for modernisation to accommodate the Harpoon missile. The Mk 26 is currently in production for the first five Aegis cruisers.

FMC Corporation, Northern Ordnance Division, 4800 East River Road, Minneapolis, Minnesota 55421, USA.

4204.231
MK 41 VERTICAL LAUNCH SYSTEM

The USN's vertical launch systems (VLS) programme has now reached the production stage with the Mk 41 VLS which will provide an improved missile launching system for surface vessels of the US fleet.

The system is based on a modular design, the basic unit being a launcher module containing eight missile cells. Each module, which consists of a structure, independently operating armoured hatch-covers, a gas-management system and requisite electronics, power supplies and support equipment, is assembled ready for installation aboard ship. Each of the eight cells in a module is designed to house a missile canister, and the system design allows any missile adapted for vertical launch to be fired from any cell. The missile canister is of corrugated steel construction and is both protective and reusable, thus serving as the shipping container and as the launcher rails for the missile. The basic eight-cell module is designed as part of a Mk 41 VLS magazine. Each of the two magazines for the Aegis cruisers (CG-47 class) consists of seven eight-cell modules, plus one five-cell 'strikedown' module, thus giving the ship a total capacity of 122 missiles. A complete Mk 41 VLS magazine of seven eight-cell modules and one strikedown module, containing 61 missiles in all, occupies the space required for one Mk 26 Mod 0 conventional GMLS with a capacity of 44 missiles.

The strikedown, or replenishment, module is almost identical to the standard eight-cell module except that a hoist supporting an articulating crane is contained in the space of three cells. The inclusion of this module in each VLS magazine provides a capability for underway replenishment of the system.

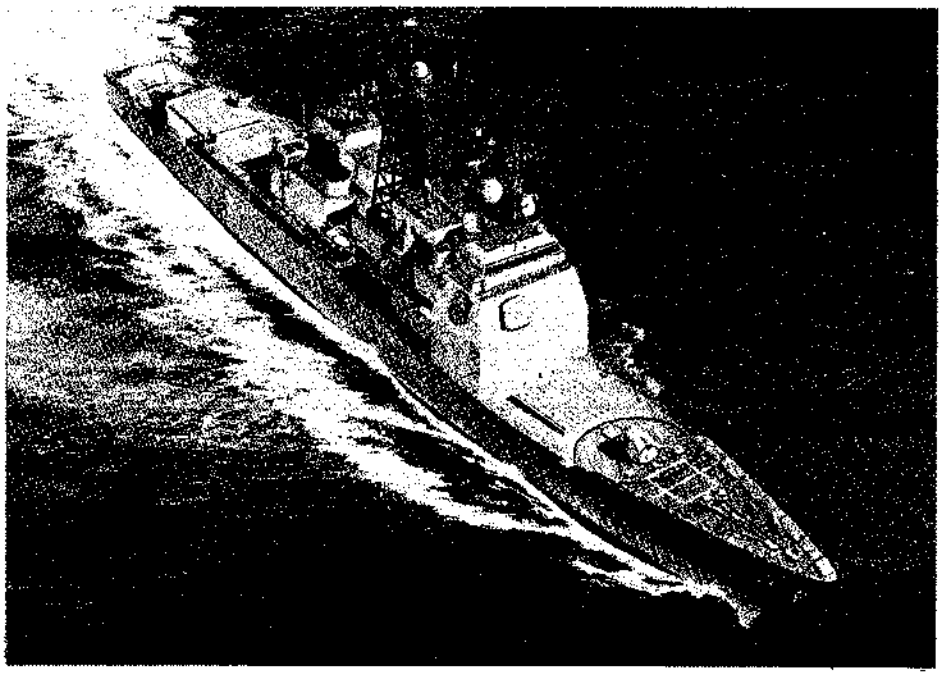
Two launch control units (LCUs) consisting of AN/UYK-20 USN digital processors and associated peripheral equipment, are located at the ship's weapons control station. These interface digitally with the appropriate ship's weapon control systems and control the launch of missiles. The Mk 41 VLS is designed to be able to interface simultaneously with up to three fire control systems, ie for air defence, surface engagement, and anti-submarine warfare systems. The initial missile compatibility specified calls for an ability to handle mixtures of Standard missiles, although provisions have been made throughout the programme for the inclusion of additional missile types later, and an important example of this is the inclusion of a requirement to accommodate missiles of 5·58 metre length and 1134 kg weight. An early addition to the VLS programme is the Tomahawk cruise missile. Integration of the ASROC anti-submarine missile capability is also nearing completion.

The hatch covers of each eight-cell module are individually heated for anti-icing and provided with an electric motor for opening and closing, these being remotely controlled. A deluge system with individual valves for each canister provides a water deluge to the missile warhead in the event of over-heating or accidental motor ignition. A separate sprinkler system provides fire protection for the other magazine spaces. Each module contains a plenum and uptake to vent the exhaust gases from a fired missile. The plenum and uptake are lined with ablative material to protect the structure against missile exhaust, and each module is capable of a minimum of 64 firings before ablative repairs are needed.

The missile, when ignited, pressurises the canister breaking the lower end cover allowing the gases to fill the plenum and exhaust vertically through the open uptake hatch at deck level. Double elastomeric seals are provided to form gas-tight joints at both ends of the canister to prevent gases entering the magazine spaces.

CHARACTERISTICS

Launcher type: Mk 41 Mod 0 (CG-47 class), Mod 1 (DD-963 class), Mod 2 (DDG-51 class)
Missiles: SM-2 (Block II), Tomahawk, ASROC (development)
Target capability: Air, surface, u/water (development)
System weight: 117 081 kg (empty magazine); 231 971 kg (loaded) (61 cell magazine)
Tactical crew: 0
Anti-icing system: Electric
Power requirements:
60 Hz, 440V AC, 3ph 207 kW (max)
60 Hz, 115V AC, 3ph 6 kW (max)
60 Hz, 115V AC, 3ph 10 kW (max)
60 Hz, 115V AC, 1ph 5·4 kW (max)
400 Hz, 440V AC, 3ph 36 kW (max)



STATUS

Developed for the USN to development specification WS 18968A, the Mk 41 VLS is in production at the FMC Corporation Northern Ordance Division and Martin Marietta Aerospace, Baltimore Division. Firing tests of a prototype launcher module at White Sands Missile Range were completed in January 1981 when six Standard missiles were successfully launched, three as single launches and the other three as a ripple firing to evaluate rapid fire capabilities. In related tests, Tomahawk cruise missiles were launched vertically from a VLS module at Point Mugu, California. Pre-production Tomahawk-capable VLS modules have been installed in the USS Norton Sound for the integration of Tomahawk/Aegis. The full Tomahawk launch capability is scheduled for all VLS ships. Procurement of Tomahawk-capable VLS for installation in 'DD-963' class ships started in 1983, all 31 ships of the class to be fitted. Installation in 'Arleigh Burke' class (DDG-51) destroyers is also planned.

MARTIN PESCADOR AIR-TO-SURFACE MISSILE

The Martin Pescador is a supersonic aircraft-launched tactical missile for use over short to medium ranges (2·5 to 7·9 km), maximum ranges being dependent upon aircraft speed at launch. It is powered by a single-stage solid-propellant rocket motor, and carries a conventional high explosive warhead weighing 40 kg. The motor exhausts through a bell-shaped nozzle, and the warhead is actuated by a direct action fuze.

The configuration of the Martin Pescador consists of the following major components: the fore-body containing radio receiver, power source, control mechanisms and logic devices; centre section with warhead and fuze; aft body section containing the rocket motor, propellant and flares; four wings attached to the aft body; and four canard control surfaces actuated by the fore-body control sub-system.

The maximum speed is Mach 2·3 and the speed at impact is Mach 1·1. The approximate time of flight is 13 s.

OPERATION

Radio command is used to direct and steer the Martin Pescador to its target. Launching is possible from any aircraft capable of a speed of Mach 0·5 or more. Launch from a hovering helicopter is possible also, in which case a range of 4·3 km can be achieved with a missile impact speed of Mach 1·1. The rear of the missile carries three flares to assist in tracking. Command signals are sent to the missile from the launching aircraft which carries the command radio transmitter. The pilot has to keep the missile on his line of sight to the target during its flight time and a button on the aircraft control column is provided for this purpose. In order that a number of Martin Pescador missiles can be launched simultaneously from several aircraft, co-ordinated changes of radio command frequency have to be taken into account; facilities for this are provided on a missile control panel in the cockpit.

DEVELOPMENT

The Martin Pescador missile has been developed by the Instituto de Investigaciones Cientificas y Tecnicas de las Fuerzas Armadas (CITEFA) on behalf of the Argentinian Forces. It should be noted that the word 'Martin' does not signify any connection with the well-known US defence contractor, or any of the missiles produced by the American concern; *Martin Pescador* is Spanish for 'Kingfisher'.

CHARACTERISTICS

Length: 294 cm
Diameter: 21·85 cm
Wing span: 73 cm
Total weight: 140 kg
Warhead: HE 40 kg
Speed: Mach 2·3 (max)
Range: 2·5 - 7·9 km

STATUS

It is possible that *Martin Pescador* was employed in A-4 Skyhawk anti-shipping strikes against the Royal Navy during the Argentinian occupation of the Falkland Islands in April-June 1982, but this cannot be confirmed at present.

In full production. New versions are under development, with increased range and with a heavier warhead. Other developments include helicopter-launched models with longer range.

CONTRACTOR

Instituto de Investigaciones Cientificas y Tecnicas de las Fuerzas Armadas (CITEFA), Zufriategui y Varela, 1603 Villa Martelli, Provincia de Buenos Aires, Argentina.

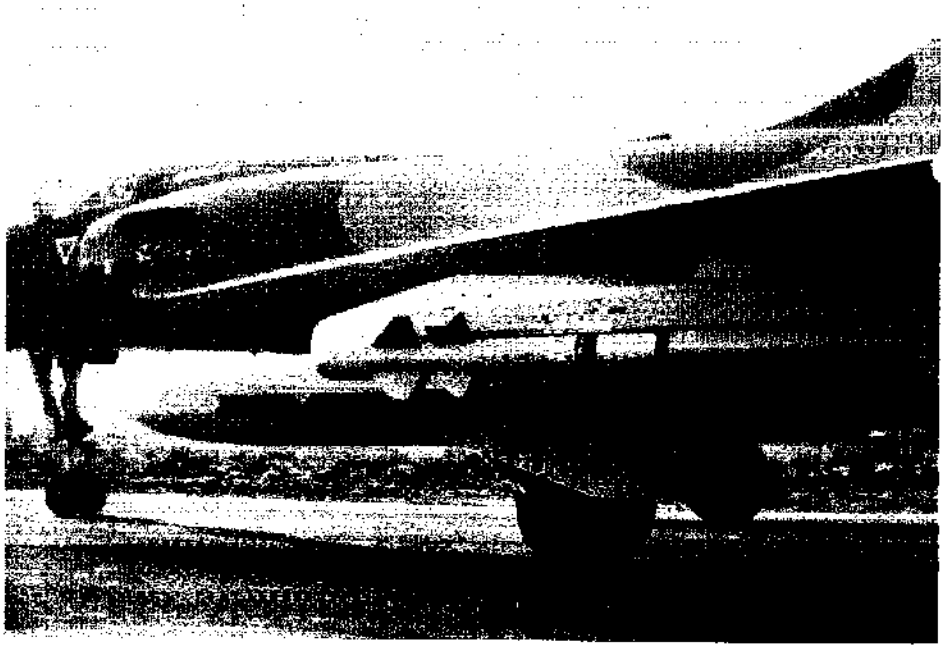
FRANCE

4887.311

ARMAT ANTI-RADIATION MISSILE

Armat is the name given by the manufacturer of an air-to-surface anti-radiation missile designed to provide protection for attacking aircraft by locking on to a defender's ground radars, homing on to its radiation and destroying its antenna, thereby disabling it.

Armat is a successor to the AS37 anti-radiation version of the Martel missile jointly developed and produced by France and Britain (**1022.311**), and is stated to be an improved and advanced development of that weapon. Electronique Serge Dassault, which was responsible for the passive radar homing head of Martel now produces an enhanced seeker for Armat. Other improvements claimed by the missile's manufacturers include a much greater range, but without significant increase in weight or size. The configuration is very similar to that of the Martel. It is probable that the system has increased operational flexibility and capabilities by the incorporation of a microprocessor in the radar data handling, threat evaluation and guidance sections of the homing system.



Armat has been designed for use with Mirage F1 and Mirage 2000 combat aircraft.

STATUS

Operational status was reached in 1984 and it was reported that by 1985 production had begun with exports to 'several foreign countries'. No other details have been disclosed.

CONTRACTOR

Matra SA, 37 avenue Louis-Bréguet, 78140 Vélizy, France.

4189.311

MATRA LASER-GUIDED BOMBS (LGB)

Matra is developing a series of laser-guided bombs (LGB) similar to the American Paveway munitions (**1534.311**) in which laser seeking guidance packages are added to standard bombs to provide increased accuracy when used against laser-marked targets. In the Matra system target illumination may be either by an aircraft-mounted laser marker or by a ground laser transmitter. In the former case a version of the ATLIS II target designator pod (**3820.393** in 1981-82 and earlier editions) is normally used, and the laser guidance sub-system for fitting on the bomb is a version of the Ariel seeker for the AS.30 laser missile (**3335.311**, below) known as the TMV 630 EBLIS and also produced by Thomson-CSF.

In the LGB application, the EBLIS is fitted in an aerodynamically shaped housing equipped with a wind-vane and carried on the nose of the bomb. The laser error detector measures the angle between the bomb velocity vector and the line between the aircraft and the target, and makes corrections by actuating electric motors to move the fins or flying surfaces to adjust the bomb's trajectory to bring it to the target. Other guidance components in the package are a guidance order computer and a roll gyroscope. These are housed in a streamline container mounted on the fore-part of the bomb and with four control vanes disposed on it in a cruciform fashion. Another package of the LGB kit consists of four larger aerofoil surfaces mounted on an extension fitted to the rear of the bomb body; these too are arranged in a cruciform pattern.

Kits have been designed for fitting to several types of bomb, eg 400 kg and 1000 kg types, and for some types semi-folding wings facilitate carriage on the underwing armament stations of most aircraft types. The complete 1000 kg LGB is also known by the name Arcole.

A feature of the Matra LGB system emphasised by the manufacturer is its ability to be used in a low-level delivery mode, in level flight and at speeds up to Mach 0·9, enabling stand-off ranges of 4 to 10 km. There may also be a lateral offset of several degrees without impairing accuracy. Weapon flight times of up to 30 s after release are provided in the design, power for control actuation and electronics etc being supplied by a battery.

STATUS

The Matra LGB programme was started in 1978 in response to a French Government requirement, and the first phase of development was completed in late 1980 with a number of successful launches of 400 kg LGBs. A special 1000 kg bomb body has been designed, specifically for the destruction of hard targets, as a French Air Force requirement. This LGB was engaged on final development trails in early 1984 and is due to enter service in 1986.

Several hundred Matra 400 kg LGBs have been ordered by foreign customers and production and export deliveries are in progress.

CONTRACTORS

Matra SA, 37 avenue Louis-Bréguet, 78140 Vélizy, France.

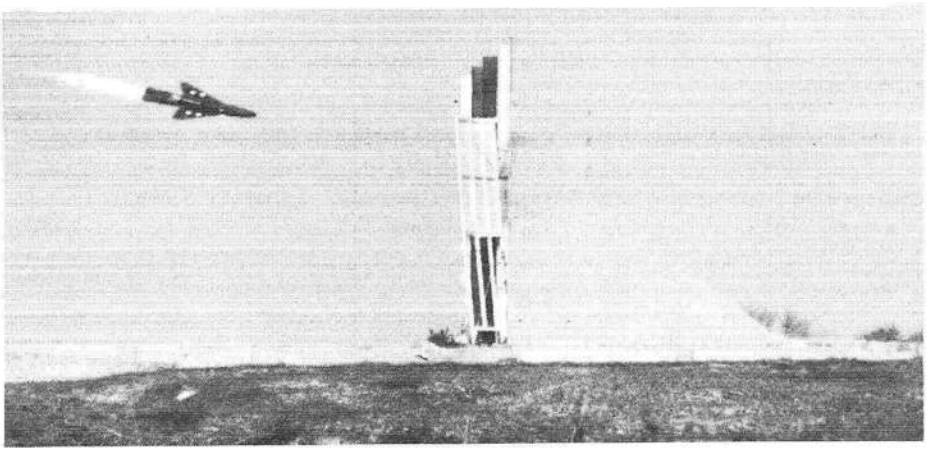
Thomson-CSF, 1 rue des Mathurins, 92222 Bagneux, France.

Matra LGB on Jaguar aircraft. Semi-folding rear fins enable bombs to be carried under the wings of most aircraft types. The laser seeker is in the small 'thimble' with two aerodynamic vanes and the guidance and control electronics are in the larger housing with four control surfaces on the nose of the bomb itself. Note laser designator pod on fuselage centre-line.

3335.311

AS.30 LASER AIR-TO-SURFACE MISSILE

Successor to the command-guided AS.30 (**1171.311** in 1982-83 and earlier editions) tactical missile which has now ceased production, the AS.30 Laser is a supersonic, self-propelled, self-rotating homing missile designed for attacking surface point targets such as ships, bridges, etc.



The missile is in the form of a streamlined body, fitted with cruciform, swept back wings which provide lift and impart rotation. Propulsion is by two-stage (boost and sustainer) solid-propellant motors.

CHARACTERISTICS

Length: 3·65 m
Diameter: 342 mm
Wing span: 1 m
Launch weight: 520 kg
Warhead weight: 240 - 250 kg
Max range: 10-12 km, depending on initial conditions

Due to high impact velocity (over 450 m/s) the hardened steel coated GP warhead can penetrate up to two metres of concrete before detonation, using a delayed fuze.

Homing by laser illumination gives the weapon system high accuracy and allows the launch aircraft to take evasive action after launch, to remain outside the effective range of enemy defences. The missile flight path comprises two phases: the pre-guidance phase which is conducted by gyro reference; and homing onto the laser-marked target by means of a Thomson-CSF Ariel homing head. The laser target designation pod is the ATLIS equipment (**3136.393**).

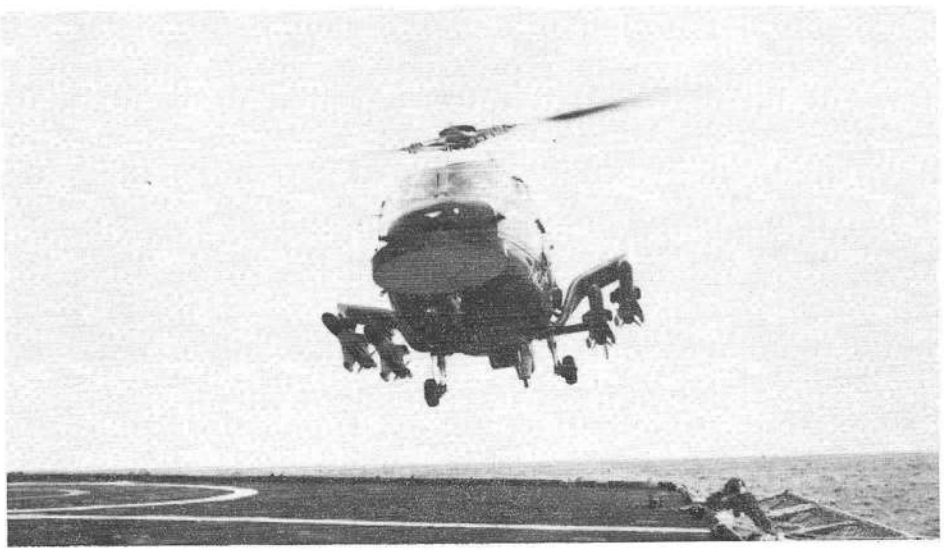
Aérospatiale AS.30 Laser missile launched from French Jaguar aircraft just before striking laser-designated target during trials

STATUS

The French Air Force has ordered a number of AS·30 Laser missiles for use with Jaguar aircraft, target designation being provided by the ATLIS pod equipment (**3136.393** in the Electro-optical (Air) section of this volume). Adaptation to Mirage F1 and Mirage 2000 is under development for export customers. Following a successful feasibility study, adaptation to the F-16 aircraft is under consideration. By the end of 1984 more than 400 missiles had been ordered.

CONTRACTOR

Aérospatiale, Division Engins Tactiques, 2 rue Béranger, 92322 Chatillon Cedex, France.



3359.311

AS.15 TT AIR-TO-SURFACE MISSILE

The AS.15 TT (TT: tous temps - all weather) is a new anti-ship missile under development for use on maritime helicopters, but which will also be suitable for alternative modes of deployment such as slow-flying fixed wing aircraft, fixed or mobile coastal batteries, or small surface craft. A coastal defence system based on the AS.15 TT has been designed jointly by Aérospatiale and Thomson-CSF, but further work has been suspended for the time being. This system was described in entry **3974.121** in 1980-81 and earlier editions of *Jane's Weapon Systems*.

The AS.15 TT has the same warhead arrangement as the AS.12 (**1174.311** in 1984-85 and earlier editions), which it is intended to replace, and can accommodate payloads weighing up to 30 kg. Range is over 15 km.

The guidance system is command-to-line-of-sight in azimuth with the missile slaved to the aircraft radar for azimuth guidance. The radar, Thomson-CSF Agrion (**3298.353**), incorporates pulse compression and frequency agility, and is equipped for automatic tracking of the target and differential target/missile range and bearing measurements required for guidance of the missile. The guidance signals from the aircraft are passed in coded form within the radar's normal transmissions. A sea-skimming trajectory is followed in the vertical plane, with guidance data obtained from a radio altimeter.

Naval Dauphin II helicopter armed with AS.15TT missiles and equipped with Agrion radar

CHARACTERISTICS

Length: 2·3 m
Diameter: 18 cm
Wing span: 53 cm
Weight: 96 kg
Warhead: 30 kg
Range: 15 km +
Guidance: Radar tracking. Radio altimeter
Propulsion: Solid

STATUS
Announced in late 1976, development began in 1978, and flight tests began in 1980. The first flight of the missile took place on 22 June 1981. The AS.15 TT will be deployed on Dauphin 2 helicopters and the AS 332 Super Puma which will be able to carry AS.15 TT and AM 39 Exocet missiles at the same time. At the beginning of 1981 there were 200 AS.15 TT missiles on order for use by Saudi Arabian forces. The first production AS 15 TT missile launch from an SA365 Dauphin naval helicopter took place in February 1984. Development is now successfully completed.
CONTRACTOR
Aérospatiale, Division Engins Tactiques, 2 rue Béranger, 92322 Chatillon Cedex, France.

1770.321
AIR-LAUNCH EXOCET (AM 39)

AM 39 is the air-to-surface version of the all-weather anti-ship Exocet missile. It is designed to be launched against naval surface targets from helicopters, maritime patrol and surveillance aircraft, and jet strike/attack aircraft.

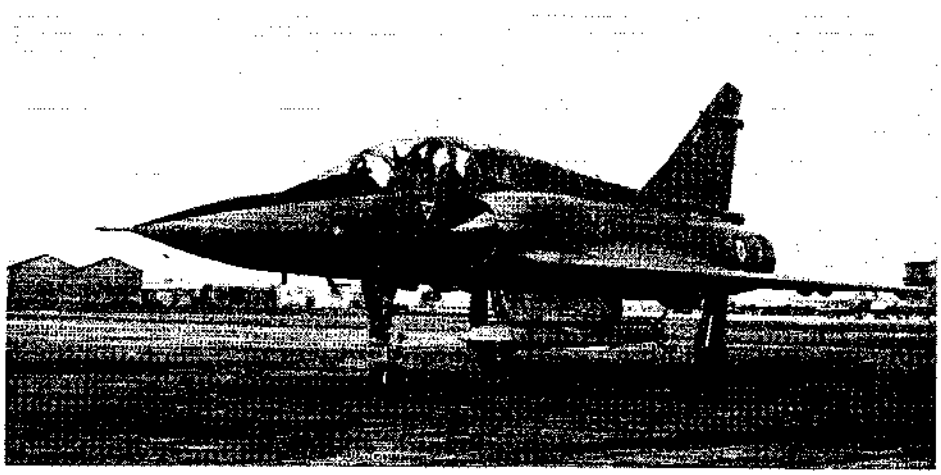
The Exocet AM 39 weapon system comprises:
(1) a command panel for insertion of operational and tactical data, and orders
(2) a missile adaptor kit which allows missile selection, initiates the firing sequence, and translates for the missile the information coming from the command panel and aircraft sensors
(3) one or more missile launchers under the aircraft wings, or alongside the fuselage, depending on aircraft type.

The weapon system uses the target range and bearing given by the aircraft's air-to-surface radar, which can be of the current type and an inertial platform or a doppler radar navigator system.

More details of the missile itself will be found in the entries dealing with the ship and land-based applications of Exocet (**2118.121** and **1156.221**).

AM 39 Exocet anti-ship missile on AS 332 Super Puma helicopter

CHARACTERISTICS
Length: 4·7 m
Diameter: 35 cm
Wing span: 1·1 m
Weight: 655 kg
Propulsion: 2-stage solid rocket motor
Range: 50 - 70 km, depending on the height and speed of launch aircraft
Flight speed: High subsonic
DEVELOPMENT
By late 1979 the AM 39 had reached operational status and tests with the Sea King and Super Frelon helicopters, and Super Etendard naval attack aircraft followed. Details of earlier development history appeared under this entry in previous editions of *Jane's Weapon Systems*
STATUS
The decision to arm aircraft of the French Navy with the AM 39 Exocet was taken by the French Government in May 1974. At present those aircraft are the Super Etendard and the Atlantic G2 maritime patrol aircraft. Six foreign governments have ordered the system for their own helicopters and for Super Etendard and Mirage strike aircraft.



The AM 39 scored its first successes in the course of the Argentinian invasion of the Falkland Islands when several Royal Navy and British merchant ships were hit by Exocets launched by Super Etendard aircraft.
CONTRACTOR
Aérospatiale, Division Engins Tactiques, 2 rue Béranger, 92322 Chatillon Cedex, France.

3635.311
ASMP AIR-TO-SURFACE MISSILE

ASMP is the acronym under which the French Air-Sol-Moyenne-Portée project to develop a new tactical nuclear stand-off missile is known. In general concept it is similar to the American SRAM (**1107.311**), although there are naturally certain differences in performance and in other respects.

The project was given formal approval in April 1978 when a design and development contract for an air-to-ground medium range missile for the French Air Force's nuclear tactical force was awarded to the Tactispatiale. Initially the ASMP will arm the new Mirage 2000 aircraft, but it will probably be deployed with Missile Division other types such as the Mirage IV of Aéroaircraft of the French deterrent 'force de Frappe' aircraft, and it might replace the AN-52 nuclear bomb on the naval Super Etendard.

The ASMP is a supersonic ramjet powered missile with pre-programmed inertial guidance and capable of a stand-off range of about 100 km. It is understood that several flight profiles will be possible which may include flight at about Mach 3 at high altitudes, carrying a nuclear warhead of an estimated yield of 100 to 150 KT. The last item is being developed by the government agency CEA-DAM.

ASMP air-to-surface missile test vehicle beneath Mirage 2000 aircraft

The propulsion system is a liquid-fuelled ramjet with integral booster. The latter, which is used to accelerate the missile to supersonic speed at which ramjet action can be sustained, is ignited in the main combustion chamber of the motor and is meant to burn away completely so that the chamber can be used for ramjet fuel burning. A smaller exhaust nozzle is employed for the acceleration phase and this is rapidly enlarged for ramjet propulsion. Two inlets are provided to admit air for combustion and to derive the necessary pressurisation.

Guidance is being developed by ESD and SAGEM and will include an inertial platform and digital computer.
STATUS
Development flight tests began in 1980, and entry into service is planned for 1985-86. The ASMP programme was officially initiated in 1978, following studies which began in 1974. Aérospatiale became prime contractor with the award of a contract valued at Fr500 million.

Operational deployment was expected to begin around the start of 1985 on up-graded French Air Force Mirage IV bombers, 18 of which are planned. French Navy Super Etendards are expected to be similarly equipped and about 50 of them may be converted by 1988. This missile may also be deployed on a number of French Air Force Mirage 2000s.
CONTRACTOR
Aérospatiale, Division Engins Tactiques, 2 rue Béranger, 92322 Chatillon Cedex, France.

4555.311
PEGASE

Pegase is the name given by its developers, Brandt Armements, to a modular stand-off ground attack weapon designed to meet potential French Government requirements. The Pegase vehicle is based on an essentially rectangular cross-section container equipped for carriage beneath the parent aircraft and equipped with fold-out wings and control surfaces to permit launch at low altitudes. The container portion of the vehicle is modular with optimised submunitions and a dispenser system to suit engagement of various categories of targets and missions. Payloads that have or are being studied include:
(1) runway cratering projectiles derived from the BAP 100 bomb (**3152.303**)
(2) anti-vehicle and equipment warhead submunitions, derived from the ABL BAT 120 bomb (**3863.303**)
(3) anti-light armoured vehicle warhead submunitions, derived from the ABL BAT 120
(4) anti-armour modules of the BM 400 modular bomb (**3865.303**)
(5) 70 mm HEAT grenades
(6) TACED sensor-aided anti-armour warhead submunitions
(7) PPGT terminally guided anti-armour warhead submunitions
(8) area denial submunitions
(9) fuel-air explosive (FAE) ammunition for blast effects.

Various types of container, of standard dimensions but internally configured to suit the different payloads, are planned to form the major portion of the Pegase vehicle. Other modules that would be used

with the payload module(s) are a power module containing either a solid rocket motor or a turbojet, and either an autonomous guidance package or a target sensor/guidance package. Various combinations of these optimal propulsion and guidance options could be employed to configure the complete weapon to suit the type of target or anticipated operational environment. The current options under consideration are set out in tabular form (right), and they permit a combination of five configurations with differing payloads and maximum ranges.

STATUS

Note: This Brandt development project now forms a major element of an international project known as Mobidic. This is covered in entry number **4842.311** later in this section.

KORMORAN AIR-TO-SURFACE ANTI-SHIP MISSILE

Kormoran is an advanced air-to-surface missile, designed principally for strikes against surface shipping. The guidance system employed provides a useful stand-off capability for the launch aircraft. Main characteristics of the missile are: length 440 cm, diameter 34·4 cm, wing span 1 metre, weight 600 kg, speed Mach 0·95, and range about 20 nautical miles.

Propulsion is by solid-fuel motors, and a hybrid guidance system is employed. Cruciform, broad chord swept wings are located just aft of the cylindrical missile body midpoint, and these are followed by a set of four in-line tail fins. A specially developed high explosive warhead is carried.

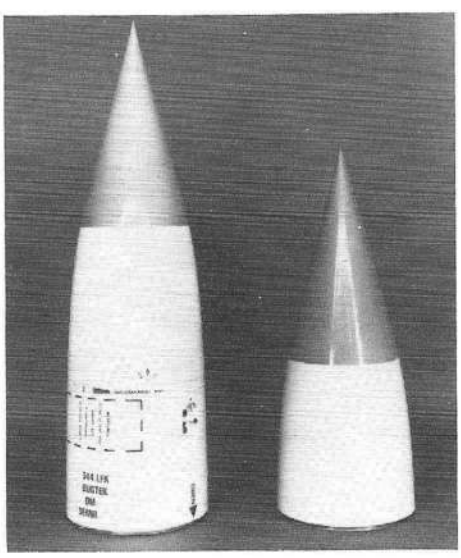
The Kormoran is roll stabilised and is steered by aerodynamic control surfaces at the rear. The missile is constructed in three main sections: the nose, containing the homing head; warhead; and motor, which also includes the rear structure and the main navigation package that is carried ahead of the sustainer motor.

The 160 kg warhead is designed to penetrate hulls without being damaged, and detonation is initiated by an impact fuze with a pyrotechnic delay set to explode the warhead approximately in the centre of the target. Liners arranged around the warhead form projectiles on detonation and their resultant kinetic energy is stated to be sufficient to penetrate up to seven bulkheads. The basic explosive effect of the warhead is sufficient to cause extensive damage, not least because of a special system of simultaneous ignition at three places, which results in detonation of the entire explosive in a shorter time.

The navigation package consists of a twin-gyro platform, an inertial computer, associated electronics, and a time switch. There is a separate course and position computer in the tail section and also a radar altimeter.

The radar homing head fitted is based on the RE 576 developed by Thomson-CSF. This is stated to be capable of either active or passive homing, and the assumed mode of operation is that when the missile has reached a height to bring it within line-of-sight range of the target, the radar receiver is switched on for an initial period during which it searches for radar signals emanating from the target. If such signals are received, the homing head will lock on and the missile will operate in a passive homing mode. In the absence of signals, the radar transmitter in the missile will be switched on and a target search, lock on, and tracking sequence will follow to enable the missile to intercept the target.

OPERATION



A typical Kormoran sortie envisages a low-level approach to a known target followed by a brief climb to above the radar horizon when the aircraft radar is turned on briefly to acquire the target. Upon acquisition, the pilot transmits the relative position of the target into his autonomous navigation system and turns off the nose radar. The aircraft then manoeuvres into an appropriate attack position and when this has been reached another brief radar transmission is made to establish target position. This and other necessary initial data are then automatically inserted into the Kormoran's navigation system. On reaching a predetermined launching range the missile is released and the aircraft makes an immediate break away.

After launch, the missile descends to its programmed flight level. In the first part of its flight it is under inertial guidance, aided by the radar altimeter. At a prescribed distance the inertial system of the missile homing head is activated and an active radar search pattern is initiated. After lock-on has been achieved, the inertial guidance is slaved and corrected in azimuth and range by the seeker head and the missile heads for the target. At a short distance from the target, the missile descends to its final flight level in order to hit the target just above the water line. This is the standard mode, but others are possible.

DEVELOPMENT

Kormoran is the largest missile project so far undertaken in West Germany, and was initiated in 1964 to meet a Navy requirement. Development started in 1967-68 with MBB as prime contractor.

Production was completed at the end of 1983, by which time, studies and design work on a Kormoran 2 version had been in progress for several years. The new missile is principally intended to arm Bundesmarine Tornado aircraft in the late-1980s and 1990s. Kormoran will have a digitised active radar seeker head, now under development by Thomson-CSF. It will be an all solid-state system, including the emitter. Comparable improvements will be incorporated to other missile sub-systems such as the warhead, propulsion and guidance.

Comparison of the radar seeker heads of Kormoran 1 and 2 anti-ship missiles. Kormoran 2 head on right is all solid-state

German Naval Air Arm Tornado armed with four Kormoran air-to-ship missiles

STATUS

The first air launch, from an F-104G, took place successfully in March 1970. Kormoran 1 has been used initially to arm West German F-104 G aircraft, followed by Tornados of the Naval Air Arm, until Kormoran 2 becomes available in the late 1980s. A total of 350 Kormoran 1 missiles were ordered for West German use, these are all believed to have been delivered. Kormoran has also been ordered for the Italian Air Force, where it will be deployed on Tornado aircraft.

Development of an improved version, Kormoran 2 had already started following a series of studies of a successor to Kormoran 1 which had been in progress since 1975. The development contract for Kormoran 2 was announced in June 1983, when the following improvements were listed: increased hit probability and penetration, better ECM protection, optimised trajectory, target selection, multiple launch, increased range, and simpler operation. Quantity production of Kormoran 2 is thought likely to begin in 1990.

VEBAL/SYNDROM AIRBORNE ANTI-TANK WEAPON

Vebal/Syndrom is the name of an experimental airborne anti-tank weapon system being studied in West Germany under a Ministry of Defence contract awarded to MBB. The name derives from the contractions VErtical BALlistic (VEBAL) and the system is intended to provide an aircraft with a capability to carry out top attacks on multiple armour targets on a single pass over the target area.

It differs from cluster weapons and other area weapons in that a relatively small number of unguided anti-tank projectiles is used to combat whatever armour is encountered within a swath of terrain on each side of the aircraft's flight path, rather than dispensing large numbers of specialised submunitions which have varying degrees of sophistication. To achieve this the VEBAL/Syndrom system requires two pods which are mounted beneath the aircraft: one houses a multi-sensor package for detecting, classifying and accurately locating the target(s), while the other carries anti-tank projectiles which are launched downward and rearwards to attack the target's vulnerable top surface.

Sensors incorporated in the detector/locator pod include an IR linescan equipment, laser and radar, and a radiometer. The last of these plays an important part in identification of the target by means of its thermal characteristics. This process and other signal processing and data handling functions are performed by digital micro-processor, which also is responsible for carrying out the calculations needed to ensure the precise instant to fire the projectiles to ensure hitting the target(s) on the first pass.

A typical projectile pod would contain about 30 tubes and would be suitable for carriage on standard NATO mountings on most types of aircraft. Experimental installations have been made on a Luftwaffe F-4F aircraft.

Reports state that operation is fully autonomous after the system is armed by the pilot prior to commencing his run over the target area, at low level and high speed. Any target encountered thereafter is automatically acquired and attacked. At a flight level of 250 feet (76 metres) the sensor pod scans a band of terrain about 100 feet (30 metres) wide.

STATUS

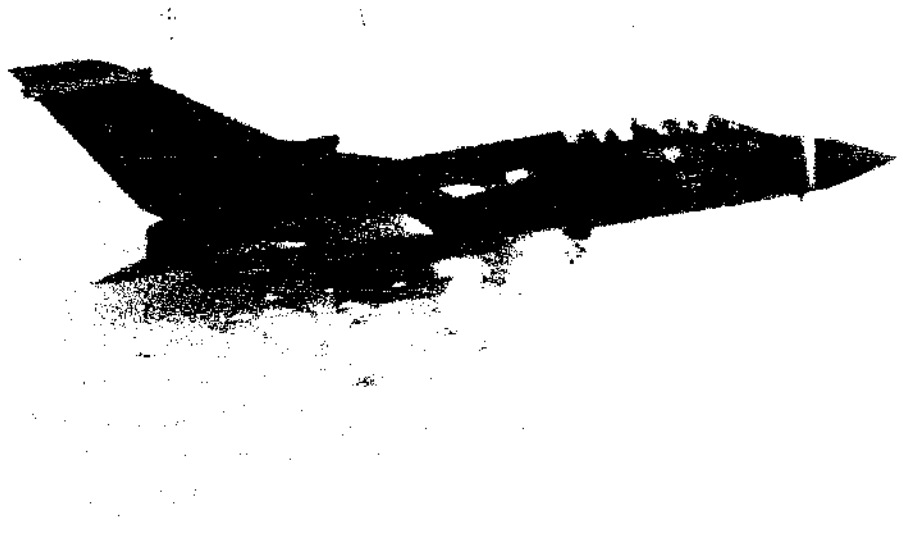
Development was started in 1977 under a contract thought to be worth about DM7 million. By late 1983 more than 500 trial sorties had been flown by the contractor, in the course of which some 100 live firings were made. In mid-1985 it was anticipated by MBB that the Vebal/Syndrom system would be ready for service introduction by the end of the 1980s.

CONTRACTOR

Messerschmitt-Bölkow-Blohm GmbH, (MBB), Post Box 8011 49, 8000 Munich 80, Federal Republic of Germany.

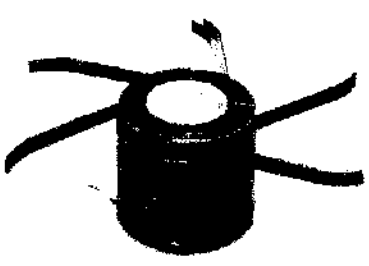
3517.311

MW-1 MULTI-PURPOSE WEAPON



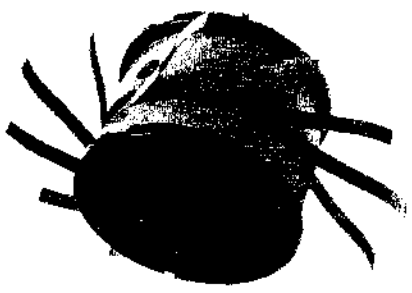
The MW-1 (Mehrzweckwaffe) is a multi-purpose cluster weapon designed and developed to engage battlefield targets such as soft- and hard-skinned vehicles moving in tactical formations over open ground; vehicles, bunkers and personnel in various battlefield or support structures or bunkers; vehicles, aircraft, runways and hardened shelters on airfields. To compensate for the limitations of the majority of earlier cluster weapons which normally carry only one type of single-purpose submunition, and often have only a limited distribution pattern, the MW-1 is provided with a range of six types of submunition, and the distribution pattern can be readily varied to suit the nature of the target(s) and the operational environment.

As employed with the Tornado aircraft, the system consists of a single dispenser 5·3 metres long and large enough to contain sufficient submunitions to successfully engage a tactical target (in the anti-tank role one dispenser on a single aircraft can deploy 4700 anti-armour projectiles). The dispenser consists of four sections each containing 28 transverse tubes, ie 112 tubes with 224 apertures. To ensure uniform distribution of submunitions laterally, four different ejection charges are used. This results in different ejection velocities and thus a varying spread of the submunitions on reaching the surface. The submunitions are ejected from both sides of the dispenser without recoil effects. The width of cover from a single pass can be preset between 200 and 500 metres and the length of pattern is variable between 200 and 2500 metres. This linear variation can be adjusted in flight by the pilot who can therefore select the required density of cover for a given target.



The MW-1 system includes six types of submunition, which can be dropped in any combination. These are:

(1) KB 44 armour piercing bomblet
(2) MIFF anti-tank mine
(3) MUSA fragmentation munition
(4) MUSPA, an airfield denial munition similar to the MUSA except for a complex sensor system
(5) STABO runway penetrator
(6) ASW hardened shelter penetrator.



The aircraft crew can adapt the coverage area to the target area until immediately prior to weapon release. Coverage width depends on the type of target, the two main types being armoured and mechanised units (Main Target Group 1 – MTG 1) and airfields (Main Target Group 2 – MTG 2). KB 44, MIFF and MUSA submunitions are used against MTG1, and STABO, MUSPA, MUSA and MIFF for engaging MTG 2.

Tornado dispensing submunitions from MW-1

MUSA/MUSPA area denial submunition for use with MW 1 system

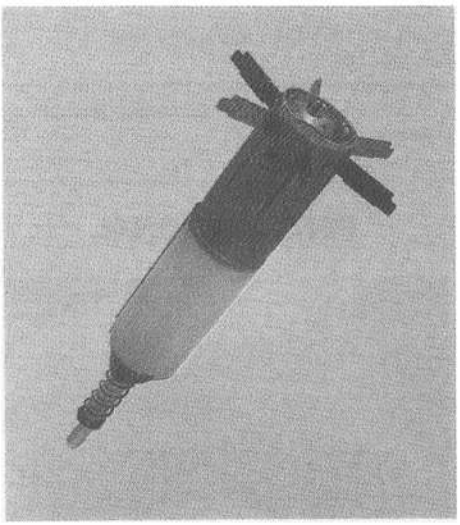
MIFF anti tank mine submunition

Like the submunitions for the British JP233 system (**5218.303**) fuze details are classified. Other known features of each are summarised in the following paragraphs.

KB 44 This AP bomblet is claimed to be capable of penetrating the top and side armour of all known tanks and is a sub-calibre projectile. Seven of them are bundled together to fill the dispenser tube cross section, each tube containing three bundles on each side, ie 42 bomblets per tube or a total of 4704 per dispenser.

MIFF is a small anti-tank mine with two plate charges, which is fired either by magnetic sensors in response to a tank hull or in response to ground vibration. Eight

mines are housed in each tube making a total of 896 per dispenser. The mine is automatically stabilised, (either end uppermost) on impact. It will detonate after an initial delay of a few seconds whenever the sensor systems are activated. There is no self-destruct time.



This weapon is not designed to create a tank barrier but to be employed in conjunction with the KB 44 against a tank formation, or with other submunitions against an airfield.

MUSA is a fragmentation submunition for destroying soft-skinned and semi-hardened targets and is suitable for use against depots or airfields where aircraft or vehicles might be in the open. The lethality range claimed for it is more than 100 metres, and it is also suitable for anti-personnel roles. It is parachute retarded in flight and rights itself on reaching the ground for maximum fragmentation effect, and then detonates. Each dispenser can carry 672 MUSA submunitions.

MUSPA This is an airfield denial submunition with an identical warhead to the MUSA, above, and it is dispensed in the same fashion. However, initiation is a far more complex matter. It has an acoustic sensor that will detect aircraft landing, taking off or taxying, and if the aircraft comes within its effective range it will detonate. There is also a self-destruct device with a random time delay to deter airfield clearance personnel.

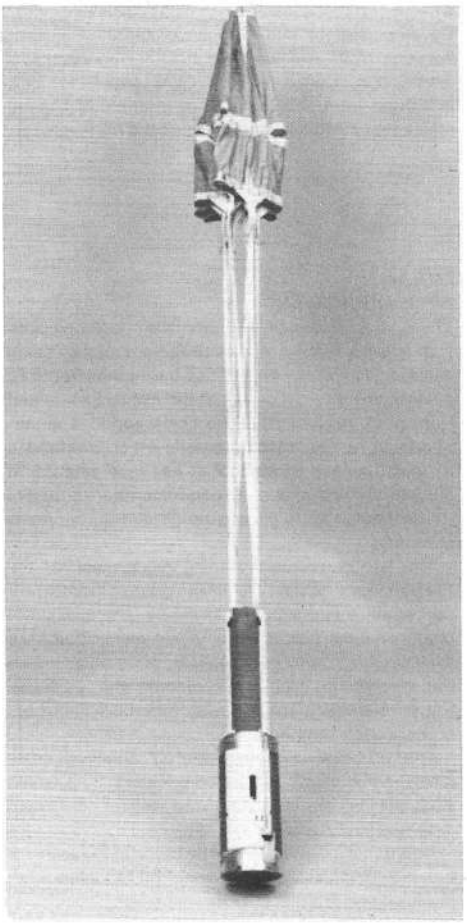
STABO is a runway penetrator and cratering munition. Its operating sequence begins with its ejection, stabilisation in flight and parachute retarded descent. During this phase a small sensor is exposed at the bottom of the charge, which when it touches the ground results in detonation of the charge. This opens up a hole in the concrete through which a follow-through projectile is fired to detonate beneath the surface to generate heave and create a crater. 234 are carried in one dispenser.

ASW is a hardened shelter penetrator designed for attacking aircraft, ammunition and other stores inside hardened shelters protected by overburden. The operating sequence begins with ejection and stabilised descent until the ASW hits the overburden,

KB 44 shaped charge anti-armour bomblet

which causes ignition of a booster rocket that projects the submunition until it reaches a harder surface such as structural concrete. At this point a shaped charge is initiated to create a hole in the concrete, through which a projectile is accelerated to detonate within the shelter.

STATUS



In production for the West German forces.

Development of the system for use against MTG 2 is expected to be completed by the end of 1985, with first deliveries to operational units planned for 1987. Apart from West German procurement, a MoU signed with the Italian Government ensures that Italy will also receive MW-1 dispenser sets.

An in-flight firing test at Eglin AFB with the Tornado MW-1 using live STABO submunitions is planned for 1986.

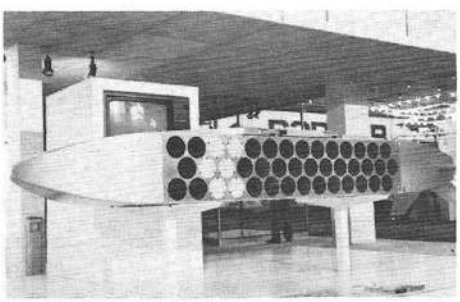
STABO runway cratering bomb for MW-1

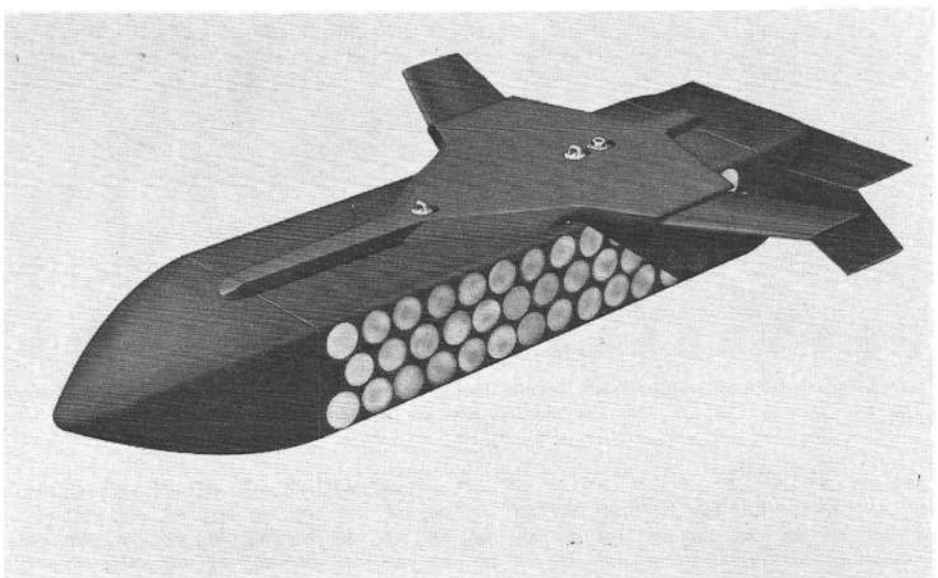
4449.311

CONTAINER WEAPON SYSTEM (CWS)



Revealed at the 1982 Hanover Air Show by MBB, the container weapon system (CWS) is apparently a continuation of the SOM stand-off missile project (**4050.311** in 1981-82 and earlier editions) which originally involved MBB, British Aerospace and McDonnell Douglas in the development of a new conventional stand-off multipurpose ground attack weapon. The project now appears to be solely an MBB programme, the American and British partners presumably pursuing various national programmes individually.

The CWS is a modular system in which various payloads are made up of appropriate modules to meet a variety of operational requirements, and which can be deployed on standard NATO 30-inch weapon lugs beneath most types of NATO military aircraft. In many ways the CWS is similar to the MW-1 multipurpose weapon (**3517.311**) developed for the Tornado, but the CWS is slightly smaller and lighter to enable it to be carried on a wider range of aircraft types. Another important difference is the provision in the CWS for free flight after release from the parent aircraft; the MW-1 container is an inert container which may or may not be jettisoned at the pilot's discretion.



The CWS is equipped with four tail surfaces and a pair of wings which unfold after release from the aircraft to permit gliding flight. There is also a version of the CWS which is fitted with a solid-propellant rocket motor to increase the effective range by extending the gliding distance. In all, four versions of the CWS have been revealed and their main characteristics are detailed below. The four versions are: freight container, submunition dispener, unpowered free-flight weapons container, and a powered free-flight weapons container. The weapons employed in both the free-flight versions consist of 42 tube-launched submunitions of the same type as those for the MW-1 system, namely runway cratering, anti-tank, anti-material and anti-personnel types. The aerodynamic design is suitable for carriage at high subsonic airspeeds and the system is intended for low-level use.

CHARACTERISTICS

Length: 3·91 m; (4·15 m, powered free-flight version)
Fuselage width: 630 mm
Wingspan: 2 m (free-flight versions)
Tail span: 1·18 m
Weights: 900 kg (freight container); 950 kg (drop-container); 1000 kg (unpowered free-flight); 1200 kg (powered free-flight)
Aircraft release height: 50 – 70 m
Mission altitude: 50 – 100 m
Submunition ejection altitude: ⩾50 m
Range: 20 km (approx)
Aircraft speed: High subsonic

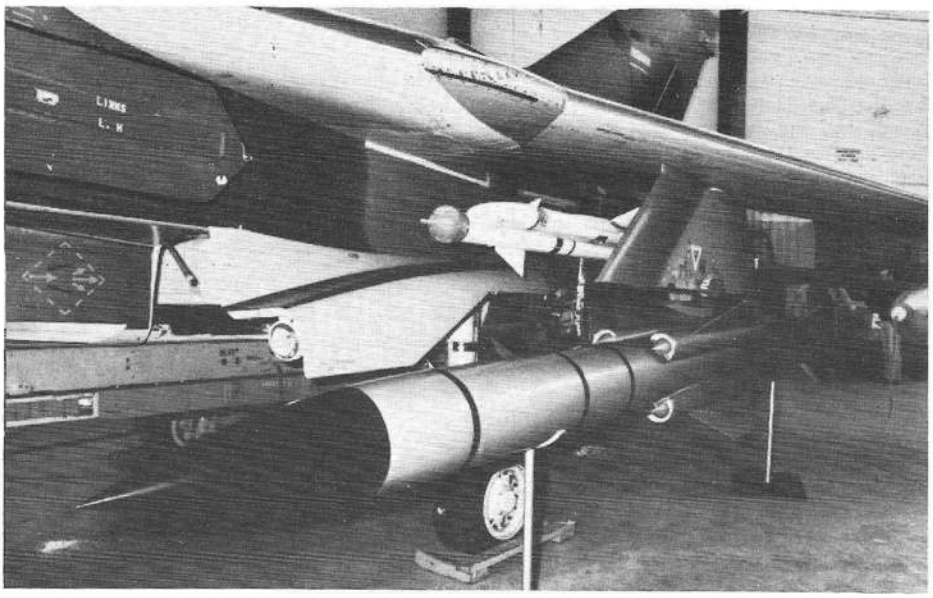
Close-up of free-flight version of MBB CWS showing 42 tubes for ejection of submunitions (T J Gander)

MBB CWS air-to-ground glide weapon for use against area targets

STATUS
Development. In mid-1983 a collaborative project between MBB and the French Matra concern was announced. Called Apache/CWS (**4554.311**) this envisages joint development of a family of ground attack stand-off weapons based on the MBB vehicle.

Completion of the development phase and production start-up is projected for 1986.
CONTRACTOR
Messerschmitt-Bölkow-Blohm GmbH (MBB), Post Box 8011 49, 8000 Munich 80, Federal Republic of Germany.

INTERNATIONAL



4450.321
AIR-LAUNCHED ANS
This is an air-launched version of the supersonic anti-ship missile, ANS (Anti-Navire Supersonique) being developed jointly by France and the Federal Republic of Germany as a successor to the AM 39 Exocet and Kormoran, respectively. The new weapon is an air-breathing ramjet powered missile which is intended to reach speeds of Mach 2 at sea level and 2·5 at altitude. Other operational requirements are an ability to manoeuvre at 10 *g*, long range and autonomous operation.

The two contractors leading the project for the French and West German governments are Aérospatiale and MBB, respectively. The division of responsibilities places airframe and seeker/guidance system design with Aérospatiale, while MBB's main duties are the propulsion system and warhead. Project management is understood to be in the hands of the French company.

The two versions (surface- and air-launched) differ solely in the laterally-mounted boosters. Ship-based ANS missiles are launched from tactical containers arranged in clusters.

Additional information will be found in the entry for the ship-launched model (**4446.221**), together with photographs of a test vehicle.
STATUS
Project definition; this phase is expected to continue to 1986, with possible entry into service in the 1990s.
CONTRACTORS
Messerschmitt-Bölkow-Blohm GmbH (MBB), Post Box 8011 49, 8000 Munich 80, Federal Republic of Germany.

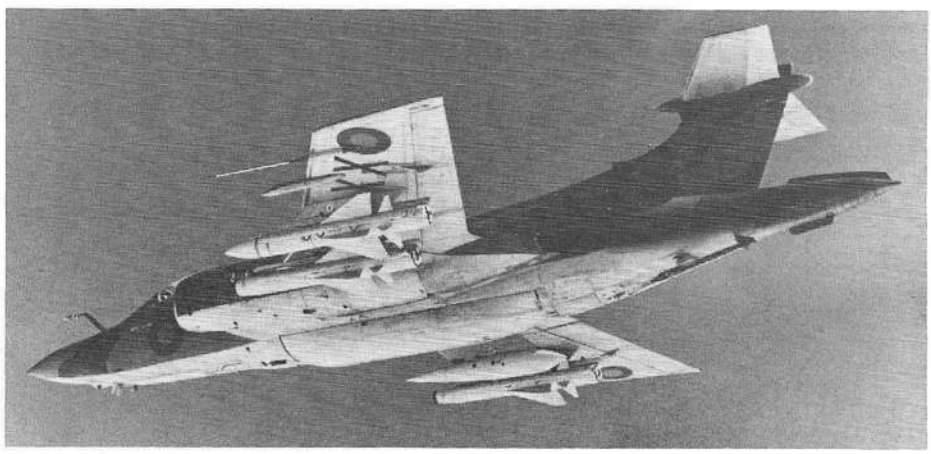
1022.311
MARTEL AS.37/AJ.168 AIR-TO-SURFACE MISSILE
Martel is an air-to-surface tactical missile with two alternative terminal guidance systems capable of offering a considerable stand-off capability. Both versions are designed to operate in an ECM environment, to which a high resistance is claimed. The two forms of terminal guidance are: passive homing on to electromagnetic radiation in the AS.37, anti-radar version; and visual guidance to a selected target by means of a nose-mounted TV camera and a data link over which both video and command signals are passed between aircraft and missile, in the AJ.168 variant. The Martel system is the product of a joint Anglo/French development programme with prime responsibility for the AS.37 resting with Engins Matra, and for the AJ.168 with British Aerospace Dynamics Group.

General configuration of the missiles can be seen from the photograph adjacent to this entry. Length of the AJ.168 is 390 cm, and of the AS.37, 420 cm; body diameter and wingspan, respectively, for both versions are 40 and 120 cm. No details of performance have been revealed, but range has been officially stated both as 'several tens of miles' and 'several tens of kilometres'. This suggests a range of about 60 km although maximum range will be to some extent dependent upon the height of launch and subsequent trajectory.

Both versions of Martel probably employ the same basic autopilot which provides guidance until either TV or radar homing systems assume control for the terminal guidance phase. There are some indications that the autopilot can be pre-programmed to provide several options of mission profile. A fundamental difference, in addition to the guidance system, is related to the two-stage propulsion assembly, which is adapted to the mission requirements specific to each version.
STATUS
In service with the British and French forces. The Martel system is used on the Mirage IIIE, Atlantic, and Buccaneer Mk II.

Use of both anti-radiation and TV-homing versions is apparently restricted to British Forces; the TV-homing AJ.168 is not used on French aircraft.



In mid-August 1977 the UK MoD announced an RAF requirement for a new anti-ship missile to arm Buccaneer and Tornado aircraft. This led to the Sea Eagle (P3T) development (**3630.311**).

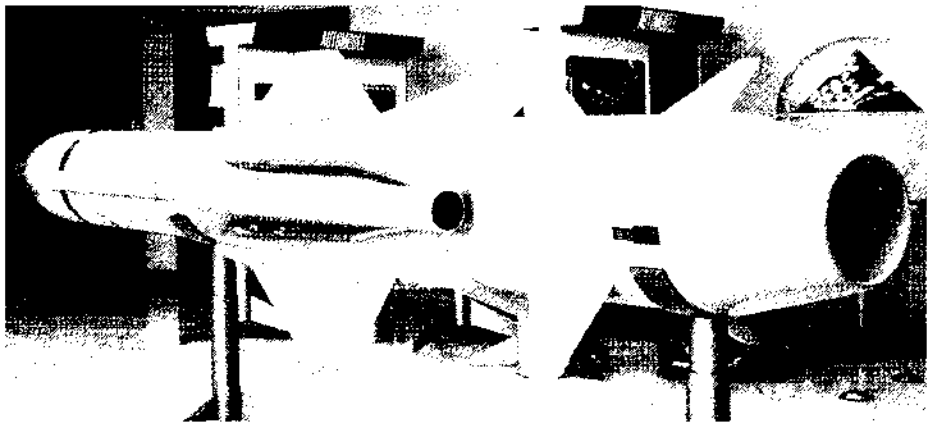
1338.321
OTOMAT ANTI-SHIP MISSILE (FRANCE/ITALY)
In addition to the ship launched and coastal defence versions of the Otomat anti-ship missile, the air launched role for this missile has also been taken into account during its development. Matra is continuing with the study of the missile's application to this role on classic maritime patrol aircraft types and also to a number of smaller twin-engined types suitable for EEZ (200 nautical mile zone) operations. Studies also embrace helicopters such as the Sea King and certain strike aircraft.

The missile is the same as in the other roles (**1336.221** in the Shipborne Surface-to-Surface Weapons section), but thanks to the higher forward speed of the aircraft launch platform, smaller boosters can be used to accelerate the missile to its normal cruise speed. The airborne system consists of a control panel, harmonisation box, selection box and launcher. Two missiles are normally carried by a helicopter, twin-engined aircraft or strike aircraft.

Target designation is fed to the selected missile from the airborne radar, and the harmonisation box computes the firing envelope and controls the firing sequence. After launch the missile descends to its normal low level trajectory automatically. The two possible modes for the final approach to the target (sea skimming or climb-and-dive) can be selected prior to launch.

The present system provides for ranges of up to 100 km, using a normal modern airborne radar for target designation, in a fire and forget technique. The maximum autonomous range remains the missile's typical maximum of 180 km (with growth potential).



STATUS

Development and studies continuing.

1771.311

HOT AIR-TO-SURFACE MISSILE

The relatively recent increase in interest regarding the use of helicopters in a specifically anti-tank role has led to the development of a helicopter installation for the HOT anti-tank weapon. The basic HOT missile is described in **2212.111** in an earlier section of this book, and the following refers to the helicopter version.

Depending upon the type of helicopter used, four, six or eight launcher ramps to accept the HOT combined container-launch-tube can be fitted, and these are elevation-slaved to the line-of-sight. For helicopter operation, a stabilised optical sighting system, APX M397, is used, this being derived from the APX M334 sight described in **7032.393** in the Equipment Section of this book.

The guidance system includes a triple-field IR localiser, with a 16° acquisition field, a 5° tracking field, and a 1° tracking field. The function of the IR localiser is to establish the position of the HOT missile relative to the line-of-sight (which normally will be maintained on target by the operator using his optical sight). Appropriate guidance signals are computed and transmitted via the command wire to maintain the missile on the line-of-sight to the target.

A prototype night-firing device is currently undergoing trials. This is the roof-mounted VIVIANE system, designed for installation on Gazelle or Dauphin helicopters after the initial trials of VENUS (viseur écarto-métrique de nuit stabilisée) nose-mounted day/night sight fitted in a Dauphin helicopter. A photograph of this equipment appears nearby and additional details will be found in entry **3856.393** later in this volume.

STATUS

In February 1985 more than 58 000 HOT missiles (of all versions) were on order and almost half that number had been produced.

Night view of Dauphin helicopter equipped with two quadruple HOT anti-tank missile launcher pods and VENUS night firing equipment in ball turret

APACHE/CWS

Under an international agreement announced in May 1983 between MBB of the Federal Republic of Germany and Matra in France, the two concerns have embarked on a collaborative programme leading to a stand-off weapon system for use by tactical aircraft against a variety of targets including airfields, aircraft and vehicle concentrations, armoured formations, etc. The project combines the German container weapon system (CWS) (**4449.311**) work that MBB has been carrying out since 1978 with the Matra company's Apache project to develop a multi-purpose modular weapon to succeed existing Durandal (**1999.303**) and Belouga (**3150.303**) weapons. It is envisaged that a modular family of ejectable-charge 1000 kg-class modular weapons will evolve capable of stand-off ranges of from ten to several tens of kilometres, suitable for dispensing a range of submunitions for attacking different types of target. The full range of submunitions available with the MW-1 system (**3517.311** in this section) ie KB 44, MIFF, MUSA, MUSPA and STABO, can be deployed with the CWS

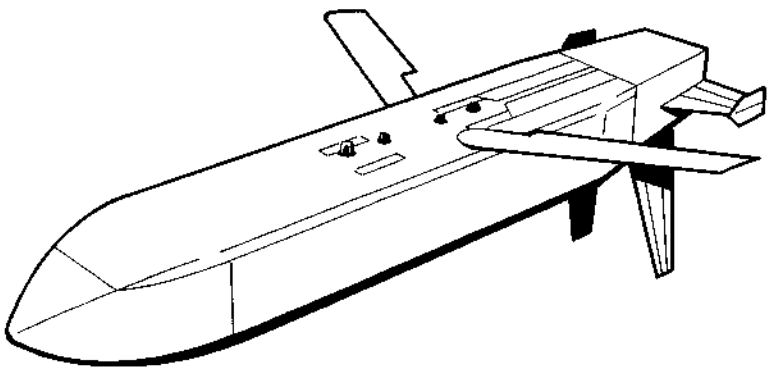
"Ghost" drawing of the Matra/MBB Apache/CWS modular stand-off weapon

The basic vehicle is largely based on the MBB CWS, with a weight of about one ton and overall length of about 4 metres, with a 2 metre centre section designed to house and dispense the submunitions. The weapon is equipped with an inertial navigation system. Folding wings will deploy after release to give a high-wing monoplane configuration. The guidance package will also differ according to the mission.

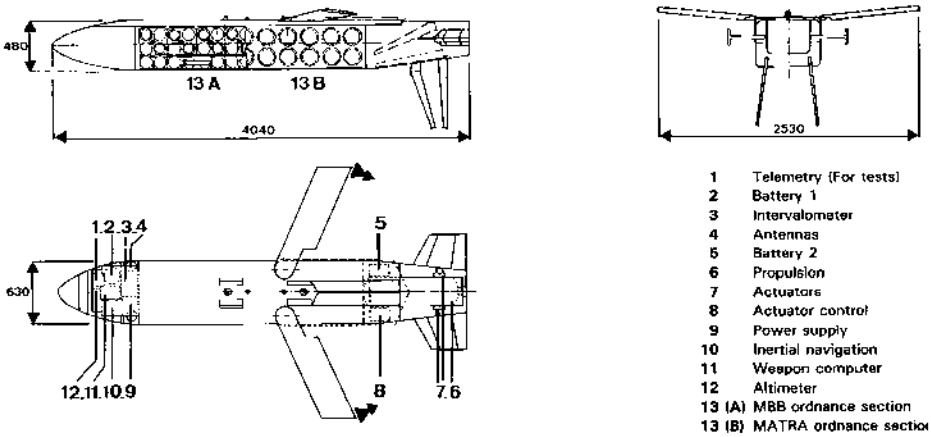
Initially, a short wing-span glider dropped from high or low altitude, and with or without a short ascending ballistic phase, is likely to give operating ranges of 7 to 15 km. Later a folding wing glider giving ranges of 25 to 30 km may follow, with the eventual objective being a powered vehicle capable of release from very low altitudes, possibly equipped with terminal guidance, with a range of up to 50 km.

CHARACTERISTICS

Version	I	II	III
Range (low-level)	12 km	25 km	40 km
Propulsion	No	Yes	Yes
Weight	1000 kg	1150 kg	1220 kg
Guidance	Inertial	Inertial	Inertial + terminal guidance
Speed at launch	Up to Mach 0·95		
Pattern size	Length up to 1000 m × width up to 350 m (optimised for each submunition type)		



STATUS



Development project. First version planned to enter service in 1989.

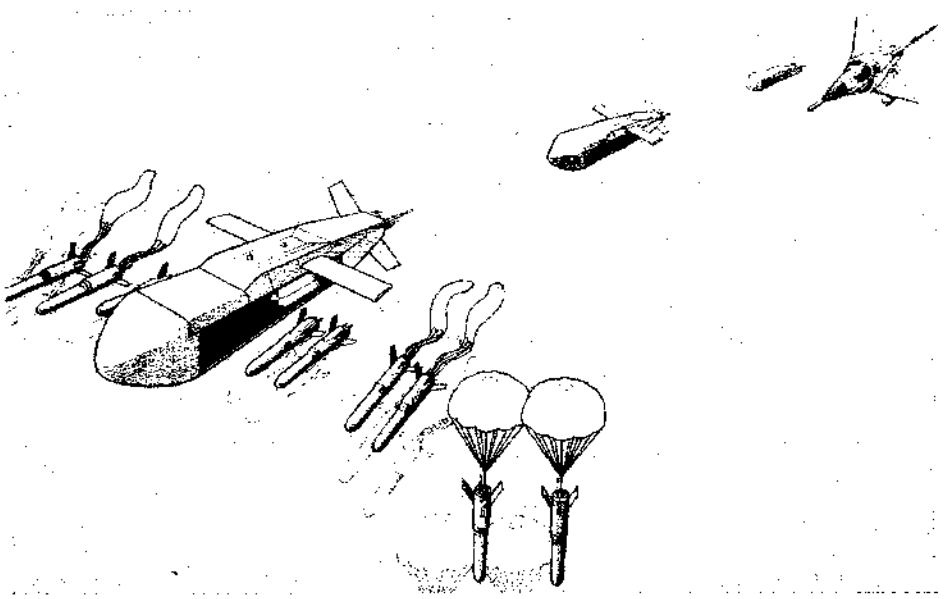
MOBIDIC



Following the signing of an agreement between Aerospatiale, Dornier and Thomson Brandt Armements in September/October 1984 the Pegase modular stand-off ground attack weapon designed by the last-named company (**4555.311**) becomes a major element of the international Mobidic project, which is a collaborative effort between these companies and Diehl to produce a similar weapon based on Brandt's Pegase II and the SRSOM II (short-range stand-off missile) project by Dornier.

The target 'in-service' date is before 1990 so that the chosen design is not expected to differ greatly from the outlines that have been given previously of the Thomson Brandt and Dornier work. The breakdown of responsibilities between the individual companies has not been finalised but it is thought that Aerospatiale will undertake the propulsion system, and Dornier will contribute the airframe and guidance expertise, with Thomson Brandt and Diehl taking care of submunitions and dispenser techniques. A demonstrator model of the Mobidic missile is expected to be ready for captive and free flight trials in 1985.

Because of the probability of significant similarity between Mobidic and Thomson Brandt's Pegase II, readers are referred to the entry for that weapon (**4555.311**) which is retained in the French pages of this edition.

STAND-OFF MISSILE PROGRAMMES

In addition to the various national stand-off missile projects being pursued by individual countries in Europe and the USA, there are several international projects directed towards both a short-range and a long-range stand-off missile.

SRSOM

Dornier GmbH is working in Friedrichshafen on a new short-range stand-off missile (SRSOM) as a contribution towards development of a stand-off missile for NATO defence forces. This weapon is seen as being of considerable importance as an effective conventional defence in the tactical role. Stand-off missiles are released by their carrier aircraft at a relatively long distance from the target, and are then guided autonomously to deploy submunitions against the target.

First prototypes of this missile had already been integrated and subjected to ground tests aboard a carrier aircraft, and flight testing had begun at the German Meppen test centre by May 1985. Using this missile as a basis, Dornier is co-operating with Aérospatiale and Thomson Brandt in France in the Mobidic programme (**4842.311**) which is intended to meet French and West German air force requirements. The German Diehl concern subsequently joined the programme as a FRG counterpart to Thomson-Brandt with responsibility for contributions in the submunitions areas.

Dornier is reported to have contributed new technology to the programme in the fields of: mid-course and high precision terminal guidance under varying terrain, seasonal and weather conditions, the so-called Intelligent Sensor System (ISS); dispensing mechanisms of low structural weight and cost; any

submunitions for different categories of target, such as moving armoured vehicles and aircraft inside shelters. Parallel testing of the dispenser with the SRSOM testing was carried out in the USA at Eglin AFB in a joint German-US programme with the American LAD vehicle (**4530.311**), when the Dornier dispenser was installed in a LAD carried by an F-4 and used to dispense submunitions at low level. The submunitions were ejected to achieve the prescribed ground cover pattern.

LRSOM

In early 1985 bids were submitted by several NATO consortia for the feasibility study phase of a long-range stand-off missile (LRSOM) project under the overall management of the US Air Force Armament Division, on behalf of the participating NATO countries, the UK, US and West Germany. This weapon is expected to appear as an air-launched cruise missile able to carry a variety of payloads ranging from tactical conventional munitions suitable for attacking high-value targets, to submunitions appropriate to a wide range of theatre targets.

Details of consortia membership that have emerged to date include the following international groupings:

(1) Boeing (US), British Aerospace/GEC Avionics (UK), MBB (FRG);

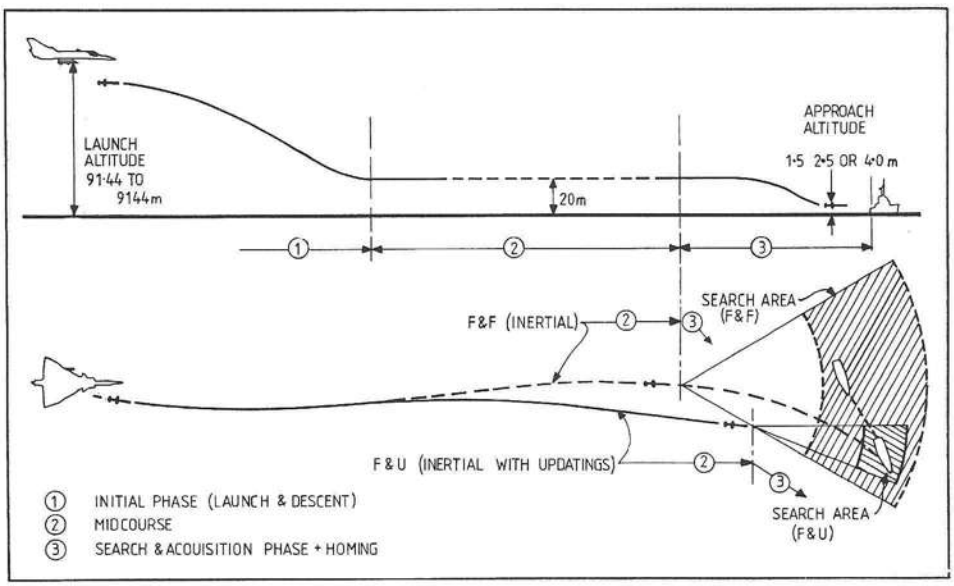
(2) General Dynamics (US), Hunting Engineering (UK), Dornier (FRG);

(3) McDonnell Douglas (US), Marconi Defence (UK), Bodenseewerk (FRG).

In June 1985, Lucas Aerospace announced a teaming arrangement for the LRSOM thrust engine with Teledyne CAE of Toledo, USA. Both these companies had been involved in the initial study phase of the programme in providing propulsion data to the main competitors. They are both collaborating with McDonnell Douglas on the Harpoon anti-ship missile programme.

ISRAEL

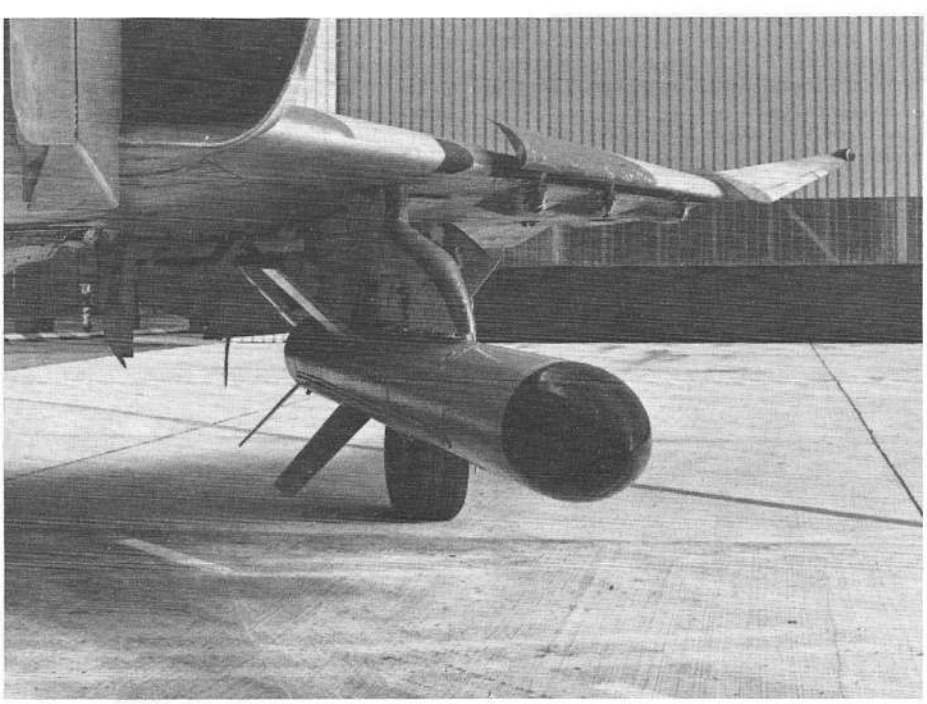
4529.321



GABRIEL MK III AIR-LAUNCHED ANTI-SHIP MISSILE

An air-launched version of the successful Gabriel III anti-ship missile (**6019.221**) was revealed by the Israeli manufacturers in the last quarter of 1982 as the Gabriel Mk III A/S, together with photographs of test and development models on an Israeli Phantom aircraft. The weapon can also be carried by A-4 Skyhawk, Kfir C2, Sea Scan and other aircraft types, principally for use in anti-shipping roles.

The missile itself was derived directly from the ship-launched Gabriel mentioned above and the developers specified two configurations. That closest to the basic Mk III missile has different aerodynamic surfaces, more suitable for carriage and launching from high performance aircraft, but with an extended range propulsion rocket motor as the ship-launched Gabriel III. This gives a range of approximately 40 km. The second derivative has the same aerodynamic modifications, but additionally uses air breathing jet propulsion for longer ranges.



The system provides all-weather, day/night, anti-ship capability against targets ranging from small fast patrol boats to destroyers and larger ships. The Gabriel Mk III A/S is an active homing, sea-skimming missile with 'fire-and-forget' and 'fire-and-update' operating modes. The I-band frequency agile radar seeker performs data processing and control functions, providing good all-weather and ECCM performance. Inertial components, a radar altimeter and a digital processor are employed for missile guidance, and four tail control surfaces steer the missile and control its flight path. A high explosive warhead weighing 150 kg ensures maximum target damage.

The solid-propulsion motor provides over-the-horizon ranges at low level and the terminal attack altitude is set before take-off in accordance with the prevailing sea state to one of three values. Other characteristics of the missile are given below and can be gathered from the adjacent illustrations.

Gabriel launch and attack profile and plan

The complete system comprises one or more missiles (depending on the aircraft type, but typically two) and the missile fire control system (MFCS) fitted in the aircraft. In the case of a Gabriel Mk III A/S installation in a fighter aircraft the main MFCS elements include: a pilot fire control panel (PFCP), missile processing unit (MPU), power supply unit (PSU), and armament interface hardware (AIH). Built-in test facilities are incorporated and operate automatically as part of the firing sequence. The AIH units are incorporated in missile loading hardpoints and the other MFCS items are fitted in various fuselage locations.

Gabriel air-launched anti-ship missile mounted under wing of F-4 Phantom aircraft

OPERATION

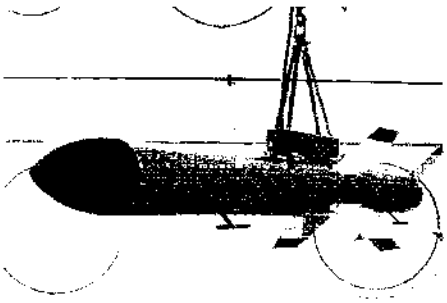
As mentioned briefly above, there are two operating modes. 'Fire-and-forget' missiles, to accomplish their objective with high probability of target acquisition have to accommodate wide search areas. The actual size of the search area depends on the missile-target range at launch. To minimise the uncertainty of target position at the time of missile seeker activation, a 'fire-and-update' facility is provided in the Gabriel Mk III A/S system in addition to the basic 'fire-and-forget' mode. 'Fire-and-update' is used on larger maritime patrol aircraft as an optional mode of deployment, and relative missile/target locations are monitored, calculated and transmitted by the MFCS to the missile in flight. For this mode, in addition to the track-while-scan facilities of the aircraft's surveillance radar, a command link to the missile is added to the MFCS installation on the aircraft.

By this technique the seeker search zone in bearing and range is reduced considerably, so that the updating facility ensures that each missile is directed toward its designated target and not against 'potential targets' (which may or may not be significant) which may be close to the actual target area. After launch, data transfer between missile and launch aircraft are entirely automatic. Thus, 'fire-and-update' is an enhanced version of 'fire-and-forget' with the advantage of a reduced search zone and improved target lock-on.

In the vertical plane, at high altitudes, the missile pitch angle is controlled by a preset angle program for the descent to the midcourse phase. At low level the missile guidance system switches to altitude command to maintain a midcourse cruise altitude of about 20 metres, before descending to 1·5, 2·5 or 4 metres for the terminal phase under pre-programmed control. In the horizontal plane, inertial guidance is used for the initial and midcourse phases for 'fire-and-forget' operation, and inertial is also used in the 'fire-and-update' mode for the midcourse phase. For both modes, seeker switch-on is under the control of pre-programmed logic in the computer. Target

detection in the search area, lock-on and terminal homing are by active radar, operating in the horizontal plane only.

Target data (range/bearing) can be supplied from sensors aboard the launch aircraft, or from external sources. Altitude, speed and attitude data required for missile launch are provided from aircraft systems. The MFCS is operated by the pilot, using the PFCP, the other units (MPU, PSU and A/H) compute and supply the power and pre-launch data required by the missile. Missile release is activated by the pilot, by pressing a missile fire button on the control stick.



Missiles operated from fighter aircraft use the 'fire-and-forget' mode for one of the following procedures:
(1) radar-range and bearing launch (RBL)
(2) manual RBL
(3) bearing only launch (BOL)

Radar RBL For this technique, the aircraft radar detects potential targets and the range and azimuth data are transferred to the MPU by using the appropriate push-button on the PFCP. Target position, relative to the aircraft, is then calculated automatically and fed into the missile up to the moment of launch. The pilot receives an indication that the predetermined launch criteria have been met, by the flashing of a fire indicator light on the PFCP.

Manual RBL This method allows target location information to be fed to the missile by manual means, by either reading this information from aircraft navigation displays etc, and entering it manually on the PFCP, or receiving target data from an external source (eg a maritime patrol aircraft, ship, or other aircraft), entering this on the PFCP, while present aircraft position is updated by using an initiation point (entered via the PFCP before take-off). The MPU will continue to calculate the target location and transfer the required target range and bearing data to the missile. When the aircraft reaches the release range (as calculated by the MPU and indicated on the PFCP) the pilot can initiate missile firing.

Bearing Only Launch In this mode the pilot uses an estimated range together with a defined target bearing. Both estimated bearing and measured range are entered via the PFCP and transferred to the missile via the MPU. The estimated range is defined as Low, Medium or High, corresponding to 20, 20 to 40 or 40+ km respectively. This operating mode is automatically selected if no other choice is made, as a fall-back mode, and in this case the aircraft is aligned to the target direction and for range the minimum weapon range is chosen.

CHARACTERISTICS
Length: 3·85 m
Diameter: 34 cm
Max span: 1·1 m
Launch weight: 600 kg
Warhead: HE 150 kg
Fuze: Impact, delayed action

Gabriel Mk III A/S air-launched anti-ship missile

Propulsion: Solid
Range: Over 60 km
Cruise speed: Mach 0·73
Launch altitude: 90 – 9000 m
Cruise altitude: 20 m
Terminal phase altitude: 1·5/2·5/4 m (pre-set)
Guidance: Inertial (plus optional command update) midcourse; active radar homing

STATUS
Entering production.

MARTE HELICOPTER ANTI-SHIP MISSILE SYSTEM

The purpose of the Marte system is the destruction or disabling of naval craft in 'all weather' conditions by means of modified and improved Sea Killer missiles launched from helicopters in a stand-off position.

The helicopter-borne missile used in conjunction with the Marte System is the Sea Killer Mk 2 (with over 20 km range and a 70 kg warhead for the Marte version).

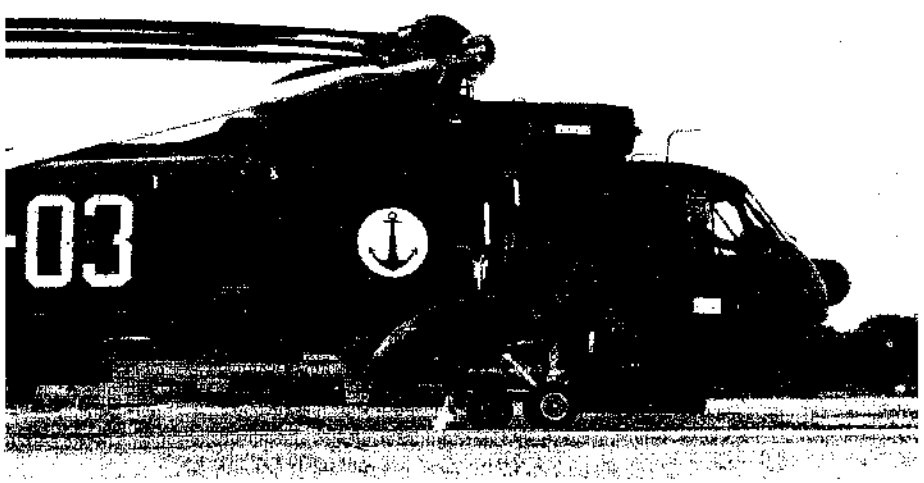
Installation of the Marte weapon system has been carried out on the Agusta/Sikorsky SH-3D helicopter, but the system is also suitable for installation on other light shipborne helicopters, such as the Agusta AB 212.

In addition to the two missiles, the Marte Mk 1 equipment carried by the helicopter consists of an SMA VM/APQ-706 I-band radar (**3309.353**) for target search, acquisition and missile guidance; auxiliary launch and guidance equipment (ALGE) which includes the missile control console (MCC); command transmitter and antenna; optical tracker and 'joystick' control; and a pilot's display unit. An Elettronica ESM system is also normally fitted to provide passive detection and other electronic warfare facilities.

The APQ-706 radar provides two different operational modes, one for operations not involving the launching mission, and the other for missile guidance. There are back-to-back antennas and two transmitter/receivers with different output powers. The radar includes a data distribution and processing sub-system and a tactical PP, display with true and relative motion presentation and a micro-B display.

The MCC is part of the tactical display PPI console and contains the operational firing panel, synchro clock unit, launching computer and power supply. Using this and other ALGE items the crew are able to either perform or monitor pre-launch sequences, and radar or optical launches. Provisions are also made for elaboration of data. The pilot's display is used to select the optimum course during the launch approach. Radar and optical command guidance modes were available in the original Marte Mk 1 system, but the newer Mk 2 system (see below) employs a different technique incorporating active radar homing.

MARTE Mk 2



Essentially, the Mk 2 version of Marte consists of the Mk 1 missile to which an active radar homing head based on that of the Otomat anti-ship missile (**1336.221**) is added to replace the command guidance system employed in the Marte Mk 1 system. Thus the Mk 2 weapon becomes a 'fire-and-forget' missile using radar homing, leaving the launching helicopter free to take evasive manoeuvres immediately after weapon release. The complete Marte Mk 2 system consists of two or four missiles, a missile firing box, a pilot's display and a data processing unit (DPU), and the system is interfaced with the aircraft search radar, gyrocompass, altimeter and doppler navigator.

The Marte Mk 2 missile is a medium range sea-skimmer based on the Sea Killer Mk 2 (see above) which has been provided with a new guidance system. The missile employs a booster motor during the launching phase and a sustainer during the cruise. It is subsonic with an average speed of about 250 m/s, and the range is in excess of 20 km. The payload is an HE semi-armour piercing warhead weighing 70 kg which is of the fragmentation type, activated by an impact/influence fuze. In the latter of these two fuzing modes, activation is by means of a proximity sensor associated with the missile radio altimeter, which provides the necessary signal when over-flying the target.

Guidance in the vertical plane is by means of the CW radio altimeter which keeps the missile at a controlled constant height above sea level up to the moment of impact. This height selected between 3, 4 and 5 metres depends on sea state and target dimension. Guidance in the horizontal plane during the initial inertial phase of flight is gyroscopically controlled towards the target, following preset direction data already provided by the system DPU before launch. After the initial phase, the missile follows a ballistic flight trajectory for a period of time corresponding to the burn time of the boost motor (approximately 1·7 s), and after booster separation, the sustainer motor is ignited automatically and missile control is initiated (roll control, accelerometric autopilot insertion etc). Vertical plane (altimeter) guidance allows the missile to follow a preset descent path to the final cruise altitude. Gyroscopic horizontal guidance maintains the missile on an optimal trajectory for detecting and tracking the target in the final phase of the attack and this occupies approximately the first 14 km of flight. The active radar homing head, after target acquisition, is responsible for control in the horizontal plane for the last 6 km or so until impact.

Other modes of operation can be employed according to tactical circumstances, for example: launch on ESM data (in radar silence conditions), or launch on radar data from another co-operating helicopter.

CHARACTERISTICS
Type: Marte Mk 2
Length: 4·48 m (with booster)
Wing span: 0·98 m
Diameter: 316 mm (max)
Launch weight: 330 kg
Propulsion: 2-stage solid, booster and sustainer
Range: 20 km
Average speed: High subsonic
Warhead: High explosive, semi-armour piercing
Fuze: Impact/proximity
Guidance: Gyro pilot and radio altimeter, active radar homing
Aircraft launch speed: 50 – 100 knots

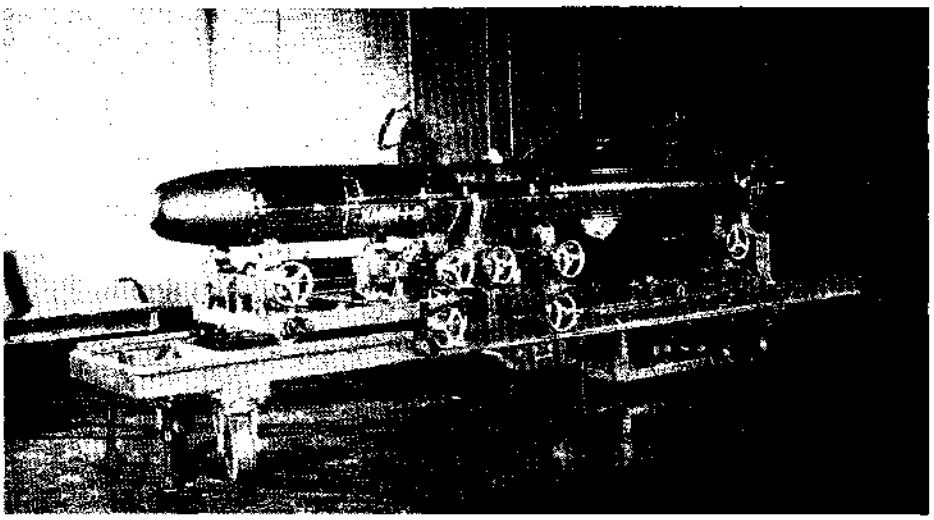
Marte Mk 2 anti-ship missile loaded on Italian naval helicopter

STATUS
The Italian Navy received the first operational prototype of the Marte system, in the SH-3D helicopter, at the end of 1977. Marte with Sea Killer Mk 2 entered production during 1978.

The Marte Mk 2 project was revealed in mid-1983 and on March 23, 1984 a 'fire-and-forget' test launch at the Salto di Quirra, Sardinia range, resulted in a successful hit on a ship target at a range of 19 km.

In June 1985 Oto-Melara and Aermacchi revealed plans to deploy the Marte system on the latter company's MB.339c trainer/light attack aircraft. An Italian Navy SH-3D helicopter launched a Marte missile against a target tug in June 1985.

CONTRACTOR
OTO-Melera SpA, 15 via Valdilocchi 1, 19100 La Spezia, Italy.



JAPAN

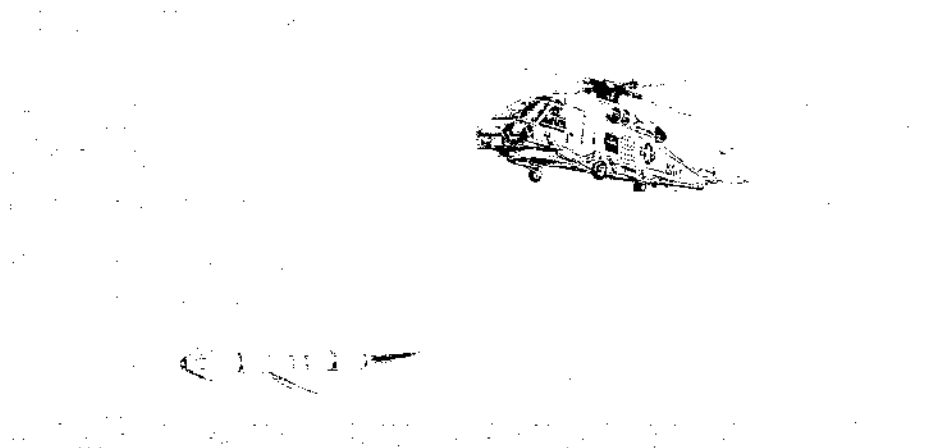
1653.311
ASM-1 AIR-TO-SURFACE MISSILE (TYPE 80)
Under the designation ASM-1 the first Japanese tactical air-to-surface anti-ship missile has been formally introduced as the Type 80 for use with the Mitsubishi F-1 close-support aircraft. No official details have been obtained but provisional characteristics are: range approximately 50 km, speed about Mach 1. An inertial system is used for mid-course guidance and an active radar seeker for terminal homing.

STATUS
In November 1973 Mitsubishi Heavy Industries Ltd was selected as prime contractor for the development of the ASM-1. Development was completed in 1979 and production commenced in 1980 to meet the requirements of the Japan Defence Agency only.

In mid-1981 a proposal to construct a new coastal defence system envisaged the use of a ground-launched version of the ASM-1 anti-ship missile which would have increased range to permit the system to be based inland but be able to reach targets 50 km off-shore.

CONTRACTOR
Mitsubishi Heavy Industries Ltd, 5-1 Marunouchi 2-chome, Chiyoda-ku, Tokyo 100, Japan.

JASDF ASM-1 air-to-surface missile on laboratory support trolley. The stencilled designation on the missile suggests US practice, in which case this is probably an early experimental round, denoted by the prefix letter 'X'



NORWAY

3070.321
PENGUIN MK 3 AIR-TO-SURFACE MISSILE
The Penguin Mk 3 missile is a growth development of the existing Penguin Mk 2 surface-to-surface missile (**1339.221**). This missile is already in service with several navies as main armament on fast patrol boats. The Penguin Missile System Mk 2 has demonstrated its ability to successfully attack surface targets in both open and confined waters with minimum exposure of the launching platform. It is being developed for the Royal Norwegian Air Force. The missile fuselage is slightly longer at 3·176 metres and the span is reduced to 1 metre. BAe Dynamics Group, Bracknell Division, has developed a new gas actuation system under contract to Kongsberg Våpenfabrikk.

Penguin Mk 3 missile is a 'fire-and-forget' weapon allowing aircraft break-off immediately after launch. Following the trajectory instructions the missile will find its way to the future target position using inertial navigation plus altimeter for reference. The missile can be launched over land and programmed to fly via a waypoint where it may descend to sea-skimming altitude and turn up to more than 90° on to its final heading. Once in the target area the target seeker is activated. When the target is acquired, the seeker locks on and guides the missile to target impact. The Penguin missile imposes very limited penalty on the aircraft performance due to its lightweight and minimal drag.

The Penguin Mk 3 missile system is designed to interface with existing aircraft fire control systems with minimum aircraft modification requirements. This is achieved by utilising an adaptor between the missile and the aircraft weapon station. The adaptor containing the retention and release mechanism for the missile, also provides space for the avionic components and attachment hardware for interface with the parent aircraft. This solution makes interface with various aircraft types possible with little or no impact on either missile or aircraft.

The air-launched version of Penguin is expected to have a useful range of at least 55 km. The modified Bullpup warhead has been retained. The missile is equipped with one solid-propellant rocket motor only. Using aircraft in the high subsonic speed range allows the booster motor to be omitted.

A helicopter-launched version of Penguin is being developed for the SH-60B and similar machines.

CHARACTERISTICS
Length: 3·176 m
Diameter: 28 cm
Wing span: 1 m
Weight: 360 kg
Warhead: Modified Bullpup, 120 kg
Propulsion: Solid sustainer, A/S Raufoss/Atlantic Research Corp
Range: 50 km +
Guidance: Programmed inertial, IR homing

OPERATION
Target designation to the missile can be accomplished using the launch aircraft radar, by placing a marker over the target on the display and pressing a button to insert this data into the missile. The same technique can also be employed to insert a waypoint into the missile guidance system program. A similar technique can be used with the aircraft head-up display, in which case the pilot first acquires the target optically. This method can also be adopted using an aircraft gunsight in lieu of the head-up display. After release the Penguin missile follows an inertially guided flight path to either the designated waypoint or to the target area. In the case of reaching the waypoint, the missile then changes course and possible altitude, to fly on to the target area. On reaching the target area the IR seeker is switched on and the missile commences the terminal homing phase. This employs one of several alternative search patterns which can be selected by the pilot before the missile is launched.

Helicopter Penguin
Penguin is being adapted for use with the American SH-60B Seahawk naval helicopter, which can carry two of these missiles. Penguin is integrated into the helicopter avionic system, utilising existing equipment for missile control and operation. This version is designated Penguin Mk2 Mod 7.

As Penguin is a 'fire-and-forget' system, the helicopter exposure time can be reduced to a minimum, with a corresponding reduction in helicopter vulnerability. Seahawk aircraft equipped in this way can operate autonomously or in a co-ordinated attack with ship-launched over-the-horizon missiles for cost-effective suppression of enemy defensive systems. Penguin thus provides helicopters of this category with an effective stand-off weapon for the anti-surface vessel role.

CHARACTERISTICS
Length: 3 m
Wingspan: 140 cm; 55 cm (folded)
Weight: 340 kg
Speed: High subsonic
Fuze: Impact
Trajectory: Variable
Range: 30 km +
Other details are the same as for the Penguin Mk 3, above.

STATUS
Studies for an air-launched version of Penguin were carried out in the mid-1970s, using an F-104 as the weapon platform. Following competitive evaluation, Penguin Mk 3 was chosen by the Norwegian authorities in 1979 to arm F-16 aircraft. possibility of using it with the P-3 Orion maritime patrol aircraft has also been studied.

Full-scale development was decided on in 1980 and contracts were awarded in that year and 1982. First live air launches took place in 1984. Entry into service is expected in 1987.

An agreement covering the purchase of an initial batch of 272 Penguin Mk2 Mod 7 missiles by the US Navy was announced in March 1985.

RBS 70 HELICOPTER SELF-DEFENCE MISSILE

In mid-1981 Bofors revealed a new application of the successful RBS 70 portable air-defence missile system (**2348.131**), in which a helicopter mounted installation comprising two four-round launcher pods and a special version of the RBS 70 sight/guidance unit is carried to provide self-defence facilities for ground attack helicopters. The helicopter also has the usual anti-tank or reconnaissance sight, including a laser designator. The system has a 'dark firing' capability also if the sight includes a night vision facility.

Targets are initially acquired using the normal helicopter sight, and the gunner tracks the target. Simultaneously the pilot is given both target indication and bearing and turns the helicopter towards the target. When the system is armed, the stabilised mirror in the control unit is slaved to the gunner's sight. On firing, the laser beam is activated and projected from the control unit mirror. After launch the missile is gathered into the guidance beam which it follows to the target. As the missile nears the target the laser in the gunner's sight is activated to illuminate the target. This locks the guidance beam onto the target, ensuring a hit. A more detailed outline of the RBS 70 guidance and control technique is given in the entry for the ground-mobile version of the system (**3617.131**), in the Mobile Surface-to-Air Guided Missile Systems section of this volume.

Bofors RBS 70 helicopter self-defence missile system installed on a Westland Lynx

CHARACTERISTICS
Length: 1·32 m
Diameter: 12 cm
Wing span: 33 cm
Propulsion: Solid, booster plus sustainer
Weight: 137 kg (pod + 4 missiles); 54 kg (control unit); 15 kg (missile)
Guidance: Laser beam-rider
Range: 5 km
Speed: Supersonic
Time of flight: 8·5 s (to 3 km)
Reaction time: < 5 s
Reloading time: < 60 s (4 rounds)

STATUS
Development project.

RBS 15F ANTI-SHIP MISSILE

RBS 15F is the designation of a new Swedish anti-ship missile for use by both Swedish aircraft and Swedish naval vessels. The latter role (**3976.221**) is being addressed first with deployment aboard 'Spica' class fast patrol boats in 1985.

The general configuration of the RBS 15F can be seen from the illustration, and the air intake for the turbojet engine will be noted beneath the missile body. An air-breathing propulsion system has been decided on to provide long range with a high subsonic speed at sea-skimming heights. In the surface-launched mode, the RBS 15F is assisted by two solid-propellant booster motors, but these will be deleted in the air-launched mode.

The RBS 15F will have a launch and leave capability and will be provided with an ECM-resistant homing head developed by Philips Elektronikindustrier. This company is producing the system fire control

RBS 15F missile beneath a Saab 35 Viggen aircraft during test flights

computer in addition to the frequency-agile radar seeker. The homing head is digitally programmable with selectable search patterns, target choice logic, and variable ECCM. The trajectory can be altered in accordance with operational demands. Prelaunch operations will be minimal in scope and all calculations will be be performed automatically by an on-board computer. A radio altimeter will ensure safe missile cruise at low levels above the sea surface. A 'heavy' warhead is produced by Förenade Fabriksverken for the RBS 15F.

CHARACTERISTICS

Length: 4·35 m
Diameter: 50 cm
Wing span: 1·4 m
Weight: 595 kg (without boosters)
Guidance: Programmed autopilot cruise with height hold, followed by active radar homing
Range: 150 km (estimated)

STATUS

On order for Swedish Air Force.

SAAB 04E AIR-TO-SURFACE MISSILE

This is an air-to-surface missile developed principally for anti-shipping strikes. The version in current Royal Swedish Air Force service is the Saab 04E which has been developed at Saab-Scania since 1968 under the SAF designation RB 04E. Principal characteristics are as follows: length 445 cm, body diameter 50 cm, wing span 2 m, and total weight about 600 kg. These figures are the same as for the earlier models but the RB 04E is stated to be technically very advanced. After launch, the missile acts independently of the launch aircraft and is automatically guided to a low-level altitude where target search and acquisition are performed at a high subsonic speed.

Guidance in the approach phase of an anti-shipping attack with the 04E is by means of a high-quality autopilot towards the target area. Precision terminal homing is by an advanced homing head, produced by Philips in Sweden.

DEVELOPMENT

The Robot RB 04 series of missiles was initiated in the 1960s and developed by the Missile Bureau of the Swedish Air Force Board (now the Defence Material Administration – Missiles Directorate). This organisation was responsible for the development of the 04C and 04D versions, but subsequent R & D has been performed by Saab-Scania.

STATUS

The RB 04E is operational with AJ 37 Viggen all-weather attack aircraft, which can carry three missiles.

Saab 04E anti-shipping missile

CONTRACTOR

Saab Missiles AB, Linköping, Sweden.

1190.311
SAAB 05A AIR-TO-SURFACE MISSILE

The Saab 05A is a radio-command guided, manually controlled tactical air-to-surface missile. It is for use against both sea and land targets but may also be used in certain air-to-air roles. Principal characteristics are: wing span 80 cm, diameter 30 cm, length 360 cm, and total weight about 305 kg.

The airframe of the Saab 05A is made of conventional aircraft materials and consists of a pointed cylindrical body with long-chord cruciform wings and aft-mounted cruciform control surfaces. A liquid rocket motor is centrally located and the motor casing forms part of the outer skin and load-carrying structure of the missile. The armament system is located in the nose and most of the control equipment at the rear of the missile. The VR 35 rocket motor is fitted with a tail-pipe which passes through the rear of the body. A pre-packaged liquid-propellant motor, supplied by Volvo Flygmotor AB, is used. The propellant tanks are placed around the centre of gravity to avoid CG-shift. Electrical power is supplied by a thermal battery. Before launching, some necessary electrical preheating of the missile is supplied from the aircraft. The hot gas for the control surface actuators is provided from a solid-propellant gas generator. An effective proximity-fuzed armament system is used.

The auxiliary airborne missile system equipment comprises a control stick, coding unit, transmitter, and antenna.

After launching, the missile is guided manually by the pilot who visually lines up the missile tracking flares and the target. The control signals are transmitted over the radio link with the transmitter in the aircraft and the receiver in the missile aft section. The guidance function, from a control stick is specially designed to provide a high degree of accuracy for both small and large off-set angles. The coded command link is difficult to jam. Guidance signals received by the missile are converted by an autopilot to control surface deflections by means of four hot gas actuators. The autopilot initially guides the missile into the pilot's field of view.

DEVELOPMENT

Developed by Saab-Scania on behalf of the Swedish Air Force, the system entered advanced testing in 1968-69. In June 1969, Saab was awarded a large contract by the Swedish Government for further development and production.

STATUS

The RB 05A is in service with the AJ 37 Viggen aircraft, and various versions of the Saab 105. Quantity production was completed in 1977 and the missile is operational with certain Swedish Air Force wings.

UNION OF SOVIET SOCIALIST REPUBLICS

1148.311
KENNEL AIR-TO-SURFACE MISSILE (AS-1)

Kennel is the NATO code-name assigned to a Soviet stand-off air-to-surface weapon carried by Tu-16 (Badger) aircraft, one beneath each wing. According to recently released American DoD figures, the AS-1 is 8·44 metres in length, and the wing span is thus approximately 4·8 metres. It is powered by turbojet motor, and its general appearance is almost identical with the Samlet coastal defence missile, and the two weapons may in fact be versions of the same missile. Estimated range is up to 50 nautical miles (90 km).

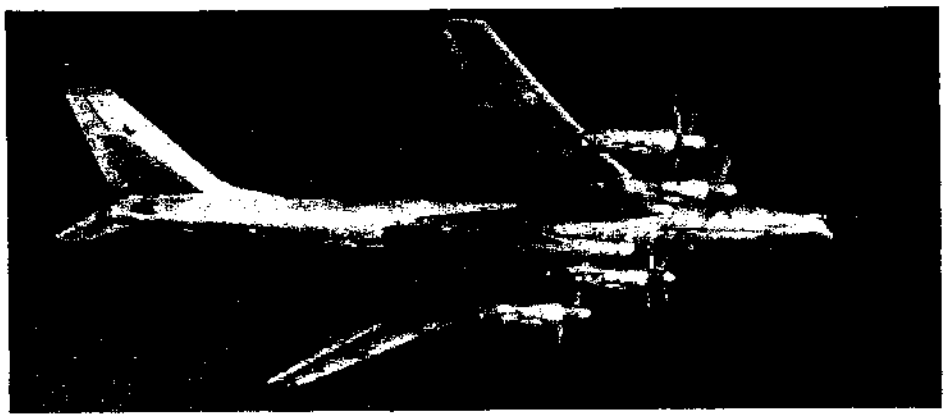
A probable operational role is anti-shipping strike missions, and external evidence of electronic equipment carried by Kennel missiles suggests that either beam-riding radar or radio command link guidance is used for the major portion of the trajectory, with either passive or active radar homing for the terminal phase. The parent Badger aircraft are provided with at least two radars on the underside of the fuselage which could serve such a mode of operation.

In addition to the Soviet forces, the Badger/Kennel combination has been supplied to various client nations of the USSR. Although now obsolete, the AS-1 probably remains in service with a few of these countries.

1150.311
KIPPER AIR-TO-SURFACE MISSILE (AS-2)

Kipper is the NATO code-name of another Soviet stand-off missile, which with Kangaroo (**1147.311**) was first seen in 1961. Official US information recently obtained indicates a length of 10 metres, which makes the AS-2 about two thirds the size of the AS-3, Kangaroo. Kipper, with a wing span of about 4·6 metres, also has an aircraft-like configuration with swept wing and tail surfaces. Propulsion is by a turbojet motor suspended beneath the missile fuselage. Most Western estimates of Kipper's range give a value of between 180 and 210 km. In general appearance Kipper resembles the American Hound Dog, AGM-28 (**1093.111** 1980-81 and earlier editions), stand-off strategic bomber weapon (now out of service with US forces).

Recent analyses have deduced that Kipper flies to its target area under control of a programmed autopilot, to which there are command override options available. Terminal homing is thought to rely on active radar homing, possibly with the alternative of passive radar guidance in some models. A high explosive warhead is carried.



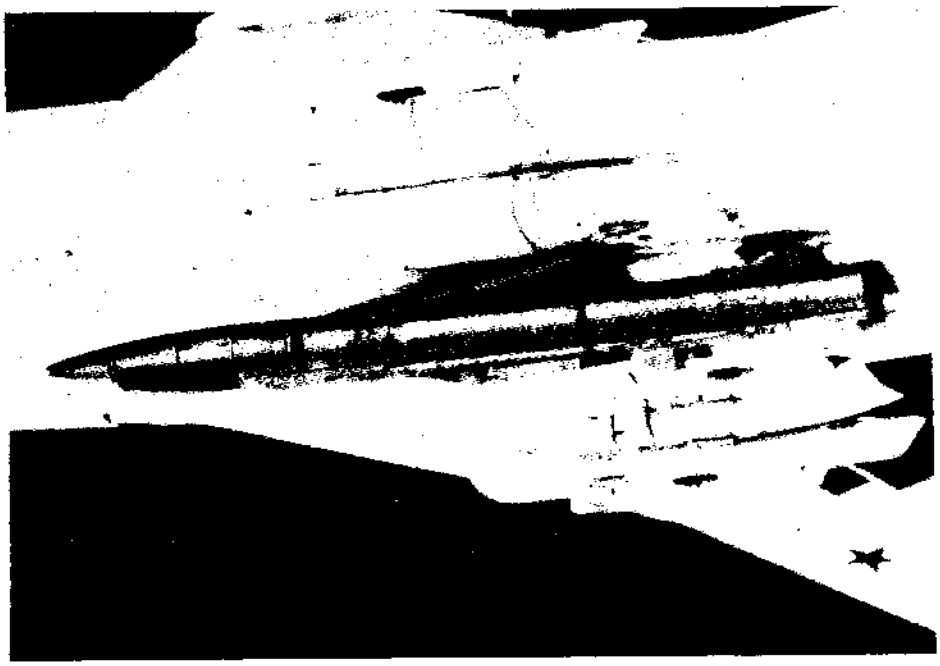
Kipper is generally considered by observers in the West to be essentially an anti-shipping missile, but the possibility that it could be used for strategic bombing of land targets should not be completely discounted. The weapon is associated with the Tu-16 Badger-C bomber aircraft.

1147.311
KANGAROO AIR-TO-SURFACE MISSILE (AS-3)

Kangaroo is the NATO code-name assigned to the largest Soviet air-to-surface missile so far revealed. First shown in public in 1961, it is associated with the Tu-95 Bear bomber aircraft and is generally assumed to have retained operational status though its operational importance has probably declined significantly as newer weapons have been deployed.

As the photograph shows, the Kangaroo has the configuration of a conventional swept-wing fighter aircraft and similar dimensions, approximately 15 metres (US official sources quote 14·96 metres) in length and with a span of 9 metres. The propulsion used has not been confirmed but is probably a turbojet engine. There is no reliable information available as to the ratio in which the relatively large payload potential of Kangaroo is allocated between range and warhead, as is borne out by the wide variation in range estimates published by different specialist sources. These extend from 185 to 650 km, and it is likely that all these ranges are possible but without access to trustworthy data of the type and weight of warhead, guidance method(s), and performance, the true range figure must remain conjectural. (A recent American Senate report stated that a nuclear warhead could be carried over a distance of 350 nautical miles (648 km), which corresponds to the higher of the two figures above.) A nuclear warhead payload of about 800 KT yield is assumed, and the maximum speed was at one stage estimated to be as high as Mach 2 but this has been reduced in recent (1985) official US estimates to subsonic speed. Recently obtained information suggests that mid-course guidance is controlled by an autopilot with command override facilities for navigational corrections, but no terminal homing facilities are thought to be carried.

In view of these considerations, the most likely role of the AS-3 Kangaroo is that of a medium/long-range stand-off strategic nuclear weapon for use against area targets, such as major cities or ports.

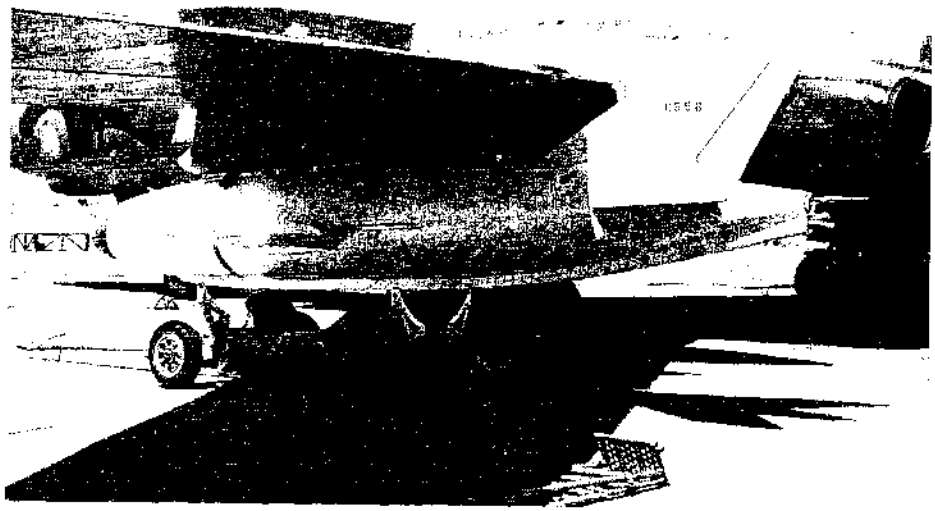


Kangaroo stand-off missile beneath Tu-95 Bear bomber aircraft

1151.311
KITCHEN AIR-TO-SURFACE MISSILE (AS-4)

Kitchen appears to be one of the most technically advanced Soviet air-to-surface missiles yet revealed. It has a fuselage of about 11·3 metres long to which are attached a pair of delta planform wings and a cruciform tail assembly. Propulsion is by rocket motor, liquid-fuel burning according to American sources, and inertial guidance is assumed for the mid-course phase of flight, after which an active radar homing provides for terminal guidance to the target. In 1981 the existence of a passive radar homing version was reported. American DoD sources have stated that a number of AS-4 versions are in use, of which two have been identified for strategic and naval roles, respectively. Alternative warheads exist for these roles, the former being nuclear with an estimated yield of about 200 KT, and the latter a conventional high-explosive payload for anti-ship or tactical missiles. Estimates of range vary widely from 300 to 800 km, and the aerodynamic features of Kitchen suggest a high cruising speed and a supersonic capability is confirmed in US DoD publications. A UK MoD statement in early 1976 gave a maximum range of 298 km but this is thought to have been an underestimate.

First seen carried by the Tu-22 Blinder, the AS-4 has since been reported as arming the Tu-95 Bear, and the Tu-26 Backfire B variable-geometry aircraft. On the Bear, the AS-4 is carried beneath the aircraft wings, and on the Tu-22 Blinder and Tu-26 Backfire in a semi-recessed position on the underside of the fuselage.



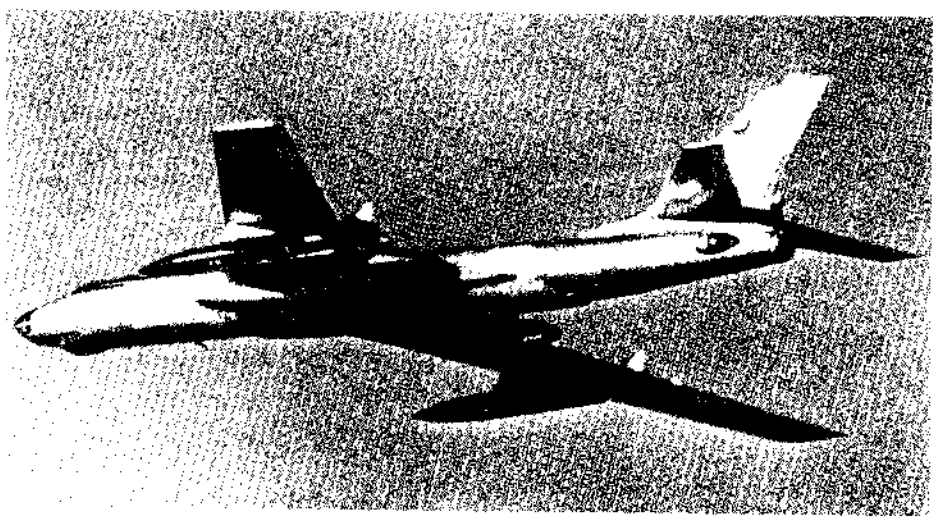
AS-4 Kitchen is carried in a semi-recessed position under the fuselage of Backfire strategic aircraft

1149.311
KELT AIR-TO-SURFACE MISSILE (AS-5)

Kelt is the NATO code-name of a Soviet air-to-surface weapon, first seen on a Tu-16 Badger bomber aircraft. It has superficial but pronounced similarities with the Kennel (**1148.311**) which also is used with the Badger, and with the Styx shipborne surface-to-surface missile (**1155.221**). A length of 8·59 metres has been officially reported for Kelt in an American government publication, with wing span about 4·3 metres. The fuselage centre-body and wings of Kelt appear to be the same or very similar to those of Kennel, while the nose section (and presumably the guidance system it carries) of Styx is employed. A rocket propulsion motor is used and the tail control surface arrangements of Kelt differ from those of both Styx and Kennel. Western estimates of range vary between 160 km and more than 320 km, but a British MoD report issued in April 1976 quoted the former figure as maximum range for the AS-5 (Kelt).

Propulsion is by a single-stage liquid-fuelled rocket motor, and guidance arrangements include an (inertial) autopilot for the mid-course phase of flight followed by active radar homing for the terminal phase. A passive radar, anti-radiation missile version of Kelt has been reported.

Applications of the AS-5 Kelt are thought to be confined to service with Soviet Naval Air Forces in anti-ship and other tactical roles.



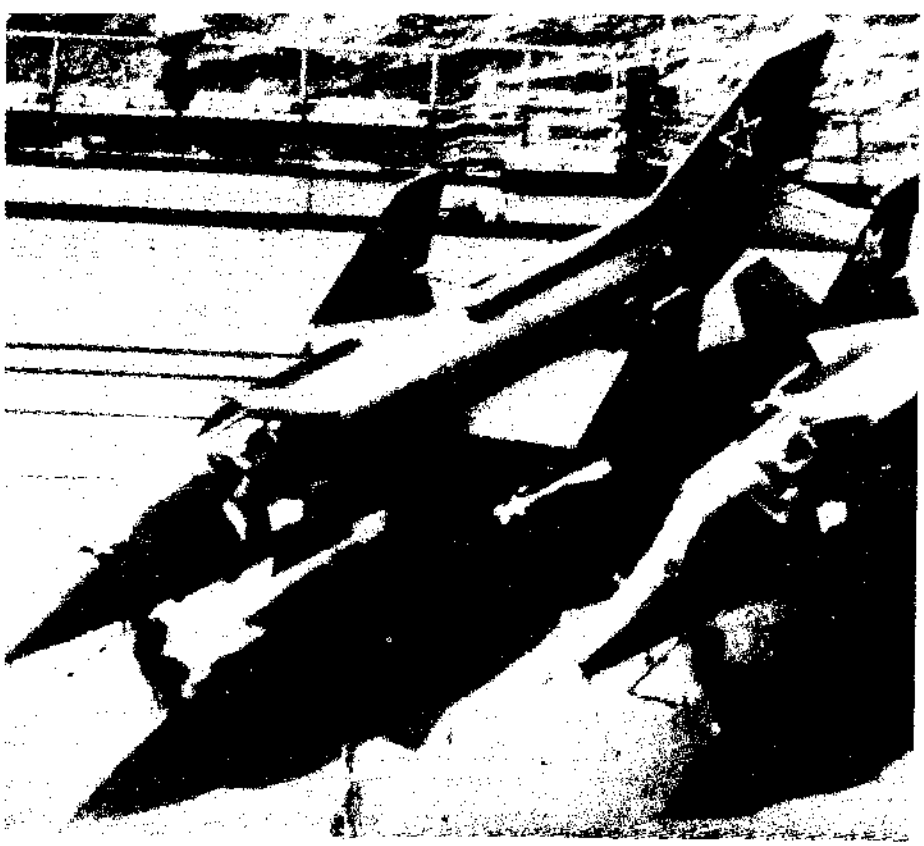
AS-5 Kelt air-to-surface missile loaded on to underwing pylon of Egyptian Air Force Tu-16 Badger aircraft

3633.311

KINGFISH AIR-TO-SURFACE MISSILE (AS-6)

Kingfish, AS-6 in the American numerical sequence, is a high performance air-to-surface missile carried by Tu-16 Badger aircraft of the Soviet Naval Air Forces, and was also thought to arm the Tu-26 Backfire variable geometry aircraft on occasion, although it is more likely to have been mistaken for the AS-4, Kitchen (**1151.311**). The configuration is similar to that of the AS-4 (although it is impossible to say if this indicates either a line of development, or even a 'family' likeness) with a cylindrical fuselage supported by short-span, long-chord stub wings of delta planform. Provisional dimensions are: length 10·5 metres and maximum span 2·5 metres. Liquid propulsion has been assumed, and estimated performance gives a range of about 200 km and a maximum speed of Mach 3. US official sources have confirmed that the Kingfish is capable of supersonic flight.

The same report also revealed that one role for this missile is anti-shipping missions in which a high-altitude supersonic cruise approach trajectory is followed by a diving attack onto the target. Another reliable source has quoted a release altitude of 11 000 metres, which is followed by a climb to a cruise height of up to 18 000 metres. Inertial mid-course guidance is employed with an active radar terminal homing phase although it is possible that a passive radar homing variant exists to provide anti-radiation missile (ARM) capabilities. More recent information has confirmed use of the AS-6 Kingfish with aircraft of the Soviet Naval Air Force, and there is said to be the option of conventional HE or nuclear warheads. The latter is reported to have a yield of some 350 KT.



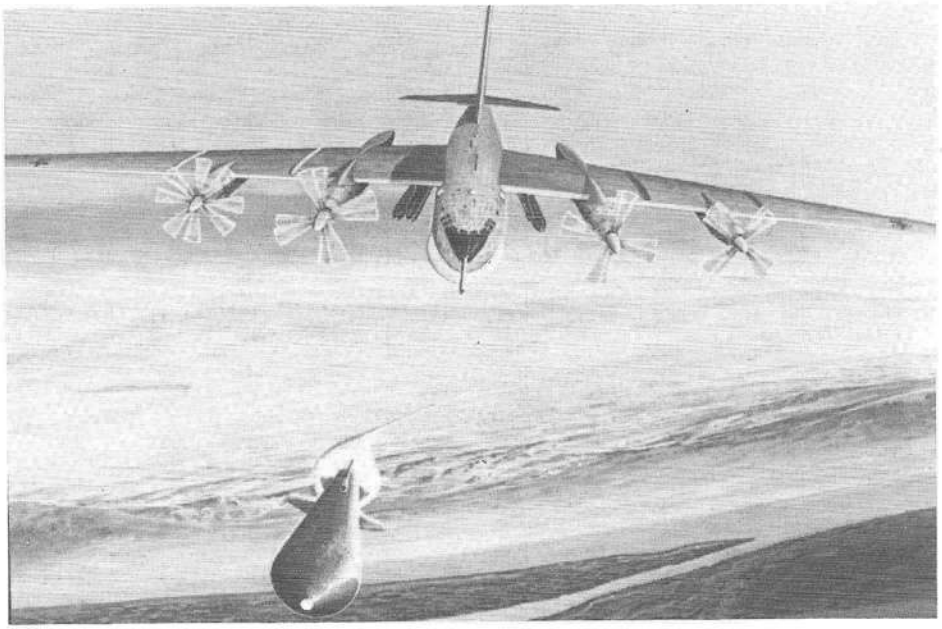
AS-6 Kingfish missiles carried beneath the wing of a Soviet Tu-16 Badger (JASDF)

3634.311

KERRY AIR-TO-SURFACE MISSILE (AS-7)

Kerry is the NATO reporting name of the air-to-surface missile numbered AS-7 in the US series. It is known to be deployed on the Su-24 Fencer variable geometry fighter-bomber aircraft, and is thought to arm other types of Soviet close support aricraft also, such as Fitter or the Forger naval VTOL machine. A solid propellant rocket motor is believed to power the AS-7, carrying an HE warhead estimated to weigh about 100 kg. Precise details of the AS-7 configuration are still awaited but early information suggests a relatively large diameter weapon with large cruciform wing surfaces set well back on the missile body, with four small canard control surfaces. Initial estimates were of a heavy missile possibly weighing as much as 1200 kg, but later assessments revised this to between 300 and 400 kg and the latter figures appear more likely. It is credited with a range of about 10 km, and radio command guidance is thought to be employed, although this has not been confirmed.

Further analysis must await more evidence, either in the form of further leaks of official intelligence reports or photographic data issued by the Soviet authorities themselves.



Yak-36 Forger carrier aircraft armament includes AS-7 Kerry tactical air-to-surface missiles

3206.311
NEW SOVIET AIR-TO-SURFACE MISSILES

Official hints and leaks of less certain origin leave little doubt that successors to the above well-known (by name, if not in detail) Soviet air-to-surface missiles are on the way, and in some instances they may well be in service already. Of the established and well-known Soviet air-launched cruise missiles described in entries above, the AS-5 (Kelt) is the most widely deployed of these missiles and is fitted on the Tu-16 (Badger), while the AS-4 (Kitchen) is fitted on Tu-95 (Bear) and Tu-22 (Blinder) bombers.

The designation **AS-9** is thought to apply to an anti-radiation missile arming the SU-19 Fencer attack aircraft although other sources attribute an anti-ship role to this weapon. Estimated range is about 80 to 90 km, and official US reports claim that this weapon is at the development stage, in which case the designation applied is **AS-X-9**. The designation **AS-X-10** has been assigned provisionally to what is thought to be a Mach 0·8 laser-guided air-to-surface missile reported as being carried by MiG-27, Su-17 and Su-19 aircraft. It is estimated to be about 3 metres long and to have a range of about 10 km, using a solid-propellant rocket motor. But, again different sources suggest an anti-radiation role for the AS-10 and indicate a range of up to 40 km, possibly being deployed on the Su-24 Fencer aircraft.

Several other new air-to-surface missiles are rumoured to be under development by the Soviet Union, and the main features attributed to three of them are as follows: the first is an approximate Soviet equivalent to the US Maverick, using electro-optical guidance with a command link, and with a probable maximum range of about 40 km (this has been provisionally designated **AS-X-11** by some sources); another is a possible replacement for the AS-4 Kitchen with a speed of Mach 3·5 and a maximum range of up to 800 km; and the last is thought to be roughly equivalent to the American air launched cruise missile (ALCM) using an air-breathing turbojet with a maximum range of up to 1200 km. In mid-1981, development of a 500 kg laser-guided bomb was also reported, but no details have emerged.

An American artist's impression of a Soviet Bear H strategic bomber launching one of its AS-15 nuclear air-to-surface missiles. This illustration suggests that four AS-15s are carried on an external pylon under each wing

Little has been added to the above by official sources since publication of the previous edition, other than the appearance of a new US designation AS-15, which is now stated to have reached operational status in 1984 when deployment began with Bear H strategic bomber aircraft. The US analysts credit this weapon with a 3000 km range carrying a nuclear payload, and it has also been suggested officially that there are two derivatives of the AS-15 under development for unstated applications.

The US reference to an AS-15 unfortunately still leaves the question of what weapons the assignments AS-12, AS-13 and AS-14 apply to. These numbers have presumably been assigned to new airborne weapons that have been detected by the US intelligence organisations, but they are as yet either too little known to justify public disclosure or the US authorities do not yet wish to reveal the extent of their knowledge of the new systems.

4556.311
SOVIET AIR-LAUNCHED ANTI-TANK MISSILES

As numerous Western air forces, the Soviet Union and several client states have adopted the practice of deploying anti-tank guided missiles on certain types of helicopter for battlefield operations and ground attack missions. The AT-2 Swatter (**2985.111**) is operational in its manually-guided B version with Hind A and D helicopters and is in the process of being replaced with the later Swatter B version with semi-automatic command-to-line-of-sight guidance missiles. Users of Swatter (in addition to the USSR) include Hungary, Iraq, Libya and Syria. The Hind E ground attack helicopter has been noted equipped with AT-6 Spiral (**3639.111**) launch tubes, two being carried on the aircraft's stub wings. The frequently sighted AT-3 Sagger (**2950.111**) can be deployed on the Soviet Hoplite armed helicopter and is operated on Yugoslav Gazelle military helicopters. In the latter installation the gunner/co-pilot occupying the left-hand seat is provided with a roof sight to assist in missile guidance.

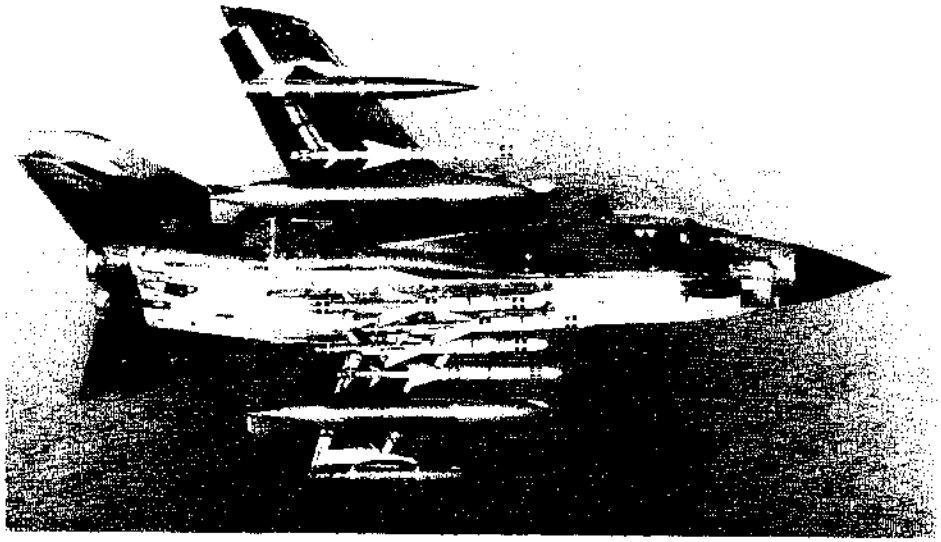
4528.311
ALARM AIR-TO-SURFACE MISSILE

ALARM is the air-launched anti-radar missile being developed by British Aerospace (BAe) Dynamics Group and Marconi for the RAF to enable it to meet an essential requirement to provide a deep penetration strike capability. ALARM is designed to counter enemy surface-to-air gun and missile defences by destroying their associated radars. Work on the Air Staff Target (AST 1228) has been proceeding for some time and culminated in a fixed price bid for development and production which was submitted to the UK MoD early in December 1982. Two competitive solutions were considered and ALARM selected in July 1983. The alternative was procurement of the American AGM-88A, HARM (**1769.311**) with some licence production in the UK.

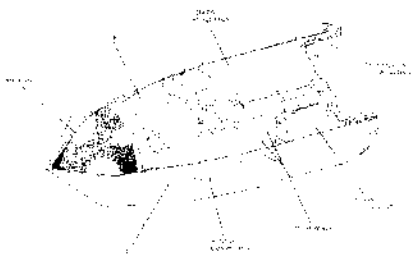


BAe Dynamics Group in association with Marconi Defence Systems (MDS) and other sub-contractors are working on the design and development of the system and have produced sub-systems which are undergoing ground tests and trials.

Other significant contributors are Thorn EMI Electronics who won a contract worth more than £4 million for the development and supply of the proximity fuze, and MBB of the Federal Republic of Germany who are developing the missile's warhead.

The fuze being developed by Thorn EMI will be based on the company's laser experience and at least two years private-venture research had already been completed before the contract award in May 1984. The new generation fuze will provide autonomous classification of targets and precise trigger point selection.

ALARM is a microprocessor-based software-controlled missile which does not require complex aircraft systems or interfaces, and it can be updated to meet changing threats and scenarios by software changes alone. The Marconi anti-radar seeker exploits UK investment in seeker technology and EW.



The complete seeker head will be programmable, enabling operators of the ALARM system to react

Tornado aircraft carrying a load of ALARMs

Maximum load of nine ALARMs takes to the air for first time under a Tornado on 13 February 1985

Schematic diagram of Marconi seeker head for Alarm

autonomously and rapidly to threat changes as they arise. This facility derives from the employment at the core of the seeker receiver of a complex digital processor that incorporates modern LSI techniques and new microwave IC materials. All software is produced in-house by MDS. The seeker package can be programmed before a mission with a list of target types and priorities. Re-programming during flight is also possible. The associated broadband microwave receiver is the first in the UK to utilise novel RF processing techniques, similar to those employed in EW radar homing and warning receivers.

The combined weight of ALARM plus its launcher is 280 kg which will allow up to four ALARM missiles to be carried by the Tornado IDS in addition to its normal attack payload. ALARM does not require dedicated aircraft, and has been designed from the outset with a high degree of autonomy. It makes small demands on the carrying aircraft and does not require complex and therefore costly aircraft modification or interfaces. It can also be fitted to fixed-wing aircraft down to BAe Hawk size as well as large aircraft and helicopters.

ALARM has a number of operational modes, among them direct attack where the missile flies to the selected target, and a loiter mode where the missile climbs to altitude and deploys a parachute from which it remains suspended until a suitable target is identified. The parachute is then jettisoned and the missile descends under gravity to home onto the target from overhead. There have been no details of the seeker cleared for publication but it is assumed to be a broad-band device and probably employs a fixed antenna.

STATUS

A detailed joint feasibility study by BAe and MDS was completed in 1982 and a submission was made to the UK MoD after certain company-funded development work had been carried out. The choice between ALARM and HARM procurement to meet AST 1228 was announced in July 1983 and a contract formally signed the following month. A UK requirement for about 750 missiles has been quoted with entry into RAF service some time in 1987.

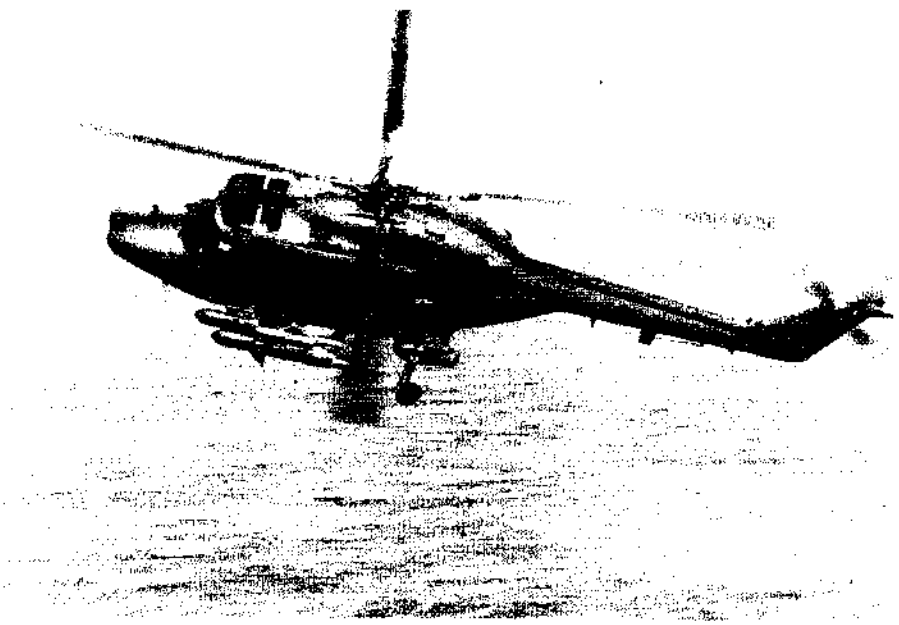
SEA SKUA HELICOPTER AIR-TO-SURFACE MISSILE

Sea Skua is an all-weather, helicopter-launched, sea-skimming anti-ship guided weapon system which is in operational use with the RN. Primarily designed for fitment to the naval variant of the Westland Lynx helicopter fitted with the Ferranti Seaspray radar, it will be the RN's principal air-to-surface light strike weapon for use against a variety of targets ranging from missile-firing fast patrol boats to coastal escorts, frigates and destroyers. Sea Skua is also suitable for fitting on other types of helicopter and fixed wing aircraft. Studies have also been carried out on a ship-launched version and this is described in entry **4553.221**

The helicopter/Sea Skua combination provides a cost-effective, rapid-reaction, surface attack capability up to, and well beyond, the radar horizon of the parent ship which retains the option of remaining passive and therefore undetected. Such a combination represents a valuable complement to long-range ship-to-ship missiles.

The missile is light enough to permit a four-Sea Skua fit on a small helicopter. Solid-propellant boost and sustainer motors are used to give the missile a range in excess of 15 km, sufficient to provide a good 'stand-off' capability for the helicopter with consequent protection from counter attack. To commence an engagement the helicopter would close the target to enable its radar to lock on and automatically track. While in this automatic tracking mode, the radar will illuminate the target with radio frequency energy, which, when reflected, provides the source onto which the Sea Skua semi-active radar homing head locks. On release from the helicopter the missile drops for a short distance under autopilot control maintaining attitude angle stabilisation in roll, pitch and yaw before the rocket motors are ignited. The Sea Skua missile then descends in stages, under control of a radio altimeter, to one of four terminal sea-skimming heights selected by the pilot prior to missile release, depending on the sea state or size of target. The missile, guided by the homing head in azimuth will fly on a proportional navigational course to hit the target. The warhead is designed to explode within the target to give high lethality. Sea Skua missiles can be fired in rapid succession if required and the helicopter is free to manoeuvre after the last missile release within the limits required to maintain target illumination.



System control equipment associated with armed release of the missiles has been designed for rapid removal and replacement, thereby reducing to a minimum any weight penalty to the helicopter when it is not required to operate in the strike role. The missile can be treated as a round of ammunition as no 'on-board' testing is required. It is delivered in a wheeled 'palletrolley' fitted with a shock absorbing system suitable for shipborne magazine stowage.

CHARACTERISTICS

Length: 2·5 m

Diameter: 28 cm (max)

Span: 72 cm (max)

Royal Navy Lynx helicopter armed with Sea Skua anti-ship missiles

Weight: 145 kg
Range: >15 km
Warhead: HE 20 kg (estimated)
STATUS
In June 1981, a multi-million pound contract for Sea Skua production for the RN was announced, and it was confirmed that initial deliveries were already being made. In May 1982 the weapon scored its first operational successes in the fighting to regain the Falkland Islands, despite not having completed the RN's formal acceptance procedure.

In addition to the RN, Sea Skua has been selected to arm naval helicopters of the Federal Republic of Germany, Brazilian, Turkish navies, and possibly Indian Navy Dornier 228 aircraft.

3630.321
SEA EAGLE AIR-TO-SURFACE MISSILE

The Sea Eagle (formerly PST) missile is described by its originators as a second generation air-launched sea-skimming anti-ship missile. It is intended as a successor to Martel and will arm Buccaneer and Sea Harrier aircraft employed by UK forces for anti-shipping operations. It may later arm RAF Tornado GR1 aircraft. A zero speed launch version for use with helicopters or as a ship-launched weapon has also been developed (**4447.221**). Active radar guidance is used and the Sea Eagle is powered by a Microturbo TRI 60 gas turbine engine which is expected to give the missile a range of about 100 km. A new multi-role radar homing head has been developed by Marconi Defence Systems Ltd, specially for use against ship targets and incorporating a digital computer that provides for over-the-horizon capability against multiple targets. In addition, this fully active seeker's computer serves as the central processor for controlling pre-launch information, management of the transmit and receive functions, target detection, acquisition and tracking. This enables the Sea Eagle to engage a single designated target within a convoy of other, but potentially less valuable, targets. Certain ECCM functions are also under the control of the missile computer.

Flight trajectories of the Sea Eagle will also be under computer control, the computer's re-programming facility being of value in this regard, and possible flight paths will include a variety of sea-skimming modes of cruise, acquisition, and terminal guidance modes. A digital inertial autopilot/navigation system is employed, with a radar altimeter for height data. Sperry Gyroscope is under contract for the gyroscopic attitude sensor for Sea Eagle and this consists of a twin gyro unit that provides roll, pitch and azimuth information to the missile control computer. The radar altimeter was developed by the Royal Signals and Radar Establishment and Plessey, and will be produced by the latter. The Ferranti F100-L microprocessor is used in the Sea Eagle to carry out the digital data processing and control functions mentioned above.

The turbine used to power the Sea Eagle is the French Microturbo TRI 60 turbojet which has a thrust of 3 kN at 28 500 rpm. The Sea Eagle airframe is probably very similar to that of the Martel (**1022.311**), but Sea Eagle incorporates an advanced warhead developed by the Royal Ordnance Factories. The zero speed launch and ship-launched versions employ a slightly modified Sea Eagle missile with two strap-on booster rockets.

Sea Harrier with two Sea Eagle anti-ship missiles leaves ski-jump ramp at RNAS Yeovilton during trials

CHARACTERISTICS
Length: 4·1 m
Wingspan: 120 cm
Diameter: 40 cm
Speed: High subsonic
Range: Up to 100 km (provisional)
Guidance: Inertial navigation plus active radar homing
Propulsion: Microturbo TRI 60 turbojet
STATUS
Development was started in 1979. Flight tests began in 1981, and the first control and propulsion test firing was completed successfully in April 1981. Planned for use with Tornado, Buccaneer, and Sea Harrier aircraft, it may also be deployed with the Tornado GR1. The go-ahead for full production was announced on 10 February 1982.

A salvo firing of two missiles from a Buccaneer took place successfully in October 1982 at a range of more than 50 km. In July 1983 an Indian Navy contract estimated at about £200 million was announced for the supply of 12 Mk 42B Sea King helicopters (with an option on eight more) which will have Sea Eagle missiles as their armament.

Deliveries of evaluation missiles for trials by No 31 Joint Service Trials Unit from Buccaneer and Sea Harriers began in early 1984. First production models left the assembly line in November 1984.

UNITED STATES OF AMERICA

1766.311
ALCM (AGM-86) AIR-LAUNCHED CRUISE MISSILE

The ALCM is the result of an initiative by the US Air Force to provide an air-launched strategic weapon for deployment on the B-52 bomber, and possibly other types.

Current development is concentrated upon the AGM-86B ALCM. This is larger than the original AGM-86A which was designed to be compatible with the SRAM (**1107.311**) rotary launcher. Dimensions were increased and a larger fuel tank was fitted to produce the AGM-86B, and in addition the wing sweep angle was changed from 35 to 25°. For internal stowage, all flying and control surfaces are folded or retracted, being deployed automatically after release from the aircraft. Dimensions in flying configuration are: length 6·3 metres, span 3·65 metres, and weight about 1270 kg. The engine is Williams International Corporation F107-WR-101 turbofan developing about 600 lb (272 kg) of thrust for a weight of 66 kg. Operating speed is high subsonic. An internal rotary launch rack enables eight long-range ALCMs to be launched in rapid succession. The design is intended for high-speed cruise flight at very low altitudes for distances of up to 2500 km, and to aid penetration of opposing defences a very low radar cross section has been achieved.

A W-80-1 nuclear warhead of the type carried by the follow-on SRAM B (**1107.311**) short range attack missile is used. The missile has an inertial navigation system which is updated by using a map-matching position updating technique called TERCOM (Terrain Contour Matching). A terrain-following system is also incorporated which allows low-level flight. The complete navigation package is integrated by the Boeing Aerospace Company into the ACLM. Boeing also provides the complete software for the system. The navigation hardware consists of a gimballed inertial platform and digital computer, both provided by Litton Industries, a radar altimeter, provided by Honeywell or Kollsman, a pitot/static probe, air data computer and temperature probe provided by Rosemount.

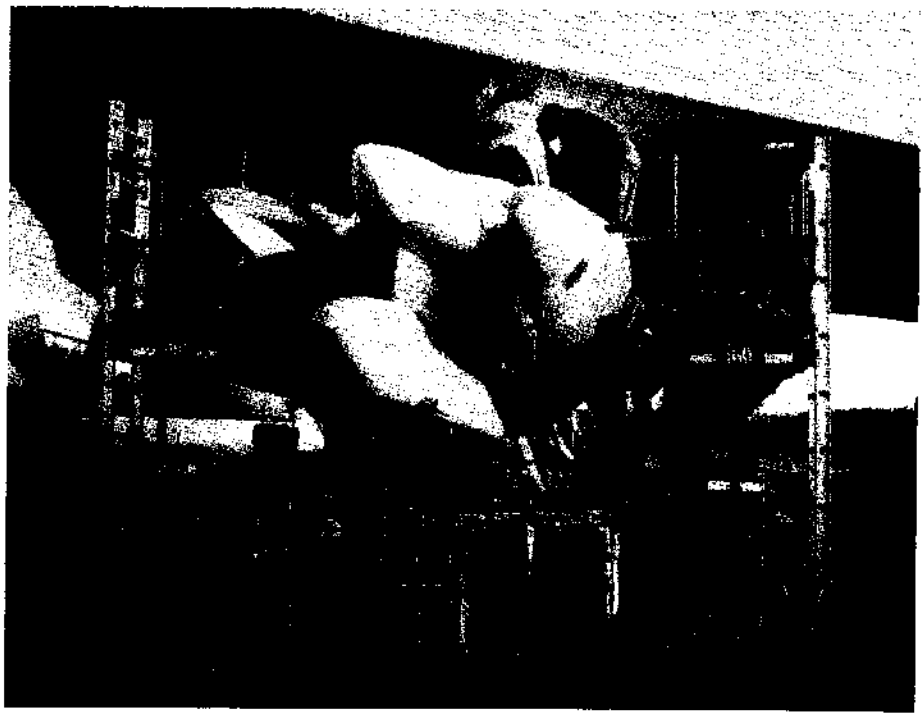
The terrain correlation updates are provided by software which processes the outputs of the air data system, radar altimeter, and the inertial platform and compares the resultant sampled terrain elevation data to a stored terrain elevation map. The correlation of the elevation profile data with the reference map provides the missile with an axis position update. The terrain correlation updates provide a very accurate position update to the missile. The inertial navigation accuracy is further improved by processing the position update through a Kalman filter in the software which refines the platform alignment, its velocity, and its instrument error sources. The initial alignment of the platform is done by an in-air Kalman filter transfer alignment to the B-52 OAS (Offensive Avionics System).

The ALCM terrain-following system is a hybrid analogue/digital system. It uses a rate gyro and body accelerometer package supplied by Northrop and a Boeing-supplied electronics package. The principal input to the terrain-following system is the radar altimeter but the air data system and inertial system also provide inputs.

STATUS
The first powered ALCM flight was made from a B-52 G release over the White Sands Missile Range in March 1976. In March 1980 the Boeing ALCM was selected for deployment with the US Air Force.

The first squadron became operational in December 1982, each aircraft carrying 12 ALCMs. By early 1985 five operational squadrons had been

equipped with cruise missiles. Between January 1984 and that time the ALCM completed 12 test flights, with 11 successes and one failure due to a missile generator.



Following an assessment of the Air Force requirements for a successor to the ALCM in 1982, and an industry contest, General Dynamics was selected to develop an advanced cruise missile (ACM) in 1983.

The fiscal year 1985 Report by the US Secretary of Defence stated that development of the ACM would incorporate the so-called 'stealth' technology to defeat enemy radar and other sensors, and would have a longer stand-off range than the ALCM.

Funding for 240 ALCMs had been budgeted by fiscal year 1984.

CONTRACTOR

Boeing Aerospace Company, PO Box 3999, Seattle, Washington 98124, USA.

1107.311
SRAM (AGM-69A) SHORT RANGE ATTACK MISSILE

The Short Range Attack Missile (SRAM) is a supersonic air-to-surface nuclear weapon carried by B-52 G/H and FB-111A bombers of the US Air Force. The former type of aircraft can carry up to 20 missiles, 12 on wing pylons and eight internally, and the FB-111A is able to load two missiles under each wing with two more in the weapons bay.

SRAM is designed to attack and neutralise enemy terminal defences, particularly the Soviet surface-to-air missile (SAM) defences. The weapon is capable of penetrating terminal defences and striking mission targets while the bombers stand off outside the range of enemy defences. It can also attack enemy SAM and anti-aircraft sites so that bombers can strike primary targets with other SRAM or conventional bombs.

The missile is 425 cm in length, 45 cm in diameter and weighs approximately 1000 kg. Range varies between 60 and 160 km, depending upon the flight profile employed, and a speed in excess of Mach 3 has been quoted.

The W-69 nuclear warhead carried is stated to be of the same size as that of the Minuteman 3 but later models are believed to be armed with W-80 warheads.

A KT-76 inertial guidance system is used, and the propulsion system is a two-stage solid rocket motor developed by Lockheed. The first stage provides initial acceleration; the second stage is activated as the missile approaches its target. Trajectory can be changed in mid-flight, and the missile can be launched to hit targets in any direction regardless of the bomber's flight path. The missile can be launched from either a high or low attack mode. The high mode is said to yield the greatest range but also increases the missile's vulnerability to enemy defences.

Four basic modes of flight trajectory can be employed: semi-ballistic, altimeter-controlled terrain following, pull-up from behind radar screening terrain followed by inertial, and a combination of inertial and terrain following. Lateral deviations in flight profile can also be programmed.

STATUS

The first production SRAM was delivered to the US Air Force in March 1972. The 750th production missile was delivered in February 1974, and a total of 1500 SRAMs have been deployed with Strategic Air Command units. The last missile was produced in 1975 and the eventual cost per missile (exclusive of warhead and other Government furnished items) amounted to $605 000 each. Formal conclusion of the SRAM production programme took place in June 1984, 20 years after it started.

The fiscal year 1986 USAF report to Congress stated that a successor to arm the B-1B and Advanced Technology Bomber will begin full scale development for initial operational capability in fiscal year 1992. Formerly known as the Advance Air-to-Surface Missile (AASM) the new weapon is now called SRAM II.

CONTRACTORS

Main contractor: Boeing Aerospace Company, PO Box 3999, Seattle, Washington 98124, USA.

Inertial guidance sub-system (inertial platform, guidance and control electronics, guidance computer, power conditioner, rate gyros): Kearfott Division, The Singer Company, 1150 McBride Avenue, Little Falls, New Jersey 07424, USA.

Aircraft pre-launch computers, B-52, FB-111: Rockwell International Corporation, Autonetics Strategic Systems Division.

Inertial measurement unit B-52: Litton Industries, Guidance and Controls Division.

Missile computer: Delco Electronics.

Radar receivers/transmitter: Stewart-Warner, Electronics Division.

Strategic Air Command B-52 bombers can carry 20 AGM-69 SRAMs, eight internally and another 12 on the wings

1102.311
SHRIKE (AGM-45A) AIR-TO-SURFACE MISSILE

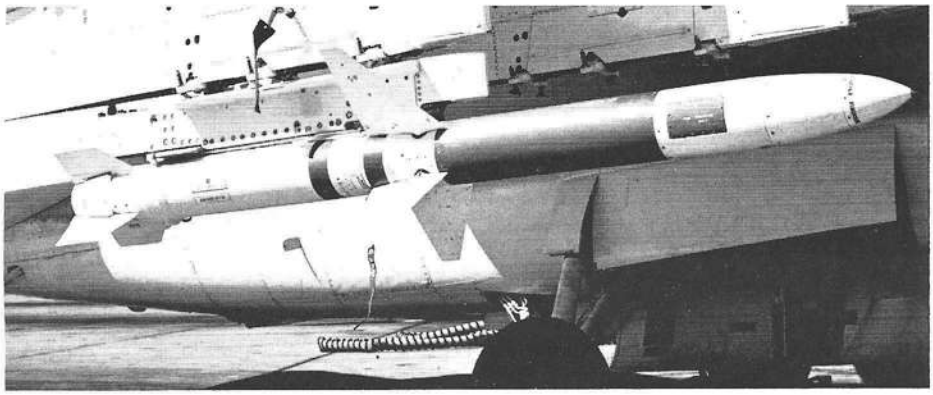
This is an anti-radiation air-to-surface missile for the destruction of ground defensive radar installations. Official details include: length 304·8 cm, diameter 20 cm, wing span 91·4 cm, weight 177 kg, solid-propellant rocket motor. Estimated speed and range are: Mach 2 and 12 to 16 km. A 66 kg high-explosive fragmentation warhead is carried.

OPERATION

Initial warning of illumination of Shrike-carrying aircraft by ground defence radars is obtained from ESM/ECM receivers installed in the aircraft. When within appropriate range, the Shrike sensor heads are switched on and the missiles fired when target acquisition has been achieved. After release, the missile radar receiver continuously senses the direction of arrival of radar radiation from the target and generates command signals for the missile guidance system to home it on to the radar.

Shrike guidance heads have been developed that are effective against enemy early warning, ground control intercept, and SAM guidance radars, each of which covers a different frequency range. The frequency range of a particular Shrike version is denoted by a suffix number to the AGM-45A designation, and there are at least 13 of these. Based

on the specific radar to be attacked, the operational commander selects the most appropriate weapon option. The US Air Force use Shrike on modified F-105 and F-4 aircraft, termed Wild Weasel aircraft, with special radar homing and warning equipment. The US Navy employs the missile on A-4, A-6 and A-7 aircraft.



STATUS

Up to fiscal year 1978 about 24 000 Shrike missiles of all models had been procured and the 1978 budget allowed for the purchase of another 600. A similar procurement was planned for fiscal year 1979.

Future anti-radar missile requirements of the US forces are likely to be met by the High-speed Anti-Radiation Missile (HARM **1769.311**). Therefore Shrike must be regarded as obsolescent but nevertheless it is probable that appreciable stocks of these missiles (with ample support facilities) still exist and would be available for operational use.

CONTRACTORS

Joint prime contractors: Texas Instruments and Sperry Rand/Univac.

Shrike AGM-45A air-to-surface anti-radar missile prepared for flight testing at China Lake, US Naval Weapons Centre (USN)

1098.311

MAVERICK (AGM-65) AIR-TO-SURFACE MISSILE SYSTEM

The AGM-65 Maverick is a precision guided tactical missile in the 225 kg class. It was developed by Hughes Aircraft Company under contract to the US Air Force for use against hard targets such as tanks, armoured vehicles, field fortifications, gun positions, concrete communication centres and aircraft shelters. The system is currently operational on the F-4, A-7, A-10, F-111, F-16, F-5 and AJ 37 aircraft.

CHARACTERISTICS

Length: 2·49 m
Diameter: 30·5 cm
Wing span: 72 cm
Weight: 210 kg (288 kg with alternative warhead)
Guidance: TV (A/B models); Laser (E model); Infra-red (D/F models)

The basic warhead is a 57 kg forward-firing shaped charge, designed for penetration through heavy armour and reinforced concrete. An alternative kinetic energy penetrator blast-fragmentation warhead has completed development and test phases. It weighs 136 kg and has a design optimised for effectiveness against major combatant ships and buried concrete fortifications. The weapon is powered by a two-stage solid fuel rocket motor and is rail launched from either single-missile or triple launcher units. Variants of the Maverick are described separately.

TV Maverick (AGM-65A/B)

This basic missile is precision guided by a miniature TV homing system in the nose section. On his TV monitor, the pilot sees the picture transmitted from the missile seeker. He slews the seeker to the target, locks the TV tracker on target, and launches the missile. The aircraft can take immediate evasive action (launch and leave) or fire successive missiles while the first missile homes automatically on to the target.

Tracker logic steers the missile for impact at the centroid of the target in order to maximise kill probability. The B model has a modified optics system with a 2·5° field of view for greater magnification of the target area and longer range identification of small targets.

More than 30 000 Mavericks have been produced, and more than 1800 launched in test, training and combat, of which 85 per cent have been direct hits. Of the total, 100 were combat firings, which yielded 87 per cent direct hits. In addition to the USA, TV Maverick has been ordered by: Egypt, Federal Republic of Germany, Greece, Iran, Israel, Morocco, Saudi Arabia, Singapore, South Korea, Sweden, Switzerland, Taiwan and Turkey.

Laser Maverick (AGM-65C/E)

Laser Maverick will provide close air support against laser-designated targets in support of ground forces. Mounted forward of missile centre and aft sections that are common to all Mavericks, the laser guidance section homes on to the energy reflected off the target by the designator.

The C model, containing the basic shaped-charge warhead, completed development flight testing with over 90 per cent direct hits on target. Targets were illuminated with various laser designators. This version did not go into production.

The production E model utilises laser guidance with the alternative 136 kg warhead in order to meet operational requirements of the US Marine Corps. Operational flight testing of that configuration was completed in the summer of 1982 with a score of 15 out of 15 direct hits.

US Air Force analysis indicates that Laser Maverick effectiveness in the close air support role is dependent on the availability of stabilised ground target designators such as the Ground Laser Designator (GLLD) or airborne laser designators, such as the A-6E TRAM, the OV-10D NOS or the US Air Force Pave Tack system. The capability of hand-held designators is adequate for use with Laser Maverick against large or static targets. This model will be integrated with A-4M Skyhawk, A-6E Intruder, AV-8B Harrier and F/A-18 Hornet aircraft.

IR Maverick (AGM-65D)

An infra-red (IR) system provides autonomous launch-and-leave guidance both day and night, and under low visibility conditions. IR Maverick retains hardware commonality with the TV and Laser Mavericks. In addition, IR Maverick's pilot operating procedures are similar, allowing the AGM-65D to be used on all aircraft types already equipped to operate TV Maverick. It can be used autonomously to locate and strike targets in the combat zone, or in the traditional night interdiction of roads and railroads; or it can be precisely slaved to other target acquisition aids such as forward looking infra-red (FLIR), radar, INS, LORAN, or radiation direction finders (anti-SAM).

Target recognition ranges with IR, day or night, are about twice the range for corresponding daylight visual recognition of typical tactical targets. The IR seeker has performance superior to TV or laser in low visibility. The long wave spectrum used penetrates battlefield smoke and dust which is opaque to visual systems. Thermal signature also provides unique advantages in detection of hidden/camouflaged targets and the determination of live from dead (cold) targets.

The missile has been successfully flight tested through US Air Force initial operational test and evaluation (IOT&E) on F-4, A-7, F-16, F-111 and A-10 aircraft. A variant of the IR seeker has also successfully completed US Air Force development test and evaluation (DT&E) on the GBU-15 glide bomb launched from an F-4.

Navy Maverick (AGM-65F)

In late 1980 Hughes received a contract for the development of anti-ship algorithms to be incorporated in the IR seeker to give the IR Maverick additional capabilities against ship targets. Designated the AGM-65F, this model combines the IR guidance unit of the US Air Force AGM-65D modified with additional tracking logic for ship targets, with the warhead and propulsion sections of the AGM-65E model. IR guidance will allow US Navy pilots to

The four current versions of the Hughes Maverick family: from front USAF AGM-65D IR Maverick, USMC laser-guided AGM-65E, USAF TV-guided AGM-65B (also exported), and the USN anti-ship AGM-65F IR Maverick

undertake attacks in darkness and poor weather, and the heavy blast penetration warhead will be used with a selectable fuze for optimum effectiveness against various types of target. Integration of the AGM-65F with A-6E and F/A-18 aircraft is scheduled.

STATUS

AGM-65D: Hughes is delivering production IR Maverick missiles against the fiscal year 1982 US Air Force procurement of 200. The 1983 fiscal year contract for a further 900 missiles has been signed, allowing for an increase in the production rate of up to 115 missiles per month. Congress has approved the fiscal year 1984 budget request for 1382 production missiles and long-lead funding for another 600.

AGM-65E: Long-lead production approval was given in November 1982 and the full go ahead in August 1983. First deliveries began in 1985, and Hughes has received fiscal years 1983 and 1984 contract awards for up to 275 missiles. The fiscal year 1985 DoD budget appropriation called for $360 million for procurement of a further 2600 missiles.

AGM-65F: The US Navy has completed a three-round DT&E flight test programme of the Navy IR Maverick, which resulted in three direct hits against ship targets. The Navy's operational test and evaluation (OPEVAL) programme began in 1985. The fiscal year 1986 US Navy budget indicates $27·8 million for 195 production missiles.

In May 1983 Raytheon was selected by the US Air Force as the second source for production of AGM-65D IR Maverick missiles, and was awarded a $49·6 million contract for evaluation and test missiles. Options for follow-on production provide for 600 more missiles. Its first production round was delivered in May 1985.

4190.311

GBU-15 MODULAR GLIDE BOMB

In the latter half of 1972 the US Air Force, with industry, instituted studies of possible ways of further enhancing the smart bomb concept by the provision of blind attack facilities and extending the effective range to permit stand-off operations by ground attack aircraft engaging high value fixed land targets.

The US Air Force refers to these later developments of electro-optical (EO) weapons as the Modular Glide Weapon System, which has now been designated GBU-15(V), a variable designator which is used for a family of weapons modules. These can be configured in various combinations to provide for various attack and target conditions. The basic module set comprises those items needed to convert standard munitions, such as the Mk 84 bomb, to EO smart bombs of the sort which were extensively used in SE Asia.

The full list of major components comprises:

(1) two warhead options: Mk 84 iron bomb, SUU-54 dispenser
(2) wing and tail surface packages: cruciform wing module
(3) two guidance modules: EO: imaging infra-red (IIR)
(4) two adaptors to join the warhead to the guidance package
(5) a control module
(6) a data link module.

The two terminal guidance modules are interchangeable so that a weapon can be provided for specific conditions: day, night, high- or low-visibility attack. The EO seeker, DSU-27A/B which is an improved version of the TV seeker used in SE Asia, is used for day light attacks. The pilot can use a direct attack mode if he can see the target prior to launching the weapon. By adding the data link module, an indirect attack is possible. In this case, the seeker TV data are transmitted back to the aircraft after launch, while command signals are sent to the weapon in the opposite direction over the data link, so that the weapon can be flown by the air crew on to the target.

The IIR terminal guidance module, WGU-10/B, which is the same as that being developed for Maverick, will provide a night attack capability.

Both warhead modules weigh 2000 lb (907 kg), the Mk 84 being intended for targets such as railways, buildings, and bridges, while the SUU-54 dispenser is intended for use against area targets such as surface-to-air missile sites. The SJU-54 disperses 1800 grapefruit-sized bomblets; initial deliveries of production models of the munition began in January 1976 and tests were carried out later that year with the CBU-75 which consists of the SUU-54 dispenser filled with BLU-63 and/or BLU-86 bomblets.

CHARACTERISTICS

Type: GBU-15(V)/B
Length: 3·91 m
Diameter: 45 cm

Two GBU-15 CWW carried beneath the wings of US Air Force F-111 aircraft

Wingspan: 1·49 m
Weight: 1111 kg

The AN/AXQ-14 data link developed for the GBU-15(V) is designed for D-band operation.

The cruciform wing was developed to improve the small wing configuration used in SE Asia. This design gives the weapon increased manoeuvrability at low altitudes and, used with the data link module, permits attacks from stand-off ranges.

The first GBU-15(V) weapon configuration to complete development is the Cruciform Wing Weapon (CWW) that combines the EO Mk 84 and cruciform wing modules. As already stated, there is the option of exchanging the Mk 84 warhead for the SUU-54 dispenser munition, in which case the FMU-123/B fuze is used.

The data link allows TV signals to be transmitted from the weapon to the aircraft so that the aircrew can command the weapon while leaving the launch area and flying directly away from hostile territory. The weapon has demonstrated a low-level, blind launch capability with target acquisition and target lock-on accomplished after weapon release.

Modification kits have been produced by Rockwell International's Missile Systems Division for two standard US bombs: the 2000 lb (900 kg) Mk 84 and the 3000 lb (1360 kg) M118E1. Kit designations are KMU-353A/B, KMU-390-/B, and KMU-359/B, the first two being TV and the last IR. The KMU-353 A/B has since been redesignated GBU-8. Each kit consists of a guidance section for mounting on the nose of the bomb; a tail assembly with four stabilising vanes having control surfaces on their rear edges, and containing batteries and a set of strakes and metal straps which serve to attach and locate the guidance and control packages on the body of the bomb.

Aircraft types equipped to carry GBU-15 are the F-4E (two plus data link pod, Pave Tack, and Loran), B-52D (three plus pod), and F-111F (four plus pod and Pave Tack). Integration of the GBU-15 with the F-15 and F-16 aircraft has been started and Rockwell's Missile Systems Division is under contract to integrate the weapon with Royal Australian Air Force F-111Cs. Extending use of the GBU-15 to other aircraft types in continuing and fitting arrangements have been checked on the Viggen, Tornado and F-18.

AGM-130

A powered version of the GBU-15, designated AGM-130, is under development which is expected to provide up to three times the range of the un-powered glide-bomb. The number and type of booster(s) is not decided at this stage but possible sources that have been mentioned include Aerojet General and Atlantic Research. Payload/warhead options also are as yet open, among the new possibilities being the BLU-106 boosted kinetic energy penetrator (BKEP) which was intended for use with the now-cancelled MRASM (**4191.311** in 1982-83 and 1983-84 editions). Approval for full-scale development of the AGM-130 was granted in late 1984, when it was stated that the weapon would weigh about 800 kg and carry Avco BLU-106 runway cratering submunitions.

STATUS

Rockwell delivered the first GBU-15 production units to the US Air Force in January 1982 and production deliveries of the AN/AXQ-14 data link followed shortly after. Under a $38·7 million US Air Force contract awarded on 21 December 1982 Rockwell is producing 250 cruciform wing GBU-15 guided bombs.

In May 1984 Hughes was awarded a $21 million contract for immediate and follow-on production of additional AN/AXQ-14 data links, this order bringing the total to over 1500 units.

The fiscal year 1986 DoD procurement budget indicated purchase of 97 AGM-130 bombs in 1986 at a cost of $48·5 million, and 100 for $51·3 million the following year. The figures for the GBU-15 for the fiscal years 1984-87 (quantities in brackets, funding in $ millions) are as follows: 1984 - (345) $60·2, 1985 - (535) $127·3, 1986 - (715) $127·9, 1987 - (650) $115·5.

Rockwell International, Missile Systems Division, Defence Electronics Operations, 1800 Satellite Boulevard, Duluth, Georgia 30136, USA.

1534.311

PAVEWAY LASER-GUIDED BOMBS

The family of laser-guided bombs (LGBs) uses a common laser guidance and control sub-assembly, with only the aerodynamic surfaces (control fins and aerofoil group) changed to match the particular size warhead. The system allows for stand-off capability while providing precision weapon delivery against a wide spectrum of targets.

The original LGB conversion kits have become known as Paveway I, following the introduction of a new set of components in 1978, the latter being known as Paveway II. One notable feature of the later system is the substitution of extending tail fins for the original fixed fins of Paveway I conversions. This and other differences are shown in the accompanying diagrams and tables.

OPERATION

The guided-bomb kit directs the weapon toward a target which has been illuminated by laser energy. The desired target can be selected by the bombing aircraft, a companion aircraft, or a ground observer. The laser energy is reflected from the target and detected by the laser guidance system. The system processes the information, computes appropriate control commands, and applies these commands to movable surfaces to effect changes in trajectory, thereby guiding the weapon to the target.

The system requires no electrical connection to the unmodified delivery aircraft and is delivered in the same manner as a conventional bomb. There is no requirement for tracking or lock-on before launch, which minimises the time required for delivery with

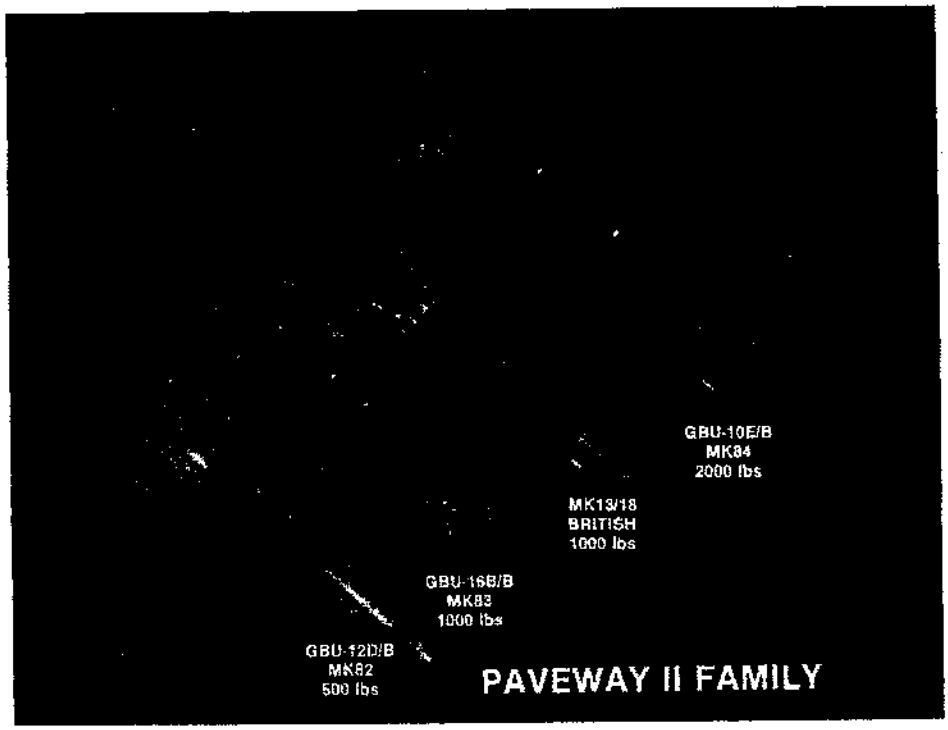
concomitant reduction in aircraft exposure to hostile ground fire.

DEVELOPMENT

The US Air Force Armament Development and Test Centre (ADTC), Eglin AFB, initiated a competitive evaluation of two laser guidance concepts for standard bombs in 1965; the first LGB flight occured in April 1965. This evaluation proved the feasibility of the concept and was followed by establishment of the Paveway programme office at Wright-Patterson AFB. Texas Instruments was selected to conduct engineering development to supply additional laser guidance kits for M117 GP bombs.

Utilising the laser guidance kit developed by Texas Instruments, two additional GP bombs (Mk 82 and Mk 84) and the M118 demolition bomb were later successfully adapted to laser guidance and operationally deployed. Evaluations were initiated in 1971 for application of the kit to the Pave Storm cluster munition and, during 1971, both cluster weapons were successfully tested, utilising laser guidance.

The Paveway II version was developed in the mid-1970s and production began in 1977. Similar to Paveway I in appearance and operational concepts, Paveway II has more advanced electronics and a folding wing aerofoil group which improved sensitivity and manoeuvrability. Paveway II also incorporates many cost-reduction features such as plastic lenses instead of glass, a moulded-plastic ringtail instead of metal, and intergrated circuitry to improve reliability and reduce manufacturing time. The folding wings also permit increased load density on the delivery aircraft.



The development of the third generation of LGBs began in 1980-81. Known as the low-level laser-guided bomb (LLLGB) or Paveway III, this weapon is designed to be delivered from very low altitudes and significant stand-off ranges. The LLLGB incorporates state-of-the-art microprocessor technology, high-lift folding wings, and an improved scanning seeker. After a successful development flight test programme, the system has undergone initial operational test and evaluation (IOT&E) and production approval was granted in mid-1983. Despite these promising results, Paveway III was cancelled in February 1985, ostensibly on the grounds of cost increases. It was reported that there are US Air Force plans to embody Paveway III know how in a improved 2000 lb bomb to be known as the Targetbuster.

STATUS

The US Air Force and US Navy utilise the GBU-10E/B (Mk 84), GBU-16B/B (Mk 83), and GBU-12D/B (Mk 82) versions of Paveway II LGBs. These weapons are compatible with the F-4, F-111, F-5, A-6, A-37, A-7, A-4, A-10, F-16, AV-8A (Harrier) and B-52 aircraft. The F-14, F-15, F-18, Mirage Tornado, Buccaneer, and Jaguar aircraft types have also been added to this list.

The LGB has been introduced into the RAF inventory and also other NATO countries. The RAF system for the Mk-13/18 1000lb warhead was developed jointly by the Royal Aircraft Establishment, Texas Instruments and Portsmouth Aviation Ltd.

In addition to US and UK operators of Paveway LGBs, Australia, Greece, the Netherlands, Saudi Arabia, South Korea, Spain, Taiwan and Thailand are reported to have been supplied.

WAAM PROGRAMME

The Wide Area Anti-armour Munitions programme (WAAM) has evolved somewhat since its initiation in the late 1970s as a result of changes in emphasis of the overall US Army/US Air force efforts in the area of tactical/theatre anti-armour and changing circumstances over the intervening years. The background to these events has been summarised under this entry number and related entries in previous editions, including the varying relationships with other complementary programmes which are connected with the main purpose of this system. The following paragraphs represent the latest known position on the current WAAM programme.

In the fiscal year 1986 USAF statement on the budget estimates it was stated that development of the sensor fuzed weapon is being continued and will provide a significant increase in effectiveness against enemy armour. The sensor fuzed weapon employs Avco Skeet IR fuzed submunitions packaged in a tactical munitions dispenser.

This concept has its origin in the Avco system previously known as ERAM (Extended Range Anti-armour Munition) in which submunitions are delivered by parachute from dispensers released by tactical aircraft flying close support or interdiction missions. Dispersed along an enemy line of advance, or directly over an enemy concentration, the ERAMs engage and destroy armoured and mechanised units. The ERAM is designed to fit into the USAF SUU-65/B dispenser which can be carried on a variety of US strike and attack aircraft, and this combination of dispenser and submunitions has been designated the CBU-92/B by the USAF.

It is capable of delivery over a wide range of altitudes and airspeeds, and once released, the dispenser splits open low over the target and ejects its ERAM submunitions. Each of the latter then deploys a parachute designed to disperse it randomly over a wide area.

DAACM

Also due to begin full scale development in 1986 is the Direct Airfield Attack Combined Munition (DAACM) which is basically a combination of Avco's BLU-106/B boosted kinetic energy penetrator (BKEP) submunition, mines such as Skeet and ERAM, and a tactical munitions dispenser, designed for use against enemy airfields. The intention is to crater runways and penetrate aircraft protective shelters.

BKEP uses a rocket motor to accelerate its warhead to the velocity necessary to penetrate the runway surface, after which it explodes causing maximum damage to the paved surface. Though originally

designed for compatibility with the now cancelled MRASM weapon. BKEP is suitable for use with the Tactical Munition Dispenser (TMD) and the GBU-15/SUU-64 (AGM 130) (**4190.311**) delivery systems. The TMD has been designated as the DAACM carrier by the USAF and this contains eight BKLP submunitions plus a quantity of mines.

Submunition ground impact patterns are controlled by varying the parachute opening times of individual submunitions. On ejection from the dispenser, fins deploy to stabilise the submunition and parachute deployment retards forward motion. The rocket motor ignites at a programmed time causing the parachute to be jettisoned and the warhead to be accelerated to impact. A time fuze detects impact and sets off warhead detonation below the runway surface for optimum heave and cratering effects.

STATUS

The WAAM programme was started in 1975 and work is concentrated at Eglin AFB, at the Armament Development Test Centre there.

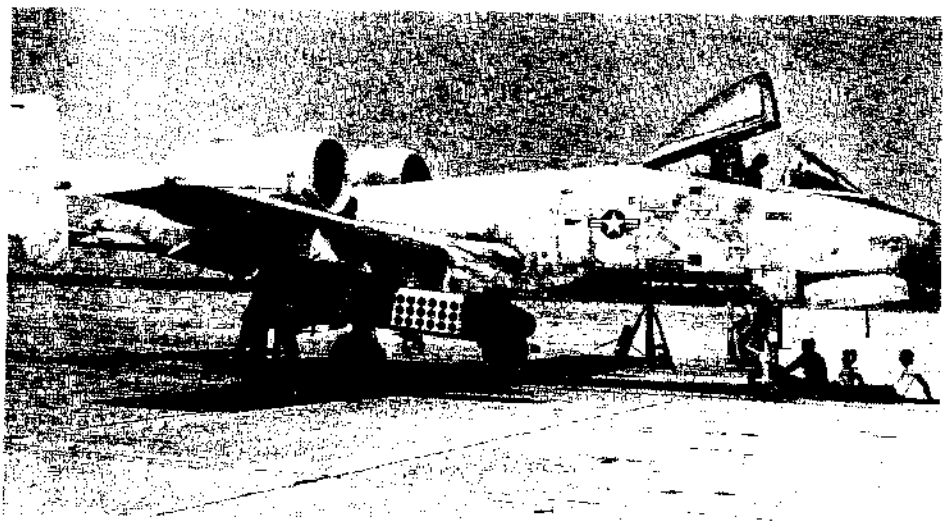
Actual or planned development funding for the WAAM programme in fiscal years 1983-1986, in millions, is as follows (year in brackets): $13·7 (83), $23·5 (84), $27·3 (85) and $12·6 (86).

4530.311
LAD LOW ALTITUDE DISPENSER

The low-altitude dispenser (LAD) system is under development by Brunswick Corporation in collaboration with the US Air Force to perfect a means of enabling low-flying tactical and other aircraft to deliver a variety of submunitions at stand-off ranges against targets such as airfields, armoured formations, vehicle concentration etc. The concept has much in common with a number of previous projects, such as the West German Stand-Off Weapon (SOW) (**4050.311** in 1981-82 and earlier editions) and Container Weapon System (CWS) (**4449.311**), British AST 1227 (**3900.311** in 1982-83 and 1983-84 editions) and JP233 airfield attack weapon (**5218.311**).

LAD is designed as an aircraft store in the 1000 to 1400 kg class for carriage on standard NATO weapon lugs, and the configuration is simply that of a rectangular-section container housing the submunitions and equipped with aerodynamic surfaces for controlling its flight path after release from the aircraft. Provision is made for the addition of a 180 kg st class propulsion motor if required which typically increases the stand-off range from between 9 and 19 km to up to 24 km. Aided by an on-board microprocessor, the latter facility enables the LAD to manoeuvre after release and fly back to engage a ground target previously over-flown by the attacking aircraft. It also permits offset target attacks and is valuable for engaging targets of opportunity.

Various methods of target designation can be employed with LAD, ranging from location co-ordinates inserted into the launch aircraft's navigation/attack system from external sources such as Precision Location Strike System (PLSS) or Pave Mover etc, or targets located by on-board targeting aids, or a pilot's helmet mounted sight. Guidance of the LAD after release may be either programmed or inertial and the former can also include climb and descent manoeuvres appropriate to the nature of the target(s) and attack.



Programming of the submunition ejection timing, LAD attitude and altitude, permits considerable adjustment of the ground pattern, with further variations being possible by means of adjustments to the lateral ejection velocities and sequencing of ejection events and use of variable retarder devices on individual submunitions. The dispensing method depends on submunition characteristics, and the more sophisticated sensor-fuzed devices can be precisely delivered with tube or air-bag dispensers. Submunitions without pattern forming devices could require a secondary dispersal system. It is understood that by 1982 at least six submunitions had been test flown and 15 types investigated, all of which were suitable for use in the LAD vehicle. Among the submunitions tested were bomblets used in the West German MBB tube-dispenser system.

STATUS

A-10 aircraft with Brunswick LAD weapon on wing station during technology demonstration flight series

4448.311
HVM SYSTEM

Under a US Air Force contract awarded in late 1981 Vought Corporation is engaged on the design and development of a guided air to ground hypervelocity missile (HVM) with the objective of demonstrating a capability of defeating all types of vehicle in an advanced armoured assault force, using small, low cost missiles which rely on kinetic energy derived from their speed for penetration. Both air- and surface-launched versions of the HVM are expected to be produced eventually, and the land-mobile

Guided test flight of hypervelocity missile (HVM)

version is already known as the Bushwhacker weapon system.

Preliminary studies of the airborne system indicate a pod-housed weapon, this containing launching tubes for up to 40 HVMs and a laser radar guidance system. The last of these items would employ a carbon-dioxide laser to provide 3-D ranging and doppler information, and would perform the functions of multiple target detection, classification, identification and prioritisation in under one second. The rockets will be equipped with a track-while-guidance system, and the laser will provide a coarse beam for rocket capture, and a fine beam for terminal guidance. The use of laser guidance is intended to make the system almost impervious to enemy countermeasures.

The rocket missiles weigh less than 22 kg and are expected to cost less than $5000 per round. They will have no moving parts and will be stabilised in flight by spin imparted by the launch tube, aided by a gyro roll sensor and a series of 'squib' rocket motors that will be used for attitude control. The rockets will reach a speed of more than 1500 m/s and will carry an inert warhead of high density, possibly a depleted uranium rod weighing 2·2 to 2·7 kg able to penetrate most modern armour plate. Estimated maximum range is about 6000 metres.

Multiple target engagement is an important capability and it is hoped to be able to demonstrate firing of several missiles delivered simultaneously against separate stationary and moving targets. Ground-launch tests in 1982 successfully demonstrated the missile's ability to receive laser guidance signals through the rocket motor plume, and an ability to operate at speeds of more than 1500 m/s in an air-launched role.

In March 1983 an HVM made a successful guided test flight using the laser guidance system after a ground launch at the White Sands Missile Range, New Mexico.

STATUS

Development. Vought was awarded an $11·2 million contract by the Armament Laboratory of the US Air Force Systems Command in September 1981. Major sub-contractors include Hercules Inc for the propellant and polyamide rocket motor case.

HARPOON (AGM-84A) AIR-TO-SURFACE ANTI-SHIP MISSILE

Harpoon is an all-weather anti-ship missile for use against surfaced submarines, patrol craft, destroyers and larger vessels, merchant ships and trawlers.

The missile is capable of being air-launched or, with the addition of a rocket booster, ship or submarine-launched. These latter versions will supplement existing missile systems and will also become operational on those ships which do not currently have a missile capability. Further details of Harpoon in these versions will be found in **2641.221** and **2797.421** in 1976 and earlier editions.

Approximate dimensions are: length 384 cm, body diameter 34 cm, span 91 cm, and weight 522 kg. Ship and submarine-launched versions have an additional booster motor, with four fins, attached to the rear of the missile. Mid-course guidance is performed by a system utilising a digital processor, and a strap-down sensor/guidance sub-system. This system uses computer techniques to process the data from the strap-down gyros to sense missile velocity in three axes and derive control signals from this information.

The missile employs an active radar terminal guidance seeker.

STATUS

In October 1972 the first powered flight was conducted at the US Naval Missile Centre at Point Mugu, California. Entry into service began in 1977. It is planned to deploy this missile on S-3 maritime patrol aircraft in addition to the P-3 and A-6 aircraft, and compatibility tests with US Air Force B-52G heavy bombers were initiated.

It was announced in April 1983 that three anti-ship Harpoon missiles had been launched successfully from US Air Force B-52 bombers against a surface target in the Pacific. Two B-52 squadrons are being equipped to deploy Harpoons. Each aircraft can carry 12 Harpoon missiles on external wing mountings.

Royal Air Force Nimrod maritime aircraft having carried Harpoon missiles as an emergency measure during the Falklands conflict, are to retain the Harpoon capability and additional missiles valued at $248 million have been ordered.

Funded and projected procurement of Harpoon by the US Navy in the fiscal year 1986 budget indicated the following quantities (numbers in brackets, funding in millions): 1984 - (315) $275, 1985 - (354) $283·6, 1986 - (395) $314·9, 1987 - (153) $184·9.

McDonnell Douglas Astronautics Company, PO Box 516, St Louis, Missouri 63166, USA.

1769.311

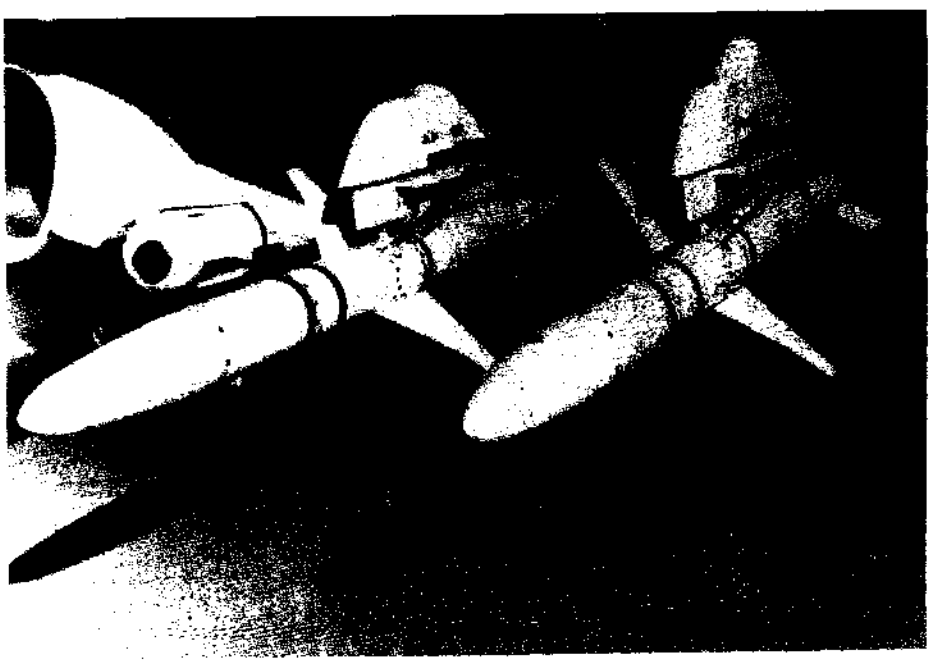
HARM (AGM-88A) HIGH-SPEED ANTI-RADIATION MISSILE

The high-speed anti-radiation missile (HARM) is entering service as a replacement for the existing Shrike (**1102.311**) and Standard ARM (**1123.311**). It is between these two missiles in terms of overall size but has a number of operational advantages, including higher speed, faster reaction, longer range and a more destructive warhead. In addition, unlike the Shrike which is configured individually to specific frequency bands, HARM has a broad-band capability, thus enabling a single missile to engage any anticipated air defence-associated surface radar (ship- or land-based). HARM also has software-controlled processing which enables new threats to be addressed by reprogramming instead of hardware modifications as enemy weapons develop. This will enable HARM to be used for the suppression or destruction of emitters other than those associated with surface-to-air systems, including early warning radars, ATC radars and weather radars whose elimination might offer tactical dividends.

The missile seeker, control section, wings and fins are produced by Texas Instruments, and the warhead, rocket motor and fuzing are being produced by other contractors. Technical direction is by the US Naval Weapons Centre, China Lake. The single seeker head employs a fixed antenna, thereby eliminating the complication and cost of gimbals and steering controls, and all pneumatic and hydraulic systems have been eliminated. It comprises the antenna array, ten microwave circuit boards and a video processor. This assembly provides direction finding facilities without requiring a moving antenna array, the latter consisting of a planar spiral-helix associated with other elements housed within a radome which itself forms an integral part of the overall RF antenna sub-system.

A 66 kg prefragmented HE warhead is carried which is triggered by a laser fuze that senses missile height above the terrain and detonates the warhead at one of two settings, depending on whether an overshoot or an undershoot is sensed. These two values are established so that maximum effect of the known dispersion pattern of the warhead fragments is utilised. It is likely that in future there will be more than two settings, which may be inserted automatically prior to launch in accordance with the target detected and engaged. Tests of fragment dispersion and damage characteristics for various typical threat radars will be established by further tests.

The other major part of the HARM weapon system consists of the aircraft avionics and controls; the US Navy will use the AN/AWG-25 equipment installed in the A-7 aircraft, and the US Air Force will utilise the avionics and displays of the Wild Weasel system to interface with HARM.



The command launch computer interfaces with the existing radar warning system and other aircraft avionics, while the cockpit control panel entails simple modifications to the existing panel to adapt it for operation of the anti-radiation missile function. The computer has efficient memory capacity to include all land- and sea-based emitters that US Navy task forces are expected to encounter. The US Air Force has a similar capability in the Wild Weasel system.

OPERATION

Three basic modes of operation for the HARM system are to be provided for the tactical air crew:

(1) *self-protect mode:* this is the most fundamental mode, and uses the aircraft radar warning receiver to detect threatening emitters. The HARM launch control computer then sorts and assigns priorities to these emissions and provides in digital language a complete set of instructions for the missile. This is achieved in a very short space of time and the pilot can fire the HARM almost immediately

(2) *target of opportunity mode:* in this mode the very high sensitivity of the missile seeker head to detect certain parameters of radar operation and also those transmissions associated with other parts of a radar installation, is utilised. It permits

AGM-88A HARM is certified for flight on A-7E, F-4G Wild Weasel Phantom and F/A-18 aircraft, and has been evaluated for use on A-6E, F-16 and Tornado

the engagement of targets by homing onto emissions that could not be detected and handled by Shrike or Standard ARMs

(3) *pre briefed mode*: this employs the long range of HARM to engage targets whose signals can be detected but are not adequate for missile lock-on, or it may be used to fire HARM on a pre-computed trajectory into the vicinity of known targets. If these targets emit while HARM is in flight, they are attacked immediately; if the target does not radiate, the HARM destroys itself

CHARACTERISTICS

Length: 4·16 m
Diameter: 25 cm
Wing span: 1·13 m
Max launch weight: 360 kg
Guidance: Anti-radiation, radar seeking, broad-band
Warhead: 66 kg prefragmented HE
Fuze: Laser proximity
Range: 20 km+ (provisional)

DEVELOPMENT

First contracts in support of HARM research and development were awarded during 1972. Among them were the following: Texas Instruments, guidance and avionics; Hughes Aircraft, systems analysis and guidance support; Itek, AN/ALR-45 radar warning receiver modifications; Lockheed, system studies; Dalmo Victor, modification of DSA-20N signal analyser; Stanford Research Institute, analysis.

In the latter part of 1974 Texas Instruments was selected as the weapon system integration contractor for HARM. If procurement is decided upon the primary US Navy vehicles to carry HARM will be the A-7E, A-18 and A-6E aircraft, and in the case of the US Air Force, the F-4G, AFB-38 fitted Wild Weasel I aircraft.

STATUS

The first production HARM was delivered to the US Navy on December 2, 1983 and another six a few days later. The remainder of this order for 80 missiles was delivered over the period ending October 1983. From the following month, Texas Instruments began delivery of 236 more missiles at a rate of 25 per month.

Planned procurement shows in the fiscal year 1985 DoD budget allocates roughly equal quantities for the US Navy and US Air Force, with the actual/projected procurement for the fiscal years 1984/85/86/87 making combined totals of 698 ($379·2 million), 1559 ($589·5 million), 2619 ($752 million) and 3706 ($930·8 million), respectively.

Operational deployment was due to commence in 1984-85.

CONTRACTOR

System integration contractor: Texas Instruments Incorporated, PO Box 405, Lewisville, Texas 75067, USA.

2831.311

TOW AIR-TO-SURFACE APPLICATION

As noted in the main description of the TOW anti-tank weapon system (**2830.111**), this weapon, like several other anti-tank weapons, can be used as armament for fighting helicopters.

Both the gunner's sight and the optical sensor are mounted on a specially developed gyrostabilised platform, which gives the tracking and control system a constant reference surface. The sight is pointed at the target by means of a joystick.

The two main current developments in airborne applications of the TOW system are installation in the 530MG Defender attack helicopter, and the C-NITE programme for US Army Cobra helicopters. The Defender is being equipped with two electro-optical systems that enable aircrews to fly low-level night missions over rough terrain and to fire TOW anti-tank missiles from behind protective cover. These are the Hughes night vision system (HNVS) and the mast-mounted sight version of the airborne TOW missile system. This is the first helicopter to be equipped with both systems.

The HNVS is being produced as a low-cost, microprocessor-controlled forward-looking infra-red (FLIR) system that can be used for a variety of missions. It is designed to reduce a pilot's work load on night missions, including low-level and nap-of-the-earth flights. It can be used as a navigation aid, for target recognition and for search and rescue.

As the pilot skims over trees and through valleys, a FLIR image is projected on his helmet visor to reveal the world outside his cockpit. He can glance in any direction and his head movements are instantly transmitted through a helmet servo linkage to a FLIR turret mounted under the nose of the helicopter. The turret is automatically aimed along his line-of-sight (LOS). The image contrast and brightness are automatically kept at the ideal viewing level, and the pilot can call for flight symbology to be superimposed, further reducing his need to look down at cockpit displays as he flies.

The mast-mounted sight version of the airborne TOW system enables the helicopter aircrew to use hills and trees for cover while scouting for targets. Once a target is spotted, the gunner can fire a TOW missile, exposing only the sight to enemy detection during the entire operation. The missile climbs into the gunner's LOS following launch, while the helicopter remains hidden.

The mast-mounted sight is an adaptation of a roof-mounted sight Hughes Aircraft developed for the British Army Lynx helicopter. The roof-mounted sight is being produced in the United Kingdom by British Aerospace Dynamics Group under licence from Hughes Aircraft.

The sight is stabilised to compensate for aircraft movement and the vibration of the rotor blades. The design allows for future installation of a laser rangefinder, an automatic target tracker, multi-launch logic, and a FLIR system.

The initial airborne TOW system built in 1975 is the anti-tank system for the AH-1 Cobra series helicopters used by the US Army and Marine Corps as well as other nations. The system also has been installed on a variety of foreign helicopters.

Under a contract from the US Army Aviation Systems Command, disclosed in late 1984, pilots of Cobra attack helicopters will be able to fly combat missions round-the-clock using a night vision system produced by Hughes Aircraft. This will give Cobras a FLIR capability and the programme is known as C-NITE (Cobra-Night).

Hughes Helicopters 530MG Defender has two E-O systems for operation of airborne TOW anti-tank missiles: mast-mounted version of TOW sight, and HNVS FLIR turret under helicopter nose

The contract also calls for modifications to enable the Cobras to fire and guide the new TOW 2 missile, day or night. TOW 2 features a more potent warhead, designed to defeat advanced enemy armour, and an improved guidance system.

The FLIR device, which makes it possible for gunners to see through darkness, smoke or haze, will be installed in the telescopic sight for the Cobra's airborne TOW missile system. In addition to firing the missile, the sight is used to accurately direct cannon and rocket fire.

There are two versions of the TOW sight now in use by the Army, the standard optical sight and the Laser Augmented Airborne TOW (LAAT) sight. Production on the LAAT sight, which contains a mini-laser rangefinder, began in 1979.

The Army will retrofit about half of its Cobra fleet, approximately 500 helicopters. Deliveries are scheduled to begin in 1986.

Hughes Electro-Optical and Data Systems Group, delivered a feasibility model of a FLIR augmented airborne TOW sight to the Army in 1979. During official tests, conducted at several Army installations, gunners used the system to score more than 90 per cent hits in both day and night TOW missile firings.

The anti-armour version of the Bell Cobra is equipped with the M65 airborne TOW system, and up to four two-round modular TOW launch pods can be carried, while still leaving the inboard pylons free for rocket or 20 mm minigun pods. The M28 turret with a 7·62 mm minigun and 40 mm grenade launcher is retained. In addition to stabilised optics and a missile tracker, the modified M65 sight has provisions for a laser rangefinder. Helmet sights allow the crew to control the turret directly or provide target acquisition for the stabilised optics.

In the air launched role, TOW has a maximum direct range of 3750 metres.

STATUS

Hughes has delivered more than 1500 airborne TOW systems throughout the world and TOW has been deployed with air and ground forces of at least 33 countries. Nine nations of the 33 operating TOW are using the airborne version, including Italy and the UK, the latter producing a special roof-mounted optical sight for Army Lynx helicopters under licence in the UK.

CONTRACTOR

Hughes Aircraft Company, El Segundo, California 90245, USA.

1391.311
HELLFIRE (AGM-114A) TACTICAL AIR-TO-SURFACE MISSILE

The Hellfire Modular Missile System (HMMS) is the US Army's latest anti-armour weapon system. Hellfire is an acronym derived from 'heliborne-launched fire and forget'. From 1976, when the US Army selected the Missile Systems Division of the Defence Electronics Operations of Rockwell International to undertake engineering development (ED), numerous Hellfire 'prototype' missiles were launched in army concept feasibility tests. Flight and ground tests were conducted during that period at the US Army Missile Command (MICOM). Operational tests were conducted in 1974, 1980 and 1981 by the US Army at Fort Hunter Liggett, California. Hellfire missiles have also been fired by the US Marine Corps. The system achieved high accuracies and hit probability in tests.

For its initial application, Hellfire has been designated as the point target weapon system for the AH-64 Advanced Attack helicopter. The AH-64 carries up to 16 missiles. These are distributed equally on four wing-mounted launchers, two inboard and two outboard. The launchers are modular in design so that the two lower rails may be removed.

Maximum length and weight of the laser missile is 1779 mm and 43 kg respectively, while the diameter is 177·8 mm with wing span of 330 mm. The Hellfire missile is also modular and will accept a variety of mission-tailored guidance modules, but the production version is the laser homing model. The tactical prototype flight test phase was conducted using the Hellfire laser seeker developed by Martin Marietta, Orlando, Florida.

Other guidance modules studied for Hellfire are the Air Defence Suppression Missile (ADSM) seeker and the imaging infra-red (IIR) seeker. Experimental ADSM seekers were successfully launched by Rockwell on prototype Hellfire missiles in 1973. All seekers will allow Hellfire to engage moving targets. The first moving target launch took place in January 1972.

Hellfire is not limited to direct line-of-sight attack. Numerous indirect flights have been performed. In the indirect mode, the laser Hellfire missile is launched without seeker lock-on. It climbs over obstacles, searches for its target, then locks on automatically and impacts with no degradation in terminal accuracy. A factor in reducing helicopter exposure time during direct fire launches and in minimising total engagement time for all missions is laser Hellfire's broad launch window. This means that the launch heading of the helicopter and the azimuth to the target may differ considerably. Thereby, precision attitude alignment criteria, common to many other systems, are essentially eliminated.

In May 1974, laser Hellfire missiles demonstrated the 'ripple fire' technique of target engagement. With this technique, missiles are launched only fractions of a second apart, at different targets, designated by laser designators on separate codes. If only one designator is used, multiple targets can still be engaged; however, time between launches increases to a few seconds. This technique is called 'rapid fire' and was first successfully demonstrated in November 1974.

STATUS

In full production for US Army and Marine Corps applications. It was anticipated that entry into operational service begins with US Army AH-64 Apache helicopters in 1985.

The US Marine Corps is equipping new AH-1T helicopters with Hellfire and work on the same modifications to 48 AH-1Ts of the US Fleet Marine Force began in 1984.

Combined procurement and funding for Hellfire for Army and Marine requirements listed in the US Secretary of Defense's fiscal year 1986 report, for the years 1984/85/86/87 (with funding in millions of dollars shown in brackets) was 4870 ($235·5m), 5780 ($252·7m), 7880 ($308·5m), 7960 ($303·6m), respectively.

In 1983 firing trials of Hellfire installed in a British Lynx helicopter, and using a Ferranti 306 laser target designator were carried out in Norway. This aircraft can carry up to eight Hellfire missiles.

In March 1985 Martin Marietta received a $126·2 million US Army contract to build 4204 Hellfire missiles (about 70 per cent of total Army Hellfire production awards: Rockwell will produce the remainder). The Army and US Marine Corps are expected to buy more than 60 000 missiles over the life of the programme.

Test firings by the US Army of 59 Hellfires in 1984 yielded a 93 per cent success rate.

PIRANHA (MAA-1) AIR-TO-AIR MISSILE

MAA-1 Piranha is the designation given to a Brazilian project to develop an indigenous air-to-air missile. The programme has been active for several years, the work being carried out by the Divisão de Sistemas Bélicos (Weapons Systems Division) of the IEA (Instituto de Atividades Espaciais – Space Activities Institute), a branch of the Brazilian Ministry of Aeronautics CTA (Centro Técnico Aeroespacial).

Piranha is intended to be an IR homing weapon with a range of about 10 km at a maximum speed of more than Mach 2 carrying a 12 kg warhead. No information concerning the configuration of the missile has been disclosed for publication, but the general characteristics and the assumed date of its origination suggest that features of contemporary missiles, such as the canard control surfaces of the Sidewinder, R550 Magic, and Shafrir, are likely to be incorporated. Land- and ship launched versions of the Piranha are envisaged.

CHARACTERISTICS

Length: 2·72 m
Fuselage diameter: 15 cm
Launch weight: 85 kg
Guidance: IR homing
Warhead: 12 kg HE
Speed: Over Mach 2
Range: 10 km (approx)

STATUS

Development began in 1977, but no production decision has been announced. Reports in early 1983 suggested that economic problems could delay production further.

CONTRACTOR

Instituto de Atividades Espaciais, 12200 São José dos Campos, SP, Brazil.

4882.331

MICA AIR-TO-AIR MISSILE

MICA (Missile d'Interception et de Combat Aerien) is the name of a Matra project to develop a new air-to-air missile that is expected to enter service in the 1990s and to be capable of meeting the requirements set out for the international AMRAAM (**3340.331**) and ASRAAM (**3622.331**) weapons, but with smaller dimensions and lower overall weight.

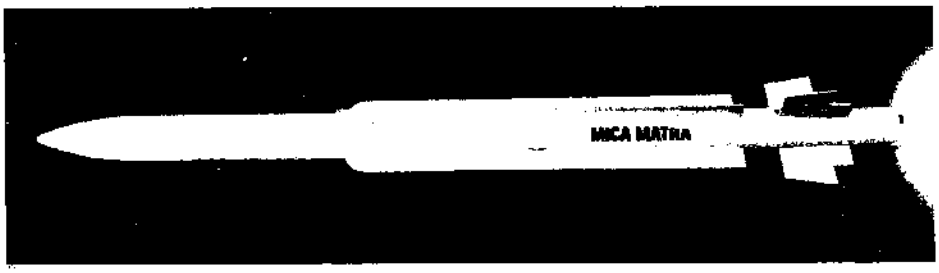
To fulfil these functions the developer envisages an operating range capability covering from several hundreds of metres to more than 50 km, exceptional manoeuvrability and high speed, within a 3.1 metre, 110 kg airframe. Other features include a multiple target capability and multi-mode operation. The latter will offer:

(1) long range interception, with inertial guidance plus inflight error correction (possibly via data link from the launching aircraft radar) and homing head terminal guidance;

(2) medium range interception, using inertial guidance and the homing head for terminal guidance; the missile thereby being fire and forget and fully self-contained after launch;

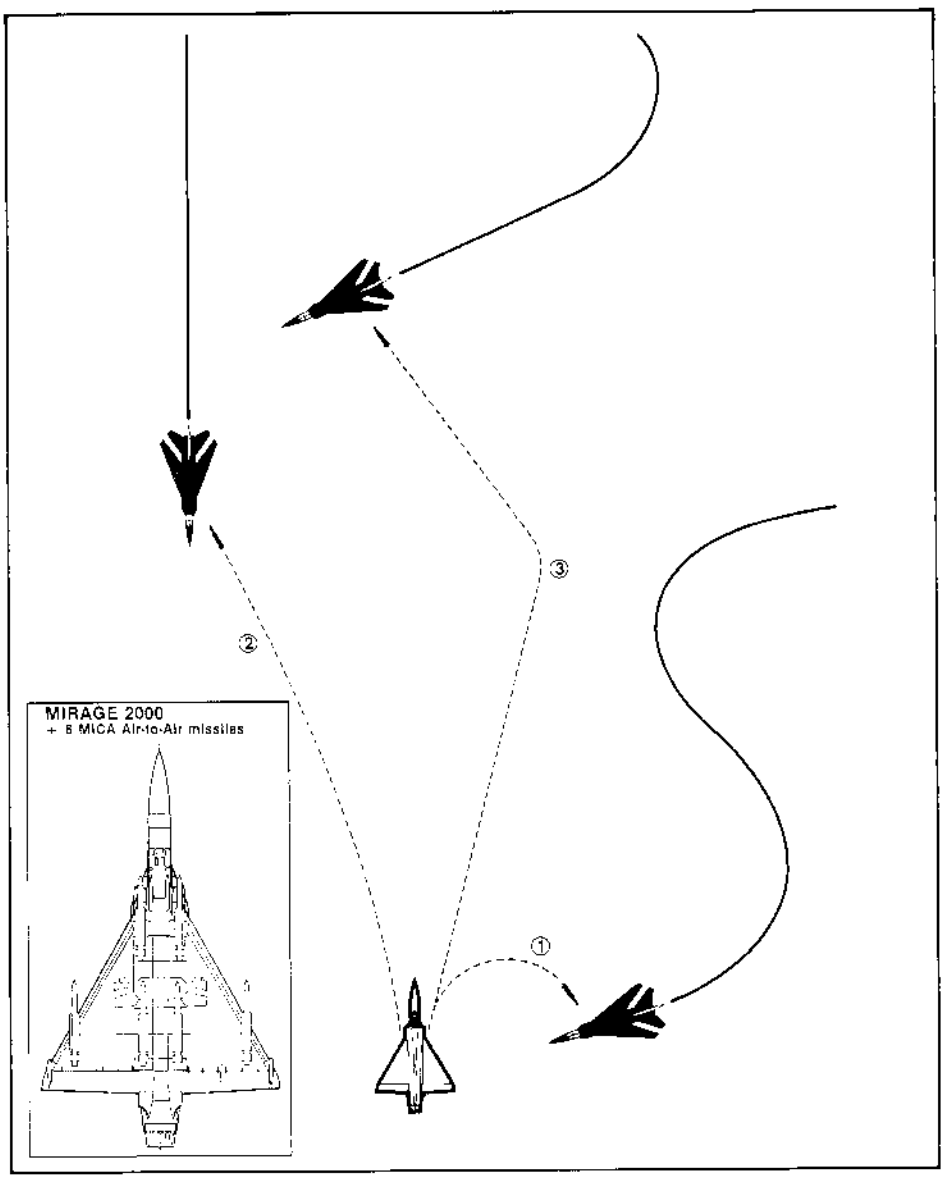
(3) dogfight combat and close range interception, in which homing head 'lock-on' is achieved before firing and release of the missile from the aircraft. The missile is fire and forget from this point and no other co-operation from the launch aircraft is needed.

The multi-mode operation requirement will probably be met by providing interchangeable homing heads for the MICA so that it may be equipped with either an active radar head or a passive IR seeker. Both types will be comprehensively protected against enemy countermeasures, and only switch on a few seconds after the inertial guidance phase (which is impervious to jamming).



The projected configuration of the MICA can be seen from the nearby photograph. The 3.1 metre long missile will be controlled by a jet-deflector system operating in the efflux of the solid propulsion rocket motor, and is expected to achieve a manoeuvring capacity under load factors greater than those of Matra's Magic air-to-air missile (**1348.331**).

STATUS



The concept definition phase has been completed, and development started by early 1985. MICA is expected to be ready for use with future fighter aircraft of the 1990s and updated existing combat machines.

CONTRACTOR

Matra SA, 37 avenue Louis-Bréguet, 78140 Velizy-Villacoublay, France.

Matra's MICA multi-purpose air-to-air missile concept for the combat aircraft of the 1990s

Typical roles that MICA is expected to fulfil, with (inset) six of the new missiles on the Mirage 2000 it will arm

1176.331

R.530 AIR-TO-AIR MISSILE

This is an all-weather all-aspect air-to-air missile system produced with alternative semi-active radar homing or IR guidance heads. Principal characteristics are: length 328 cm, diameter 26 cm, wing span 110 cm, weight 195 kg. Maximum speed is Mach 3 and range 18 km. Apart from the homing heads the two versions of the R.530 are identical. Propulsion is by a two-stage solid-propellant Hotchkiss Brandt motor of 8500 kg static thrust. Either of two types of high explosive warhead produced by the same concern, and weighing 27 kg, can be fitted.

The IR homing version is stated to be capable of successful interceptions from any aspect, relying upon heat from either the jet engine and its exhaust from the rear quarters and local airframe hot-spots by aerodynamic heating when attacking from the front.

The semi-active radar homing head is produced by Electronique Marcel Dassault under the designation AD26 and this is for use with an I-band target illuminating radar.

STATUS

Production ceased in 1980, when deliveries amounted to at least 2400 missiles, of which 45 per cent are stated to have been exported to 12 countries. Many of these weapons are likely to remain in service.

CONTRACTORS

Matra SA, 37 avenue Louis-Bréguet, 78140 Velizy-Villacoublay, France.

AD26 homing head: Electronique Marcel Dassault, 55 quai Carnot, 92 Saint-Cloud, France.

1348.331

R550 MAGIC AIR-TO-AIR MISSILE

The Matra R550 Magic is designed for 'close-combat' operations (from less than 500 metres to more than 6 km), with consequent emphasis upon the ability to withstand high load factors imposed by the severe manoeuvre demands required. The general configuration of the weapon is shown in the accompanying photograph. Propulsion is by a Hotchkiss Brandt solid rocket motor, and operational range is reported to cover from 200 metres, or less, to as much as 10 km. Twist and steer control of this missile is effected by the canard arrangement of fins at the forward end of the weapon. A SAT IR homing head provides guidance, and the missile launcher houses a liquid nitrogen container to provide cooling for the IR sensor.

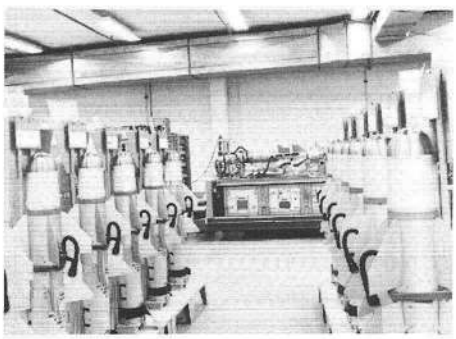
CHARACTERISTICS
Type: R550 Magic
Length: 275 cm
Wing span: 66 cm
Diameter: 16 cm
Weight: 90·7 kg
Guidance: IR homing

Magic 2

In mid-1983 it was revealed that an improved version known as Magic 2 was under development to go into production in 1984. This model employs a new solid-propellant rocket motor, a new IR homing head using the latest technology for high sensitivity, and a new electromagnetic proximity fuze.

The main operating characteristics remain very similar to those of the R550 Magic but with the important addition of a front quadrant attack capability to give an all-aspect engagement facility.

STATUS



Both the French Air Force and Navy have the R550 in their inventories and Magic has been operational since 1975. By April 1983 more than 7000 missiles had been ordered, with some 75 per cent being for export to 15 countries, including: Ecuador, Egypt, Greece, India, Iraq, Kuwait, Libya, Oman, Pakistan, Saudi Arabia, Spain, South Africa, Syria, and United Arab Emirates. Among the aircraft types that have been fitted are: Mirage III, V and F1, Crusader, Jaguar, Sea Harrier, Super Etendard, Macchi 326K, and Hawk Alpha Jet.

Series production of Magic 2 began in 1984 and this model has been ordered by several countries. Adaptation of Magic 2 to the Mirage 2000 aircraft has also been completed, and it is now in service.

At January 1, 1985 orders amounted to a total of 7400 missiles, with 75 per cent for export customers.

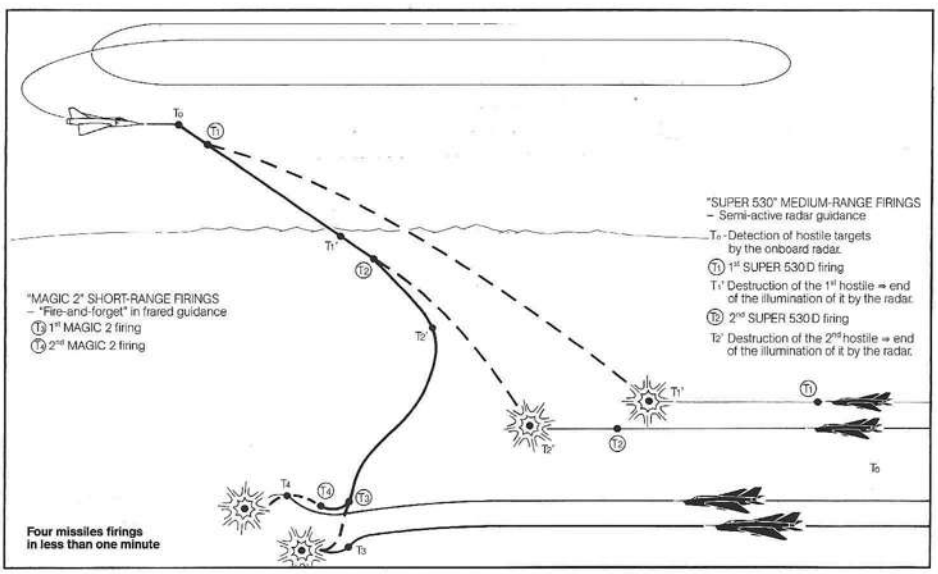
CONTRACTOR

Matra SA, 37 avenue Louis-Bréguet, 78140 Velizy-Villacoublay, France.

Magic 2 series production started in 1984. A batch of missile front sections containing electronics and controls await testing

Matra's two newest air-to-air missiles in current service: Super 530D left, and Magic 2 right

1349.331
SUPER 530 AIR-TO-AIR MISSILE



This is a successor to the Matra R.530 weapon, intended to meet the higher speed and altitude performance requirements of the latest generation of interceptor aircraft.

Two versions have been produced: the Super 530F, which has been operated with the Mirage F1 since 1979; and the Super 530D. The latter is actually a new missile, though with some common items of equipment with the Super F and the same apparent configuration. However, digital processing, a new doppler mode homing head, and increased rocket power lead to increased performance (roughly double in terms of range as that of the Super F, it is claimed).

With a design concept for reaching targets flying at very high altitude and at high Mach numbers, it comprises: a 'long-wing' of low width, which gives it exceptional aerodynamic qualities, in particular in the area of load factors at altitudes greater than 70 000 feet (21 330 metres); a motor with a very high acceleration rate, which allows the interceptor aircraft to fire with vertical separations of more than 25 000 feet (7620 metres).

The Super 530 is equipped with an electromagnetic homing head developed by Electronique Serge Dassault (ESD) and a Matra autopilot, and the missile employs proportional navigation. Steel and steel honeycomb is used for the structures, and this with a ceramic radome allows the Super 530 to withstand speeds of about Mach 4 and manoeuvres of up to 25 *g*.

CHARACTERISTICS
Length: 354 cm
Tail-fin span: 64 cm (fore), 90 cm (aft)
Body diameter: 26 cm
Wing: Long-chord, small area type, approx 50 cm span
Weight: 245 kg
Homing head: ESD electromagnetic, semi-active
Proximity fuze: Thomson-CSF radar
Propulsion motor: Thomson-Brandt, solid composite
Warhead: Thomson-Brandt, 30 kg, fragmenting
Range: Compatible with Cyrano 4 radar/F1 system
Performance: Shoot-up, shoot-down capability permits engagement of targets more than 7000 m above or below launch aircraft, ECM incorporated
Speed: Mach 4 - 5

Matra interpretation of how a Mirage 2000 with two Super 530D missiles and two Magic AAMs detecting low-level intruders (Mach 0.9 at 300 ft) could deal with them

STATUS
The French Air Force awarded contracts for the start of series production at the end of 1977, and French squadrons were equipped from January 1980 onward, this model being designated Super 530F. Following service with the Mirage F1, it is intended for use with the Mirage 2000 in a new version with greater range and snap-up engagement capability, advanced technology, and enhanced ECCM. This is the Matra Super 530D which will be operational in 1986.

In test firings of the Super 530D with the Mirage 2000 aircraft and the RDI radar, effective ranges of more than 40 km have been achieved.

At January 1, 1985 orders for a total of 1350 Super 530 missiles had been received.

CONTRACTOR
Matra SA, 37 avenue Louis-Bréguet, 78140 Velizy-Villacoublay, France.

4510.331
AATCP HELICOPTER MISSILE SYSTEM

This is a project to employ the short-range anti-aircraft SATCP Mistral missile (**4198.131**) for helicopter applications such as air-to-air combat between battlefield helicopters, or for the self-protection of helicopters employed in an anti-armour role. In French service, Mistral is known by the initials AATCP from the French for 'very short-range air-to-air .

The concept is similar to that embraced by the American HVM programme (**4448.311**) and the Soviet use of SA-7 Grail missiles with the Hind helicopter. This heliborne version of the Mistral missile can be mounted on a support protection helicopter as main armament with a gun as the complementary weapon. It can also be mounted on anti-tank helicopters as self-protection armarment.

The possibility of homing head pre-pointing makes the missile firing easier, and further improvement derives from the ability to choose the scanning pattern of the homing head. Thanks to the fire and forget guidance employed by the Mistral, the launching helicopter is free to manoeuvre immediately after firing the missile. Other significant operational characteristics are the 3 kg warhead and proximity fuze, short system reaction time, high missile velocity, and these limit the target's ability to take cover before missile arrival.

The missiles are carried in a twin-round launcher and the number of these launchers fitted depends on the type of helicopter and other weapon/equipment loading factors. Typically, four launchers with eight missiles would be fitted on a support protection helicopter.

CHARACTERISTICS
Missile: AATCP (Mistral)

French Gazelle helicopter with Mistral missiles loaded

Length: 1.8 m
Diameter: 90 mm
Weight: 17 kg
Warhead: 3 kg
Fuze: Impact, laser proximity
Guidance: IR homing
Range: 300 – 6000 m
Peak speed: Mach 2.6

STATUS
Development project. Pre-development studies took place in 1982.

CONTRACTOR
Matra SA, 37 avenue Louis-Bréguet, 78140 Vélizy-Villacoublay, France.

INTERNATIONAL

3340.331
AMRAAM (AIM-120A)

The AIM-120A advanced medium range air-to-air missile (AMRAAM) programme originated in the United States as a joint US Air Force/US Navy study and development project for a new beyond-visual-range air-to-air weapon to replace the AIM-7 Sparrow missile, The AMRAAM programme subsequently evolved into an international project with NATO participation and, with the advanced short-range air-to-air missile (ASRAAM) project (**3622.331** below), it forms an important NATO 'family of weapons' programme. Under this arrangement covering future air-to-air missile requirements, the US is responsible for development of AMRAAM while European NATO members are free to undertake development of a new generation of advanced short-range air-to-air missiles.

The Memorandum of Understanding (MoU) covering the AMRAAM development was initiated in April 1978; progress of the project up to that date, when it was pursued as a joint US Air Force/US Navy programme, is described under the above entry in the US pages of this section in previous editions of *Jane's Weapon Systems*. The air-to-air family of weapons MoU negotiations were completed in February 1980.

AMRAAM will be compatible with F-14, F-15, F-16 and F-18 aircraft as well as Tornado and other air defence and air superiority interceptor aircraft operated by NATO in the late 1980s. It will satisfy the NATO staff requirement for medium-range air-to-air missiles, and the AMRAAM staff target was written by NATO Air Forces Armaments Group SG/13 and is approved by all participating states (with the exception of France). The design calls for an all-weather, all-aspect, radar-guided missile capable of engaging numerically superior aircraft forces before they come within visual range, and there will be a capability for multiple launches at ranges greater than this and for these launches to become autonomous soon after launch to enable the launching aircraft to manoeuvre and/or engage more targets quickly. It is being developed as a successor to the AIM-7F/M Sparrow. Experimental models were built competitively by Hughes and Raytheon and after a fly-off competition, the Hughes design was chosen by the US Air Force in December 1981.

It is anticipated that production AMRAAMs will have about 60 per cent of the weight of the current AIM-7 Sparrow, with the following characteristics which have been issued provisionally by the US Air Force.

CHARACTERISTICS
Length: 3·65 m
Diameter: 178 mm
Wing span: 526 mm
Tail span: 627 mm
Weight: 152 kg
Guidance: Inertial to target area, active radar homing
Speed: Supersonic

The guidance system will employ digital techniques based on a microprocessor and other engineering details include a TWT transmitter, an integrated RF processor on the seeker gimbal, and a steel fuselage structure requiring no thermal protection. It is planned to use semi-custom and standard production LSI chips extensively. The multifunction microprocessor combines navigation, autopilot, data link, radar, fuzing, missile sequencing and self-test in one data processor.

Information given to the US Congress contains

US Air Force F-16 has Hughes AIM-120A AMRAAM on mid-wing pylon, prior to test flight at Holloman AFB

details of how AMRAAM is likely to be used with the F-16 aircraft, and this is summarised here. The aircraft radar will be modified to provide a track-while-scan (TWS) facility and includes a programmable signal processor. The latter will allow multiple target discrimination and tracking, provide software control of radar signal processing to improve responses to ECM, and provide improved air-to-ground features. The TWS mode will be capable of simultaneously tracking multiple targets while continuing to search a large airspace volume for other potential targets. Simultaneous launches of up to eight missiles at multiple targets will also be possible with AMRAAM, and its active radar seeker permits the aircraft to follow a launch-and-manoeuvre pattern, which in the case of a single target engagement follows the following sequence:

(1) in the pre-launch phase the aircraft radar acquires and tracks the target, and an on-board computer calculates the launch acceptability zones and displays the information to the pilot
(2) during the launch phase the pilot first makes his decision to launch the AMRAAM, and inertial reference data on the target and the launch aircraft are fed into the missile computer to provide the necessary initial information
(3) the AMRAAM leaves the aircraft
(4) the inertial mid-course phase is carried out using inertial data provided by the aircraft's avionics system prior to launch and guidance laws stored in the missile computer to navigate the missile to a calculated point in space where the missile seeker will go into the active mode. The aircraft avionics system will display to the pilot the time-to-go to initiation of the active mode, and he continues to track the target on his radar until that point is reached
(5) the terminal phase begins when, at the calculated point, the seeker transmitter is turned on, and the target is detected. The seeker then tracks the target and the missile completes the intercept.

DEVELOPMENT

In 1983 Hughes embarked on a six-month feasibility study into the use of the AIM-120 missile as the basis of a new point defence weapon for ships. Sea AMRAAM, as the project was dubbed was the subject of a contract awarded by US Navy Sea Systems Command, and announced in August 1983.

STATUS

A four-power air-to-air family of weapons MoU was signed by the Federal Republic of Germany, France, the UK and USA in August 1980, under which the US will develop AMRAAM and Britain and Germany will develop the next short-range missile. France adopted 'special observer' status and is not committed to full participation. In June 1984 British Aerospace was chosen as lead contractor in a European consortium of four companies (BAe, MDS, MBB and AEG-Telefunken) to study European manufacture of AMRAAM.

The AMRAAM programme completed the initial concept phase in February 1979 when the US Air Force selected Hughes and Raytheon from five bids for validation phase contracts. During this 33-month phase both contractors built and demonstrated their respective models of the AMRAAM, and in December 1981 the Hughes design was selected for full-scale development. A projected total of about 20 000 missiles are expected to be in US Air Force and US Navy inventories.

Under the $421 million full-scale development contract awarded to Hughes in December 1981, the company is expected to produce 98 test missiles altogether. This contract contained provisions for establishing a US second source for production. The US Air Force selected Raytheon to fulfil the latter function and the international MoU allows for a European production line to be established.

The 1985 US Defence Budget contained sums of $207, $186·7 and $217·7 million in fiscal years 1983/84/85, respectively, and proposed $413 million to fund procurement of 174 missiles in 1985. The 1986 budget request was $431 million for 90 missiles.

The European consortium set up to deal with procurement of AMRAAM and ASRAAM (see **3622.331** below) in February 1985 decided that European AMRAAM production was technically feasible and went on to study the economic viability of European manufacturing.

3622.331

ASRAAM (AIM-132) PROGRAMME

The AIM-132 advanced short-range air-to-air missile (ASRAAM) programme began as a joint US Air Force/US Navy project but following the signing of a NATO 'family of weapons' Memorandum of Understanding (MoU) between the USA and certain European nations responsibility for this new generation weapon now rests with the latter countries (see **3340.331**, above). The ASRAAM requirement is for a successor to the AIM-9 Sidewinder missile in the early 1990s and the plan is for European and American needs for these weapons to be met by production on both sides of the Atlantic.

Advance short-range air-to-air missile (ASRAAM) test vehicle

The European signatories to the air-to-air family of weapons MoU were France, the Federal Republic of Germany and the UK, but with the first of these having only 'special observer' status in respect of both AMRAAM and ASRAAM studies. This however apparently provides France with the option of entering into collaborative production arrangements at a later date. The nominated lead contractors in Britain and Germany are British Aerospace Dynamics Group and Bodenseewerk Gerätetechnik, collaborated in a feasibility study completed in 1983. Both concerns are applying experience gained in a variety of previous experimental and developmental work, for example the UK short-range air-to-air missile (SRAAM) programme carried out by British Aerospace in the late 1970s. A late model arising from this project was successfully fired in August 1980, when it intercepted an airborne target over the Aberporth range in Wales. The missile was without wings and was steered by swivel nozzle thrust vector control, using an IR seeker. The launch was from a Hunter aircraft and the trial was set up to demonstrate performance under severe intercept conditions. The motor and actuation system were developed by IMI Summerfield and Sperry Gyroscope, Bracknell, and the missile is controlled in roll by a Sperry motor bleed actuation system that vents exhaust gases through four tangential thrusters.

In the Federal Republic of Germany, Bodenseewerke developed in the late 1960s and early 1970s the Viper air-to-air missile as a successor to the AIM-9B/FGW Mod 2 Sidewinder. Viper was equipped with a unique Bodenseewerke two-axis platform IR seeker head of advanced design, giving the high performance missile an all aspect attack capability. After termination of the Viper development in 1974

and selection of the US Navy's AIM-9L Sidewinder, a joint US/FRG back-up programme combining the Viper guidance section and the AIM-9L aft section was launched in 1975. Under this programme, called ALASCA (all aspect capability), two test firings of ALASCA missiles took place in 1980.

In the UK, Marconi Defence Systems are known to be working on a number of missile seeker concepts and designs suitable for small diameter missiles capable of short-range air interception missions.

STATUS

Feasibility studies completed in 1983 were followed by project definition, with production contract to be awarded after satisfactory completion of trials. A new company, BBG (Bodenseewerk British Aerospace GmbH) was formed in November 1983 to carry out the development and production of ASRAAM. BBG is jointly owned by BAe and Bodenseewerk.

In April 1985, the contracting authority for the programme, Bundesamt fur Wehrtechnik und Beschaffung (BWB) announced the award of a contract to BBG for a two-year project definition phase, although work has commenced prior to contract signature. BBG expected to place major sub-contracts with BAeDG, Bodenseewerk and Raufoss of Norway, and at the end of the two year definition phase a decision on full development will be taken.

PYTHON 3 AIR-TO-AIR MISSILE

Python 3 is the name given to the third-generation successor developed to follow the Israeli Shafrir II air-to-air missile. It was first revealed publicly at the Paris Air Show in June 1981, and bears a close resemblance to the Shafrir, which in turn reveals much of the influence exerted by the US Sidewinder on its design. Python 3 is IR homing also, and a solid-propellant rocket motor can be reasonably assumed. The rear aerodynamic control surfaces exhibit the same gyroscopically-actuated stabilising tabs that are found on Shafrir, the Soviet Atoll and certain Sidewinders. The canard control surfaces are of similar triangular planform as those of Shafrir but it is not known if they are actuated by the same (pneumatic) technique.

It is almost certain that improvements have been made to the seeker system and its cooling arrangements, as well as to other sub-systems such as the fuze and propulsion. Israeli sources report that the guidance system is much more sophisticated than that of the earlier Shafrir missile, and the acquisition envelope has been expanded so that engagements can be undertaken from all target aspects. Maximum and minimum engagement ranges are quoted as 15 km and 500 metres, respectively. The warhead charge consists of about 11 kg of high explosive.

Python 3 air-to-air missile

CHARACTERISTICS

Length: 3 m (approx)
Weight: 120 kg
Warhead: HE, 11 kg
Max range: 15 km
Minimum effective range: 500 m

STATUS

Official information on when Python 3 became operational has not been forthcoming, but there have been reports of its use in air battles over Lebanon in Mid-1982.

CONTRACTOR

Rafael Armament Development Authority, Ministry of Defence, PO Box 2082, 31021 Haifa, Israel.

1659.331

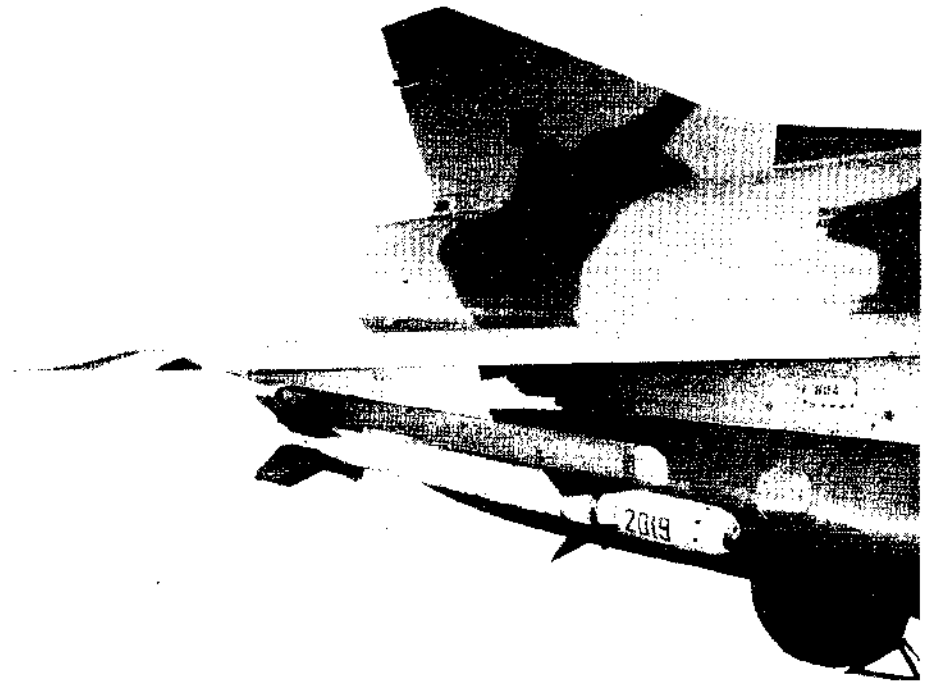
SHAFRIR AIR-TO-AIR MISSILE

Shafrir is an air-to-air, IR homing missile for use against high performance aircraft at heights up to 18 000 metres (60 000 ft). It is a relatively small missile, 16 cm diameter and 260 cm long, with pneumatically-operated control fins at the fore-end and stabilising surfaces at the rear. The latter are fitted with the gyroscopically-actuated tabs found on the Sidewinder and Soviet Atoll missiles, for roll stabilisation. Approximate launch weight is 93 kg, of which the warhead accounts for 11 kg. Contact and proximity firing of the warhead are provided.

Simplicity was a major design objective, and both missile and aircraft-fitted elements of the Shafrir weapon system have been kept to the minimum. Electronics are solid-state. Apart from the firing circuit, no aircraft-installed equipment is needed.

The missile and its launcher are mounted under the wing of the aircraft and attached to a specially-designed adaptor.

The current version is the Mk 2, the Mk 1 model is understood to have been the first pre-production version. The rumoured Shafrir Mk 3 is thought to have become the Python 3 (**4185.331**).



OPERATION

Firing of Shafrir is on a 'see-and-shoot' basis. When a target is detected within the firing range, the audio signal is heard and an indicator light in the cockpit is automatically operated. This indicates that the missile launch button can be used. From this point, the guidance system is completely independent of the launching aircraft.

STATUS

Shafrir has been launched in air combat with a high kill ratio (75 per cent) on numerous occasions, according to official Israeli sources and more than 200 kills were credited to Shafrir during the October 1973 conflict. Details of export sales have not been released officially but among countries believed to have been supplied are: Chile, South Africa and Taiwan.

The successor is the Python 3 (**4185.331** above).

ITALY

1656.331

ASPIDE MULTIROLE MISSILE

Aspide is a high performance multirole missile, optimised for air-to-air and surface-to-air missions. It is based on the use of a semi-active radar, with monopulse receiver, guidance system which ensures all-weather and all-aspect operation. The missile directly homes onto the target through proportional navigation.

Principal characteristics are: length 3.7 m, body diameter 20.3 cm, wing span 100 cm (air-to-air) or 68 cm (surface-to-air), fin span 80 cm (air-to-air) or 62.5 cm (surface-to-air), launch weight 220 kg. Propulsion is by means of a single-stage solid-propellant rocket motor which will give speeds of more than Mach 2 in the surface-to-air role and up to Mach 5 in the air-to-air role.

Aspide can be employed on most modern high performance interceptor aircraft for which this missile constitutes the primary weapon, being very effective both at very high altitudes and for very low level engagements (few metres) as well as in snap-up and snap-down geometries. In this role it has been included in the weapon inventory of the Italian Air Force for the F104S-ASA Starfighter interceptor (improved version of the original F104S). In the surface-to-air role, Aspide is operational in the Albatros naval point-defence weapon system (**1551.281**), and in the Spada ground-based point-defence weapons system (**2250.131**) for vital permanent objectives air-defence. The two above mentioned systems are in service with the Italian Navy and Air Force respectively.

Technical areas in which major objectives have been achieved are seeker range, sub-clutter visibility, fuzing system, multiple target effectiveness, ECCM capabilities, functional modularity of construction, reliability, and ease of maintenance. Thin-film microwave circuitry developed by Selenia is incorporated in the design.

DEVELOPMENT

Development was started in late 1969 and concluded in 1977. Flight tests began in July 1974. Captive test by an Italian Air Force aircraft had proved the main radar seeker functioning and performance. Autopilot flights with programmed trajectories tested the missile flight control capabilities. Both the warhead and the proximity fuzing system had been live-tested against a number of different targets representative of the postulated threat spectrum. The complete test programme was regarded as highly successful and proved the full realisation of design objectives.

The contractual firings took place beginning from 1976 to the end of 1977 at the Italian MoD Missile Range (Sardinia), where prototypes and production pilot-line missiles were fired, firstly from a ground based test-bed then from an actual system installed on a floating platform.

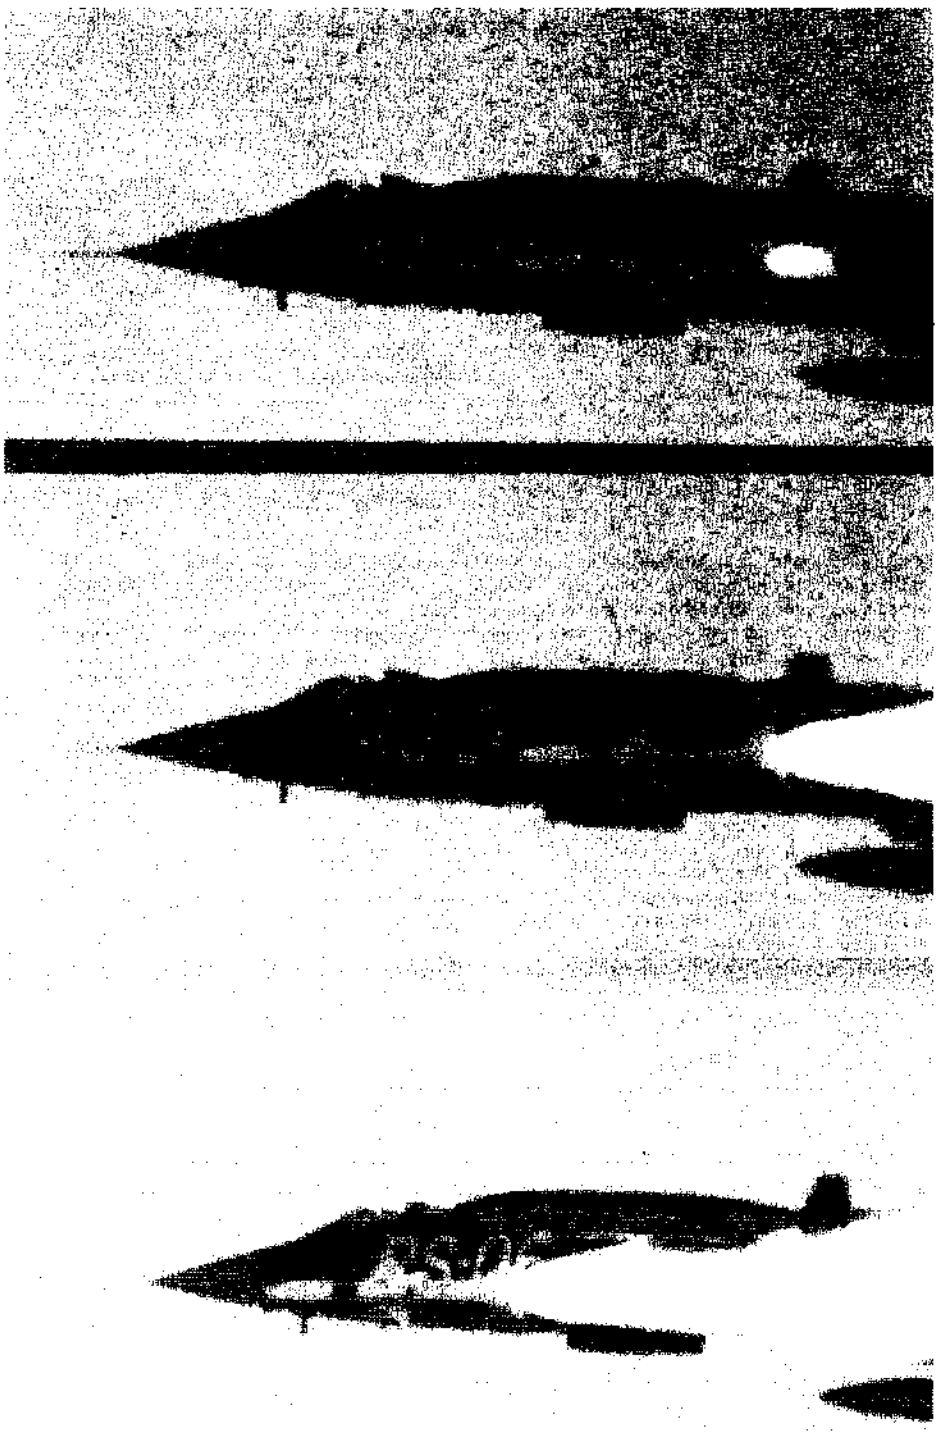
The contracting agency is the Italian MoD with direction of the programme under the General Direction of Aeronautic Constructions (Costarmaereo).

STATUS

Full operational firings from vessels of the Italian and foreign navies equipped with the Albatros system were successfully carried out beginning from 1979. Some firings were also made from ships equipped with the NATO Sea Sparrow weapon system or its Dutch variant (**4775.231**). This was made possible by an adaptation kit developed by Selenia. The system adaptation is readily reversible in either direction and can be carried out even at sea.

Several operational firings have been also carried out from the Spada system during 1983 and 1984. A number of systems are now operational for defence of permanent Italian Air Force installations.

Demonstration firings were made in October 1981 with a Skyguard system (**2377.181**) modified for the guidance of the Aspide missile fired from a four cell launcher developed to this purpose. This system, named Skyguard/Aspide, has been selected by the Italian Army for air-defence on the battlefield. A campaign of extensive trials will be carried out by 1986 for the technical and operational evaluation of the system by the Italian Army.



For the airborne deployment, carriage flights were carried out firstly to demonstrate the transportability of the Aspide missile from the F104S-ASA, alone or in different armament configurations. Subsequently a campaign of autopilot firings were successfully made to verify the correct execution of the missile separation and the various interfaces between missile and aircraft. In 1985/86 a number of operational guided firings against live targets are planned.

The first batch of production missiles was delivered in 1977 for use in the Albatros system; production is continuing at full rate at the manufacturer's plant on behalf of more than a dozen of foreign customers in addition to the Italian Armed Forces for their previously mentioned four systems.

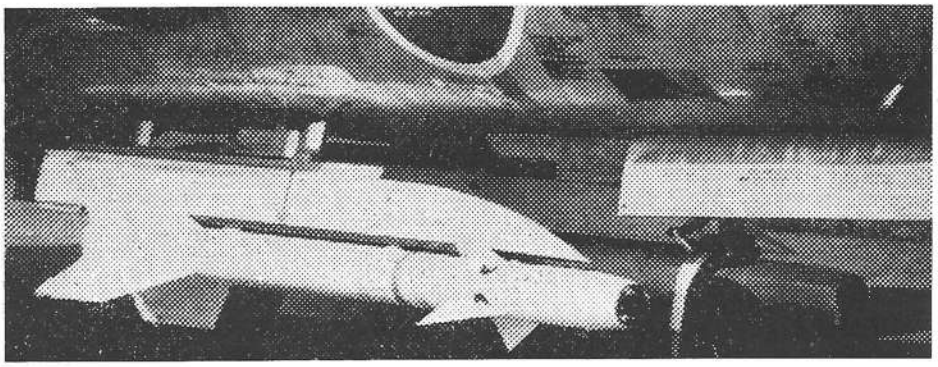
MITSUBISHI AAM-1 AIR-TO-AIR MISSILE



Few details have been disclosed of the air-to-air missile which is replacing the Sidewinder on F-86F and F-104J interceptors of the Japanese Air Self Defence Force. Unofficial data include a missile length of about 2·6 metres and a launch weight of 70 kg. Range is in the region of 7 km. Guidance is by IR homing.

STATUS

It has been reported that the AAM-1 had already entered operational services by 1969, and a total planned production of 330 units had been delivered by late 1971.

SOUTH AFRICA

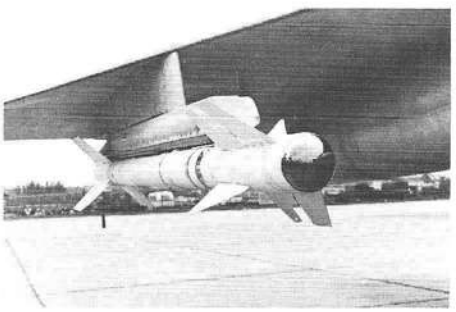
4526.331
KUKRI AIR-TO-AIR MISSILE

Kukri is the export version of the South African Air Force's (SAAF) V3B IR-guided dogfight missile and like V3B, it is used with a helmet-mounted sight. Compatibility with existing aircraft and weapon systems was maintained by conforming to the Sidewinder Aero 3B and M550 Magic launcher mechanical and electrical interfaces. Development of the earlier V3A system started at the end of 1971 and it went into production in 1975. It was the first air-to-air missile to be coupled to a helmet sight and is still operational. The SAAF operational requirements evolved over the years and work on V3B, an upgraded version of V3A, was started in 1975. System improvements included an IR-head with a bigger look angle and high sensitivity, an increased helmet sight designation angle and an upgraded motor. V3B went into production in 1979. The export version, Kukri, is now available to selected customers, and the system is cleared for use on the Dassault-Breguet Mirage III and Mirage F1 types. Trial installations have been made on other aircraft types. Both V3A and V3B are currently operational with the SAAF.

Kukri is a highly manoeuvrable dogfight missile with an asymmetric double-canard aerodynamic configuration. In one plane there are two fixed canards in front with two double-delta moveable canards aft and in the other plane there are two simple delta movable canards. The canards are actuated by a hot gas servo and twist and steer control is employed. The triangular canards give roll control and the double-delta canards control pitch acceleration. The tail fins rotate freely around the rear end of the rocket motor. A double base solid-propellant rocket motor and a conventional fragmentation warhead are used.

The missile is delivered in two sections, the first being the motor and warhead assembly and the second the guidance, control and fuzing assembly (GCF). Assembly of the two sections can be effected in a few minutes using standard tools and a simple alignment jig.

A helmet sight is coupled to the missile, thereby giving the pilot an off-boresight target acquisition capability. The helmet sight consists of an IR diode array attitude measurement system and interface electronics to the missile.



The launcher contains the clean air cooling system for the missile IR detector as well as the necessary power supplies and helmet sight interface electronics. It is mounted on the wingtip in the case of the Mirage F1 and on an underwing strong-point in the case of the Mirage III.

OPERATION

Besides the special flying helmet and consequent modifications to the personnel connector on the ejection seat, installation of the Kukri missile system requires some minor aircraft wiring modifications and the addition of three black boxes – the reference unit, the pre-amplifier and the data processing unit. The first two of these must be mounted in the cockpit while the data processing unit can be installed in any suitable location.

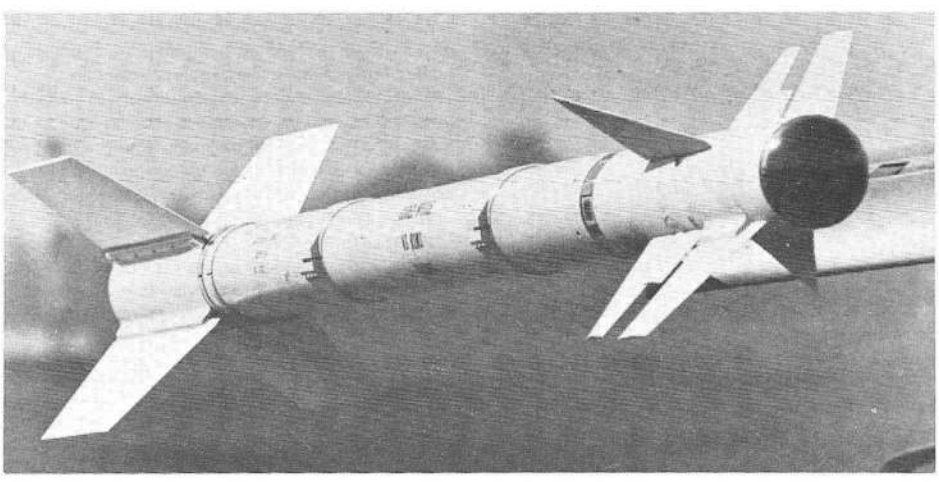
This system was designed to be as simple as possible in operational usage and all the controls related to mode switching, target designation and missile firing are situated on the joystick and the throttle. The pilot simply has to look at the enemy aircraft and when target acquisition is signalled by an audio tone in his headset, he designates the target, thereby putting his missile in the tracking mode. Once the missile is tracking the target the pilot can move his head at will. The missile can be fired while tracking or even in the aiming mode, provided that the audio tone is present.

The pilot's decision making is further simplified by the aiming reticle extinguishing automatically when the target is outside the helmet sight designation limits.

Indigenously developed V3 Kukri missile on SAAF aircraft

The missile can be fired over the entire flight envelope of the clean aircraft (any speed, altitude and load factor). Minimum operational range is 300 m and the maximum varies between 2 km at low altitudes to in excess of 4 km at high altitudes.

CHARACTERISTICS



Missile
Length: 2944 mm
Diameter: 127 mm
Tail fin span: 530 mm
Fixed canard span: 420 mm
Weight: 73·4 kg
Launcher
Length: 2495 mm
Weight: 32 kg
Data processing unit
Dimensions: 238 × 226 × 82 mm
Weight: 3·8 kg
Reference unit
Dimensions: 85 × 31 × 57 mm
Weight: 0·17 kg
Preamplifier
Dimensions: 132 × 102 × 36 mm
Weight: 0·34 kg
Pilot's helmet
Weight: 2·3 kg
Minimum range: 300 m
Max range: 2 km at sea level; 4 km + at high altitudes
Manoeuvrability: 25 g sustained; 35 g peak
Max speed: Launch velocity + 500 m/s
Launch limitations
Max load factor: 7 g
Max altitude: 50 000 ft (15 240 m)
Max speed: Mach 1·8

STATUS

The V3A went into production in 1975 and both it and the later V3B are operational with the SAAF. Production of the V3B began in 1979. The export version of the V3B, Kukri, has been available since 1982.

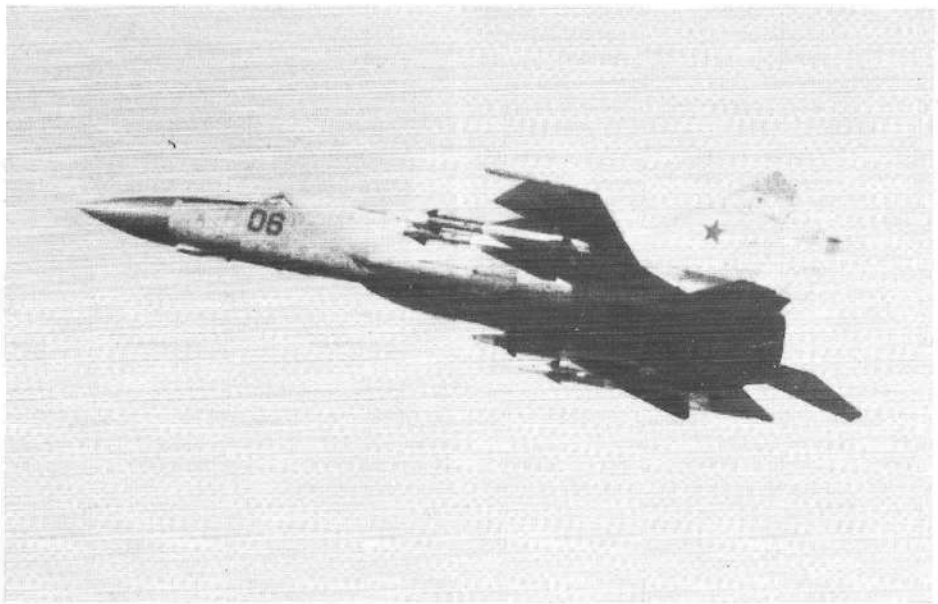
South African V3 Kukri air-to-air missile

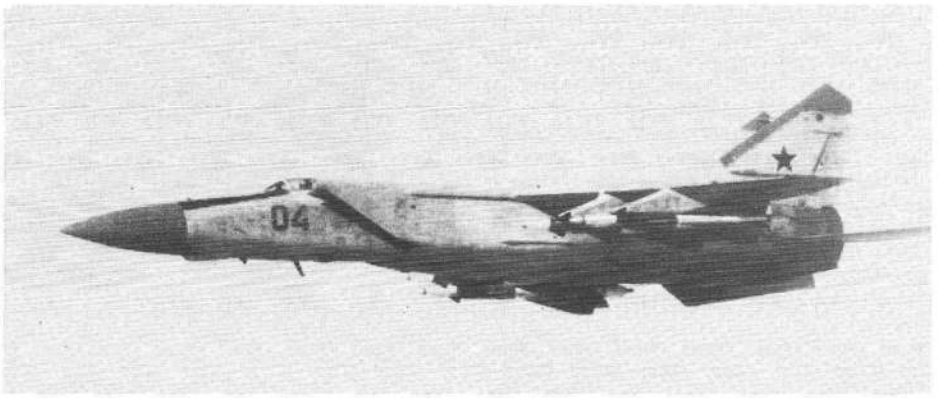
UNION OF SOVIET SOCIALIST REPUBLICS

3337.331
ACRID (AA-6) AIR-TO-AIR MISSILE



The AA-6, NATO code-name Acrid, was the first of a new family of Soviet air-to-air missiles to be seen by the West, when the first picture of it on a MiG-25 Foxbat aircraft was published in Western magazines in the closing months of 1975.

The resemblance to the earlier AA-3 Anab (**1144.331**) is quite clear, but AA-6 is appreciably larger, having an estimated length of 6·29 metres. This dimension refers to the radar-guided version of the missile there being also an IR homing model which has a length of about 5·8 metres. Two of each type are carried on the Foxbat, the latter type of missile carried on the inner pylons. The launch weight is likely to be in the region of 750 kg, with the radar version somewhat heavier than the IR model. This weight includes a warhead of up to 100 kg, probably high-explosive fragmentation type.



The AA-6 is thought to be the Soviet approximation to the American Phoenix long-range air-to-air missile, although it is doubted if it has that weapon's multiple target capability. However it is possible that the IR homing version is launched very shortly after the initial radar-guided Acrid missile to a similar point in space where it is anticipated that the IR seeker will detect and lock-on to its own target. Such a mode of operation would be feasible and useful against multiple targets approaching together. For maximum efficacy, the AA-6 would require an inertial- or autopilot-controlled mid-course phase, and it would enable the radar-guided version to fly to the target area without requiring target illumination by the aircraft's radar if an active homing head is incorporated. The size and weight of the AA-6 tend to support this suggestion.

Estimates of range for the radar version have varied between sources but generally seem agreed on figures in the neighbourhood of 40 to 50 km. These may prove to be on the conservative side as may the estimates of about 20 km for the IR homing model. However, the latter case is subject to greater variations due to the operational and environmental circumstances, eg day or night, altitude, weather, aspect of target and sun, etc.

The wings of the Acrid missile plainly have control surfaces and it is conjectured that the canards are also used for control purposes. Solid propulsion is assumed, and most estimates credit the AA-6 with a speed of about Mach 2·2.

Foxbat interceptor armed with AA-6 Acrid missiles

AA-6 Acrid air-to-air missiles on MiG-25 Foxbat E aircraft

STATUS

Acrid is the standard armament of the MiG-25 Foxbat, which can carry four such missiles. In addition to the Soviet air forces, other users include the Libyan Air Force and perhaps Algeria and Iraq. The AA-6 has been reported more recently on Su-15 Flagon D and E aircraft.

1145.331
ASH (AA-5) AIR-TO-AIR MISSILE

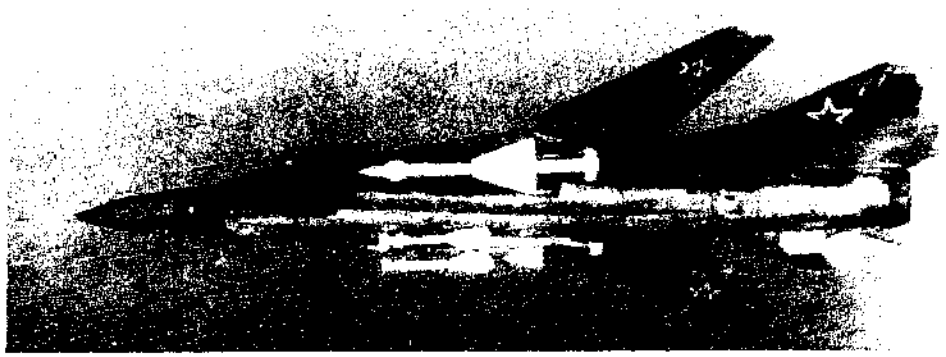
Ash is the NATO code-name assigned to large missiles carried beneath the wings of Soviet Tupolev Fiddler long-range interceptor aircraft. Four such missiles, which are assumed by Western observers to be air-to-air weapons, can be carried by each aircraft. Both I-band radar-guided and IR homing versions are in use, two radar homing missiles generally being carried on the wing outer pylons and two IR homing missiles on the inner pylons of the Fiddler interceptor.

Estimated dimensions are: length 530 cm, wing span 130 cm, diameter 30 cm. Cruciform wing and tail surfaces, in-line, are fitted, the former having a sharply swept delta planform. The tail fins have little sweep on either leading or trailing edges and are mounted close behing the wing trailing edges.

The size of the missiles, parent aircraft, and the large nose radome of the latter, suggests that they are intended for long-range interception. A British MoD report of April 1979 gave a figure of about 30 km as the range. It was also stated that some thousands had been produced.

STATUS

Ash has been reported in service with the forces of Bulgaria, Czechoslovakia, East Germany, Poland and Romania, in addition to the Soviet Union.



Radar and IR guided Ash air-to-air missiles on Soviet Fiddler aircraft

3338.331
APEX (AA-7) AIR-TO-AIR MISSILE

Apex, AA-7, is one of three later generation Soviet air-to-air missiles which became known in the West in 1976. Preceded slightly by the AA-6, Acrid, (**3337.331**) which was revealed in late 1975, Apex is comparable to the American Sparrow and is thought to be a successor to AA-3, Anab, (**1144.331**) to which there is some resemblance. However, Apex is clearly of superior performance and somewhat larger. In particular, the provision of a supplementary set of control surfaces at the rear of the missile, in addition to the canard fins ahead of the wings, indicates high manoeuvrability. A 'look-down', 'shoot down' capability against low-level targets is also claimed for this missile.

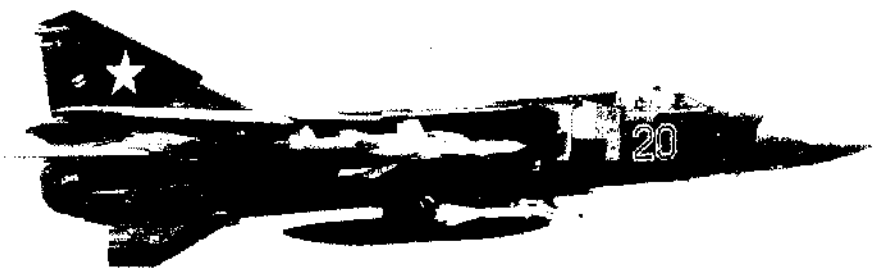
Both radar-guided and IR homing models have been reported, and the US Defence Intelligence Agency refers to AA-7a and AA-7b versions. One of each type comprises the standard armament of the interceptor version of the MiG-23 aircraft.

Estimated length of the radar version is about 4·3 metres, with the IR homing model slightly shorter. Weight is probably between 300 and 350 kg, of which the warhead could account for up to 40 kg. Solid propulsion is assumed, and ranges for the radar and IR versions are probably in the region of 35 km and 15 km, respectively.

Soviet MiG-23 Flogger B all-weather interceptor carries varied armament of air-to-air missiles with AA-7 Apex radar homing weapons on outer weapon pylons and smaller, IR guided AA-8 Aphid missiles on inboard stations

STATUS

Apex is used on MiG-21 and MiG-23 aircraft and is also carried on the MiG-25 Foxbat E.



3339.331
APHID (AA-8) AIR-TO-AIR MISSILE

Aphid, AA-8, is thought to be a small close combat air-to-air missile, possibly derived from the AA-2 Atoll (**1146.331**) although almost certainly a replacement for that weapon. It may be deployed with the MiG-23 Flogger aircraft, but if it is indeed an Atoll replacement, the list of aircraft types with which it can operate will be considerably longer.

Radar and IR homing models are reported to exist, but to date the only photographs seen are of what is assumed to be an IR guided version. Estimated length is about 2·1 metres for the radar version and slightly less for the IR model. Launch weight is about 54 kg, with a warhead of some 7 to 9 kg of the high explosive type. Probable range is about 8 km for the IR Aphid and rather more for the radar version.

STATUS

In use with MiG-23 Flogger and MiG-21 Fishbed aircraft. Soviet Navy carrier-borne Yak-36 Flogger aircraft have been noted carrying AA-8 Aphid missiles.

MiG-23 Flogger G armed with AA-7 and AA-8 air-to-air missiles

4768.331
AA-9 AIR-TO-AIR MISSILE

AA-9 is the numerical designation assigned by the US authorities to the air-to-air missile deployed with the sighted MiG-31 Foxhound interceptor aircraft entering Soviet service. According to US official sources, the AA-9 was designed for use with the MiG-31 specifically. This aircraft is reported to have a capacity of eight AA-9s. No NATO reporting name has been associated with the AA-9 missile at the time of publication, and neither have there been any official or unofficial details of the weapon's performance or physical characteristics published. The main function of the missile is understood to be long-range interception with, it is claimed, a 'snap-down' capability for engagement of low-flying targets which may or may not be cruise missiles. Until there is more information and some idea of the weapon's configuration and size, further conjecture at this stage is of dubious value.

4820.331
AA-10 AIR-TO-AIR MISSILE

The new missile designed for use with the recently introduced Soviet MiG-29 Fulcrum, and Su-27 Flanker combat aircraft has been assigned the number AA-10 in the US sequence. Very few details of the AA-10 have been made public, and no photographs have been obtained, but the official US view is that the weapon is a medium range air-to-air missile with similar capabilities to the AA-9 (**4768.331** above).

A DoD assessment of Soviet military resources states that the MiG-29 Fulcrum aircraft can carry six AA-10 missiles, and the larger Su-27 Flanker carries a similar load. A more detailed appraisal of the AA-10 must await more information and, ideally, photographic evidence.

US artist's impression of MiG-29 Fulcrum armed with AA-10 missiles and escorting a Backfire bomber

1144.331
ANAB (AA-3) AIR-TO-AIR MISSILE

Anab is the NATO code-name assigned to the Soviet air-to-air missile first seen carried by theYak-28 (Firebar) in 1961. It was subsequently seen on the Su-9 (Fishpot) interceptor, and is known to have been adopted as a standard weapon by the Soviet forces.

The existence of both I-band radar and IR homing versions has been reported. A radar system with which the AA-3 Anab has been employed is known within NATO by the code-name Skip Scan. Length of both versions is estimated at approximately 360 cm, diameter 28 cm, wing span 130 cm. Anab has a cylindrical body with a large cruciform wing assembly at the rear of the missile, and a set of four in-line fins ahead of the wings, and about one-quarter of the missile length from the nose end.

Solid fuel propulsion is assumed, and the range has been quoted by the UK MoD as in excess of 16 km. The same source also estimated total production as certainly in the thousands.

This weapon has been in operational use for a considerable time and it is reasonable to assume that it has been the subject of periodic improvements and updates in the same way as some long-life western counterparts have been modified.

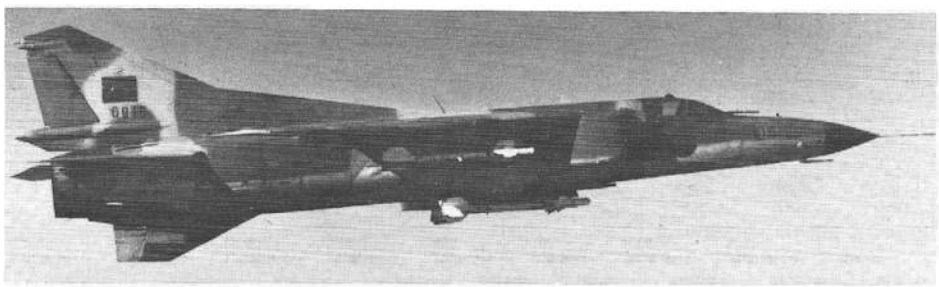
Yak-28P Firebar armed with AA-3 Anab air-to-air missile

STATUS

Believed to be in the process of withdrawal from Soviet forces, but this could take a considerable time to complete. In addition to the USSR, other nations supplied include Bulgaria, Czechoslovakia, East Germany, Hungary, Poland and Romania. Aircraft types which are, or have been associated with either or both versions of the AA-3 Anab include: Su-9 Fishpot, Su-15 Flagon, and Yak-28 Firebar.

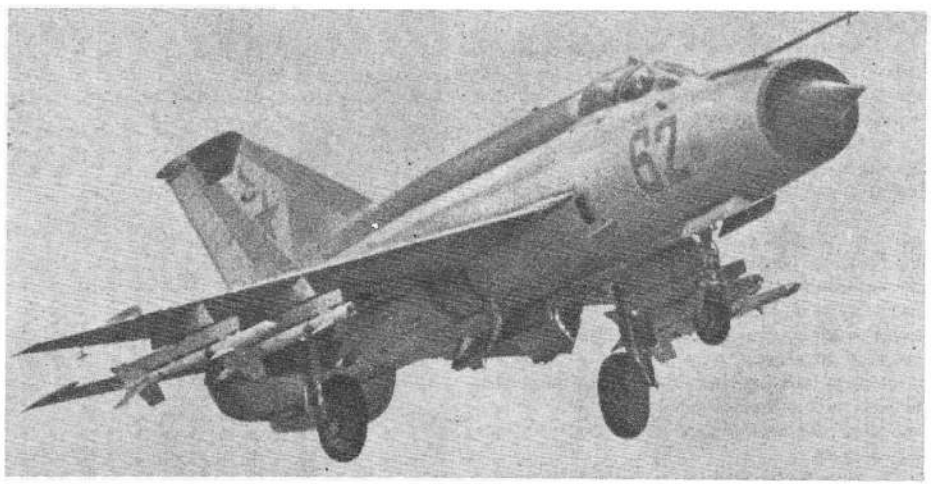
1146.331
ATOLL (AA-2) AIR-TO-AIR-MISSILE

Atoll is the NATO code-name assigned to a Soviet air-to-air missile, believed to bear the USSR designation SB06 and/or K13A.



This missile closely resembles the American AIM-9B, IR homing Sidewinder and is of similar dimensions and (estimated) weight. Atoll dimensions are: length 280 cm, diameter 12 cm, forward control surfaces span 45 cm, tail plane span 53 cm. The so-called Advanced Atoll, ie the semi-active radar homing model, is an estimated 30 cm longer than the IR guided versions, the extra length consisting of an extended nose section which is presumed to house the radar receiver and antenna package. Solid-propellant and conventional high explosive warhead are assumed.

Diametrically opposed pairs of the forward control surfaces are linked and work in unison for missile steering. The rear surfaces incorporate small tabs in which are inserted gyroscopic wheels driven by the airstream. It has been deduced that these are locked until after missile launch, and that their subsequent purpose is to provide additional stabilisation and/or a measure of control augmentation for missile steering.



STATUS

Atoll has been widely deployed with MiG-21 (Fishbed) interceptors of the Soviet home forces and on export versions of this aircraft. Known foreign users include Egypt and India. The latter country, which has over 50 MiG-21s, has facilities for Atoll production under licence.

In addition to the Warsaw Pact countries, there is an impressive list of foreign users which includes: Afghanistan, Algeria, China, Cuba, Egypt, Finland, India, Iraq, North Korea, Syria, and Viet-Nam, and the full list of non-Soviet operators of Atoll is thought to number 20 or more countries. In addition to the Indian licence-built version, there is also an indigenous Chinese model.

Libyan MiG-23 Flogger E armed with four standard AA-2 Atoll IR homing air-to-air missiles (USN)

MiG-21 Fishbed interceptor is armed with both standard IR homing AA-2 Atoll air-to-air missile and radar guided Advanced Atoll (on outer wing weapon stations)

It is now thought to be obsolescent with Soviet air forces, probably to be replaced by the AA-8 Aphid (**3339.331**).

UNITED KINGDOM

1774.331
SKY FLASH AIR-TO-AIR MISSILE

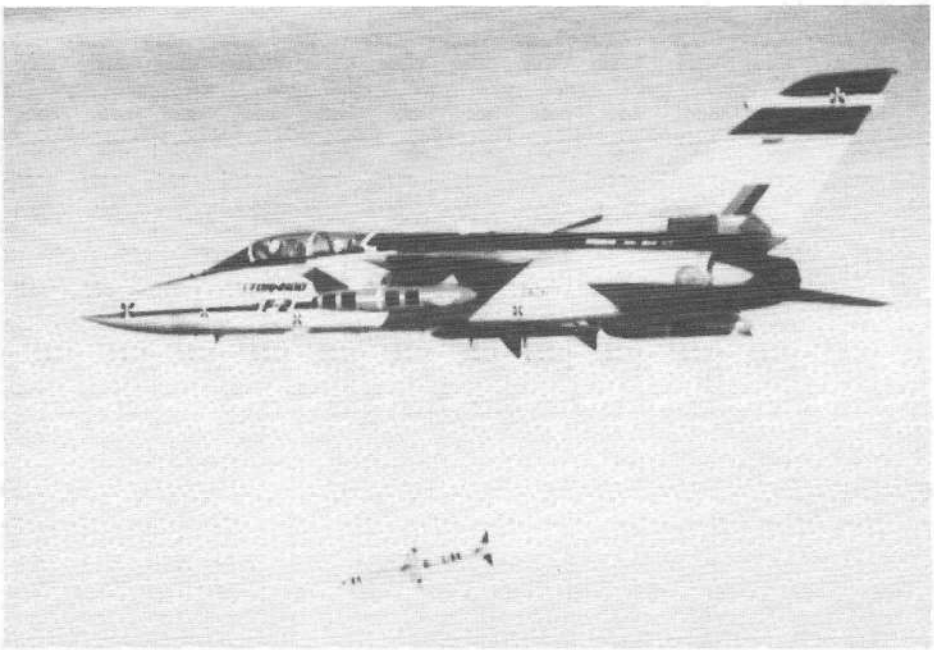
Sky Flash, formerly known as Project XJ521, is a medium range all-weather air-to-air missile based on the Raytheon Sparrow missile but with a completely new electronics suite and of considerably improved performance. It is a semi-active radar guided missile capable of attacking both subsonic and supersonic targets from very low to high altitudes and has an all-round attack capability. It employs a new advanced guidance system developed by Marconi Defence Systems at Stanmore, Middlesex, and a new advanced fuze system developed by Thorn EMI Electronics Ltd, at Hayes, Middlesex. The MDS seeker employs the monopulse technique which provides very high resistance to ECM. The missile has a snap-up capability which allows launches from low levels (100 metres or less) to intercept high altitude targets; a complementary snap-down facility enables targets to be engaged from above against a background of ground clutter. The autopilot and power systems have been updated by British Aerospace Dynamics Group to include solid-state electronics and thermal batteries. BAe also manufactures the missile structure and carries out final assembly and testing of the complete weapon.

CHARACTERISTICS

Length: 3·7 m
Wing span: 1·02 m
Diameter: 203 mm
Weight: 192 kg
Range: 40 km
Guidance: Semi-active radar, monopulse
Warhead: 30 kg
Fuze: Radar proximity
Propulsion: Solid Aerojet Mk 52 Mod 2

DEVELOPMENT

In mid-1985 details emerged of a potential Swedish/UK collaborative project to develop a new version known provisionally as Sky Flash 90. A major difference would be the adoption of an active radar homing head, to be developed by MDS, and the current Aerojet propulsion motor would be replaced by a higher performance unit called Hoopoe produced by Royal Ordnance. Swedish interest in the project is related to the RSAF JAS 39 Gripen combat aircraft.



STATUS

Project definition was completed in 1973 with the development programme following immediately. A contract for full production was awarded by the MoD in 1975.

R & D and RAF evaluation trials were completed in 1977. These trials entailed a variety of attack

situations and were completed successfully. Several firings of the non-warheaded missiles produced direct hits and others passed within lethal miss distance of targets.

Targets were representative of a range of hostile aircraft and some were enhanced to produce severe glint and thus pose a severe test of the accuracy of the missile's guidance. Firings were also made against targets with only a small echoing area, and others in exacting ECM and target manoeuvring conditions and against multiple targets. Targets were engaged successfully at near sea level and also at high altitude in snap down, snap up, level and manoeuvring attacks.

Sky Flash firing from Tornado F2

In December 1978 a £60 million contract with the Swedish Forsvarets Materielverk for the supply of Sky Flash missiles to arm RSAF JA37 Viggen all-weather fighter aircraft was confirmed. This follows a two-year integration programme and deliveries of the Sky Flash (Swedish designation, RB71) began in the third quarter of 1980. In the course of the JA37 integration programme, and during routine RAF squadron practice firing, the weapon's high performance obtained in evaluation trials was confirmed.

In December 1983 BAe announced the successful conclusion of a reliability verification and firing programme for the Swedish authorities. At the same time it was revealed that the BAe Lostock plant had completed the 1000th Sky Flash missile.

Sky Flash is in service with RAF Phantoms and will be used with the Tornado F2, from which it has been fired. It has also been fired successfully from the F-16.

CONTRACTORS

Prime contractor: British Aerospace Dynamics Group, Manor Road, Hatfield, Hertfordshire AL10 9LL, England.

Homing head: Marconi Defence Systems Ltd, The Grove, Warren Lane, Stanmore, Middlesex HA7 4LY, England.

Fuze: Thorn EMI Electronics Ltd, Springfield Road, Hayes, Middlesex UB4 OLJ, England.

Main sub-contractor: Raytheon Company, Missile Systems Division, Bedford, Massachusetts 01730, USA.

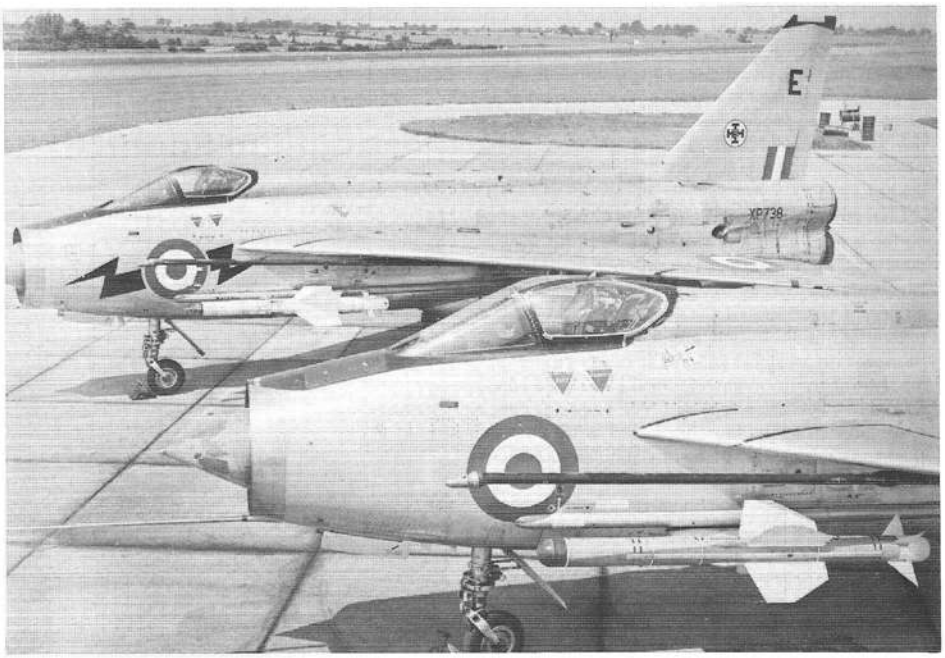
1080.331

RED TOP AIR-TO-AIR MISSILE

IR homing air-to-air weapon for use against sub- and supersonic aircraft. All-altitude operation is possible against manoeuvring targets and all-aspect attack capabiity is provided by the Red Top homing and guidance system.

At one time referred to as Firestreak Mk IV (**1079.331** in 1980-81 and earlier editions), Red Top has a similar configuration and dimensions of the same order, but performance is considerably higher as a result of the application of advances in technology.

Red Top retains the configuration of four fixed wings and four moving rear control surfaces. Wing and control surface planforms and sections differ from those of Firestreak, and match the unofficially quoted speed of Mach 3. The IR guidance system has been further developed to allow target interception from virtually any direction, and a hemispherical nose houses the IR sensor.



Internally, the warhead (31 kg) has been moved forward next to the fuzing system, and the control actuators have been located nearer to the surfaces they operate.

The power of the internal solid propellant booster rocket motor provides a range of at least 12 km.

Missile dimensions are length 3·27 metres, diameter 22·2 cm, wing span 90·8 cm. Up to four missiles can be carried without significant detriment to aircraft performance.

STATUS

Red Top is still available for service with RAF Lightnings and with aircraft of this type flown by the Kuwaiti and Saudi Arabian Air Forces, but should be regarded as obsolescent.

RAF Lightning interceptors carrying Firestreak (upper) and Red Top (lower) air-to-air missile

UNITED STATES OF AMERICA

4186.331

ASAT ANTI-SATELLITE WEAPON

Funded under the heading of Space Defence Operations (PE12450F), the US Air Force is developing a prototype miniature air-launched system (PMALS) to meet a need foreseen for an aircraft-launched anti-satellite (ASAT) capability. This need is justified in the DoD Fiscal Year 1982 Report of January 1981 as being necessary in the absence of agreements limiting the use of space to peaceful purposes but while facing a previously tested Soviet ASAT system. Under these circumstances, it was stated, the US President (Carter) directed that vigorous efforts to develop a US ASAT should be undertaken.

Despite this, it is understood that the three main contractors now engaged on this task were already working on this problem, and had been for a considerable period. Boeing for instance is believed to have been occupied in this way since 1975, or earlier, part of the time under contract to Vought. Both these concerns are collaborating with a third, McDonnell Aircraft, in the development and testing of an advanced technology interceptor missile capable of being launched from an F-15 fighter aircraft. The latter is required to be capable of preparation for the ASAT mission from the standard 'line' configuration in six hours or less.

The weapon envisaged for the PMALS tests comprises a first stage based on the Boeing SRAM (**1107.311**) short-range attack missile, an Altair III second stage provided by Vought and a miniature vehicle warhead terminal stage, also a Vought responsibility. McDonnell is modifying the F-15 for the ASAT role, including provisions for housing the 'carrier aircraft equipment' (CAE) package in the F-15's weapons bay. Guidance algorithms for the aircraft, launch and missile initiating procedure will be stored in the F-15 aircraft computer, and the F-15's head-up display will be employed to provide steering cues to the pilot for launching the ASAT weapon. The SRAM-based first stage is being modified by Boeing to carry the Altair III second stage, the basic SRAM having a range of between 60 and 160 km depending on the flight profile etc, at speeds of Mach 3 or more, under inertial guidance and carrying a very respectable payload. No details have been released on the Vought Altair III second stage vehicle beyond

the fact that it is the fourth stage propulsion unit of the Vought-built Scout space launch vehicle.

The prototype vehicle resembles a conventional tactical missile about 5·4 metres long and between 40 and 50 cm in diameter. Weight has been estimated at about 1200 kg, of which the miniature homing vehicle payload is believed to account for some 16 kg.

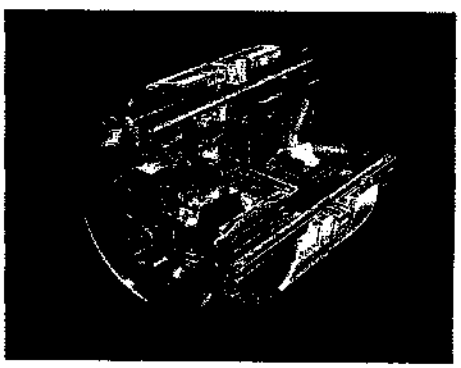
The satellite 'kill' mechanism has not been disclosed but the possibility of the ASAT terminal stage making a direct hit on the target has been reported; this is one aspect that may be assumed to be a major aspect of the experimental development programme for ASAT.

STATUS

Preliminary work by ASAT contractors is thought to have started in the 1970s. Vought was awarded a four-year $268 million contract in late 1980 for ASAT development, and Boeing reported its work during 1980 to be worth $6·7 million.

A Space Defence Operations Centre (SPADOC) was established at the NORAD Cheyenne Mountain Complex in 1979/80 to provide command, control and communications to manage space defence operations. This is being modified to handle ASAT operations and these changes are being carried out with hardware and software developments on a schedule to suit ASAT tests.

In June 1983 it was reported that the US Air Force 318th fighter/interceptor squadron, based at McChord AFB, Washington, was being re-equipped with F-15 aircraft (replacing F-106s) to operate ASAT weapons. The first F-15 was handed over in June 1983. The first test flight launch took place in January 1984.



In November 1984 the US Air Force conducted an infra-red probe test of the booster, booster guidance system and miniature vehicle flight sensor using a star as the infra-red source. The ASAT missile was launched from an F-15 which took off from Edwards AFB, California. The test was conducted in air space over the Western Test Range at Vandenburg AFB, California.

Cut-away drawing of ASAT Miniature Vehicle

F-15 Eagle aircraft carrying ASAT missile

1085.331

FALCON (AIM-4D) AIR-TO-AIR MISSILE

This is a lightweight air-to-air missile similar in size and configuration to the AIM-4C but equipped with the improved IR homing head of the larger AIM-4G Super Falcon. This gives better performance against high-speed manoeuvring targets and confers all-aspect attack capability. Principal characteristics are: length 198 cm, diameter 16·25 cm, wing span 50·8 cm, weight about 60 kg, solid fuel motor, high-explosive warhead, speed Mach 4.

DEVELOPMENT

Chronologically, development of the AIM-4D took place after that of other members of the Falcon series, such as AIM-4E, F, and G (which see) and its former designation was GAR-2B. As air defence missiles, earlier Falcon versions were designed for the interception of bomber aircraft. AIM-4D development was undertaken to improve performance sufficiently for the engagement of enemy fighter aircraft. This was undertaken under a joint US Air Force/Hughes programme.

STATUS

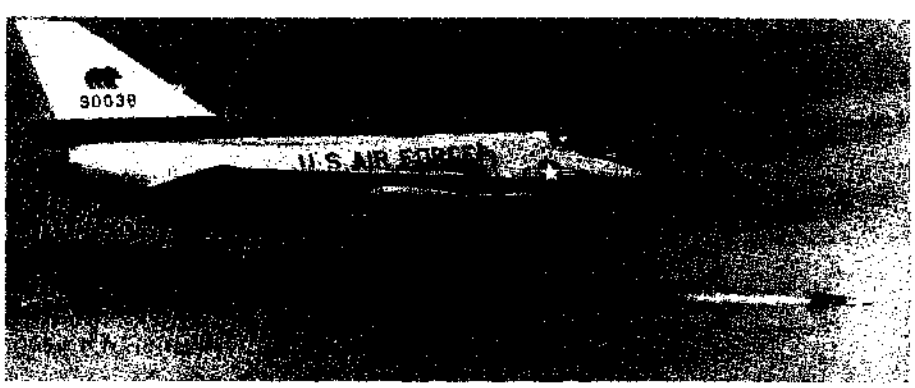
AIM-4D was used by the US Air Force Tactical Air Command and Air Defence Command, and was carried by F-4, F-101 and F-102 aircraft types. Thousands of AIM-4B and C Falcons were converted to AIM-4D standard.

It is currently carried by CF-101 interceptors of the Royal Canadian Air Force and on Japanese Air Self-Defence F-4J tactical aircraft.

A similar version, known as the HM-58 has been built under licence in Sweden, where it bears the designation RB28.

CONTRACTOR

Hughes Aircraft Company, Canoga Park, California 91304, USA.



1086.331

SUPER FALCON (AIM-4E/F) AIR-TO-AIR MISSILE

This missile represents an interim stage in the development of the Falcon series, coming between the AIM-4A and C and the AIM-4F and AIM-4G models. In general configuration the AIM-4E more closely resembles the AIM-4F.

This was equipped with an improved radar guidance system providing increased accuracy and greater resistance to ECM. A new solid fuel, two-level thrust rocket motor was installed to provide a high launching thrust followed by a lower level thrust to sustain missile velocity.

Guidance is by semi-active radar homing as in the AIM-4A. The AIM-4E was powered by a longer burning solid fuel rocket motor to provide longer range, a higher launching speed, and a higher combat ceiling than earlier models. A more powerful high explosive warhead was also fitted. Only about 300 models of this version were produced before being succeeded by the later variant, the AIM-4F. The wings are extended forward by fillets, and weight and dimensions are slightly increased to: length 218·4 cm, diameter 16·5 cm, wing span 60·9 cm, weight about 63·5 kg, in the case of the AIM-4E, and length 218·4 cm, diameter 16·7 cm, wing span 60·9 cm, weight 68 kg, for the AIM-4F. Speed of the AIM-4F is in excess of Mach 3.

California Air National Guard F-106 fires a radar-guided AIM-4F Falcon missile during firing practice

DEVELOPMENT

The AIM-4E was originally developed as the GAR-3 and was introduced in 1958. It was succeeded two years later, after 300 units had been produced, by the AIM-4F (formerly GAR-3A).

STATUS

Aircraft equipped include the F-106 Delta Dart interceptor.

CONTRACTOR

Hughes Aircraft Company, Canoga Park, California 91304, USA.

1087.331
SUPER FALCON (AIM-4G) AIR-TO-AIR MISSILE

The AIM-4G Super Falcon is the IR seeking counterpart of the AIM-4F missile. It is equipped with an IR detector system which enables it to lock-on to smaller targets at greater ranges than earlier Hughes IR missiles. The same seeker is used in the AIM-4D Falcon. Compared with the AIM-4F Super Falcon, the AIM-4G is shorter (105·7 cm) and weighs slightly less (65·7 kg). A high-explosive warhead is fitted. Unofficial weight is 128 kg, and speed Mach 3.

DEVELOPMENT

The AIM-4G was developed under the original designation GAR-4A, in parallel with the GAR-3A (AIM-4F). It was introduced in 1959-60.

STATUS

The AIM-4G is carried in mixed loads with the AIM-4F in the US Air Force and US Air National Guard F-106s.

CONTRACTOR

Hughes Aircraft Company, Canoga Park, California 91304, USA.

1099.331
PHOENIX (AIM-54A) AIR-TO-AIR MISSILE

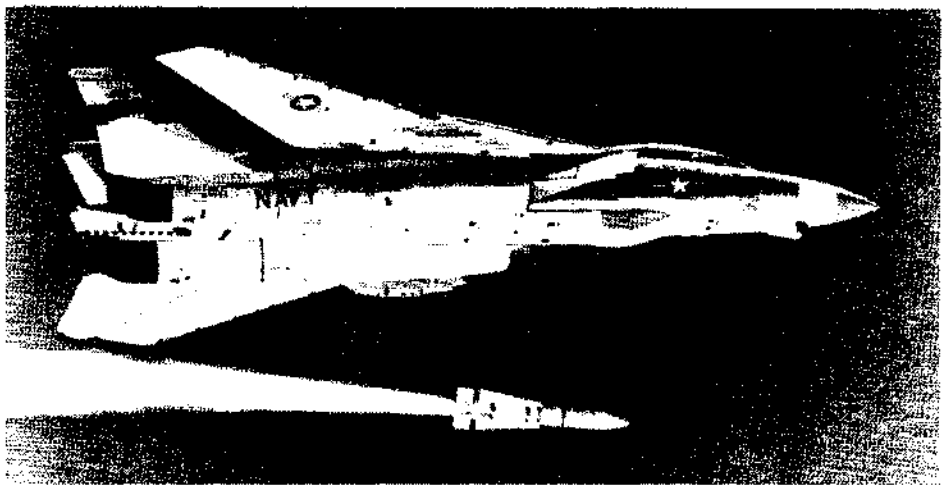
This is a long-range, high performance air-to-air weapon, now in use with US Navy F-14 Tomcat interceptor aircraft. Officially issued characteristics include: length 396 cm, diameter 38 cm, wing span 91·4 cm, weight 380 kg, radar homing, and a Mk 47 Mod 0 solid-propellant rocket motor by North American Rockwell Rocketdyne Division. Estimated range is between 60 and 90 nautical miles (110 to 165 km).

The complete Phoenix weapon system consists of the Hughes AWG-9 fire control and armament system – also referred to as WCS (weapon control system) – and the AIM-54, AIM-7 and AIM-9 missiles, together with the M61 Vulcan 20 mm cannon. The following paragraphs are concerned with the AIM-54 Phoenix missile, details of the other missiles (Sparrow and Sidewinder) will be found elsewhere in this section of *Jane's Weapon Systems*.

OPERATION

During the cruise phase of missile flight, Phoenix guidance is by sample data, semi-active radar homing, the AWG-9 serving as target illuminator.

The Phoenix missile incorporates a small doppler radar transmitter which is switched on to provide target illumination during the terminal guidance phase and in short-range engagements.



The AWG-9 can launch up to six missiles simultaneously against six separate targets, and the AIM-54's principal operational role is to attack enemy bombers at long range before they are able to launch cruise missiles against ship targets.

DEVELOPMENT

The Phoenix concept was initiated in 1960 and Hughes was selected as prime contractor by the US Navy in 1962. Flight testing began in 1965, and the first successful intercept was in September 1966. The simultaneous attack capability was demonstrated in March 1969 when two drones were successfully engaged.

Phoenix procurement was initiated during fiscal year 1971. F-14 flight trials started in April 1972, and in December of that year four jet drone targets were successfully engaged by four Phoenix missiles launched and directed by the AWG-9 system of an F-14 Tomcat.

The current and projected threat for the 1980-90 period includes platforms and weapons not originally considered, all of which may be encountered in a severe ECM environment. To meet these threats the US Navy initiated development of an improved Phoenix (AIM-54C) and the first of 15 engineering development models was delivered to the US Navy Pacific Missile Test Centre at Point Mugu, California, in August 1979.

Third engineering model of improved AIM-54C Phoenix air-to-air missile after launch from US Navy F-14 Tomcat over Pacific Missile Range

The Phoenix improvement programme involves a new programmable digital signal processor, a digital autopilot with a strap-down inertial reference for the missile, and a solid-state transmitter/receiver for the active radar terminal guidance mode. The digital signal processor will perform many autopilot functions, offering expanded high-altitude performance capacity for increased ECCM logic, flexibility for the future, and an increase in reliability by using fewer parts. The mechanical flipper actuators and servo amplifier functions are not changed. The Naval Weapons Centre at China Lake, California, also developed a new target detecting device, and the US Navy is finding out the possibility of fitting the AIM-54C with a new warhead and fuze.

STATUS

The first Phoenix units were operational by spring 1974.

In the course of fiscal year 1977, the Phoenix Improvement Programme was started to improve the reliability and performance capability of the missile to cope with the projected threats of the 1990s.

In 1978, under a $41 million contract, Hughes developed a new digital electronics unit, a solid-state transmitter/receiver, and a digital autopilot for the improved Phoenix. In addition, the US Naval Weapons Centre at China Lake has developed a new target detection device for the AIM-54C.

The first AIM-54C engineering development model was delivered in August 1979, one of 15 ordered. Between mid-1981 and early 1982, 30 pilot production AIM-54C missiles were delivered to the US Navy for captive flight, technical evaluation and operational testing.

Fifteen engineering model AIM-54C missiles were delivered between August 1979 and June 1981, and delivery of the first production model was made on schedule in October 1981. The missile has successfully completed the contractor development and US Navy Technical Evaluation Launch programmes, and in 1984 was undergoing a US Navy Operational Evaluation. In early 1985 flight tests began in connection with a further enhancement of Phoenix. This programme will integrate the 'sealed' AIM-54C Phoenix missile with US Navy F-14A and F-14D fighter aircraft and ensure compatibility. A major feature of the sealed Phoenix is the addition of internal heaters that eliminate the need for the F-14D to provide the missile with temperature conditioning liquid prior to launch. The US Secretary of Defense, in his 1986 Report to Congress revealed procurement plans for Phoenix missiles for fiscal years 1984-87, as follows, with quantities in brackets and funding in millions of dollars: 1984 – (265) $332·8; 1985 – (265) $365·7; 1986 – (265) $393·5; 1987 – (420) $542·8.

Prime contractor, missile, AN/AWG-9, and LAU-48 launcher: Hughes Aircraft Company, El Segundo, California 90245, USA.

Motor: North American Rockwell.

Motor, second source: Aerojet General Corporation.

Mk 334 proximity fuze: Downey Plant.

AWG-9 computer: Control Data Corporation.

4767.331
SIDEWINDER (AIM-9) AIR-TO-AIR MISSILE FAMILY

The family of air-to-air missiles that evolved from the original AIM-9B weapon developed by the US Navy in the 1950s is now an extensive one comprising numerous versions, with the latest model having the designation AIM-9P. Most of the earlier variants have been described and/or illustrated individually in previous editions of this book under various entry numbers from **1103.331** to **3812.331**. (All previous entries for Sidewinder are included in the Numerical List of Entries at the back of this volume.) The entry that follows is an attempt to summarise the main elements of the evolution of this successful and widely used missile.

The principal Sidewinder models that have been produced in significant quantities are:

AIM-9B

First model to be extensively deployed by US Navy and Air Force. More than 40 000 examples produced by Ford Aerospace, who also upgraded more than 10 000 Sidewinder guidance and control sections.

AIM-9D

Almost 1000 produced for the US Navy. Has guidance and control section improvements to allow expanded engagement envelope.

AIM-9E

Designation of modified AIM-9Bs with new seeker for US Air Force. About 5000 produced.

AIM-9H

Solid state electronics in guidance and control section for higher performance and manoeuvrability. More than 3000 supplied to US Navy.

AIM-9J

Major modifications to AIM-9E seeker servo and electronics for increased performance. About 7600 produced using kits supplied by Ford Aerospace.

AIM-9L

Used by US Navy and Air Force and extensively exported. Has all aspect engagement capability. 5500 guidance and control sections produced by Ford Aerospace for US programme.

AIM-9M

Most advanced model in production for US Navy and US Air Force. Improved guidance performance in the tactical combat environment.

AIM-9B Sidewinder air-to-air missile mounted on wing of F-104A Starfighter

AIM-9N

Formerly the AIM-9J1, which was the result of a major change in the AIM-9J electronics. Approximately 7000 produced.

AIM-9P

More than 21 000 examples produced for US forces and export, either as reworked AIM-9B/E/J models or as new manufacture. Incorporates improved guidance, an active optical fuze and an improved rocket motor. Ford Aerospace is engaged on a further improvement programme and this is currently known as the Improved AIM-9P, which has increased IR acquisition and guidance performance and optimised fuze design.

DEVELOPMENT

The AIM-9A was the prototype of the Sidewinder and was first fired successfully in September 1953. The first production version (AIM-9B) joined the US Air Force in 1956, but has some limitations in use (inability to engage targets close to the ground or head on, for example). Subsequent versions eliminated these shortcomings, and most 'B' models were later upgraded to the 'E' or AIM-9P status. Some AIM-9Bs were equipped with reduced smoke rocket motors and used for special missions or training roles, these being designated AIM-9B-2.

The AIM-9E has an improved guidance and control system and the rounded nose of the AIM-9B is replaced with a more sharply tapered nose cone. Some of these were given the reduced smoke rocket motor and were designated AIM-9E-2. This model has been in the US Air Force inventory since 1967.

The AIM-9J modification of the AIM-9B/E, with greater manoeuvring capability, higher speed and increased range, was first issued in 1977 to equip the F-15 and other Sidewinder compatible aircraft.

Production of the AIM-9L began in 1976. This has a more powerful motor, improved tracking and manoeuvring ability. A more advanced active optical fuze increases missile lethality and resistance to ECM. An FM-AM conical scan pattern increases seeker sensitivity and gives better tracking stability. This is the first model Sidewinder with the ability to attack from all angles, including head on. The AIM-9M was also in production in 1982, and this model has the all round capability of the AIM-9L, plus higher performance and increased resistance to IR countermeasures.

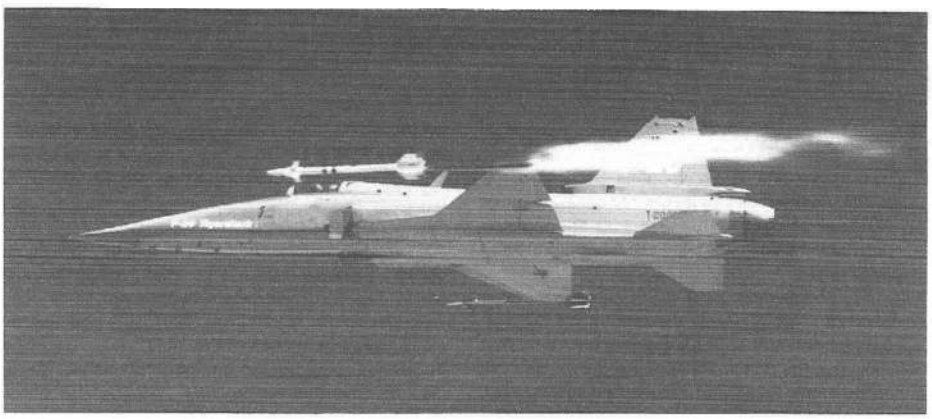
The AIM-9P is an upgraded version of the AIM-9J which enable targets to be engaged at longer ranges, and deliveries of this model began in 1978. The AIM-9P-1 has an active optical target detector instead of the IR influence fuze; the AIM-9P-2 has a reduced smoke rocket motor; and the latest version AIM-9P-3 has both the above modifications.

The characteristics in the following table apply to the AIM-9L model.

CHARACTERISTICS

Length: 2·87 m
Diameter: 12·7 cm
Fin span: 619 mm
Launch weight: 86·1 kg
Guidance: IR homing
Warhead: Annular blast fragmentation HE
Power plant: Mk 36 Mod 7/8 solid propellant rocket

STATUS



The 1985 report of the US Secretary of Defense indicated funding (in $millions) for the following quantities of Sidewinder missiles in fiscal years 1983 to 86: 83-2420 ($141·2); 84-2050 ($135·6); 85-1000 ($71·2); and 86-1220 ($92·6). In addition to US production for US forces and certain export contracts, a European consortium led by the Federal Republic of Germany and including Italy, Norway and the UK has been created to manufacture the AIM-9L for their own use.

SPARROW III (AIM-7E/F and AIM/RIM-7M) AIR-TO-AIR AND SURFACE-TO-AIR MISSILE

The Sparrow missile is one of the most widely-used US weapons. Its versatility has been demonstrated in surface-to-air applications in addition to its original role as an air-to-air missile. The present production version, the AIM/RIM-7M is the fifth model of the Sparrow III family which includes the AIM-7C, E and F models.

The AIM-7E and F are still in the operational inventory of the US Air Force, US Navy and several allied nations. A variant of the AIM-7E designated the RIM-7E-5 is used in the surface-to-air role in the US Navy's Basic Point Defence System. Another AIM-7E variant, the RIM-7H-5, is used in the NATO Sea Sparrow Surface Missile System. The RIM-7H-5 has folding wings and clipped fins to reduce the size and weight of the deck launcher/containers.

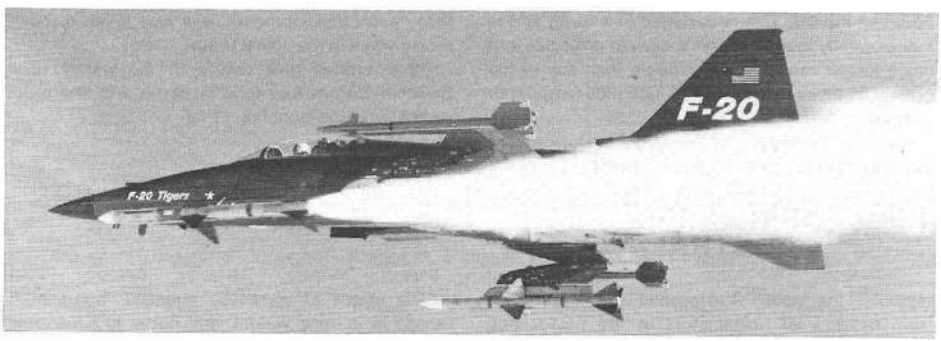
The Sparrow AIM-7F is a medium-range, all-weather, all-aspect, semi-active guided missile that is compatible with both CW and pulse doppler illumination. The AIM-7F is similar in external appearance to earlier Sparrow missiles. It is 3·6 metres long and 0·2 metre in diameter. The AIM-7F has a wingspan of 1 metre, a tailspan of 0·8 metre and a total weight of 228 kg.

It features a more powerful rocket motor that provides both extended range and faster speed to intercept, an improved 40 kg continuous rod warhead that is triggered by either contact or proximity fuzes, and greatly increased lethality. An all solid-state seeker provides greater sensitivity and reliability and permits snap starting the missile in less than two seconds.

After a competitive flyoff with General Dynamics, Raytheon was awarded a contract in 1978 for the full-scale development of the AIM/RIM-7M Sparrow missile. This development, now complete, has provided an inverse monopulse seeker that includes a digital signal processor, a new autopilot and a new fuze. The results are performance improvements in seeker sensitivity that permit picking out targets from the heavy clutter in look-down, shoot-down environments. It also provides greater immunity to the growing and changing countermeasures threat. The design features isolation mounting, reduced parts count and built-in test, which contribute to improvements in reliability and maintainability. The AIM/RIM-7M is a common missile with all-weather, all-aspect capability in both air-to-air and surface-to-air applications.

The AIM-7M has the same outside dimensions as the AIM-7F but features a monopulse seeker head which provides improved performance in natural clutter or ECM. The RIM-7M version, by adding the folding wings and clipped tail fins will be compatible with the NATO Sea Sparrow launcher.

The digital processor which controls the AIM/RIM-7M is reprogrammable as the ECM threat changes and offers potential for further growth in missile capability.



STATUS

The AIM/RIM-7M is in full rate production and began entry into active US Air Force and US Navy service inventories in 1983. Current US procurement plans call for the US Air Force and US Navy to be equipped with more than 14 000 AIM/RIM-7M missiles. Initial deliveries began in 1982.

UNDERWATER WARFARE SYSTEMS

In this section will be found information on those weapons concerned primarily with underwater targets (submarines) or which operate in the underwater environment for the major portion of their functional life (torpedoes). Under the US heading details will also be found of undersea surveillance projects.

Related entries will be found later in the Systems Section (Naval Fire Control Systems) and in the Equipment Section (Sonar and Underwater Detection).

Anti-submarine Torpedoes

The torpedo is a major anti-submarine weapon. It may be launched directly from a torpedo tube on a surface vessel or submarine, from a drone or missile launched from a ship, or from a manned aircraft or helicopter. All available information on torpedoes will be found in this section, and torpedo fire control systems will be found elsewhere in the Systems Section.

Drones and Missiles

Drone torpedo-launchers and torpedo-carrying missiles are also dealt with in the Systems Section. Their names and reference data are listed below.

Name	*Entry No*	*Country*
Asroc	**6001.241**	USA
ASW-SOW	**4181.441**	USA
FRAS-1	**3968.241**	USSR
Ikara	**6002.241**	Australia
Malafon	**1179.241**	France
SS-N-14	**3969.241**	USSR
SS-N-15	**3970.441**	USSR
SS-N-16	**3970.441**	USSR
Subroc	**1128.441**	USA

Of these it should be noted that Asroc has a dual role – as a carrier of either an A/S torpedo or a depth charge. The submarine-launched missile Subroc (**1128.441**) is not at present a torpedo carrier but implementation of the new US ASW-SOW (combined anti-submarine warfare stanoff weapon programme) (**4181.441**) will remedy this deficiency as a homing torpedo is under consideration as one of the probable payloads planned for this new weapon.

The details of the Soviet weapons, because of the usual lack of direct evidence, should be regarded as provisional although the information given is considered to be accurate within these constraints.

Depth Charges

Relatively simple cylindrical depth charges that can be rolled or catapulted into the sea are the longest-established anti-submarine weapons: they were first used by the RN in the First World War. They are generally depth-fuzed and have a low sinking rate, thus giving the launching vessel time to get clear. They are still used extensively by many navies: a typical weight of the depth charge is 150 kg and a launcher can project the charge up to about 150 m.

Depth Charge Mortars

Towards the end of the Second World War a more streamlined type of depth charge with a higher rate of sinking was introduced by the RN and subsequently other navies. The intention was to project charges ahead of an attacking ship so that they could be fired more accurately while still in sonar contact, otherwise lost when the attacking ship ran over the submarine to deliver conventional depth charges. Such mortars have been developed in several countries, Squid (**6007.241**) and Limbo (**6008.241**) in the UK being two examples and the Italian Menon being a third. The Menon launcher, which exists in three- and six-barrelled forms, is notable for the length of its tubes and has a range of about 1500 m compared with 350 to 1000 m for the two British devices. A single-barrel mortar is fitted on some Italian frigates and corvettes. This is said to have a range of about 1000 m and a rate of fire of 15 DCs/minute.

Another weapon in this category is the French four-barrelled mortar. This is mounted in a turret and is automatically loaded. It fires a heavier projectile and has a longer range (about 2750 m) than any of the others. All these mortars fire 12 inch (305 mm) depth charges.

It is believed that the Soviet Navy has not adopted the streamlined form of depth charge. They do, however, use depth charge mortars, but it is thought possible that they use compressed air to propel the charge whereas other countries use an explosive cartridge.

Nuclear Depth Charges

Also introduced by the USN is the nuclear depth charge. To take this clear of the launch vessel a rocket is required, and these depth charges have so far been associated only with Asroc (**6001.241**) and Subroc (**1128.441**), but the ASW-SOW (**4181.441**) now being developed is expected to include nuclear depth charges as an optional payload.

Multiple Short-range Rocket Launchers

Another British innovation of the Second World War was the multiple launcher for small (about 25 kg) rockets with impact fuzes. Devices of this nature are widely used by many navies and are commonly known by the name Hedgehog, which was applied to the first US 24-rocket launcher, even though they may not be of identical design. The modern American Hedgehog (which has been considerably elaborated since it was first introduced) has a range of about 350 m; a smaller eight-rocket device known as Mousetrap has a range of about 200 m.

Medium-range Rocket Launchers

One of the most widely adopted developments of the years since the Second World War has been the medium-range (300 to 3600 m) anti-submarine rocket launcher. Brief details of the French system (**2057.241**) and the Swedish system (**6021.241**), on which the French system is based, are given, and although it differs in some important respects from these systems, the Norwegian Terne system (**6022.241**) is in this general weapon category. The USN has also developed systems of this kind, the current one being known as Weapon Alfa, successor to Weapon Able. Many such developments have also taken place in recent years in the Soviet Union.

Other entries give details of the widely used Swedish Bofors four-tube launcher and the more recent two-tube launcher.

AUSTRALIA

2018.241
ANTI-SUBMARINE MORTAR SYSTEM

An improved version of the AS Mk 10 (Limbo) anti-submarine mortar system (**6008.241**) has been developed in Australia. The design of the Limbo system dates from about 1955 and technological advances since then made it possible to overcome certain disadvantages of the system. In particular, the new development eliminates the use of rotating electric machinery in the pitch and roll servo loops – with consequent saving in power, deck-level weight, and noise – to reduce the weight and noise level of the loading mechanisms (pneumatic for Limbo) and to eliminate the mechanical problems that can arise from the use of uniselectors in the fuze-setting system.

In the new design the metadyne servo control system for pitch and roll has been replaced by an electric system using silicon-controlled rectifiers to control the launcher drive motors; the pneumatic rammer has been replaced by a smaller and lighter electrical device, and the fuze setting system has been redesigned to use solid-state logic circuits with which have been incorporated additional supervisory circuits that permit checking of the setting before launching.

One effect of all these changes, apart from reduction in cost, weight, and noise, is a manning reduction from seven to three.

STATUS

All production equipments have been delivered to the Royal Australian Navy.

IKARA ANTI-SUBMARINE WEAPON SYSTEM

The concept of Ikara is the employment of a guided missile to deliver an anti-submarine homing torpedo to the target submarine. The missile is launched from a surface ship which uses a computer to calculate the torpedo dropping position. Target information from the firing ship's own sonar, or via a remote radio linked source, together with information regarding the in-flight position of the missile and other data such as ship's posit on, wind, etc are processed by the computer to maximise kill potential.

The guidance system ensures that the missile flies to the continuously updated optimum dropping position.

After release from the Ikara vehicle, a lightweight anti-submarine torpedo such as the Mk 44 or Mk 46 descends by parachute. When the torpedo reaches the sea the parachute is discarded and the torpedo carries out a homing attack on the target submarine.

In 1982 a number of additional optional torpedo payloads was announced; these included the British Stingray, Swedish TP42, Italian A244/S and Japanese Type 73.

The Ikara vehicle is 3·42 m long, has a wing span of 1·52 m and an overall height of 1·57 m, and the main structural strength is provided by the two-stage Murawa combined boost and sustainer rocket motor that powers it. Flight speed is high subsonic and maximum range is estimated to be about 20 km. In previous versions of the system Ikara is launched at a fixed elevation of 55°, generally from a trainable launcher, but in 1982 a 'boxed' version of the system was revealed in which Ikara vehicles are carried in individual container/launchers which are bolted to the ship's deck.

OPERATION

Ikara is capable of attacking enemy submarines out to the maximum range of the ship's sonar regardless of the weather conditions.

Target information from the ship's long-range sonar is fed into a computer which calculates the dropping position, taking into account such factors as ship's own course and speed, wind effect and target movement during time of flight. The outputs from the computer are passed to the missile via the guidance system, a ship-mounted radio/radar system enabling the missile to be tracked and guided accurately to the drop zone where command signals initiate the torpedo release sequence.

The Ikara launcher ensures that the missile takes up its correct flight path as quickly as possible, while the automatic handling system ensures rapid reloading from the magazine, where the missiles are stowed with their torpedoes attached.

The layout of the magazine and handling area varies considerably between the classes of ships already fitted with Ikara, and designs are available to cater for the differing requirements of ships ranging from 1500 tons upwards.

DEVELOPMENT

Initial design was undertaken by the Australian Government. The version to meet RN requirements was subsequently developed in a joint Australian/British programme.

BRANIK

The requirement to fit Ikara to the Brazilian 'Niteroi' class Mk 10 frigates gave rise to the development of a third version of the system. Known as BRANIK, this version again differs from the Australian and RN versions in the way in which the launcher and missile obtain computer service. In the 'Niteroi' weapon control system two fire control computers (Ferranti FM 1600B) are used to control all the ship's weapons. The BRANIK system employs a special-purpose missile tracking and guidance system which is fully integrated with one of these computers. A lightweight semi-automated missile handling outfit is also incorporated in the new version.

BRANIK was the subject of a joint development programme by the Australian Government, Vosper Thornycroft, British Aerospace Dynamics Group (BAeDG), and Ferranti.

In April 1982 the Australian Minister of Defence announced a programme to improve the system and extend its operational life by reducing size and weight and improving reliability and performance. Current Australian plans relate to development of a system in which Ikara may be used in a containerised form (possibly modified to have folding wings) together with SSMs such as Otomat to comprise a ship's weapons fit.

Work is well advanced on a new version of the Ikara system that incorporates the Italian Otomat anti-ship missile guidance system and a modified Ikara vehicle with a new launcher. The project is essentially a joint Australian and Italian venture. Oto Melara presented details of the new combination of Otomat and Ikara, in which a new design of 'box' launcher is used to house an Ikara missile modified with folding wings and equipped with the Otomat guidance system. The PRT 406 Ikara missile transponder is a single LRU comprising a power supply unit, logic unit, IF/RF and transmitting RF head unit, and receiving RF head and antenna unit, all integrated into the upper tail fin of the Ikara.

The modified Ikara can carry as its payload any one of the US Mk 44 or 46, Swedish Type 42, Italian A244/S or UK Stingray lightweight torpedoes, and probably the new Italian lightweight torpedo (A-290) believed to be under development, when this is ready. By providing the Ikara with the Otomat guidance system, the former weapon can employ over-the-horizon attack facilities available to the anti-ship missile, with consequent tactical and operational benefits.

Similarly, a ship fitted with boxed Ikara and Otomat has significant advantages in being able to deploy both categories of weapon at the same time, without requiring separate guidance and control systems for each type of missile. The ant.-submarine Ikara system enjoys considerably extended range with improved accuracy potential.

STATUS

In service with the Royal Australian Navy and the RN, and in four ships of the Brazilian Navy. The combined value of orders for the Australian, Brazilian, and British navies is in excess of £100 million. The thousandth Ikara missile from the production line was delivered to the RAN in July 1977.

AS-228 DEPTH CHARGE

The AS-228 depth charge is an anti-submarine weapon with a hydrostatic pressure activated fuze that permits its use against targets at depths from 100 to 1600 feet (30 to 490 m) and the detonation depth can be preset to any one of 19 depths between these limits. The detonator also incorporates three safety measures for handling and transportation, inertia, and submarine action. The charge itself can be launched by conventional methods from naval vessels or from aircraft, including helicopters. The fuze, manufactured by Cardoen Explosivos, is also supplied as a separate unit as a replacement for outdated fuzes in depth charges and bombs of other manufacture.

This company also manufactures underwater hand grenades for use as an anti-diver weapon for the protection of ships moored or anchored in insecure

Cardoen AS-228 anti-submarine depth charge

Bangalore Torpedo demolition charge

Cardoen anti-frogman underwater grenades

waters. These are operated by hydrostatic fuzes and can be set to explode at depths between 4 and 12 m. Thrown overboard at intervals alongside warships they offer a defence against the attentions of frogmen.

Another product is the Bangalore Torpedo demolition charge, consisting of four pipe charges of light aluminium or steel containing 5 kg of Pentolyte and Mexal explosive.

STATUS

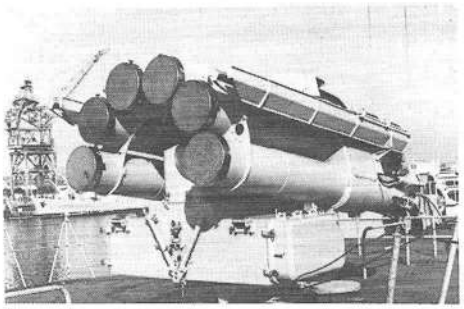
FRANCE

2057.241
ANTI-SUBMARINE WEAPON SYSTEM

This system comprises an anti-submarine rocket launcher associated with a sonar and a computer. The rocket launcher is remotely controlled, aiming and rocket fuzing being determined by the computer, which in turn receives input data from the sonar.

The launcher is made by Creusot-Loire under licence from Bofors and is a six-tube device with automatic reloading from a magazine. It fires single rockets or salvoes as required, and will accept any of the range of Bofors 375 mm rockets, thereby giving a choice of ranges from about 655 m to about 3625 m. Rate of fire can be up to one round per second.

The most recent version is that equipping the Aviso 69 class of the French Navy and E71 class escorts of the Belgian Navy.



The computer calculates ballistic data for initial velocities of 100, 130, 165, and 205 m/s for the different rockets that may be used with the systems.

Input data from the sonar comprise the location and rate of change of position of the target.

Creusot-Loire is licensed by Bofors for the manufacture of the twin-tube rocket launcher (**2368.241**) and the corresponding munitions. Nine equipments have been installed or are in the course of fabrication.

Creusot-Loire six-tube anti-submarine rocket launcher

1179.241
MALAFON SURFACE TO SUB-SURFACE MISSILE

Malafon is a shipborne weapon consisting of a radio command guided winged vehicle carrying a homing acoustic torpedo. It is intended primarily for use from surface vessels against submarines, but may also be used to attack surface targets.

The Malafon missile has the appearance of a small conventional aircraft with short, unswept tapered wings, and a tailplane fitted with endplate fins. Principal dimensions are: length 6·15 m, diameter 0·65 m, wing span 3·3 m, and the launch weight is 1500 kg. Maximum range is about 13 km.

OPERATION
The missile is ramp launched and propelled by two solid-fuel boosters for the first few seconds of flight. Subsequent flight is unpowered. A radio altimeter is fitted to the missile to maintain a flat trajectory at low level. On reaching the target area, approximately 800 m from the target's estimated position, a tail parachute is deployed to decelerate the missile. The homing torpedo is thus ejected from the remainder of the vehicle and enters the water to complete the terminal guidance phase of the attack by acoustic homing.

Target detection and designation in the case of submerged targets is by means of sonar and by radar in the case of surface targets. These sensors, as appropriate, are used during the flight of the missile to provide data on the target for the generation of command guidance signals which are sent via radio command link to guide the missile. Missile tracking is aided by flares attached to the wing tips.

DEVELOPMENT
Development started in 1956 and by 1959 a total of 21 test launches had been made, 15 from the ground and six from an aircraft. The first sea launch and guidance test took place in 1962. Evaluation of the complete weapon system took place in 1964, during which time over 20 launches were made. Operational trials were carried out the following year.

STATUS
It is understood that Malafon was deployed in an interim form on French Navy vessels, while full development trials were still in progress, these installations probably being updated as development continued. These fittings have been referred to as Malafon Mk 1 systems. Deployment of the latest versions includes installations in the guided weapons frigate *Suffren*, five modified T47 class destroyers and five corvettes.

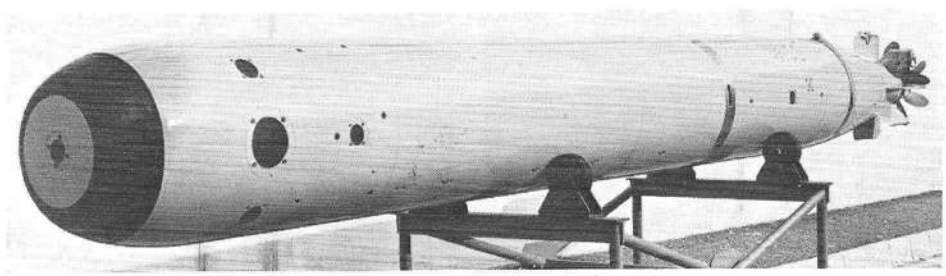
CI-1 SUBMARINE TARGET

The CI-1 is used for training torpedo launching crews in anti-submarine warfare and for the evaluation of new operational techniques and tactics. It can also be employed in the testing and evaluation of new torpedoes or other underwater weapons. It simulates in a very realistic fashion the characteristics of a submarine and permits effective training under ideal conditions and at a reasonable cost.



The target itself has the appearance of a large electrically powered torpedo (see photograph). It carries acoustic equipment that allows for the generation of the same acoustic responses as a submarine illuminated in the same conditions as those produced by the active sonar of a homing torpedo. It can equally function as the transmitter of a torpedo, with passive detection and localisation being carried out by surface vessels. The CI-1 also has low frequency devices used for target localisation purposes.

It has ample power storage capacity and can be navigated for up to eight hours in the course of an exercise, or the period prior to an exercise, at its minimum speed.

STATUS
In production and operational.

7501.441
ACOUSTIC TORPEDOES L3, E14, and E15

These torpedoes, which are further described individually in the entries that follow, have been designed with as many common parts as possible.

The weapon systems use part of the equipment pertaining to the submarine weapons of frigates and submarines. The sonar equipment detects, identifies, and gives the position, route and speed of the target and, depending on the type of sonar, the depth of submergence. From these data, the fire control system determines the straight path leading the torpedo near the target and conveys the relevant information to the torpedo tube stations and to the torpedoes. The torpedo follows this route until its homing equipment picks up the target. This then guides the torpedo either to impact or sufficiently close to the target to cause the proximity firing mechanism to operate.

Speed and range performances are selected to match the ranges of the sonar equipment carried by current French vessels.

The effective area of the explosive charge is consistent with the accuracy of self-guidance and with the operating requirements of the proximity fuze.

Propulsion is provided by a high-speed electric motor in series which drives, via a differential inverter-reducer, two contra-rotating propellers. The motor is rated from 40 kW (L3 and E14) to 50 kW (E15). Energy is provided by a storage battery comprising 76 A/h (L3 and E14) or 120 A/h (E15) Ni-Cd cells. The propulsion motor, operating as a rotary converter, powers the acoustic self-guidance system, and supplies the magnetic firing system and its ancillaries (50 V, 400 Hz, single-phase).

An automatic pilot guides the torpedo during the approach phase: it consists of an electric gyroscope which is started by air pressure within 0·4 seconds, and operates in conjunction with a depth regulator that controls the rudders via two pneumatic servo-motors. A 250-barye air tank starts the gyroscope briskly and supplies the servo-motors and the operating gear that sequences the various components.

OPERATION

The L3 torpedo, which is strictly an anti-submarine weapon, incorporates the AS-3 active acoustic self-guidance system. Ultrasonic pulses are transmitted from and received by a bank of magnetostrictive transducers pendular-mounted in the torpedo nose, the arrangement being such as to enable range, bearing and elevation to be measured.

Location in azimuth and elevation is used to guide the torpedo according to a pursuit curve: the self-guidance system sends to the servo-motors, via electric valves that bypass the automatic pilot, the commands providing diving, rising, and lateral control. These commands are applied for about the duration of the interval between successive pulses and cease as soon as the self-guidance system no longer confirms them.

A pendular system restricts the angle of pitch of the torpedo from +10 to −40°.

As the torpedo nears the target, the pulse rate increases to improve the accuracy of pursuit and of the acoustic exploder mechanism.

On reception of a first distance echo less than 20 m away, the exploder mechanism is triggered, bringing about explosion of the charge 3·5 seconds later. (If used for range practice, an adjuster stops the torpedo when 150 m from the target.) If the torpedo overshoots the target beyond its assumed position, it proceeds with a specific search run.

If after a computed time the torpedo has not detected the target at the previous position it starts a circular search (if in shallow water) or a helical search (if in deep water).

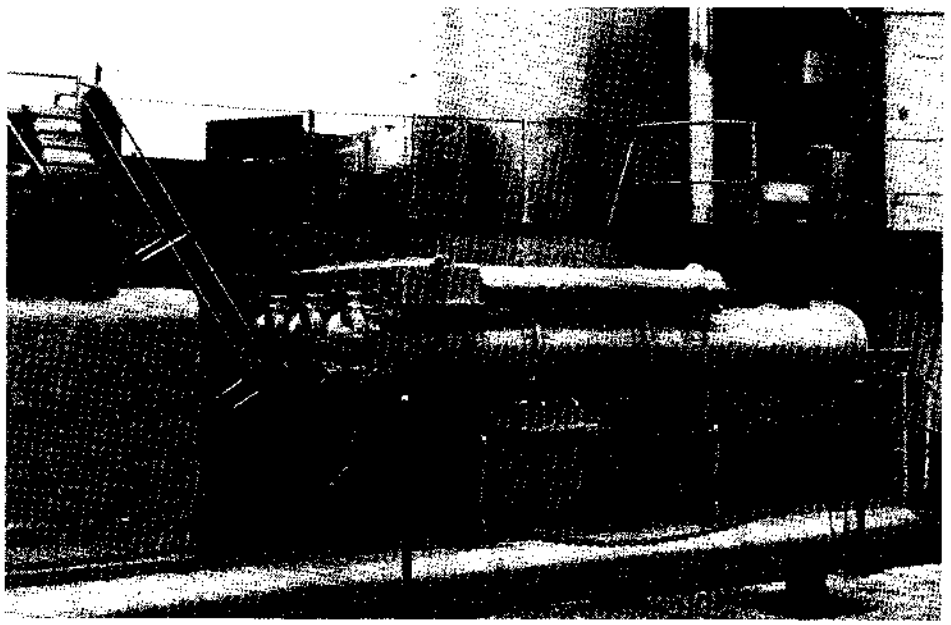
The E14 and E15 torpedoes can be used only against surface ships or against noisy submarines when close to the surface.

The E14 torpedo has the same geometry and mechanical features as the L3 but the self-guidance system is passive. A bank of four transducers, in conjunction with a phase detector detects the target-radiated noise within a 1 kHz bandwidth. This unit supplies two voltages whose difference enables it to locate the target in azimuth. After amplification and when these voltages have reached a given value, the self-guidance system sends lateral control commands by means of electric valves whereby the servo-motors abut against a limit switch (on/off control).

On nearing the target, the self-guidance system initiates the counter-command. The torpedo rotates in the same direction until it receives the counter-command. This avoids 'break-off' of the torpedo when nearing the bows of the target, or permits resumption of an attack that aborted owing to the proximity fuze.

The magnetic proximity fuze system (M-7) is passive. Two probes detect the space variation of the magnetic field. When the torpedo passes under the target a signal of significant form develops which triggers the exploder mechanism of the charge. The range is about 4 m under the hull of a frigate.

The protective system is designed so that arming the exploder system and the authorisation to transmit the self-guidance system commands cannot take place until a 350 m run from emergence from the torpedo tube has been accomplished.



The E15 torpedo has the same self-guidance system as the E14 but the geometry, range, and explosive charge are different.

Triple 21 inch (550 mm) anti-submarine torpedo tube mount of French pattern (Stefan Terzibaschitsch)

1163.441
E14 ACOUSTIC TORPEDO

This is a conventionally-shaped, submarine-launched, anti-ship (or anti-submarine in certain circumstances) torpedo with a strong body in light alloy and a laminated nose cone, with the following five compartments:

(1) acoustic passive self-guidance and electro-magnetic firing device
(2) explosive charge and impact fuze
(3) secondary battery
(4) air tank and automatic pilot
(5) electric motor for propulsion.

CHARACTERISTICS

Length: 4191 mm
Diameter: 550 mm
Weight: 900 kg
Speed: 25 knots
Range: 5500 m
Explosive charge: 200 kg
Submersion: Can be set between 6-18 m (continuously variable)
Guidance: Acoustic, passive, average range 500 m
Firing: Contact (inertial) and influence (magnetic)
Target: Surface vessel from 0-20 knots and submarine at shallow depth

STATUS

Quantity production. The equipment is in service with the French forces and supplied for export.

CONTRACTORS

Programme direction: Direction des Constructions Navales (DCN), 2 rue Royale, 75200 Paris Naval, France.

Etablissement des Constructions et Armes Navales (ECAN) de St Tropez, 83990 Saint Tropez, France.

E15 ACOUSTIC TORPEDO

A conventionally-shaped, submarine-launched, anti-ship (or anti-submarine in certain circumstances) torpedo with a strong body in light alloy and a laminated nose cone, the E15 is a lengthened version of the E14 model 1 torpedo. It has the following five compartments:

(1) acoustic passive self-guidance and electro-magnetic firing device
(2) explosive charge and impact fuze
(3) secondary battery
(4) air tank and automatic pilot
(5) electric motor for propulsion.

CHARACTERISTICS

Length: 6000 mm
Diameter: 550 mm
Weight: 1350 kg
Speed: 25 knots
Range: 12 000 m
Submersion: Can be set between 6-18 m (continuously variable)
Guidance: Acoustic, passive, medium range
Explosive charge: 300 kg
Firing: Contact (inertial) and influence (magnetic)
Target: Surface vessel from 0-20 knots and submarine at shallow depth

STATUS

Quantity production. The equipment is in service with the French forces and supplied for export.

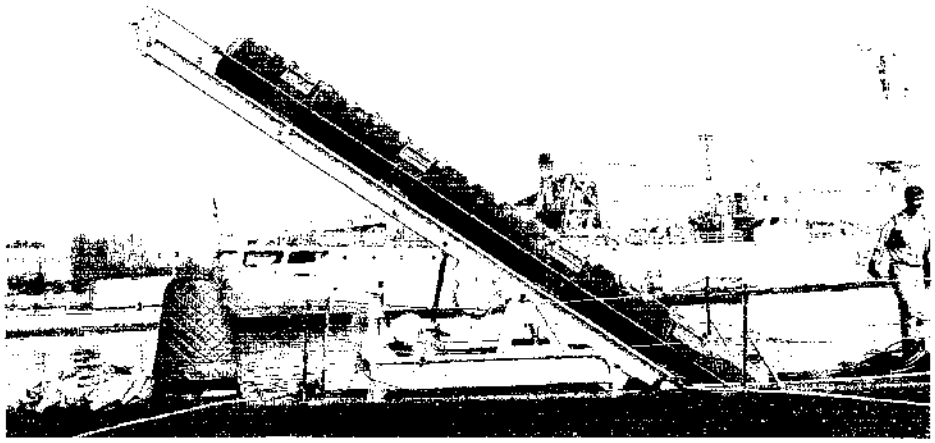
Manufacturer: Thomson Sintra Activités Sous-Marines, 1 avenue Aristide-Briand, 94117 Arcueil Cedex, France.

3623.441
F17 TORPEDO



The F17 is a new electric torpedo designed principally for submarine launched attacks on surface ships. It can be employed in a wire-guided mode of operation or in an automatic homing mode and changing between modes can be effected instantly from the control panel aboard the launching vessel. Normally the final attack phase is under automatic control.

There is a multi-mode version, the F17P, which is equipped with an automatic homing head that provides active/passive target seeking. The F17P can be launched by either surface ships or submarines against surface or underwater targets.

The torpedo is electrically powered by silver-zinc batteries which are activated automatically at launch.

CHARACTERISTICS
Length: 5914 mm
Diameter: 533 mm
Weight: 1410 kg
Guidance: Wire and automatic homing
Target: Surface vessels and submarines

STATUS
Production.

Loading an F17 torpedo in its protective container in 'Agosta' class submarine.

CONTRACTOR
Direction des Constructions Navales (DCN), 2 rue Royale, 75200 Paris Naval, France.

Etablissement des Constructions et Armes Navales (ECAN) de St Tropez, 83990 Saint Tropez, France.

1165.441
L3 ACOUSTIC TORPEDO

This is a conventionally-shaped, ship-launched or submarine-launched, anti-submarine (to 300 m) torpedo with a strong body in light alloy and a laminated nose cone, with the following five compartments:

(1) acoustic active self-guidance and electro-magnetic firing device
(2) explosive charge and impact fuze
(3) secondary battery
(4) air tank and automatic pilot
(5) electric motor for propulsion.

CHARACTERISTICS
Length: 4300 mm
Diameter: 550 mm
Weight: 910 kg
Speed: 25 knots
Range: 5500 m
Max submersion: 300 m
Explosive charge: 200 kg
Guidance: Acoustic, active, range approx 600 m with favourable inclination of the target submarine. Type AS3T
Firing: Contact (inertial) and proximity (acoustic)
Target: Submarine from 0-20 knots and up to 300 m depth

STATUS
Quantity production. The 550 mm diameter version of the weapon is in service with the French forces. A 21 inch (533 mm) version has also been designed and is available for manufacture but not in production. Its performance is the same as that of the 550 mm version, but its length is 4318 mm (170 inches), its weight 900 kg, and its diameter, of course, 21 inches.

CONTRACTORS
Programme direction: Direction des Constructions Navales (DCN), 2 rue Royale, 75200 Paris Naval, France.

Etablissement des Constructions et Armes Navales (ECAN) de St Tropez, 83990 Saint Tropez, France.

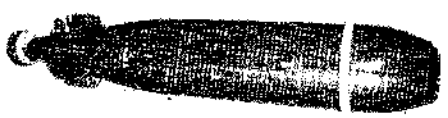
L3 acoustic torpedo launch



2096.441
L4 AIRBORNE ACOUSTIC TORPEDO

This torpedo is designed to be launched from aircraft or from the ASW missile Malafon (**1179.241**). It is suitable for attacking submarines navigating under water at speeds below 20 knots.

It is a conventionally-shaped torpedo having a body made of removable sections of moulded magnesium alloy and comprising the following main compartments:

(1) head section containing the guidance system, the acoustic firing circuits, and the warhead (which is contained in a removable canister) with its inertial percussive firing mechanism
(2) centre section containing the battery and priming elements
(3) tail section containing the air reservoir, the propulsion unit (electric motor driving two contra-rotating propellers through a reduction gear), and the steering mechanisms.

In addition there are the launching devices designed to insert the torpedo smoothly into the water. These comprise a parachute stabiliser and release mechanism aft and an ejection cap forward.

French L4 air-launched torpedo

OPERATION
Once in the water the torpedo describes a circular path until its detection mechanisms locate the target, after which it changes course and homes on the target. On reaching its target the warhead is detonated either by the acoustic proximity mechanism or by an impact fuze.

CHARACTERISTICS
Length: 3·13 m including parachute stabiliser
Diameter: 533 mm
Weight: 525 kg
Warhead: 100 kg
Speed: 30 knots
Guidance: Active acoustic homing
Target: Submerged submarine at up to 20 knots

STATUS
In service with the French Navy. The L4 now exists in a modernised version, capable of operating in shallow water and attacking submarines at depths from periscope depth to very deep cruising. A version suitable for launching from torpedo tubes of surface vessels has also been developed. This differs from its predecessor principally only in length (3·30 m) and mass (570 kg).

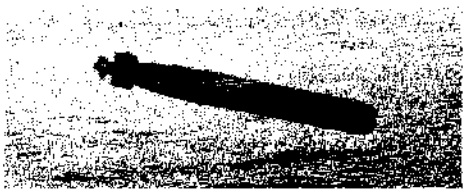
CONTRACTOR
Direction des Constructions Navales (DCN), 2 rue Royale, 75200 Paris Naval, France.

Etablissement des Constructions et Armes Navales (ECAN) de St Tropez, 83990 Saint Tropez, France.

2128.441
L5 MULTIPURPOSE TORPEDO

Most recent of the 'L' series of torpedoes, the L5 is powered by silver-zinc batteries which are activated at launch.

There are four models:



L5 Mod 1
L5 Mod 3
L5 Mod 4
L5 Mod 4P

The lighter L5 Mod 1 (1000 kg) is intended for use by surface vessels, the heavier L5 Mod 3 (1300 kg) being for submarine launch. Both models are of 533 mm calibre and have a speed of 35 knots. The L5 Mod 4 is solely for anti-submarine use, and the L5 Mod 4P is a multipurpose version.

All models are fitted with a Thomson-CSF active/passive homing head. This has various operating modes, such as direct attack or programmed search with either of the two homing techniques.

STATUS
All versions of the L5 are operational. The Mod 4 models are derived from the Mod 1 and have the same weight and dimensions. The Mod 4 versions are in production for the French Navy and for export. Belgium is among the foreign users of the L5.

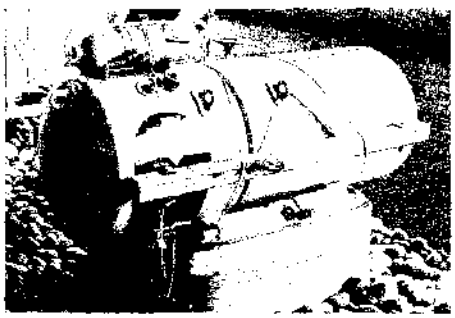
L5 torpedo about to enter the water (DCN photo)

2146.441
Z16 SUBMARINE-LAUNCHED TORPEDO
This is a large submarine-launched anti-ship torpedo. Electrically propelled and free-running, with gyro angle and running depth preset, for target interception, before discharge, it maintains course for a predetermined distance. If no target is encountered the torpedo switches to a zig-zag pattern.

CHARACTERISTICS
Length: 7·2 m
Diameter: 550 mm
Weight: 1700 kg
Speed: 30 knots
Guidance: Preset plus pattern
Range: 10 km
Submersion: To 18 m
Explosive charge: 300 kg
Firing: Magnetic proximity or contact
STATUS
Obsolescent.

3526.441
THOMSON-CSF SEA MINES
Thomson-CSF is responsible for the production of a variety of sea mines, both war types and for training purposes. Brief details of some current models are given in the following paragraphs.

TSM 3510 (MCC 23)
This is an operational seabed mine designed to be deployed from submarines, and its shape and dimensions are appropriate to its discharge from submarine torpedo tubes (see illustration). Full details of the type of operation employed have not been revealed, but the TSM 3510 probably is of the multiple sensor variety relying upon magnetic, pressure, and acoustic sensors for detection of the target vessel. The sensitivity can be adjusted to suit the depth of the mine and the type of ship(s) intended as targets. The mine is maintained in a passive condition during storage by a locking bar, and is armed prior to insertion into the torpedo tube by the withdrawal of two safety pins.

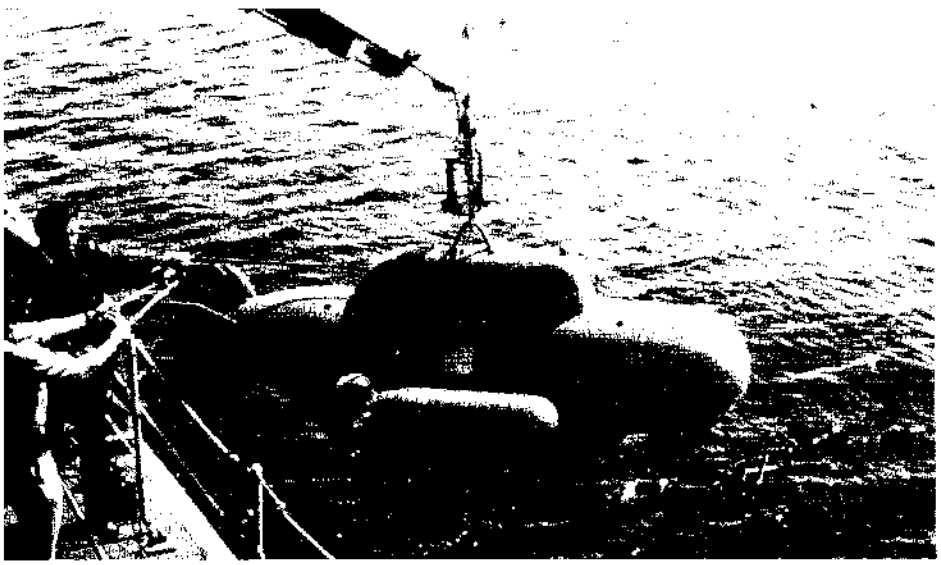


TSM 3510 (MCC 23) submarine-launched sea mine

CHARACTERISTICS
Length: 2368 mm
Diameter: 530 mm
Weight: 850 kg (loaded)

TSM 3530 (MCT 15)
This mine is a seabed defensive mine for deployment from surface ships. It is launched from rails and settles on the bottom after a parachute-retarded descent. The TSM 3530 is armed by clockwork activated time delay, the elapsed time between sowing and arming being preset.
CHARACTERISTICS
Length: 1100 mm
Diameter: 1200 mm
Weight: 1500 kg (loaded)

TSM 3500 (ED 28B)
This is a recoverable exercise mine for training purposes, such as crew training for minesweeping operations. It is equipped with a magnetic and acoustic detection system, and other items include a float with firing devices and logic circuits that process detected signals. A smoke grenade is fixed to the float, simulating a mine explosion after the mine counter has reached the preset selected number of runs. A ferro-concrete sinker, to which the mine is tethered by a cable, is launched with the mine. The cable is sheared when the clock reaches the time for the mine to ascend and the float rises to the surface to enable the mine to be recovered.
CHARACTERISTICS
Length: 1550 mm
Diameter: 550 mm
Weight: 210 kg in air; 175 kg in water
Sinker: 950 × 800 × 400 mm, 420 kg in air



TSM 3500 (ED 28B) exercise mine with sinker attached

TSM 3515 (MCED 23)
This is a recoverable exercise mine for minesweeper crew training, and it has the same basic functions as the TSM 3500. It is launched from submarine torpedo tubes.

TSM 3517 (MCEM 23)
This model is intended for training submarine crews in mine-launching tube loading and in minelaying. It is identical with MCED 23, but without magnetic and acoustic sensor system.
STATUS
In service with the French and other navies.
CONTRACTOR
Thomson-CSF, Divisions Activités Sous-Marines, BP 53, 06802 Cagnes-sur-Mer, France.

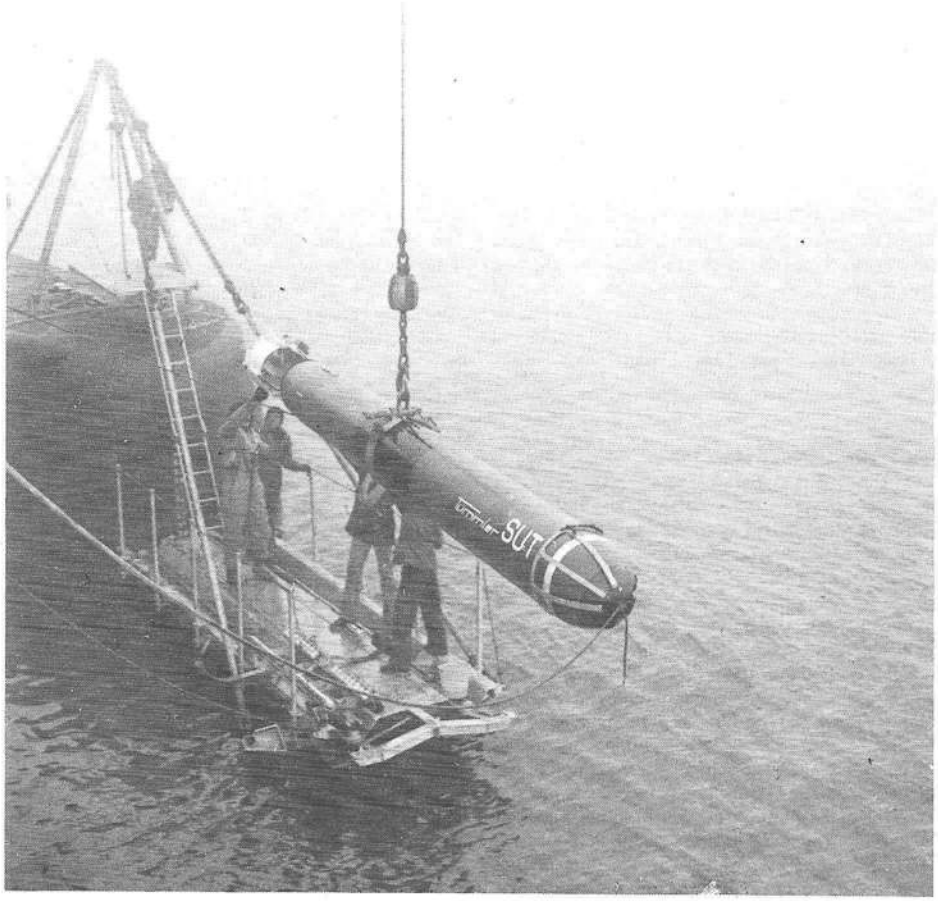
4415.441
ECA 38 (PAP 104) MINE DISPOSAL SYSTEM
The ECA 38 (PAP 104) system has been developed as a means of remotely placing a mine disposal charge alongside a mine which has previously been located by a minehunting sonar and identified by the PAP 104 vehicle. The ship equipment consists basically of four main parts: a wire-guided submersible vehicle which carries the destruction charge and is equipped with a TV camera (two vehicles per ship), a control console, a TV monitor, and a remote control box. An optional device for moored mines is now entering service. An identification sonar is now proposed as an option in the vehicle to allow positive identification in turbid waters. A new set of equipment permits partially used wire bobbins to be reconditioned.

Preparing to place PAP 104 mine disposal vehicle into the water

Overall dimensions of the submersible vehicle are: length 2·7 m, width 1·2 m, height 1·3 m, weight 700 kg (including the explosive charge). Operating range is 500 m at depths of 100 m or less with standard motors (300 m or less with optional special motors) and battery life is sufficient for five sorties. The maximum speed is 5·5 knots. Two standard versions of the PAP are proposed:
(1) Mk III for depths to 100 m with TV sensor
(2) Mk IV for depths to 300 m, with TV or near-field sonar, and new motors with reduced magnetic field.

A new Mk V version, with re-designed electronics and improved performance was introduced at the French Naval Exhibition in October 1984. A piloting simulator, known as SIMPAP, is available for training personnel. The ECA 38 (PAP 104) system also includes spares, technical assistance, maintenance equipment, maintenance and operational training and documentation.
DEVELOPMENT
The system was designed and developed by Société ECA from a French Navy operational concept.
STATUS
More than 250 vehicles have been built or ordered for the navies of Australia, Belgium, France, West Germany, Malaysia, Netherlands, Norway, United Kingdom and Yugoslavia, and for the European Tripartite Minehunter. Negotiations with other navies are in progress.
CONTRACTOR
Société ECA, 17 avenue du Chateau, BP 16, 92190 Meudon, France.

GERMANY (FEDERAL REPUBLIC)



2570.441
SURFACE AND UNDERWATER TARGET (SUT) TORPEDO

The SUT torpedo is the latest and most versatile member of the Seal, Seechlange and SST 4 family of torpedoes (**2178.441** and **2000.441**). It is a dual-purpose wire-guided torpedo for engaging both surface and submarine targets. The SUT can be launched from submarines and surface vessels, from fixed locations or mobile shore stations. Its electrical propulsion permits variable speed in accordance with tactical requirements, silent running and wakelessness. The wire guidance gives immunity to interference with a two-way data link between vessel and torpedo. The acoustic homing head has long acquisition ranges and a wide search sector for active and passive operation. After termination of guidance wire, SUT continues operation as a highly intelligent homing torpedo, ie with internal guidance programs for target search, target loss etc. The large payload with combined fuze systems ensures the optimum effect of explosive power. The SUT operates at great depths as well as in very shallow waters. Consort operation permits exploitation of the full over-the-horizon range of the SUT.

CHARACTERISTICS
Length: 615 cm (662 cm with guidance wire casket)
Diameter: 533 mm

STATUS
In service and in production.

CONTRACTOR
AEG-Telefunken, Naval Technology Division, Wedel/Holst, Federal Republic of Germany.

AEG-Telefunken Surface and Underwater Target (SUT) torpedo

2178.441
SEAL/SEESCHLANGE TORPEDOES

These two wire-guided, heavyweight 21 inch (533 mm) torpedoes were developed especially for use in the Federal German Navy; Seal for use against surface ships, and the smaller Seeschlange against submarines. There is a high degree of equipment commonality between the two weapons. Major differences are that the anti-submarine model has half the propulsion battery capacity of the Seal, but is fitted with three-dimensional sonar. The following main features apply to both types.

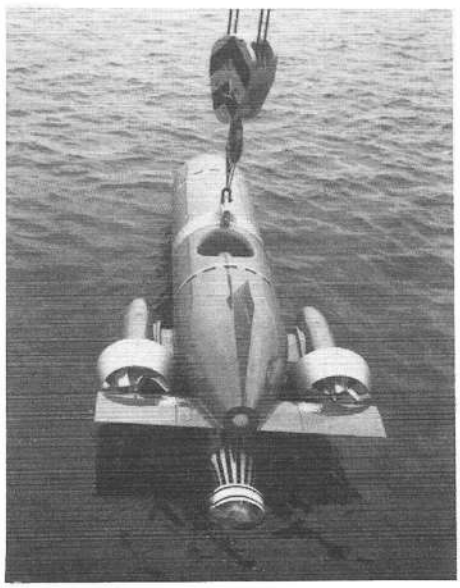
It is possible to transmit all essential data to the torpedo throughout its run via a dual-core guidance wire. Similarly, actual torpedo running data are simultaneously transmitted to the ship. An active/passive homing head is fitted with a steerable transducer array. Attack options following acquisition are either by manual or computer control from the launch ship, or by self-homing by the torpedo.

Provision is made for a programmed run after guidance-wire pay out or loss of signals from the on-board fire control system. Different programs adapted to various tactical situations are available and can be selected via the guidance wire.

Launch arrangements include compressed air firing from surface ships and swim-out from submarines. There are no limitations on ship movements during the launch and guidance phase. The electric propulsion system employed provides long running distances, permitting launch from beyond target defence area. Torpedo speed is selectable.

Other features are: combined impact and proximity fuze; full performance in shallow or deep water; three-dimensional internal stabilisation; identification of different targets and high hit probability; automatic system check before firing.

CHARACTERISTICS
Seal
Length: 608 cm (655 cm with guidance wire casket)
Diameter: 533 mm
Weight: 1370 kg
Warhead: 260 kg
Firing: Magnetic proximity or impact
Seeschlange
Length: 415 cm (462 cm with guidance wire casket)
Diameter: 533 mm
Warhead: 100 kg
Firing: Magnetic proximity or impact



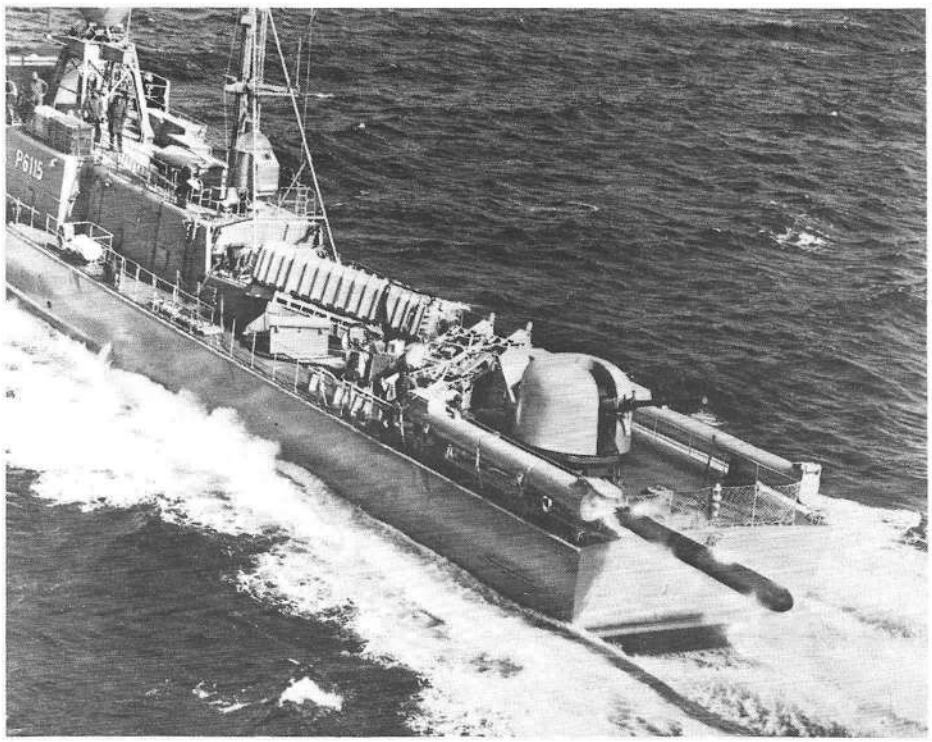
STATUS
Both torpedoes are in service with the West German Navy aboard Class 206 submarines. Seal is also deployed on surface ships, in particular on the Type 142 and 143 fast patrol boats. Seal has been modified to form the special-surface target torpedo SST 4 (**2000.441**) and the dual-purpose surface and underwater target torpedo SUT (**2570.441**).

CONTRACTOR
AEG-Telefunken, Naval Technology Division, Wedel/Holst, Federal Republic of Germany.

4421.441
PINGUIN MINE COUNTE[illegible]MEASURES VEHICLE

Under a long-term development programme for the Federal German Navy a series of remotely controlled underwater vehicles for mine countermeasures operations has been developed by MBB. Two of these craft have played a significant part in this programme: the first, known as Pinguin A1 was designed by MBB under a pre-development contract awarded by the Government and led to a second prototype in the shape of the present Pinguin B3. The Pinguin B3 is a remotely controlled, unmanned underwater craft which is a very important element in the complete minehunting system. The input of target information (derived from minehunting sonars) will enable it to travel at any selected distance from the seabed and to be guided almost automatically towards a mine-like object. The Pinguin B3 can then identify the mine, and if necessary, release a mine disposal charge to destroy it. A second charge is carried and the Pinguin craft is intended to continue its mission and proceed to destroy a second mine.

The Pinguin vehicle can be operated freely within the whole operating volume at all depths and ranges between the minehunter and maximum. Equipped with one or two cutters, it can counter moored mines also.



Pinguin B3 remotely-controlled underwater minehunting craft carries two mine destruction charges and sensors for navigation and identification

CHARACTERISTICS
Vehicle: Pinguin B3
Length: 3·5 m
Hull diameter: 70 cm
Wing span: 1·5 m
Height: 1·4 m
Mass: 1350 kg
Propulsion: 2 variable propulsion electric motors, 1 controllable lift motor
Power supply: Internal nickel-cadmium battery
Diving depth: 100 m
Speed: (Standard) 6 knots, (max) 8 knots
Endurance: 60/120 minutes
Payload: 240 kg, 2 × mine disposal charges, cutter
Sensors: TV camera; sonar
STATUS
Transition to series production.
CONTRACTORS
MBB, Marine and Special Products Division, Hünefeldstrasse 1-5, 2800 Bremen, Federal Republic of Germany.

Messerschmitt-Bölkow-Blohm GmbH (MBB), PO Box 801109, 8000 Munich 80, Federal Republic of Germany.

2000.441
SST 4 SPECIAL SURFACE TARGET TORPEDO
The SST 4 torpedo is comparable in its dimensions, construction, and capabilities to the Seal weapon (**2178.441**) except for those features which can only be applied within the operational area of the West German Navy. In this respect the SST 4 has been adapted to a standard international version.
CHARACTERISTICS
Length: 608 cm (655 cm with guidance wire casket)
Diameter: 533 mm
Guidance: Wire-guided, dual core with two dispensing systems; active/passive homing sonar
Propulsion: Electric
Submersion: To 100 m
Warhead: 260 kg
Fuze: Impact and proximity
STATUS
In service on Class 209 submarines, fast patrol boats of the 'Combattante I and II' and 'Jaguar II' classes, introduced into various NATO and South American navies.
CONTRACTOR
AEG-Telefunken, Naval Technology Division, Wedel/Holst, Federal Republic of Germany.

Federal German class 143 fast patrol boat launches AEG-Telefunken torpedo from stern tube

3628.241
TROIKA MCM SYSTEM
The problem of sweeping mines without endangering men and material has been solved by the new Troika system. The concept is based on using three unmanned minesweepers which are radar tracked and remotely controlled from a ship-based operations centre, in order to clear specified laps from acoustic and magnetic influence mines.

The self-propelled minesweepers, designated HFG-F1, are equipped with minesweeping facilities which are accommodated in hollow steel cylinders encased by a ship-like hull. The overall design of the minesweepers is characterised by extremely high shock resistance. Its propulsion system consists of a diesel-driven hydraulic power transmision and a combined rudder propeller. For optimum operation, even in rough seas, an autopilot is provided.

The magnetic sweeping field is generated by two coils, mounted forward and aft on the cylinder. For acoustic minesweeping two medium frequency acoustic hammers and one towed low frequency acoustic displacer are provided.

The Troika system as used in the Federal Republic of Germany under the navy designation HL 351 uses a converted coastal minesweeper as carrier for the minesweeping operations centre. The system was defined by AEG-Telefunken which also developed the remote control equipment. The latter comprises a horizon-stabilised X/C-band precision navigation radar, a digital target extractor, a master console and three control displays. Each of the latter is associated with one unmanned minesweeper, on the one hand, and with a remote action system operator console, on the other. The control displays allow the radar image of the swept channel to be greatly magnified so that a high degree of precision is achieved in guiding the unmanned minesweepers along the specified tracks electronically inserted into the radar image.

Control commands are sent to the minesweepers in the form of multiplexed data messages, using a UHF link, which provides high reliability. Their responses and functions are monitored automatically by an integrated monitoring system. The last main feature is the reference buoy which provides a geographically stabilised radar image and constitutes a vital component in this Troika configuration.

Operating principles of Troika remote minesweeping system

STATUS
Delivery since mid-1979.

4766.441
FG 1 SEA MINE
The FG 1 is a so-called ground mine, designed to damage or destroy either surface shipping or enemy submarines and warships.

The mine casing is cylindrical configuration, constructed mostly of non-magnetic material, and the mine itself consists of two sections which are combined by means of a clamping ring. The first (smaller) section is the control section which contains the firing mechanism and the safety and arming unit with its ancillary items. The other section contains the explosive charge.

An interface section, located at the bottom of the control section, houses the firing system, which is an electro-pyrotechnic link between the fuze system and the charge. The FG 1 mine is equipped with a proximity fuze. Sensors in the fuze system detect physical fields generated by the hull of a vessel which are then evaluated by the fuze system. If their vessel is within the effective range of the mine, (ie if the signals reach a predetermined level) the charge is detonated.

Depending upon the version, the mine is equipped with various sensors and fuzes. These differences can be established from the external modifications to the mine and the different equipment and sensors attached to it.

Laying can be performed by submarines or surface ships. Prior to laying, the power circuit is connected by inserting a plug into the carrier system. In a live

launch, arming of the safety and arming section and water pressure switch is by means of a rope attachment. For surface vessel laying, this function can be performed manually.

CHARACTERISTICS

Length: 2310 mm; 710 mm (control section); 1600 mm (charge section)
Diameter: 534 mm
Total weight: 770·5 kg; 143·5 kg (control); 627 kg (charge)
Charge: 535 Kg HE
Service depth: 60 m (max)
Negative buoyancy in water: 291·5 kg

STATUS

Production. For training a recoverable mine, FG1-Ex, is available.

CONTRACTOR

Fuhn-Werke, PO Box 8, D-8560 Lauuf a.d. Pegnitz, Federal Republic of Germany.

3625.441
VS SM600 SEA MINE

The VS SM600 is a multi-sensor influence seabed mine intended for use against medium-tonnage and large surface ships and submarines. This mine is an influence device fitted with a set of sensors coupled to sophisticated processing electronics. Features include a capability for remotely sensing and accurately recognising the magnetic, acoustic and pressure signatures of a wide range of ships and submarines.

Thanks to its extreme flexibility, the mine can be accurately tuned both by a local setting or by a remote control facility so that it can be triggered by the passage of a selected type of vessel. At the same time, the mine possesses good immunity to sweeping operations. The size of the explosive charge is adequate for the destruction of the largest vessels. It can be laid from surface ships, by submarines through a torpedo tube, or parachuted from an aircraft.

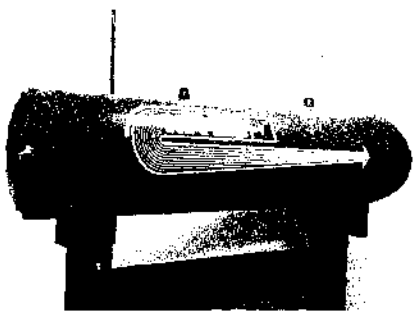
CHARACTERISTICS

Length: 2750 mm
Diameter: 533 mm
Weight: Approx 760 kg
Charge weight: 600 kg, TNT
Sensors: 4 – magnetic, pressure, acoustic (LF), acoustic (AF)
Laying depth: 10 – 150 m
Arming time: 1-32 h, adjustable
Safety devices: 5, redundant (safety pin, soluble disc, and pressure device)
Targets: Surface ships, submarines – conventional or nuclear
Additional features: Long-time arming delay; auto-neutralisation; ship counter; anti-removal device

STATUS

Production complete.

CONTRACTOR

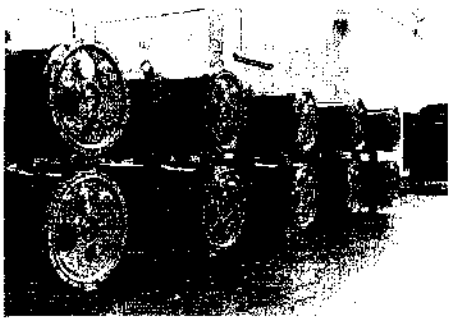


Valsella Meccanotecnica SpA, 25018 Montichiari, Brescia, Italy.

3624.441
MISAR MR-80 SEA MINE

The MR-80 seabed mine is actuated by a combination of influence effects from the target and is able to damage or sink surface vessels and submarines of all types, either conventional or nuclear-powered. Its shape is cylindrical, with the body made of epoxy resin and fibreglass; this renders the mine very resistant to sea corrosion and makes it lighter than previous generation mines. The fore-part contains the explosive charge, while the tail section contains all the actuation, priming and operating devices and it is closed by means of a cover, within which the hydrophone, the extender, the entrance membrane of the pressure sensor and the hydrostatic starter are placed.

All influence devices are connected to a central unit (the 'Final Logic'), where all delay functions, safety intervals, sterilisation, influence combinations, ship counting, anti-removal and firing control are located. By means of a remote control device it is possible to control the mine from a control box linked to the mine by a cable. It is possible to dispense with the latter, in which case the control box is connected to a special acoustic transmitter. A special receiver-decoder is located in the mine, with the other influence devices.



The hydraulic compensator for the pressure sensor, the sole plate supporting all the electronic modules and the magnetic sensor are linked to the cover by slides that run inside the tail section. By unscrewing the bolts of the crown, the tail cover is easily removed with all the devices linked to it; in this way every part of the mine is accessible for assembly and adjustment operations.

MR-80 seabed mine

CHARACTERISTICS

Type: Seabed mine, actuated by a combination of influence sensors: magnetic, pressure, low-frequency acoustic, audio frequency acoustic
Diameter: 533 mm
Length: Mod A 2750 mm; Mod B 2096 mm; Mod C 1646 mm
Weight: 600 - 1130 kg according to model and type of explosive
Explosive charge: TNT, HBX-3 or similar HE; 400 - 920 kg according to model
Laying: Surface vessels; submarines through torpedo launching tubes; by aircraft
Depth of use: 8 – 300 m for surface targets and for submerged submarines
Power supply: Dry lithium or alkaline-manganese batteries
Selectivity and range: Obtained by adjustments of the discrimination of the signals coming from the sensors

MISAR MR-80 mines at depot

Remote control: By cable; cableless on request
Firing system: Pressure, magnetic, acoustic signals in any combination; modular
Arming and sterilisation delay: Infinitely variable up to 999 days. Electronic (quartz) clock
Targets: All surface vessels and submarines
Working temperature: -2·5 to +35°C
Storage life: 30 years with a maintenance mean time of 5 years
Operational life: 500 - 1000 days
Versions: Warhead; inert with data transmission device or smoke signal for exercises

STATUS

In production and in service.

CONTRACTOR

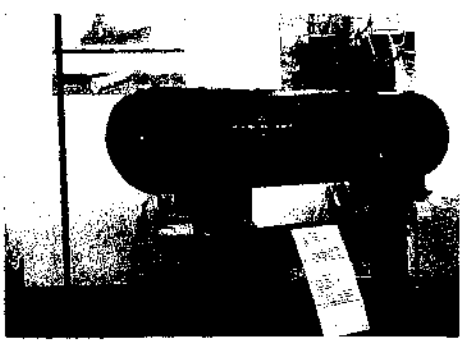
MISAR SpA, Via Brescia 39, 25014 Castenedolo, (Brescia), Italy.

4414.441
MISAR MR-80/I EXERCISE MINE

The MR-80/I ground influence mine is the inert version of the MR-80 mine and has an identical configuration but is designed for exercises, training and trials. Mines are equipped before laying with the appropriate devices for the particular intended use. The GP Mk-1 device on the tail contains a flare to simulate actuation of a mine, and a buoy which enables a mine to be recovered by rope at the end of an exercise.

A complete range of accessories and auxiliary instruments are available for mine warfare research and development activities and investigations concerning the capability of minehunters and sweepers against any type of influence mine; target signatures (acoustic, magnetic and pressure); the best mine settings for maximum effectiveness; and the development of new MCM techniques.

CHARACTERISTICS



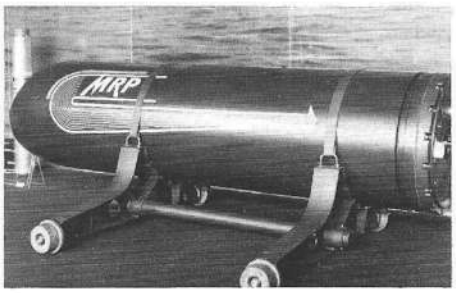
Type: Exercise, recoverable, influence mine
Diameter: 533 mm
Length: 2096 mm (or according to the model in war stock)
Weight: 750 kg (or according to the model in war stock)
Method of laying: Surface vessels, submarines and aircraft

STATUS

In production and in service. In May 1984 MISAR announced the signing of a five year contract with the Royal Norwegian Navy Materiel Command for the supply of a system of exercise ground mines. Norway is the latest of a number of NATO navies using MISAR systems.

CONTRACTOR

MISAR SpA, Via Brescia 39, 25014 Castenedolo, (Brescia), Italy.

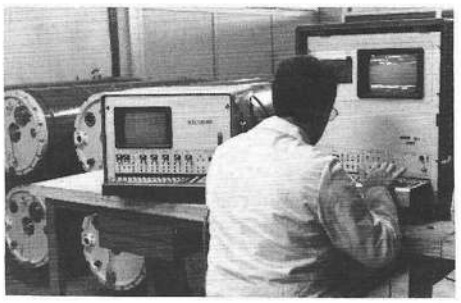


MR-80/1 exercise version of MR-80 general purpose mine

4863.441
MISAR MRP SEA MINE

The MRP advanced general purpose sea mine is a weapon which uses a microprocessor firing device that increases the capability of computation of the system, so achieving the maximum effectiveness and discrimination of the target-countermeasures. Its mechanical, structural and explosive characteristics are the same as used in the MR-80 general purpose ground mine.

The central programming unit UCP is used to compile the operator settings, mine programming and testing.



MRP advanced general purpose sea mine

CHARACTERISTICS
Type: Advanced general purpose sea mine
Diameter: 533 mm
Length: 2096 mm
Weight: 680-780 kg
Explosive type: HBX-3 or TNT
Charge weight: 530 kg TNT, 630 kg HBX-3
Depth of use: 5-300 m
Firing system: Microprocessor controlled by pressure, acoustic and magnetic influences. Wide range of selectivity on the threshold, times, combination logics and localisation logic.

MISAR Flexible Exercise Mine MRP/I

The exercise version of the MRP is a reliable system usable for basic/advanced training, mine sweeping/mine hunting exercises, sea trials and simulations, research on target signatures and new MCM techniqes, and enemy mine simulation. The equipments used with the exercise version are the same as those used in the war version.

CHARACTERISTICS
Diameter: 533 mm
Length: 2096 mm
Weight: 700 kg approx

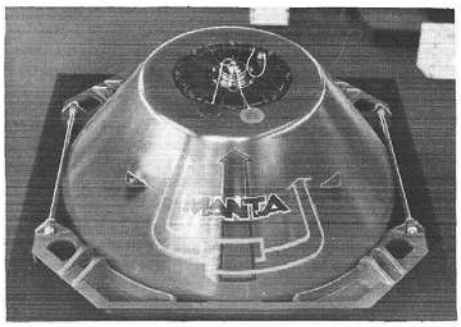
Operator with MRP/I and UCP central programming unit

Depth of use: 5-300 m
Firing system: Microprocessor controlled by the pressure, acoustic and magnetic influences. Wide range of selectivity on the thresholds, times, combination logics and localisation logic

STATUS
In production and in service.

CONTRACTOR
MISAR SpA, Via Brescia 39, 25014 Castenedolo (Brescia), Italy.

4005.441
MISAR MANTA MINE



The Manta mine can damage, sink or destroy amphibious and landing craft, small and medium-sized surface vessels, and submarines. It operates at depths between 2·5 and 100 m. The mine remains effective underwater for more than one year. Its weight and shape are such that it rests firmly on the sea bottom even in running or tidal waters. The mine is about 370 mm high and has a diameter of about 980 mm. Total weight is about 220 or 240 kg depending on the explosive. The mine consists of two units: the body containing the explosive, and the igniter which comprises all the safety, target detection and firing devices. The mine is equipped with all the safety devices needed for handling and transport. The priming device keeps the detonator away from the explosive until the maximum operating depth is reached so as to prevent any explosion due to a casual ignition.

Electronic circuits include:

(1) Delay circuit: started by the priming device, this enables an actuation delay from 0 to 63 days adjustable by steps of one day to be set
(2) Pre-alarm device: this detects the noises caused by the passage of the targets and energises the sensing circuit
(3) Sensing circuit: activated by the pre-alarm circuit, this enables the firing circuit
(4) Sterilising circuit: this sterilises the mine after an adjustable preset time.

The mine can be equipped with an anti-lift circuit.

CHARACTERISTICS
Targets: Landing craft, small and medium-sized surface vessels, submarines
Explosive: 140 kg TNT or other explosives
Laying depth: 2·5-100 m
Laying craft: Surface vessels, underwater operators
Diameter: 980 mm
Height: 380 mm
Weight: About 220 kg
Firing system: Pre-alarm and influence firing circuit

MISAR Manta mine

STATUS
In production and in service.

CAM COUNTER-MINE CHARGE

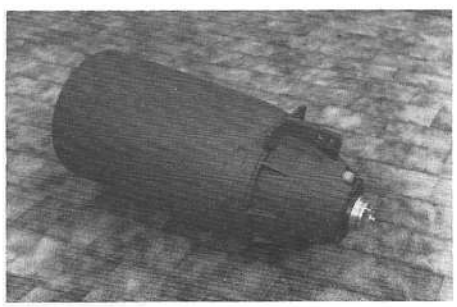
MISAR manufactures this charge for use with automatic mine-clearing systems during minehunting missions. The charge comprises:
(1) explosive charge
(2) igniting device
(3) priming device

These parts are easily and quickly put together; the charge, with its safety devices, can be positioned fully-assembled aboard the minehunter.

CHARACTERISTICS
Max diameter: 360 mm
Length: About 815 mm
Total weight: 110 kg
Main charge weight: 80 kg
Max working depth: 150 m

CAM-T Counter-mine Charge

This charge, also produced by MISAR, is similar to the CAM charge, but with some changes to make it more suitable for mine clearance operations carried out by a diving team.



CHARACTERISTICS
Max diameter: 360 mm
Length: 815 mm
Total weight: 110 kg
Main charge weight: 80 kg
Max working depth: 150 m

CAP Counter-mine Charge

This charge is similar to the CAM type, but it contains a smaller quantity of explosive.

CHARACTERISTICS
Max diameter: 250 mm
Length: 770 mm (approx)
Total weight: 43 kg
Main charge weight: 30 kg

STATUS
In production.

MISAR CAM counter-mine charge

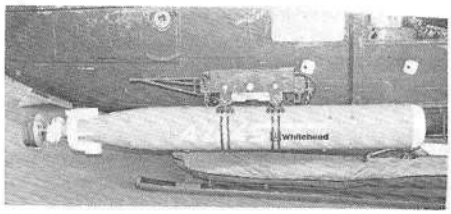
2003.441
SUBMARINE- OR SURFACE-LAUNCHED TORPEDO TYPE A 184

The A 184 is a compact dual-purpose, wire-guided, electrically propelled torpedo equipped with an AG 67 panoramic homing head, controlling both course and depth. It is suitable for use against both submarines and surface vessels. It is a dual-speed weapon, carrying a high explosive charge and capable of operating to considerable depths. The fire control system used is the CCRG (console for computation, representation and guidance), which exists in different versions for submarines and surface vessels. The former is described in **3252.481** later in this volume. The launchers are B 512 and B 516 for submarines and surface ships, respectively, although the A 184 may also be used with other launchers for 533 mm torpedoes.

Commands carried by the guidance wires include: course, depth, acoustic mode (active/passive/combined), enabling point, stratum, speed, impact and influence fuze setting, torpedo stop. Replies from the weapon include: course, distance, depth, acoustic mode, speed, other data on interrogation. The fire control system displays the targets, processes their parameters, and computes the torpedo data during its run. This enables the weapon to be wire-guided up to the stage where the target can be spotted acoustically and intercepted.

CHARACTERISTICS
Diameter: 538 mm
Length: 6 m
Weight: 1300 kg
Propulsion: Electric, silver-zinc battery
Output: 125 bhp
Warhead: HE
Range: >14 km using 2 guidance wires

Type A 184 dual-purpose torpedo



STATUS
Production.

2004.441
SURFACE- OR AIR-LAUNCHED LIGHTWEIGHT TORPEDO TYPE A 244/S

The A 244 is an electrically propelled lightweight torpedo, suitable for use in normal depth or shallow waters. It is intended for anti-submarine operations carried out by surface vessels, helicopters or fixed-wing aircraft.

The original version was equipped with a USEA AG70 homing head but the latest model (A 244/S) is fitted with an advanced guidance system known as the CIACIO-S manufactured by Elsag. This incorporates a torpedo homing head which is capable of both active and passive modes to close on its target. It is able to discriminate between decoys and real targets in the presence of heavy reverberation by special signal modulations and signal processing. The head has a large search volume which is covered by multiple preformed beams which follow a number of self-adaptive search patterns. Other features of the CIACIO-S system are: provision of presettable or programmed combinations of signal processing, spatial filtering and tactical manoeuvres to automatically match the torpedo performance to the current tactical situation; and a wide range of search, attack and re-attack courses that can be implemented in the programmer to suit other operational requirements.

Type A 244 lightweight torpedo on helicopter

CHARACTERISTICS
Diameter: 324 mm
Length: 2·7 m
Propulsion: Electric
Guidance: Active/passive sonar, self-adaptive programmed patterns

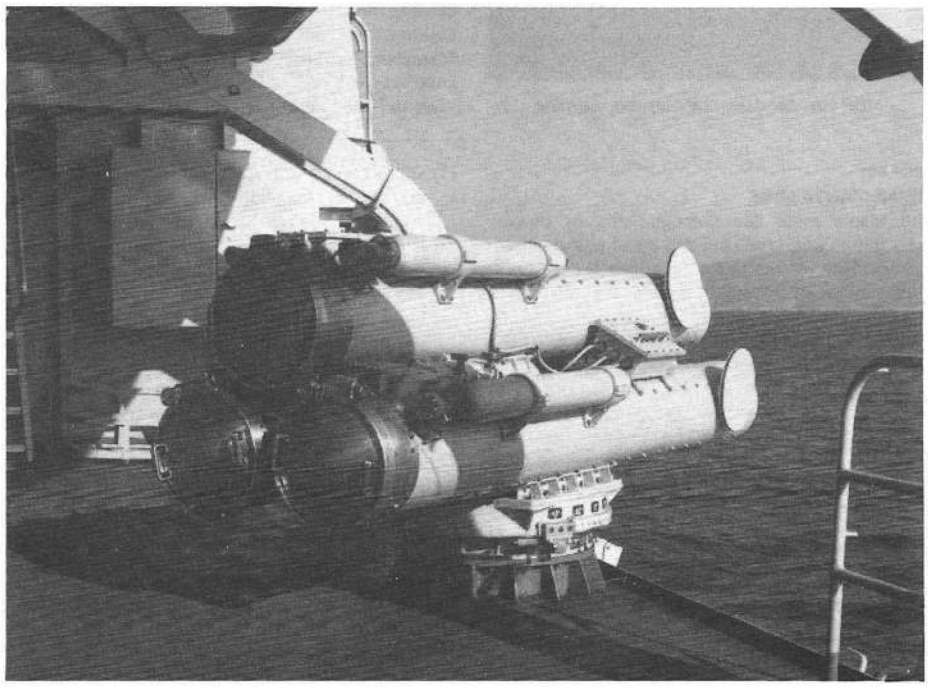
In May 1982 it was revealed that the A 244/S can be used as the payload of the Ikara anti-submarine weapon system (**6002.241**) and there is an Italian programme involving Whitehead Motofides, British Aerospace, CNR and Oto Melara to study such a system.

STATUS
In production for various overseas navies.

CONTRACTOR
Whitehead Moto Fides, Division of the Gilardini SpA, Via di Levante 48/50, 57100, Livorno, Italy.

3872.281
ILAS-3 TORPEDO LAUNCHING SYSTEM

The ILAS-3 torpedo launching system is designed for the operation of lightweight anti-submarine torpedoes such as the A 244/S, Mk 44, and Mk 46. The system employs two triple-barrel launchers which are pedestal mounted and equipped with thermostatically controlled heaters, and compressed air is used for discharge of the torpedoes from the launch tubes. Launch interlock switches are provided. The system is remotely controlled from a shipborne torpedo control system, also made by the same company, which allows the launcher operator to:



(1) select both the launcher and the individual tube designated for discharge
(2) select the preset data for the torpedo based on information from the combat information centre
(3) initiate the launch command for the designated torpedo.

DEVELOPMENT
The ILAS-3 system was jointly developed by Elsag and Whitehead Motofides.

STATUS
Production. Numerous systems are on order for several navies.

CONTRACTORS
Elsag-Elettronica San Giorgio SpA, Via Hermada 6, 16154 Genoa, Italy.

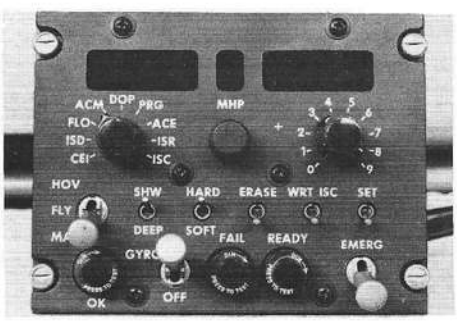
4412.341
APS SERIES AIRBORNE TORPEDO CONTROL SYSTEMS



These systems are designed to allow remote selection, presetting and launch of the A 244/S torpedo, and other existing types of lightweight torpedo, from any type of helicopter or fixed-wing aircraft. The systems are normally supplied in one of two configurations.

Configuration 1: For helicopters fitted with dunking sonar. The torpedo control can be carried out either in the hover or in forward flight. In the former case, data from the dunking sonar is processed by the control panel computer to determine the target course and speed, and the computer then determines the optimum torpedo presetting values which are sent automatically to the selected torpedo. The hit probability is also calculated and displayed on the control panel to assist in decision taking.

Configuration 2: For fixed-wing aircraft and helicopters not fitted with dunking sonars. This configuration is intended for torpedo launch in forward flight rather than in the hover.

STATUS
In production.

CONTRACTOR
Whitehead Moto Fides, Division of the Gilardini SpA, Via di Levante 48/50, 57100, Livorno, Italy.

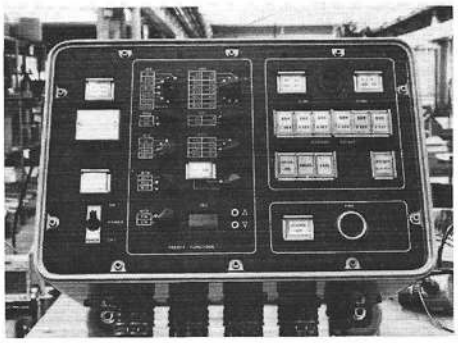
4413.241
SPS SERIES SHIPBORNE TORPEDO CONTROL SYSTEMS

This covers a range of modular integrated torpedo control systems produced by Whitehead Moto Fides. The SPS systems allow remote selection, presetting and launch of the A 244/S and other existing types of lightweight anti-submarine torpedoes and can be supplied in different configurations as follows:



Basic configuration: The torpedo remote control is manually performed by the operator using a control panel installed in the ship's action information room.

Option 1: The control panel is interfaced with the AIO. In this case the optimum torpedo presetting values, which vary with the tactical and kinematic situation, are determined and updated by the AIO computer and automatically sent to the selected torpedo through the control panel. When Option 1 is adopted Whitehead supplies suitable software to give the AIO the capability of displaying information on the ship's recommended launching areas which respectively correspond to given values of the hit probability.

Option 3: This option is intended for light vessels not fitted with AIO. The remote control panel is directly interfaced with the sonar. It determines and updates the target's course and speed and computes the optimum presetting data which are sent to the selected torpedo. A display is incorporated in the control panel to show the tactical situation and the ship's recommended attack manoeuvre.

STATUS
Production.

CONTRACTOR
Whitehead Moto Fides, Division of the Gilardini SpA, Via di Levante 48/50, 57100, Livorno, Italy.

3873.491
MIN MINE COUNTERMEASURES SYSTEM

The MIN (Mine Identification and Neutralisation) system developed and produced for the Italian Navy by Elettronica San Giorgio (ELSAG) and Riva Calzoni, has the capability of identifying and neutralising both bottom and moored mines. The system consists of:

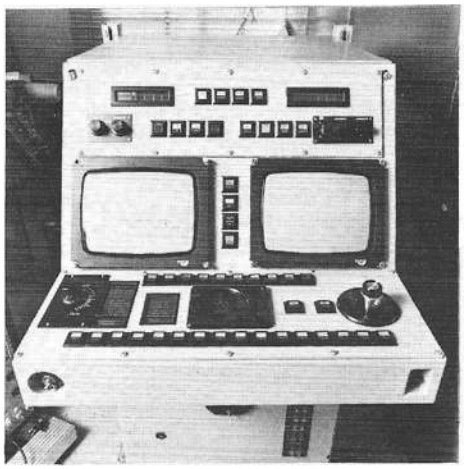
(1) one self-contained, hydraulically powered, wire-guided submarine vehicle mounting a TV camera and a high definition sonar transceiver
(2) a main console in the minehunter operations room for vehicle guidance and control
(3) one portable auxiliary console for guidance and visual control of the vehicle during launching and recovery operations
(4) operational accessories, such as auxiliary battery charging station, oleo-pneumatic power pack recharging, support system for the vehicle etc.

The vehicle is guided from the ship, via a coaxial cable stored on a reel, through two pairs of thrusters, each consisting of a propeller driven by a hydraulic motor, and a main propeller, fixed to a shaft orientable in the two planes. In the centre of the vehicle there is an oleo-pneumatic power pack to energise all the hydraulic equipment. Below the power pack there is a stowage for the bottom mine destruction charge.

When used against moored mines the vehicle must be equipped with a cutting device carrying an explosive cutter. The vehicle is also provided with a flashing light and an acoustic marker for localisation and recovery; an acoustic transponder to aid manoeuvring of the vehicle from the ship's sonar display; a compass, echo sounder, depth gauge and attitude indication device for supplying information to the main console. This latter is fitted with control levers and a joystick for speed and direction control of the vehicle during the search and approach to the mine.

The TV and the sonar monitors, with their associated control devices on the console, provide the operator with information regarding the underwater scenario.

STATUS



Series production. No contract details received.

TERNE III SURFACE TO SUB-SURFACE MISSILE

This is a shipborne medium/short-range anti-submarine unguided multiple missile system.

OPERATION

Ship's sonar provides submarine position for prediction of the Terne launcher elevation and bearing data. The six-barrelled launcher can be used for firing single or multiple salvoes of solid fuelled rockets on an unguided trajectory. A hydro-acoustic (proximity) fuze detonates the warhead. A six-missile salvo can be fired in five seconds. Reload time is 40 seconds, and is automatic.

CHARACTERISTICS

Range: Up to 3 km
Firing sector: 360°
Launcher: Sextuple remote-power-controlled. Automatic loading from manually loaded magazine hopper. Special launcher protection against ice and arctic conditions
Missiles: Length 2 m; diameter 20 cm; Fuzing: proximity, time, and impact

STATUS

In production by Kongsberg since 1960. Fitted in Royal Norwegian Navy ships.

CONTRACTOR

Kongsberg Vapenfabrikk, Postbox 25, 3601 Kongsberg, Norway.

SWEDEN

4862.241
ELMA ASW GRENADE SYSTEM

To meet new threats from intruding small and medium-size submarines into coastal waters, particularly in Scandinavia where detection among islands and in shallow waters is difficult, the Swedish Navy has concentrated efforts into ways of combating this situation. A recent successful result of these efforts is the ELMA anti-submarine grenade system.

The ELMA lightweight ASW system is now entering service on board all fast attack craft and MCM vessels of the Royal Swedish Navy. The system is the outcome of collaboration between the Navy and an industrial team consisting of FFV for the ammunition, and Saab Missiles for the launcher and electronics.

A ship system comprises four Saab LLS-920 launchers, each with nine tubes, supplementary control electronics and power supply. The tubes and support structure are of non-magnetic stainless steel, and the launchers are mounted on deck with a tube elevation of 30 degrees. Tubes are loaded from the

ELMA ASW grenade system launchers aboard a Swedish FPB

muzzle with the grenades, and from the rear with the propulsive charges. Grenade firing is initiated from the bridge in a programmable pattern when a submarine target has been identified and located.

The LLMA grenade carries a shaped charge specially designed for good submarine hull penetration qualities. It is stated that the blast jet will make a hole in a boat's pressure hull after passing through the waterfilled superstructure. The grenade has a patented feature that prevents it bouncing or tumbling when striking a hard surface moving through the water.

CHARACTERISTICS
System
Number of grenades: 9, 18, 27 or 36 per salvo
Range: 250 - 300 m (approx)
Dispersal: Adjustable
Grenade
Calibre: 100 mm
Length: 267 mm
Weight: 4·2 kg
Equipment weights and dimensions
Launcher: 103 kg, 460 × 920 × 620 mm
Relay unit: 7 kg, 330 × 230 × 110 mm
Firing unit: 6 kg, 330 × 230 × 148 mm
Power supply: 34 kg, 610 × 315 × 210 mm
STATUS

6021.241
TYPE 375 ANTI-SUBMARINE WEAPON SYSTEM
This is a shipborne surface to sub-surface medium-range anti-submarine unguided missile system.
OPERATION
Ship's sonar provides submarine position for prediction of Bofors 375 launcher elevation and bearing data. The launcher has either two or four tubes and can fire single- or multiple-shot salvoes. A special design of missile nose ensures a predictable and accurate underwater trajectory. The launcher is reloaded by automatic means from the magazine which is disposed directly below the launcher.

Missiles have three types of rocket motor giving differing range brackets. The missile trajectory is flat thus giving a short time of flight to minimise target evasive action. Fuzes are fitted with proximity, time, and DA devices.
DEVELOPMENT
The initial version of the system, comprising the four-tube launcher and the M/50 rocket, was developed in the early 1950s, and became operational about 1956. The two-tube launcher was developed in 1969-72 and the Nelli rocket in 1969-73. A version made in France by Creusot-Loire under licence from Bofors is described in **2057.241** above
STATUS
The twin-tube launcher (**2368.241**) and anti-submarine rockets are in production for a number of navies.
CONTRACTORS
Launcher and missile: AB Bofors, 691 80 Bofors, Sweden.
Predictor system: Various: (eg Philips Elektronik AB, Sweden; Ferranti Ltd, England; and NV Hollandse Signaalapparaten, Netherlands).

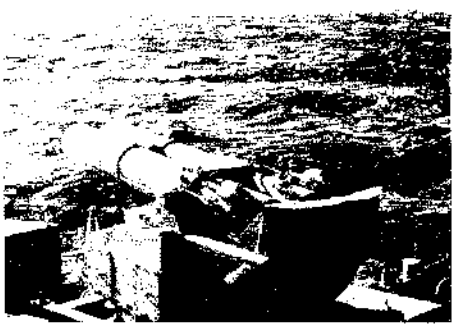
2369.241
SHIPBORNE FOUR-TUBE ANTI-SUBMARINE ROCKET LAUNCHER
The Bofors 375 mm four-tube anti-submarine rocket launcher is electro-hydraulically driven, has an integral fixed-structure loading hoist with a rotatable rocket table, and is remotely controlled.

In an emergency the launcher can be hand laid using a follow-the-pointer device and the hoist can be hand operated. Otherwise remotely controlled electro-hydraulic laying machinery is used. Fuze setting is with the rocket in the tube. The rocket table holds eight rounds. Reload time for four rockets is three minutes, and the minimum interval between firings is one second. The manning complement for continuous firing is four men.
CHARACTERISTICS
Weight, excluding rockets and flame guard: 7·3 t
Traversing speed: 18°/s
Elevating speed: 10°/s
Traverse limits: –130°
Elevation limits: –15 to +90°
Power supplies: 440 V, 60 Hz, 3-phase
Power consumption: Loading 11 kW (mean); tracking 3·2 kW (mean)



'Mogami'-class Japanese frigate with Bofors four-tube A/S rocket launcher before bridge. Launcher is built under licence in Japan by Mitsubishi HI

STATUS
Design was started in 1948 and the launcher first went into service with the Royal Netherlands Navy, which had initiated the work, in 1954. Since then it has been supplied to Argentina, Colombia, France, Federal Republic of Germany, Japan, Portugal and Sweden.

No longer in production. Superseded by the two-tube launcher
CONTRACTOR
AB Bofors, 691 80 Bofors, Sweden.

2368.241
SHIPBORNE TWO-TUBE ANTI-SUBMARINE ROCKET LAUNCHER
The Bofors ASW rocket launcher is used for firing anti-submarine rockets at close and medium ranges. The launcher has an integral motor-driven twin hoist for loading both tubes at once, and a rotating loading table. The laying mechanism is electro-hydraulic with choice of local or remote operation. Fuze setting is with the rocket in the tube. The rocket table holds four rounds and the total number of rockets in the operating room is 24. The shortest time between successive firings is one second; the time for firing six ready rockets (four on the table and two in the tubes) is one minute and the firing rate for continuous fire is two rockets every 45 seconds. The manning complement during continuous firing is three men.

CHARACTERISTICS
Weight, excluding rockets but including flame guard and deck plate: 3·8 t
Traversing speed: 30°/s
Elevating speed: 27°/s
Traverse limits: Unlimited
Elevation limits: (Mechanical) 0 to +90°; (for firing) 0 to +60°
Power supplies: 440 V, 60 Hz, 3-phase
Power consumption: Tracking 6 kW (mean)
STATUS
In production.

Bofors twin tube ASW rocket launcher

2474.441
TORPEDO TYPE 42 (TP 42)

This 400 mm diameter torpedo was originally intended as a successor to the Royal Swedish Navy's TP 41 and was designed for use against submarines and surface targets. The Type 42 (TP 42) torpedo is the base model for several derivatives, among them the TP 421/422 operated by Swedish forces, and a recent derivative designated TP 427.

The TP 42 model can be launched from ships or helicopters and offers combined wire guidance plus a passive homing capability. The TP 427 offers these facilities together with improved data transmission and signal processing techniques. The self-adaptive homing device employs correlation principles to assist sonar operation under adverse conditions. It can be preset to attack surface or submarine targets, and can be launched from submarines, surface vessels, helicopters, fixed-wing subsonic aircraft, or other vehicles such as the Ikara ASW missile. It may be wire-guided from a cruising or hovering helicopter after launch without a parachute. Torpedo speed changes can be effected under computer control, via the wire-guidance link, or preset control.

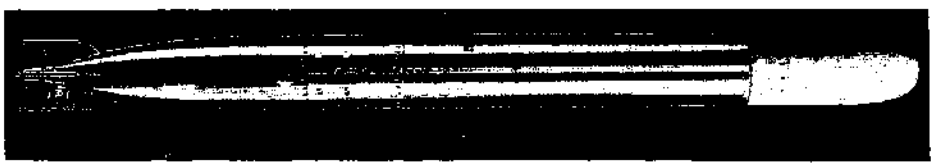
Swedish TP 427, a developed version of the TP 42 torpedo

Design work is in progress of a still more advanced version, the TP 43XO.

CHARACTERISTICS
Length: 260 cm including wire guidance section
Diameter: 400 mm
Weight: 298 kg
Weight of explosive payload: 50 kg (approx)
Weight of wire section: 27 kg
Propulsion: Electric, 2-speed, silver-zinc battery
Fuze: Impact and proximity

STATUS
In production for the Royal Swedish Navy.

CONTRACTOR
FFV, Ordnance, 631 87 Eskilstuna, Sweden.



2367.441
TORPEDO TYPE 61 (TP61)

Torpedo Type 61 is a long-range, high-speed 21 inch (533 mm) wire-guided weapon carrying a 250 kg explosive charge. Designed for use against surface targets, it can be launched from surface vessels, submarines or coastal defence and can be adapted readily to fit a variety of launch tubes and fire control systems.

A thermal propulsion system is used which operates with hydrogen peroxide as an oxidiser. This results in an almost invisible wake, and also gives the TP61 an extremely long range, generally three to five times that of a modern electrically-propelled torpedo at the same speed.

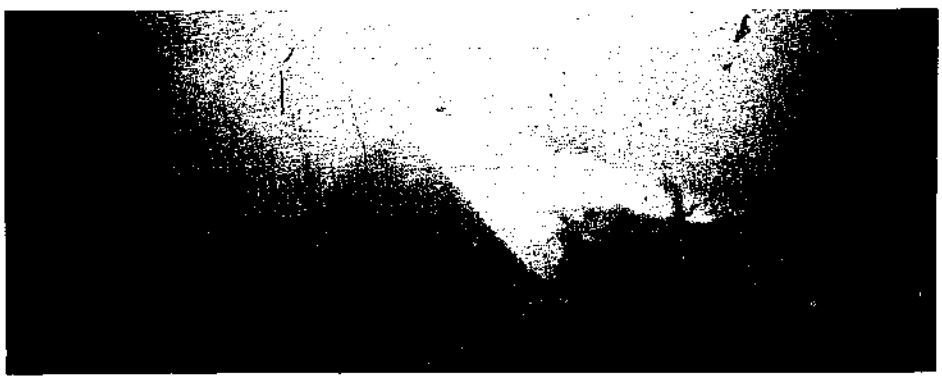
Maintenance requirements are low; storage time without overhaul is ten years with only routine checks each year, and the torpedo will remain operational in its tube for up to four months without overhaul.

Special techniques employed in the handling of hydrogen peroxide have proved to provide a high level of safety.

TP 617, latest version of Swedish Type 61 long-range torpedo

CHARACTERISTICS
Length: 702·5 cm
Diameter: 533 mm
Launch weight: 1796 kg
Propulsion: Thermal, wakeless
Warhead: 250 kg HE
Fuze: Impact and proximity
Course lateral dispersion: <0·003
Speed keeping dispersion: Approx 0·003

STATUS
The torpedo is in production and has been delivered in large numbers for the Royal Swedish Navy (where it is designated TP 613) and is in operational service with some NATO countries, including, it is believed, Denmark and Norway. A developed version of this torpedo, designated TP 617 and including an on-board digital computer, digital data transmission and final acoustic homing, with longer range performance, went into production in 1983.



CONTRACTOR
FFV, Ordnance, 631 87 Eskilstuna, Sweden.

4883.441
BOFORS SEA MINES

Current sea mine production by the Swedish Bofors organisation is concentrated on two types of influence mine introduced in the latter part of 1984: the Rockan GMI 100 ground mine, and the MMI 80 moored mine.

GMI 100 Rockan: This 175 kg weapon is an influence ground mine which is mainly intended for use as an anti-invasion deterrent against small and medium-tonnage vessels in coastal waters, inlets, and confined waters such as harbours. It may also be deployed in deeper waters against submarines to protect friendly routes and bases. A feature of the design is the shape which enables mine laying over a wide area while the minelayer covers the minimum distance. This is achieved by shaping the mine in a casing that enables it to plane, or glide, in the water for a distance of up to twice the depth of the water it is being laid in. This also enables mines to be sown in pairs from each side of the ship, or for mines to be spread out directly from the quay.

Another advantage of this shape is its low profile which makes it difficult to detect by mine-hunting sonar and other anti-mine techniques. The mine is constructed of an outer shell of reinforced plastic containing an explosive charge, a fuze with arming unit, and a sensor/electronic unit. The outer shell has sliding runners to enable the mine to be moved on a mine rail, orientated either along or across the rails. The shell can be opened easily for maintenance or for adjustments etc.

After resting on the seabed for a time the Bofors Rockan gound mine becomes very difficult to detect both visually and by mine-hunting sonar

CHARACTERISTICS
Length: 1015 mm
Width: 800 mm
Height: 385 mm
Weight: 175 kg
Laying depth: 5 – 100 m
Glide coefficient: 2 (approx)
Glide speed: 2 m/s (approx)
Weight of explosive: 105 kg
Minimum distance between mines: 25 m

MMI 80 Moored Mine: This is an influence mine for use against small and medium-tonnage surface ships and submarines. It is suitable for laying in water 20 to 200 metres deep. The mine itself consists of a buoyancy section of cellular plastic, which also contains the explosive charge, the fuze and the sensor/electronics package (which is similar to that of the Rockan, but adapted to the moored mine role).

The MMI 80 is programmed to anchor itself automatically at the desired depth which is set on a pressure sensitive device before sinking. A Manostat 80 sinker unit is employed with the MMI 80, and the mine can be laid from rails.

CHARACTERISTICS
Length: 1125 mm
Width: 660 mm
Height: 1125 mm
Total weight: 415 kg
Sinker weight: 240 kg
Weight of explosive: 80 kg
Bottom depth range: 20 – 200 m
Mine depth range: 10 – 75 m
Minimum distance between mines: 25 m

STATUS
Production.

3968.241
FRAS-1 ANTI-SUBMARINE WEAPON

FRAS-1 (free-rocket anti-submarine) is the designation that has been assigned to the anti-submarine missile associated with the forward twin launcher (SUW-N-1) in 'Moskva' class helicopter carriers and 'Kiev' class aircraft carriers. FRAS-1 is reported to have a maximum range of up to 30 km and to consist of an Asroc-type weapon (**6001.241**) in which a rocket is used to project a nuclear depth

charge to the neighbourhood of the suspected target, as determined by sonar and other means, after which the rocket separates from the charge which sinks to a suitable depth before being detonated by either a straightforward pressure/depth fuze or some type of proximity fuze. It has been conjectured that the probable yield of the nuclear payload is in the region of five kilotons.

Provisional dimensions are: length 6·2 m and diameter 55 cm.

Armament of Kiev class carriers includes RBU-6000 ASW rocket launchers, SUW-N-1 twin launch ramp for long-range ASW weapons, eight SS-N-12 SSMs, twin launch ramp for SA-N-3 air-to-surface missiles, and twin 76 mm DP guns (G. Jacobs)

3969.241

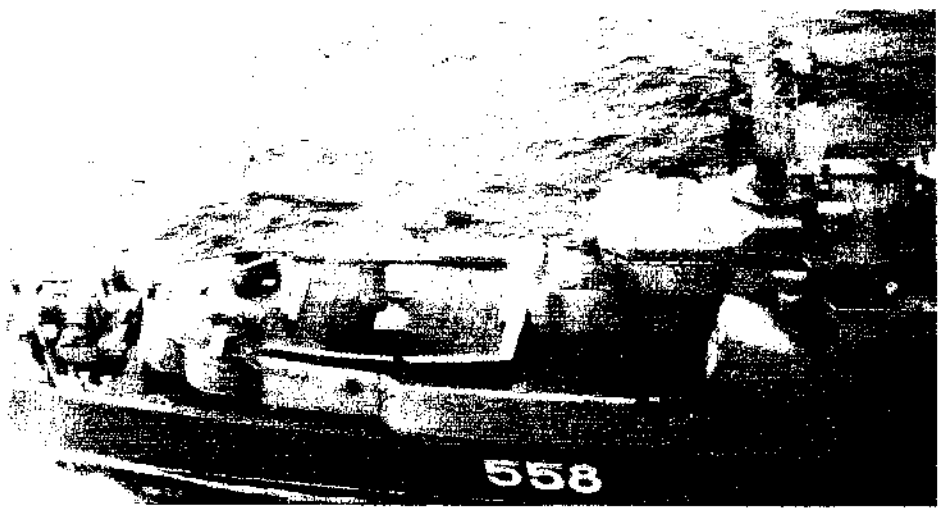
SS-N-14 ANTI-SUBMARINE WEAPON (SILEX)

The SS-N-14 (Silex) is thought to be somewhat similar in concept to the French Malafon (**1179.241**) or the Australian Ikara (**6002.241**) anti-submarine weapons in which a subsonic winged vehicle carries a homing torpedo to the position of the target submarine and can have its course corrected during flight so as to allow for submarine movements and make an accurate drop. In the Soviet case, however, it is believed that a nuclear warhead can be carried instead of the torpedo and has a weight of about 100 kg and a yield in the low kiloton range. No confirmed photographs of the SS-N-14 have been released for general publication, and indeed, for many years, it was thought to be an anti-ship missile system rather than an anti-submarine system. The evidence which has caused this change of assessment has not been released but is believed to be conclusive.

It is also believed possible that the SS-N-14 has an anti-ship capability and may be able to drop a homing torpedo outside a ship's normal defensive cover. No confirmation of this possibility has ever been seen.

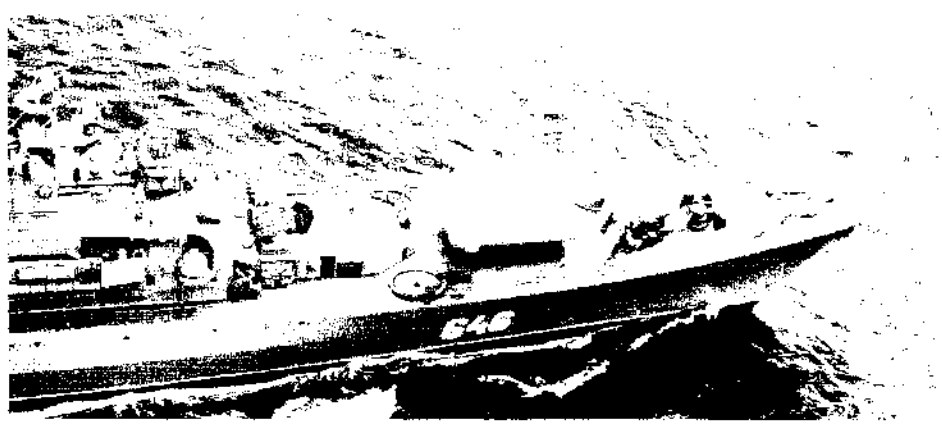
CHARACTERISTICS

Length: 7·6 m



Max range: 55 km

Payload: Nuclear warhead or homing torpedo

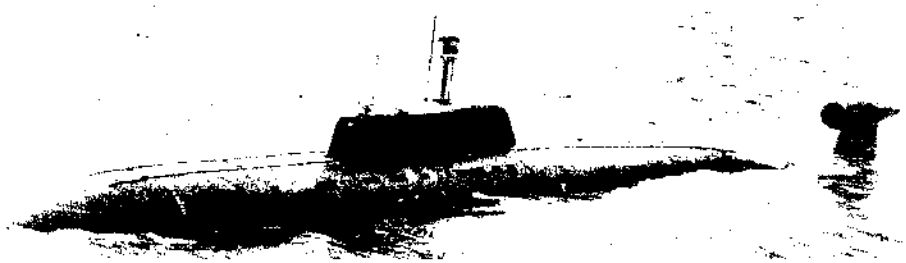


Trajectory: Programmed/radio command flight to target area under autopilot control with command override capability. Speed is about Mach 0·95 at 750 m above sea

STATUS

Operational since 1968 and fitted in 'Kirov', 'Krivak', 'Kresta II' and 'Kara' class ships. Later Soviet classes noted with this weapon system include the 'Udaloy' class of anti-submarine destroyers which are fitted with two quadruple launchers.

Port quad launcher for SS-N-14 (Silex) ASW missile aboard 'Kara'-class cruiser Petropavlovsk. *Also to be seen is a SA-N-3 twin ramp launcher and two RBU 6000 12-barrelled rocket launchers* (G. Jacobs)



Krivak I-class frigates have a quad SS-N-14 launcher and two forward RBU 6000 rocket launchers for ASW engagements (G. Jacobs)

3970.441

SS-N-15/16 ANTI-SUBMARINE WEAPON

The SS-N-15 is reported to be an anti-submarine weapon of the same general type as the American Subroc (**1128.441**), a system in which a submarine-launched missile follows a short underwater path before broaching the surface to follow an airborne trajectory for the major part of the distance to the target area. On reaching the latter, a depth charge bomb is released to continue on a ballistic trajectory until it enters the water near the target, sinking to the optimum depth before detonation. This type of weapon relies upon accurate localisation of the target in the first instance, followed by rapid launch and flight to the target area before the target has time to travel far from its last known position. Maximum range was originally estimated as about 35 km but later official US figures suggest between 45 and 50 km. The same source also confirms the torpedo-tipped version of this weapon which carries a homing torpedo payload instead of the depth charge. In the homing torpedo carrying version the weapon is designated SS-N-16.

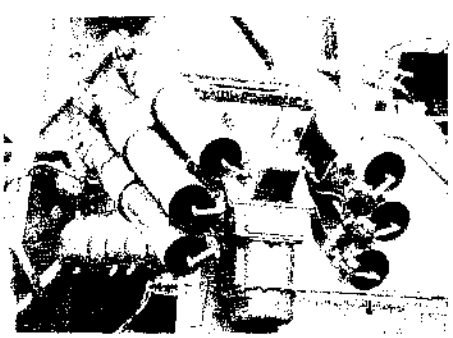
New 'Sierra'-class nuclear powered attack submarines have stern mounted towed array sonar pod and armament includes ASW missiles

Ka-27, NATO code-name Helix, naval helicopter is embarked on Red Fleet vessels for ASW (Helix-A) and missile beyond-the-horizon guidance (Helix-B) roles

STATUS
The SS-N-15 is probably in 'Papa', 'Alfa', 'Victor III', and 'Tango' class Soviet submarines. Other classes of submarine which may be equipped to operate this weapon include some 'Charlie II' class and 'Victor I or II' boats.

4422.241
SOVIET ANTI-SUBMARINE ROCKET LAUNCHERS
There is a wide variety of anti-submarine rocket launchers in the Soviet fleet although all appear to operate on much the same principle of firing charges in a pattern ahead of an attacking ship from a mounting which can be trained and elevated under remote control. Two different calibres of 250 mm and 300 mm have been reported and the weight of the bombs in the 250 mm versions has been estimated as 180 to 200 kg. Few details are available of the many different systems but such as are known are given below. The systems may be designated as either RBU or MBU and the associated number is understood to mean the maximum range possible in metres.

MBU 1800: A five-barrelled 250 mm calibre system fitted in some of the smaller and older ships and now probably obsolescent. The launching tubes are in two horizontal rows with three in the top row and two in the bottom row.

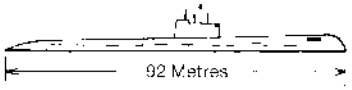


MBU 2500: A sixteen-barrelled 250 mm calibre system of much the same vintage and design as the MBU 1800 with two horizontal rows each of eight launching tubes about 1·6 m long. Depth bombs are loaded by hand. The system is fitted in the older cruisers and destroyers although also in the more modern but smaller 'Petya I'.

MBU 4500A: A six-barrelled version hitherto seen only in the one major fleet support ship 'Berezina'. It is thought to be of 300 mm calibre with a launching tube 1·5 m long and to use automatic reloading.

MBU 6000: The most modern system, probably of 300 mm calibre, and fitted very widely. Launch tubes are arranged in circular fashion and it is believed that they are reloaded automatically by bringing them to the vertical and then indexing one by one while depth bombs are loaded from below. Range is 6000 m and the launch barrel length has been extended to about 1·8 m.

MBU 1200: A six-barrelled system which is fitted normally on the quarters of larger ships such as the 'Krov', 'Kara' and 'Kresta'. Almost certainly it has a range of no more than 1200 m and is probably intended to deal with torpedoes if they can be detected in the closing stages of an attacking run.



STATUS
The MBU 6000 and 1200 are in widespread use throughout the Soviet fleet with the MBU 1200 being reserved for the larger ships.

Part of the threat posed to the ASW forces of the West by Soviet attack submarines

---

2995.441
533 mm TORPEDO
Certainly until recently, and possibly on a continuing basis, the standard calibre of torpedo in service in the Soviet Navy has been 533 mm. A torpedo of smaller calibre was in use on torpedo boats and escort vessels before the Second World War, but this is now to be found only on P-4 patrol boats.

It may confidently be assumed that torpedo development in the USSR has generally proceeded along lines similar to those of developments in Britain, France, and the USA and has probably taken the form of development from wartime German pattern-running and homing torpedoes.

It is, however, worth noting that somewhere around the late 1950s a version of this torpedo with a nuclear warhead was deployed in some submarines, and this was confirmed in 1981 when a Soviet 'Whiskey' class

Stern view of 'Kara' class cruiser Petropavlovsk *shows hangar and alighting area for 'Hormone' ASW helicopter. SA-N-3 missile launcher and associated Headlight radar group, and port and starboard 5 tube 533 mm torpedo launchers* (C Jacobs)

submarine ran aground in Swedish waters. The Soviets would regard it as normal practice to fit alternative nuclear warheads to their torpedoes. Swedish sources estimate a warhead yield of about 15 kilotons.

Two distinct stages have been distinguished in the development of surface vessel launchers for torpedoes of this calibre, and the fact that the launchers are of slightly different lengths at these two stages may indicate that the corresponding torpedoes are also different - but it does not necessarily do so. One 533 mm torpedo believed to be the 1957 pattern, is said to be 825 cm long - which is as large as torpedoes go. It is carried by submarines and torpedo boats. Both surface target and ASW models exist in the Soviet range of 533 mm diameter torpedoes.

The dates of introduction of these two launcher groups appear to have been about 1948/49 and 1957/58. Apart from the difference in length just mentioned the principal change appears to be from manual local training to remote power training. One-, three-, and five-tube launchers are found in the earlier series; two-, three-, four- and five-tube launchers in the later.

STATUS

All the above types of launcher seem still to be in service, as also, presumably are the torpedoes. 533 mm torpedoes are also a standard weapon on Soviet submarines, and the 'Foxtrot' and 'Whiskey' class boats are equipped with four and two 533 mm stern torpedo tubes, respectively.

Other countries operating Soviet 533 mm torpedoes include: Albania, Bulgaria, Chinese People's Republic, Egypt, Finland, German Democratic Republic, India, Indonesia, Iraq, North Korea, Libya, Poland, Romania, Somalia, Syria, Viet-Nam and Yugoslavia.

2997.441

LIGHT TORPEDO

Of comparatively recent development, a 406 mm torpedo is now in service with some submarine chasers and light destroyers of the Soviet Navy. This is launched from trainable tubes that are only about five metres long, so the torpedo must be quite a small one. These torpedoes are believed to be similar in concept to the American Mk 44 and Mk 46 torpedoes (see later in this section) and are principally anti-submarine weapons. They are deployed aboard 'Hotel II and III' class ballistic missile submarines, 'Echo I' class nuclear attack submarines, 'Echo II' class missile submarines, and 'November' class boats, and are fired from special stern countermeasures tubes, similar to those found in British 'Oberon' and 'Porpoise' class submarines. Quintuple mounts are fitted in 'Petya 1' class frigates, and 'Mirka' class frigates. Fixed mounts exist on a number of small patrol classes. Bulgaria is known to operate Soviet 406 mm torpedoes.

3627.441

SOVIET SEA MINES

Soviet sea mines in current use fall into four major categories: moored, seabed, floating, and nuclear, and brief notes on each category appear in the following paragraphs.

Defensive moored mines: The main type is the basic contact moored mine that uses an inertia-type firing mechanism which can either be galvano-contact, contact-mechanical or contact-electrical. The mines come in three sizes: small, medium and large according to the explosive charge carried. The two smallest mines are designated YaRM and YaM. The former has an explosive charge of 3 kg and is used in rivers and lakes; the latter has an explosive charge of 20 kg and is used in lakes and shallow coastal areas. Both have the conventional spherical shape with horns and small sinker units. The medium-sized moored contact mine is believed to be confined to the large stocks of the elderly M08/39 series used for coastal defence barriers. This also is spherical with horns and sinker unit but has an explosive charge of about 120 kg. The largest moored contact mine types are cylindrical with explosive charges in excess of 200 kg. These mines are matched by large stocks of an antenna mine variant for defensive ASW barriers and an acoustic influence activated variant for use in areas of strong tidal or current action. The antenna mine is believed to have a 30 m antenna above and below the mine casing and the acoustic mine has a 30 m target location distance. All three types of moored mine have apparently been exported to Soviet client states and the Warsaw Pact nations.

Offensive bottom mines: There are two basic types of conventional ground influence mines used by the USSR: the AMD-500 and AMD-1000 series. The number refers to their weight in kilograms. The AMD-1000 is reported to be the only one capable of laying by submarine, whereas both the AMD-1000 and AMD-500 can be laid by ship and aircraft. In the last case the designation is reported by Middle Eastern sources to change to KMD-1000 and KMD-500, respectively. The two series are produced in four variants:

(1) magnetic influence that relies on either the intensity of the horizontal or vertical component of the target's magnetic field or the rate of change of the target's field
(2) acoustic influence using either or both low frequency and high frequency noise generated by the target
(3) pressure influence in which the passage of the target over or near the mine causes a reduction in pressure within the water column adjacent to the mine
(4) combination influence in which two or all three of the above influences are combined in a single sensor unit.

For greatest selectivity in target and to maximise sweeping difficulties the combination systems most likely to be used are magnetic-pressure and acoustic-pressure; although the presence of mines with all three influences would be logical for specialist targets such as NATO MCMV forces.

Normal laying depth would be between 4 and 70 m, although the larger AMD-1000 would be effective against submarines down to 200 m. It is assumed that both types can be fitted with ship counter units, anti-handling devices and self-timed neutralisation devices. Both types have been exported widely to Soviet client states and the Warsaw Pact countries. However the pressure influence variants are likely to be restricted to the Soviet Navy and Pact states that are considered trustworthy.

Offensive moored ASW mines: There are three basic types, two of which for delivery by submarine, ship or aircraft are classed as rising mines and the third assessed for delivery by submarine or ship is known as the underwater electrical potential (UEP) mine. All three have their origins as strategic ASW barrier mine types for use in areas adjacent to NATO submarine bases. The rising mines can also be expected to be encountered on transit and choke point zones frequented by NATO submarine and surface units, as they have a secondary anti-ship capability. Of the two rising mine types one is designed for use on the continental shelf (believed to have the NATO code-name Cluster Bay) and the other is an improved version for use on the deeper continental ledge region (believed to be code-named Cluster Gulf). Both are thought to be tethered torpedo-shaped devices fitted with a rocket propulsion unit and an active/passive acoustic sensor device. The target is initially detected by the passive component of the detection system and located by transmissions from the active part. If the target is confirmed as being within the vertical attack zone, the tether is cut and the rocket ignited. The very fast upward speed will allow very little time for the target to evade the device if its launch has been detected. Nothing much is known about the UEP mine other than that it relies on the target's electrical field for detection. It is the presence of these three mines in the Soviet Navy inventory that has prompted the RN to introduce the deep sweeping capability into its MCMV forces to protect the UK's submarine bases.

Nuclear mines: The Soviet Union is believed to have a small stockpile of nuclear mines with yields varying between 5 and 20 kilotons for use against high value surface units, and base targets. Laying of these mines is almost certainly assigned to specially selected SSK/SSN units.

The primary Soviet offensive minelaying platform is the 'Foxtrot', 'Whiskey', 'Tango' and 'Kilo' SSK force because of their covert laying capability. Offensive ASW and ground influence mines would be laid by these boats round European NATO bases and at choke points, while overseas bases, SLOCs and deep water choke points would be assigned to the SSN force. Reactive minelaying and renewal of the fields once laid could be accomplished by the Soviet Naval Air Force with Badger A/G, Blinder A and Backfire B aircraft. Defensive minelaying and selective offensive laying in areas contiguous to the Soviet homeland would be undertaken by the surface fleet and the maritime patrol aircraft.

UNITED KINGDOM

6008.241

LIMBO ANTI-SUBMARINE MORTAR SYSTEM (AS Mk 10)

This is a shipborne surface-to-sub-surface medium-range anti-submarine mortar system. Mortars are stabilised in pitch and roll by a metadyne system referenced to the ship's stable platform.

OPERATION

Ship's sonar provides submarine position data to a predictor which computes mortar elevation and lateral tilt. The triple-barrelled mortar fires a pattern of three mortar bombs which are programmed to give a three dimensional explosive pattern ahead of the firing ship. The bombs can be set to explode at variable depths down to 375 m using hydrostatic fuzes and are also fitted with DA fuzes: the fuze setting is by remote control through relays and uniselectors. Loading is accomplished by pneumatic power horizontal ramming from a magazine which is located alongside the mortar.

Weight of the projectile is about 175 kg with a 92 kg HE warhead and range is about 900 m.

DEVELOPMENT

Developed by Admiralty Underwater Weapons Establishment during the 1950s. Ship fitted in the early 1960s.

STATUS

Operational in British and Commonwealth destroyers and frigates and in many other vessels. See also **2018.241** for modified Australian version.

CONTRACTORS

Manufactured to MoD (Navy) designs by several contractors.

2552.441

TORPEDO Mk 8

Quite possibly the longest-lived of all torpedo designs and certainly a remarkable survival in an otherwise reasonably sophisticated navy, the Mk 8 torpedo, which was designed in the early to mid-1930s, was certainly in service in the RN, including nuclear-powered submarines, until 1973, and may possibly still be in service with some minor vessels and is almost certain to be found in some other navies.

Although it can scarcely be regarded as reasonable that so unsophisticated a device should continue to be the primary armament of the principal attack submarines of the RN it should perhaps in justice be said that, within its limitations, it has performed well

and given service which is honourable as well as long. The latest known versions are the Mods 2, 3 and 4, all for surface ship targets.

CHARACTERISTICS

Length: 670 cm
Diameter: 21 inches (533 mm)
Weight: 1521 kg
Propulsion: Compressed air
Speed: 40 - 45·5 knots
Range: 6400 - 4570 m
Warhead: HE 340 kg
Submersion: To 18 m
Guidance: Preset course angle and depth

STATUS

Obsolescent. Being replaced in RN service by the Tigerfish torpedo (**2440.441**).

2440.441
TORPEDO TIGERFISH (Mk 24)

Tigerfish is the name given to the production weapon derived from a redevelopment of the Mk 24 torpedo (**2472.441** *1971-72*). The weapon is a 21 inch wire-guided/acoustic homing torpedo fitted with impact and proximity fuzes and is designed for submarine launch against submarine and surface targets.

Wire guidance is used in the initial stages of an engagement up to the point where the torpedo's automatic three-dimensional active/passive acoustic homing system can control the run into the target. Wire is dispensed from both torpedo and submarine so as to avoid any wire stress due to their relative motion. The torpedo is roll-stabilised by controlling ailerons on retractable mid-body stub wings and is steered by hydraulically powered cruciform control surfaces mounted at the tail.

The torpedo carries its own computer which is connected through the guidance wire to the computer of the submarine's torpedo fire control system. During the wire guidance phase the on-board computer responds to the demands of the submarine computer, and on the homing run it interprets the data from the homing system sensors and calculates and commands the appropriate course, subject to a priority overriding steer-off azimuth control from the submarine.

During a homing run using the torpedo's active sonar the interrogation rate is progressively increased, as the torpedo nears the target, so as to improve system accuracy. The interrogation rate is controlled by the on-board computer, which is thus performing several functions during this phase: interrogation control, sonar data computation, torpedo steering control, and data transmission to the submarine to update its own computer memory.

Both the Mod 0 and Mod 1 Tigerfish have similar external profiles and are propelled by a powerful two-speed electric motor driving a pair of high efficiency, low noise, contra-rotating propellers.

CHARACTERISTICS

Length: 6·464 m
Diameter: 21 inch (533 mm)
Weight: 1550 kg (in air)
Speed: Dual high/low selectable at all times, max 50 knots (estimated)
Range: 21 km (estimated)
Fuze: Impact and proximity
Propulsion: Electrically driven contra-rotating propellers; 2 speeds

DEVELOPMENT

Among the various improvements being examined in the continuing development programme are ways of enabling the weapon to complete successfully fully automatic terminal homing engagements when climbing from depth towards the most difficult types of surface target. A modification kit has been developed which enables Mod 0 torpedoes to be upgraded to Mod 1 standard.

STATUS

In production for the RN. The Mod 0 version has been in service for some years and the Mod 1, higher performance model, was becoming available in mid-1978. Data given above relate to the warshot torpedo; there are also exercise and dummy (handling) versions. The exercise version is similar to the warshot but has rechargeable batteries, becomes buoyant at the end of the run, and has an instrumentation pack for data analysis in place of the warhead.

Tigerfish has been released for export to some foreign navies. The first of these to be identified being Brazil, which in 1982 ordered the Mk 24 Tigerfish for a new generation of Brazilian submarines designed and built in West Germany.

CONTRACTOR

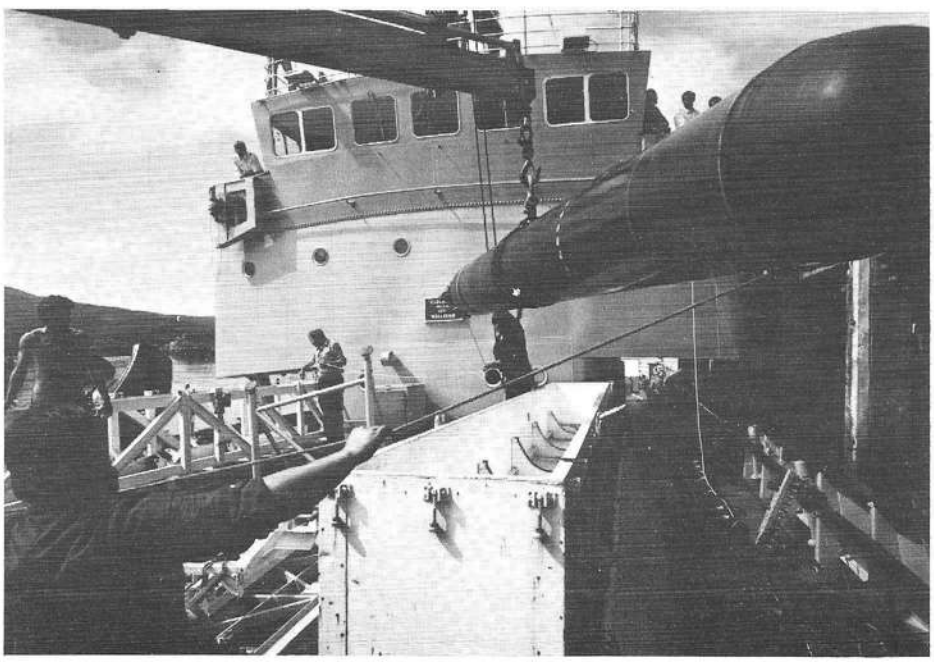
Marconi Underwater Systems Ltd, Elettra Avenue, Waterlooville, Hampshire PO7 7XS, England.

4559.441
SPEARFISH TORPEDO

Spearfish is the name given to the heavyweight torpedo designed to meet the RN Naval Staff Requirement (NSR) 7525, and currently at an advanced stage of development. Like the existing Mk 24 Tigerfish it is a wire-guided torpedo about 6 m long and with a diameter of 533 mm and an in-air weight of approximately 1850 kg. It is capable of being launched from all types of submarine at their normal operating speeds and depths. Although externally very similar in appearance to the Tigerfish, Spearfish is very different internally and has more in common with the TVX underwater test vehicle (**4416.441**) and the lightweight Stingray torpedo (**2448.441**). Like the latter, Spearfish includes on-board digital computers which permit sophisticated adaptive operation of the torpedo's guidance system in response to changing environmental, tactical and operational circumstances, as well as being a major element in the functioning of the weapon's homing sonar sub-system.

This capability is enhanced by the ability of the guidance wire cables to exchange data between torpedo and launch submarine in addition to the guidance commands transmitted from the submarine. Thus it is theoretically possible to enjoy the full benefits of a 'programmable' software e the attack guidance package in the weapon until, for reasons of autonomously. The wire dispensing system is the subject of a £4 million development contract necessity, the link is severed and the awarded torpedo is free to completto STC's Defence Systems Division and is said to be able to carry about 70 data messages per second in each direction. The on-board computer, probably a 1412AL, acts as an operational control and is responsible for adjustment of speed, attitude, direction and depth of attack.

The sonar transducer array in the nose of the vehicle is capable of both passive and active modes of operation, the former being the favoured one for the intitial stages of an attack, and the option of changing to active homing remains if target behaviour indicates awareness of the attack. Digital signal processing techniques are employed to ensure maximum freedom from acoustic jamming and other sources of unwanted noise (eg self-noise, natural noises etc).



A major difference between Spearfish and its predecessors is the propulsion system used. Both Tigerfish and Stingray employ electric motors, but for the new weapon this method lacks the power density demanded by the Spearfish performance range and speed specifications and a Sundstrand type 21TP01 gas turbine engine working with a pumpjet is used to achieve long ranges and high speeds (about 60 knots). This engine burns OTTO fuel to which are added sea water and hydroxyl ammonium perchlorate, increasing the energy content by 40 per cent by weight, or 70 per cent in terms of volume.

The warhead is believed to consist of a newly developed and highly classified directed energy high explosive device capable of penetrating modern advanced separated skin outer and pressure hulls used in the latest submarines. Fuzing, detonation and initiation arrangements of comparable sophistication would also clearly be needed to complement the advanced warhead.

DEVELOPMENT

Based on similar considerations to those which led the USN to embark on the ADCAP (advanced capabilities) improvement programme for the Mk 48 heavyweight torpedo (**2823.441**) (improvements in submarine threats in general, and the Soviet 'Alfa' class submarines in particular). The RN foresaw the need for an eventual replacement for the Mk 24 Mod 1 Tigerfish with appreciably higher performance characteristics. This was initially conceived as a combination of the new homing technology then being embodied in the Stingray lightweight torpedo (**2448.441**) and thermal propulsion to field a heavy torpedo capable of high speed and deep submersion coupled with sophisticated target seeking. At that stage (1976-77) the project was known as Naval Staff Target 7525, but subsequently became an NSR (with the same number). A feasibility study covering the original scheme for incorporating the advanced Stingray homing and guidance system in a heavyweight torpedo was the subject of a contract awarded to Marconi Space and Defence Systems in 1977.

This was followed in 1979 by a competition between the projected Spearfish, and procurement of the US Mk 48, which after much lobbying at many levels eventually resulted in a UK MoD contract worth about £500 million for development and initial procurement of Spearfish as well as including a sum for completion of the Stingray programme. Much related experimental and trials work was carried out

Early development model of Spearfish heavyweight torpedo during in-water trials

in these periods by government agencies using the AUWE TV1 and TVX test vehicles, leading to many valuable inputs to the Spearfish design and development effort.

STATUS

Work on Spearfish development models began early in 1982 and examples were available for in-water trials in the first quarter of 1983. New, purpose-built facilities have been constructed for production of Spearfish as well as for other torpedoes such as Tigerfish and Stingray. No in-service date for Spearfish has been officially disclosed but it is believed to lie between 1987 and 1989.

CONTRACTOR

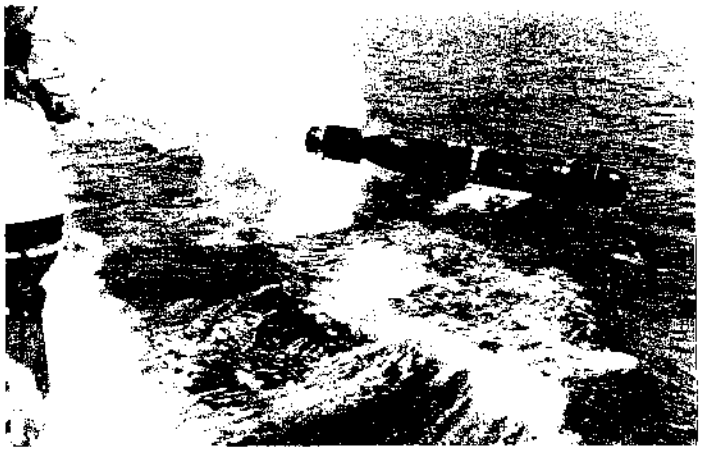
Marconi Underwater Systems Ltd, Elettra Avenue, Waterlooville, Hampshire PO7 7XS, England.

2448.441

STINGRAY TORPEDO

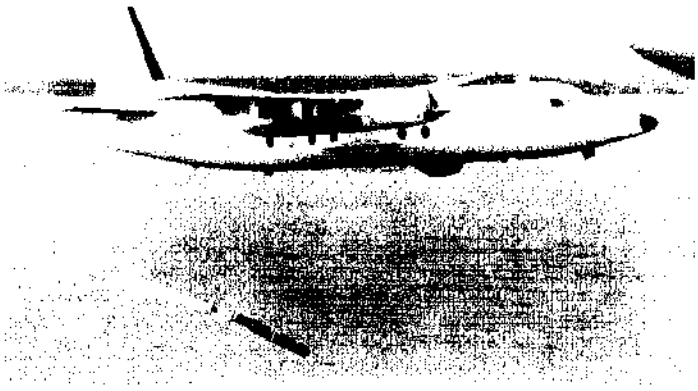
Stingray is an autonomous acoustic homing lightweight torpedo now entering service with the RN and RAF, and claimed to be the most advanced anti-submarine torpedo in the world with a capability for countering submarine threats effectively until well into the 1990s. It is designed for launching from helicopters, fixed-wing aircraft, and surface ships over a wide range of speeds and sea states. It is claimed to be unique in that its multi-mode multi-beam sonar, quiet high-speed propulsion system, and fully programmable on-board digital computer enable high performance both in shallow water where sonar conditions are notoriously difficult, and also in deep water. Stingray's computer enables it to make its own tactical decisions during an engagement to optimise the various homing modes to suit the underwater environment and the behaviour of the target. Both trials and simulation show that the single shot kill probability is very high indeed. The on-board computer enables the torpedo to be tuned to meet a nation's particular requirements by varying the software programs.

Vehicle hydrodynamics are accomplished by an electro-hydraulically driven proportional control system developed by BAe Dynamics Group, Bracknell (formerly Sperry Gyroscope Ltd). The four control surfaces are mounted aft of the propulsor. The new sea-water battery gives extended endurance and no performance degradation with depth.



No official performance details of Stingray have been cleared for publication, but informed comments which have been published enable a few deductions to be made. One such comment, in an indirect comparison with the US Mk 46 torpedo, claimed that it and Stingray had very similar speed, diving depth and endurance characteristics; from known performance of the Mk 46, this implies a maximum depth capability of as much as 750 m, a maximum speed of at least 45 knots and an endurance of about eight minutes at that speed. It was also hinted that anticipated propulsion improvements might enhance Stingray's speed appreciably, and hence its range. Elsewhere, it was claimed that the conventional blast type warhead of the Mk 46 is limited in effect against the deeper-diving submarines with extensive outer hulls that are now entering service, but Stingray is expected to be effective in this respect against the strongest pressure hulls going to sea with the Soviet fleet. Other sources believe that in place of blast type torpedo warheads, some form of directed-energy payload is required to counter modern submarines. Such devices require highly accurate guidance to ensure that the torpedo strikes its target in the most vulnerable place at the right angle. This suggests that Stingray therefore incorporates both very precise guidance and an enhanced warhead, but this cannot be categorically confirmed as yet.

STATUS



Marconi was appointed main contractor in October 1977. A £215 million contract from the UK MoD was signed in November 1979. The first production acceptance vehicle produced at the Nestor plant was delivered early in August 1981. Contract acceptance trials began April 1982 and the design certificate was issued in December 1982. The torpedo was deployed during the Falkland Islands conflict in 1982.

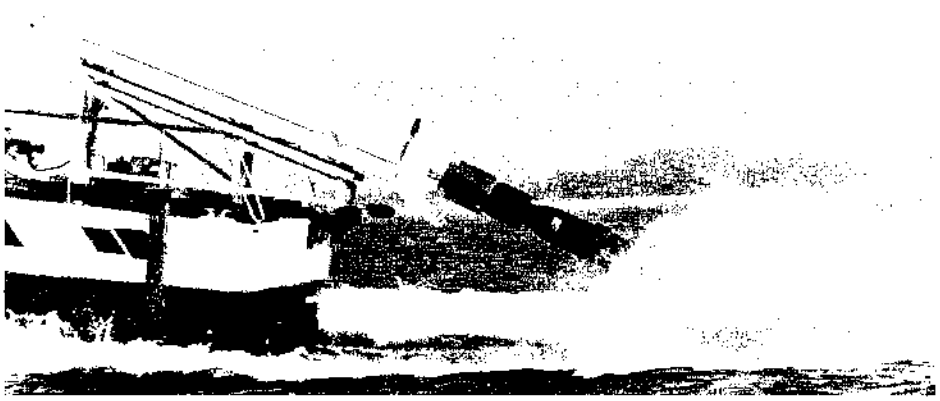
Stingray lightweight torpedo launch

Stingray trials from F27 maritime patrol aircraft prior to entering Royal Thai Navy service

---



4765.441

KINGFISHER LAUNCH SYSTEM

To enable the Stingray lightweight torpedo (**2448.441**) to be operated from a variety of surface vessels, in addition to its primary role of air launch, Marconi Underwater Systems has designed a modular torpedo launch system called Kingfisher. By its adoption it is possible to equip small sea craft for ASW duties, and once used the empty launch assemblies can be rapidly removed and replaced with new, complete units when the ship is back in harbour. Turn-around and reloading time could be as little as 30 minutes.

The basic Kingfisher system consists of a single launch command console (LCC) linked to the multiple launcher tube array. The operator at the LCC can select any tube for launch, preset the torpedo attack pattern and pre-launch data, and fire the weapon. Launcher and torpedo status signals are recorded and interlocked at the LCC to give complete control. In addition to firing in earnest, there is provision for the operator to order safe jettison of the weapon if the circumstances warrant this.

The launcher array consists of a series of individual self-contained launcher modules, fitted in support ramps mounted on the after deck of the vessel. The link to the command operator at the LCC is via a single cable running throughout the ship. Signal distribution and switching between launcher modules is by a unit delivered and mounted as an integral part of the launcher array.

The Kingfisher containerised lightweight launch system for Stingray

Launch of the torpedo is by means of a single command from the LCC, and this initiates the automatic launch sequence: opening the muzzle door, removing tube/interfaces and ejecting the weapon using stored energy. Once the torpedo is in the water, its stability 'back-pack' ensures that the initial plunge is controlled whilst the sea water battery is energised. After the first few seconds of immersion the propulsion and control system is activated, automatically releasing the back-pack. The attack then commences in the normal manner.

STATUS

No contract details have been disclosed.

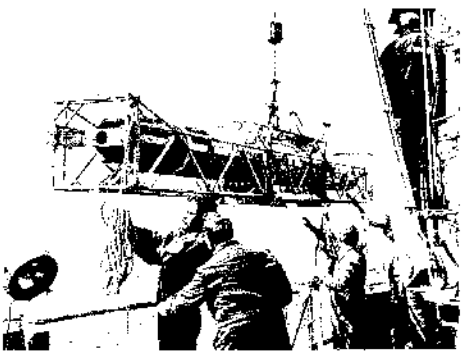
4416.441
TVX UNDERWATER TEST VEHICLE



TVX has been developed to provide a payload carrier to explore new ideas in anti-submarine weapons and warfare, and will be used to assist the development of both lightweight air-dropped and heavyweight submarine-launched torpedoes. It is similar in size and shape to a heavyweight torpedo but, instead of the normal torpedo payload, has a compartment in the nose in which experimental equipment can be accommodated. This enables almost any aspect of torpedo research to be carried out and new propulsion systems can also be tested by replacing the appropriate section of the basic TVX assembly.

The vehicle has a 1412AL digital computer based control system and an SGP 500 three-axis gyro reference unit. The computer controls speed, depth, and safety factors. Control is almost entirely through software which can be adapted quickly to particular payloads so that TVX can simulate all types of modern torpedo.

The vehicle is normally launched from a ship. It is capable of rates of turn of 40° per second and pitch angles of ±28° with speeds varying between 28 and 60 knots. Range is 7·5 km with operating depths of 3 to 300 m.

STATUS
Five-year design and development of three vehicles completed with successful sea trials in 1980.

CONTRACTOR
British Aerospace Dynamics Group, Bristol Division, PO Box 5, Filton, Bristol BS12 7QW, England.

Preparing for tests with TVX developmental vehicle

4482.441
SEA URCHIN MINE

Sea Urchin is a multi-influence ground mine which may be deployed in water depths to 99 m by mine layer or other surface vessels, submarines or transport aircraft. It is effective against submarines, warships, merchant ships, patrol craft and landing craft. The mine consists of a warhead section, available in two sizes, to which is attached a sensing and processing unit (SAP) containing the sensors, batteries, safety and arming unit, microprocessor and electronics. The SAP is common to both warhead sizes to provide maximum flexibility at minimum cost.

Other salient features include: programmable mission parameters for acoustic, magnetic and pressure sensors with individual or multi-influence actuation; selectable activation delay; multiple target count; and selectable sterilisation delay. Sea Urchin is computer-controlled with a simple setting procedure. There are interlocking safety and arming mechanisms with radiation protection. A self-test facility includes automatic sterilisation if a malfunction is detected.

The mine can be activated and triggered by the acoustic signature of a passing ship, a ship's magnetic signature, the change in water pressure caused by a ship, or a combination of all three. The acoustic, magnetic and pressure sensors are selectable before deployment. In addition, an adjustable ship counting device will enable the mine to be triggered after a predetermined number of ships have passed overhead. The microprocessor ensures that the mine will not detonate until the ship target is at optimum range. Delayed activation is provided and a further device enables the mine to become sterile or inoperative after a preceterminec period.

Sea Urchin naval ground mine two 350 kg warheads and SAP module

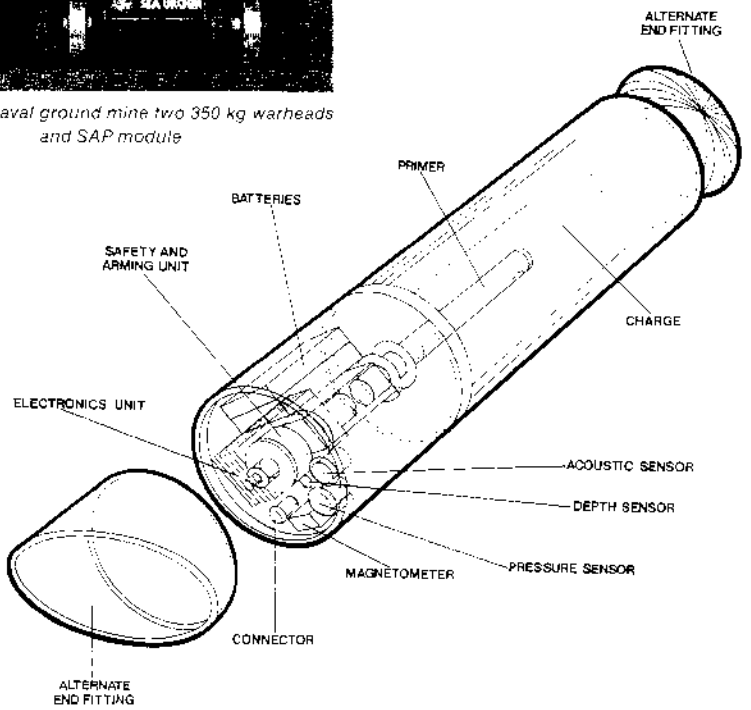


Diagram of internal arrangement of Sea Urchin mine's component parts

CHARACTERISTICS
Diameter: 533 mm (21 inches)
Lengths: 1442 mm (SAP + 1 w/hd module); 2540 mm (SAP + 2 w/hd modules)
Nominal mass: 569 kg (SAP + 1 w/hd module); 1058 kg (SAP + 2 w/hd modules)
Weight in water: 255 kg (SAP + 1 w/hd module); 506 kg (SAP + 2 w/hd modules)

STATUS
Development. Construction of a new facility for underwater weapon production and testing was announced by BAe in 1983.

CONTRACTOR
British Aerospace Dynamics Group, Bristol Division, PO Box 5, Filton, Bristol BS12 7QW, England.

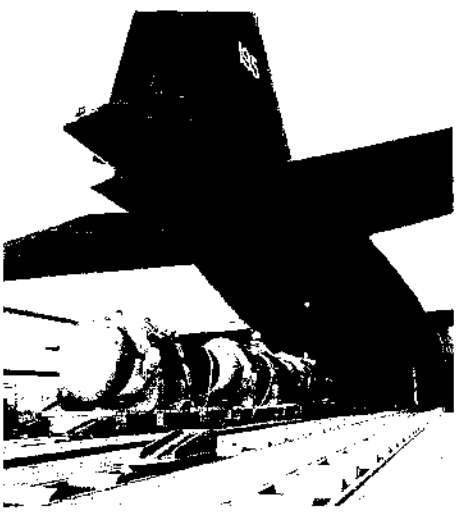
STONEFISH MINES

Marconi Underwater Systems Ltd, in conjunction with the Royal Ordnance plc has developed a family of advanced mines comprising warshot, exercise and training versions. Stonefish, as this family is known, is designed on the modular concept enabling mines to be made up to meet any tactical, exercise or training requirement. All variants may be deployed from surface ships, submarines and aircraft.

The warshot variants are provided with warhead sizes up to 600 kg. The warhead, together with the appropriate launch kit and a standard tail unit containing the sensors, signal conditioning and processor package, can be configured to cover the range of launch vehicles, depths and targets. The basic sensor pack comprises acoustic, magnetic and pressure sensors. The signal processing includes signal conditioning and information processing, the setting of thresholds, mine logic and sterilisation delay times. The mine programme can be modified by means of a portable pre-setter charging threat and operational conditions before the mine is deployed.

The Stonefish warshot versions have a storage life of over 20 years and an in-water or laid life of over 700 days. They are intended to be laid at depths of between 5 and 90 m for surface targets and down to depths of 200 m for submarine targets. To provide training in mine countermeasures Stonefish is available as an exercise variant.

The exercise variant is capable of assessing minehunting and minesweeping effectiveness in its true environment. When laid it is available for data gathering relevant for target selection, together with a facility to emulate known mine characteristics and will provide proof of minefield effectiveness. The main features are:



(1) command
(2) acoustic command system - enabling mine states to be integrated or changed
(3) digital signal processing
(4) available as a seabed test platform for sensor/processing development.

The training variant is inert but can accept all the available equipment options to facilitate classroom instruction, handling, programming and test trials. The refurbishment life for stored warshot weapons is up to ten years.

Mines of the Stonefish family are up to 2·5 m in length, with a diameter of 530 mm and all up weight varying up to 990 kg depending on configuration.

The Stonefish pre-setter, designed as a self-contained unit employs a microprocessor and incorporates built-in data checking during input, and automatic test facilities.

STATUS
Production.

Stonefish is compatible with various launch platforms, including the C-130 Hercules aircraft seen here

Marconi Underwater Systems Ltd, Elettra Avenue, Waterlooville, Hampshire PO7 7XS, England.

4483.441

TOWED UNMANNED SUBMERSIBLE (TUMS)

TUMS is capable of operating at full ocean depths, performing search, identification, classification and recovery of objects on the seabed. It provides for illumination, photographing and tele-viewing of underwater objects. The system comprises a deep tethered submersible (DTS), a depressor and the associated tether and cabling. The DTS, which contains all the necessary sensors, instruments and manipulators, is tethered to the depressor but manoeuvres independently, either in the towed or in the hovering mode.

The depressor is attached to the surface vessel by a heavy cable and serves as a passive decoupler, isolating the DTS from ship motion and cable instabilities. It also serves as a stores carrier and a recovery vehicle for small objects retrieved from the seabed.

STATUS

Entering service with the RN.

CONTRACTOR

British Aerospace Dynamics Group, Bracknell Division, Downshire Way, Bracknell, Berkshire RG12 1QL, England.

4763.441

TRANSPORTABLE ACOUSTIC RANGE

The transportable acoustic range (TAR) developed by British Aerospace provides portable ranging facilities, where fixed facilities are not available, to determine a ship's susceptibility to acoustic mines.

Developed initially for the Royal Navy this system enables simple and rapid 'go/no go' checks for mine hunting and mine countermeasures vessels prior to deployment on mine warfare activities. The range is simple to operate with visual indication being presented on an electronics unit. No special underwater acoustic experience is required of the personnel using the system.

The TAR equipment consists of an underwater unit, containing a hydrophone which is laid on the seabed in the desired location, an associated shore-based electronics unit and a cable drum carrying a 900 metre cable and a strain relief block. The cable carries signals from the underwater unit via the cable drum and a 30 metre link cable to the electronics unit.

The underwater unit can be deployed in depths between 10 and 50 metres, and within this range automatic gain compensation adjusts all signals to a depth of 10 metres. The unit measures 990 × 990 × 610 mm, and weighs 50 kg. With its cable the cable drum weighs approximately ½ tonne. The electronics unit separates the received broad-band noise into seven octaves covering the mine sweeping range (8 – 500 Hz). Each channel is monitored and compared with a preset reference level and visual indication of the noise level is provided on one of three lamps; amber for levels equal to the preset standard, green for lower levels, or red for levels higher than the standard. Settings for the preset levels may be derived from previous rangings of each ship or the class of ship. The electronics unit measures 610 × 610 × 610 mm and weighs 15 kg.

Systems with different frequency coverage, to embrace the complete sonics range used for acoustic mines to the torpedo homing bands, for instance, the contractor can deliver a suitable TAR. By using the tape amplifier in the electronics unit it is possible to take recordings of noise signatures for more detailed analysis at a later stage. By the addition of frequency analysis equipment it is also possible to employ the system to provide more elaborate and permanent noise ranging facilities.

STATUS

In production and supplied to the Royal Navy.

CONTRACTOR

British Aerospace Dynamics Group, Bristol Division, PO Box 5, Filton, Bristol BS12 7QW, England.

4417.441

DEEP MOBILE TARGET

The Deep Mobile Target (DMT) is a fully instrumented self-contained, unmanned, boat-launched, vehicle for use on ASW trials and training exercises designed to simulate the dynamic and acoustic characteristics of submarines and carry out pre-programmed manoeuvres. It was originally conceived as a deep diving mobile torpedo target to obviate the costs, risks, and delays associated with weapons trials versus a submarine and its functions were later expanded to provide a trials and ASW training facility with torpedoes, sonars, sonobuoys and acoustic tracking facilities.

DMT is supplied to meet the customer's requirements for sonar frequencies. It normally carries two sonar/sonics outfits which are interchangeable at base. When used in conjunction with a three-dimensional underwater tracking system, it is fitted with a Thorn EMI synchronised acoustic transmitter (SAT) Type 5 for compatibility with US, UK, German, Italian and Japanese tracking ranges. A miss distance indicator is incorporated.

DMT is easy to handle and recover with high availability and reliability. The recovery system is initiated by command, exhaustion of the propulsion battery, by deviating outside the preset depth limits, or by program run completion. The design is modular and repairs are effected by replacing modules.

CHARACTERISTICS

Length: 3·28 m

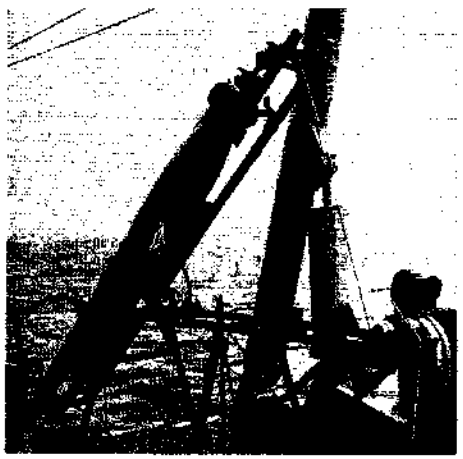
Diameter: 0·324 m (12·75 inches)

Weight: 236 kg

Speeds: Stop, 8 knots, 14 knots, and 22 knots

Endurance: From 100 minutes at 8 knots to 8 minutes at 22 knots

Depth: 366 m max



Rates: 10°/s turn rate; 45° climb/dive angle; 9·5 m/s climb/dive rate

STATUS

DMT was developed in collaboration with the UK MoD at the Admiralty Underwater Weapons Establishment and has been supplied to the British MoD and several other naval authorities.

4418.441

THORN EMI UNDERWATER ACOUSTIC RANGES, SYSTEMS AND TARGETS

Systems to monitor accurately the track and performance of underwater weapons are essential to develop fully the effectiveness of torpedoes and other underwater missiles and vehicles. Thorn EMI Electronics has been involved over a long period in the design, supply and operation of such systems for the Royal Navy and produces three types of equipment to meet specific evaluation requirements. All three systems achieve the objective of accurately tracking a torpedo, missile or other weapon system while under the surface of the sea during its final approach to the target or during the discharge/deployment phase.

The systems available are:

(1) Portable Acoustic Tracking System (PATS)
(2) Target-Centred Tracker (TCT)
(3) Fuze Activating Static Target (FAST)

Portable Acoustic Tracking System (PATS)

The PATS is a high performance system capable of tracking up to four underwater objects simultaneously over a large area. The objects may include the weapon, the target, the launch vessel or any other suitably instrumented vessel in the firing range area. The system is fully transportable and may be deployed as a surface range suspended from anchored buoys, or laid on the sea bed in shallow water.

In the buoyed arrangement these mooring buoys are anchored in a triangular form approximately 200 metres apart. This then becomes the centre of the tracking range and practice firings can take place in an area 4·5 km around the range centre. The three hydrophones are suspended at the selected depth from small floatation buoys which are in turn attached to each of the mooring buoys when the range is in use. The hydrophones are connected by floating cables to a range support ship normally moored to one of the main buoys. Data is processed on-board the range vessel and will normally be transmitted via a radio link to a completely self-contained base station on land where the tracks are computed and displayed in real-time. Alternatively, the base station may be taken on-board the range vessel allowing an entirely sea-borne operation to be mounted.

In shallow water an alternative form of the PATS may be used whereby the hydrophones are placed on the sea bed again in a triangular form. Cables from each hydrophone laid on the bottom connect to the range vessel which is moored close to the range centre and data is again passed to the base station via a radio link.

Target Centred Tracker (TCT)

The TCT is an in-service Royal Navy system developed for the evaluation of underwater weapon systems. TCT is a dual mode acoustic tracking system capable of short range (300 metres) high resolution, high accuracy, three-dimensional tracking coupled with a long range (3000 metres) distance measuring mode. The system may also be used to measure the instant of fuze activation of a suitably instrumented weapon.

The system may be used during the development and proving phases of a new weapon system and for routine in-service weapon effectiveness firings. The 'in-board' system is fully portable and may be rapidly installed on any vessel or installation fitted with an appropriate hydrophone array.

The prime uses for the TCT system are:

(1) to measure and display the approach and 3D trajectory of the terminal phases of an underwater weapon attack on static or underway target submarines, unmanned mobile targets, static targets or fixed installations
(2) to measure and display the discharge trajectory of any underwater weapon (sub-launched missile, stand off weapon, torpedo, mine, decoy etc) from a submarine or fixed underwater tubes or dischargers. This may include measurement of the deployment/fall back of torpedo cable dispensers or missile shrouds after water exit separation etc
(3) to measure and display the deployment and trajectory performance of bottom-launched weapon systems.

The TCT may be supplied as a 'stand alone' system incorporating on-board computing and display together with digital data storage and recording for subsequent off-line processing. Alternatively it may be supplied as part of a total attack/discharge system interfacing with the ships weapon and navigation

systems either via discrete interfaces or via a highway.

The system has been used extensively by the Royal Navy both for torpedo attack and discharge measurement and for sub-launched (Sub-Harpoon) discharge both in the R & D and fleet exercise role. The system has been used in an open ocean environment and on instrumented weapon ranges where compatibility with the weapon range system is required.

Fuze Activating Static Target (FAST)

An alternative to using a target submarine for underwater weapon evaluation is to use the FAST frame. The frame is covered with wire mesh panels to simulate the magnetic field of a submarine and is also fitted with an acoustic transmitter to provide a signal for the torpedo's homing system. The system's four hydrophones are mounted on the frame which is lowered to a maximum of 100 metres below the water surface. All the processing equipment for tracking the torpedo is fitted inside the ship supporting the FAST frame. The frame is designed to fold for easy storage and deployment.

Distance Measuring Equipment (DME)

The DME forms the basis of many of the available tracking systems and enables the slant range between a mobile or static acoustic transmitter and a receiving hydrophone to be measured with great precision. The equipment is automatic in operation requiring minimal operator attention. Modular design enables tracking systems to be configured to meet the user's immediate needs whilst allowing expansion later to a more complex tracking system if needed.

Acoustic Transmitters (Pingers)

The weapon to be used must be fitted with an appropriate acoustic pinger. This may take the form of a small hull section for a torpedo or missile, or

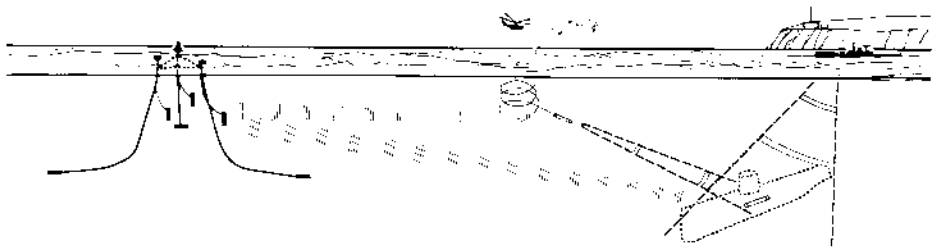

Diagram of arrangement of Thorn EMI portable acoustic tracking system with hydrophones suspended from surface buoys

individual sub-assemblies for fitting within the weapon system envelope, discharge capsule or shrouds. The pinger may transmit either the HF or LF signals as appropriate or in certain applications both transmissions may be required. Each transmission will normally comprise two pulses, one to determine range and one to provide a direct measurement of the weapons operating depth. When operating with a suitable instrumented weapon the instant of fuze activation may be transmitted by the pinger and registered by the tracking system. The pingers are normally battery powered giving a completely self-contained package incorporating automatic 'power up' functions.

Noise Ranging

The noises radiated underwater by ships and submarines have become the subject of critical investigation. The sophistication now achieved in the development of acoustic homing torpedoes, acoustically operated mines and the submarine, has forced Navies throughout the world to employ every means to carry out programmes of noise reduction to avoid detection and to improve their ability to detect and classify sounds created by other vessels.

The measurement and analysis of underwater noise radiated by ships and submarines is a specialised field involving the latest technologies in a most hostile environment. For more than a decade Thorn EMI Electronics have provided the specialist equipment and computer software and developed the skills required to carry out the sophisticated analysis which is necessary. Ranges for the analysis of underwater radiated noise designed and developed by Thorn EMI Electronics have included deepwater facilities where submarines may be operated at full speeds and static facilities where detailed investigations may be carried out in the absence of noise due to the movement of the ship or submarine through the water.

Thorn EMI Electronics Ltd, Defence Systems Division, Albert Drive, Sheerwater, Woking, Surrey, England.

4420.441

VERSATILE EXERCISE MINE SYSTEM

The Versatile Exercise Mine System (VEMS) provides facilities for the assessment of the effectiveness of ground minesweeping systems and the tactics employed for the clearance of such weapons. It may also be used in mine warfare research and development programmes. A VEM simulates the actuation system of any magnetic, acoustic, pressure or combination influence ground mine and is programmed to record exercise data for subsequent detailed analysis. Provision is made for two-way communication via a transponder fitted to the mine between the exercise vessel and the mine itself. Data transmitted includes a mine sensor actuation signal and mine-to-ship ranges. The mine remains on the sea-bed for up to six months before recovery and servicing is necessary.

Recovery is initiated by triggering the mine's recovery mechanism using a coded acoustic signal. The mechanism frees the mine of mud and silt by compressed air from the air bottle in the ballast section and then automatically releases the buoyant section which floats to the surface to serve as a buoy to mark the position of the heavier ballast section, which is subsequently recovered by using the 200 m long recovery rope that tethers the two sections to each other. The mine is normally laid from a mine countermeasures vessel, either by a special laying trolley that forms part of the system or by slipping from a davit. It may also be laid by a helicopter at

Versatile Exercise Mine (VEMS) is realistically shaped to provide the correct type of sonar return for mine hunting and is also equipped to simulate a combined influence ground mine. After use for mine sweeping and mine hunting training, a signal is sent from the surface which causes the mine to separate into two. The smaller portion containing the computer and sensor unit floats to the surface and a rope is used to haul the remainder of the mine to the recovery vessel.

speeds of less than ten knots and flying below a height of 6 m.

CHARACTERISTICS

Weight: 560 kg

Length: 2·71 m

Diameter: 533 mm

Simulated mine types: Magnetic, acoustic, pressure, combination

STATUS

In production and in service. An order from the USN for two complete VEM systems was disclosed in March 1983.

CONTRACTOR

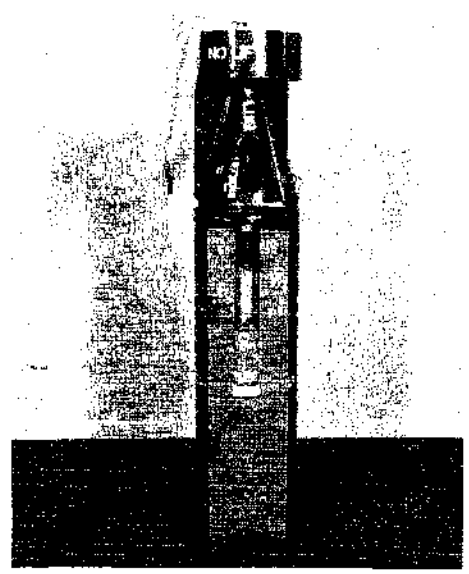
4764.441

DEPTH CHARGE MK 11 (MOD 3)

The Mk 11 Mod 3 depth charge is a new version of the depth charge Mk 11 series with fuzing mechanisms and safety features that are designed specifically to allow its deployment from helicopters and maritime patrol aircraft. It can be used against surface vessels and submarines in shallow water.



The depth charge consists of a 4 mm mild steel outer case which contains the explosive filling, fuzing and arming devices. The tail section is designed to break off on impact with the water and this facilitates hydropneumatic arming and detonation. The depth charge is fuzed by a unit that comprises a valve, a pistol unit, a detonator placer assembly and a primer assembly. Arming is only possible if the safety wire fitted to the tail section is withdrawn on release.

Two realistic exercise versions of the Mk 11 depth charge are produced for training: one is intended for

Inserting fuze in Mk 11 depth charge

basic drill procedures in weapon preparation and handling, and the other is for use by aircrews in carriage and release practice.

Sectioned Mk 11 depth charge

CHARACTERISTICS
Length: 97 cm (body section); 1·39 m (with tail)
Diameter: 279 mm
HE filling: 80 kg
Weight: 145 kg (fully prepared)

STATUS
Production. In November 1983 the contractor was awarded a US contract for a quantity of Mk 11 Mod 3 depth charges for competitive evaluation by the US Navy in a two-year programme.

CONTRACTOR
British Aerospace Dynamics Group, Bristol Division, PO Box 5, Filton, Bristol BS12 7QW, England.

UNITED STATES OF AMERICA

3195.441
AMERICAN UNDERWATER SURVEILLANCE

The current US philosophy regarding defence against the principal ASW threat (Soviet submarines) can be summarised as relying on engaging these submarines in forward areas and at barriers before they can get within attacking range of US forces. To do this reliance rests primarily on American attack submarines and long range P-3 patrol aircraft supported by underwater systems.

The ability to locate enemy submarines within broad ocean areas is essential to the task of containing the large Soviet submarine force, and fixed undersea surveillance systems have played a major role in this for some years. Consolidation and expansion of such systems continues, and funding of the Sound Surveillance System (SOSUS, see below) is sustained at a consistently significant level. To improve US submarine surveillance capabilities, the 1986-90 programme continues funding for two new systems mentioned in the following paragraphs: the mobile SURTASS, and the rapidly deployable, air-dropped system (RDSS), which are designed to supplement the fixed sensor systems.

SOSUS

SOSUS (Sound Surveillance System) consists of fixed undersea acoustic networks of passive hydrophone detector arrays deployed in the Atlantic and Pacific Oceans, and this is stated to provide significant detection capabilities. However, over the years (SOSUS was conceived in the 1950s) it was inevitable that the network gradually expanded as increments were added to enlarge the coverage. Most of these additions were the subject of various classified programmes, of which most details remain secret apart from isolated programme code-names. Among the latter are 'Caesar' and 'Collosus' referring to the US Atlantic and Pacific segments of the SOSUS network. Hydrophones designated AN/FQQ-10(V) are located at intervals of 5-15/miles along a linking cable connected to the shore station(s). Similar shore stations are said to exist beyond the USA (eg the Aleutian Islands, Canada, Denmark, Iceland, Italy, Japan, Korea, Philippines, Spain, Turkey, UK) these being included in programmes code-named 'Barrier' and 'Bronco'. Constantly changing threat characteristics call for significant system improvements and the USN embarked on a two-phase SOSUS improvement programme. The specific aims of this programme remain classified in detail but are known to include improvements to the communications elements of the system and complementary improvements to the signal and data processing segments, thereby facilitating greater operational utilisation of the data obtained by the undersea sensor arrays.

Funding of the SOSUS programme remain fairly constant as figures from the fiscal year 1986 DoD budget for the years 1984-87 indicate: $80·2, $82·1, $85·8 and $106·8 millions, respectively.

The ultimate objective for the SOSUS system is the complete integration of all undersea surveillance sensor systems into a fully co-ordinated and centrally controlled network, IUSS.

SURTASS

SURTASS (Surveillance Towed Array Sensor System) is a successor system to the AN/BQR-15 Towed Array Surveillance System (TASS), already operational with the US fleet (see **1984.453**). This mobile surveillance system complements fixed networks by providing the essential flexibility to respond to changes in Soviet submarine deployment patterns and by extending coverage to remote ocean areas not monitored by fixed systems. They can also serve as emergency reserve facilities if fixed networks are disabled. There are two shore-based data processing centres (one on the East Coast of America, and one on the West Coast) to which acoustic target information gathered by the towed arrays is relayed. After processing, target information is transmitted back to operational ships at sea. Five or more ships are planned for each of the two processing centres, operating in waters to the east and west of the American continent, respectively and funds for a total of 14 of these ships had been appropriated by fiscal year 1985.

Whereas the BQR-15 is towed by submarines, slow, small surface ships will tow the long SURTASS arrays back and forth over designated patrol lines. Funds have been set aside for a special type of platform to operate SURTASS, designated T-AGOS. The first two ships were delivered in 1984 and others will be added at a likely rate of two per year for the next few years.

SURTASS commenced full-scale development in fiscal year 1976. Testing was carried out at sea during 1977. Technical evaluation of SURTASS was completed in March 1978 and operational evaluation took place from May to June 1978. The first full tests of the SURTASS system, including the satellite link and data processing, took place in July 1979, and the system was declared ready for operational evaluation, which began in March 1980. Introduction to US Fleet service began in late 1984.

Congress has appropriated funds for the first 12 T-AGOS SURTASS ships and funding was sought in the 1986 budget for two ships per year in fiscal years 1986 and 1987 at a cost of $121 and $119 million, respectively.

RDSS

RDSS (Rapidly Deployable Surveillance System) is designed to use air-deployable, bottom moored, long-life passive acoustic buoys as the main sensor system in a new mobile monitoring system. It will be emplaced by aircraft to provide undersea surveillance coverage on an urgent basis if required in areas of special interest. It could be used to replace or augment existing systems for long periods. RDSS buoys are capable of use in shallow water and areas unsuitable for either SOSUS or SURTASS techniques. The basic design allows for the transmission of data from the RDSS buoy to existing maritime patrol aircraft for either real-time readout or recording for later replay and analysis. Two versions of RDSS buoys have been identified, as Mod 0 and Mod 1, respectively. The former transmits its data to P-3 or S-3 maritime aircraft for analysis and presentation on the aircraft (it is also recorded for later processing), while the Mod 1 design is intended to send information direct to an ASW processing centre which will utilise the data without delay. The Mod 0 buoy is regarded as a 'near-term' item, and the Mod 1 is thought likely to take longer to reach operation. The approval for full-scale development of the system was given in August 1981, after a lengthy study and research programme. Development funding budgeted for fiscal years 1984/85/86/87 $16·2 million, $10·6 million, $15·4 million and $20·8 million, respectively. Tests in 1985 were expected to enable plans for future RDSS to be formulated.

TACTAS

TACTAS (Tactical Towed Array Sonar) is intended to remedy the deficiency of current ASW surface ships in passive detection and classification capabilities against submarines. A long-range (direct path, first and second convergence zone) is required which can be used with other systems (LAMPS Mk III). The TACTAS programme will provide a number of different towed array systems for surface ship use. The AN/SQR-18A is a successor development of a towed array tested under a previous (classified) programme, and operational evaluation was completed in February 1976. The array is designed to be towed at high speed and is being installed on all 46 FF 1052 class ships and Naval Reserve FFG-7 frigates. The AN/SQR-18A will be followed by the AN/SQR-19 system which will give active FFG-7, DD-963, DDG-993, DDG-51 and CG-47 classes of ship a passive detection capability. The SQR-19 is in full-scale development with delivery of the first production system planned for 1984. The first system was installed on the destroyer *Moosbinggen* late in 1981 for technical and operational evaluation. Excellent results were reported and deployment of the SQR-19 is expected in the late 1980s. Present funding plans call for 12 sets to be procured in fiscal year 1984 at a cost of $116·7 million, 10 in 1985 costing $112 million, 16 in 1986 costing $165·4 million, and 19 proposed for 1987 at a cost of $184 million.

3966.241
LAMPS MK III

The USN LAMPS (Light Airborne Multipurpose System) has been designed to extend and enhance the capabilities of surface ships, particularly in anti-submarine warfare (ASW) and increased effective operational range for the weapon systems fitted in surface vessels of the US fleet. This system extends the electronic and acoustic sensors and provides a reactive weapon delivery capability for destroyers and frigate class ships by operating manned helicopters from them. Sensors, processors, and display capabilities aboard the helicopter enable the three-man crew to extend the ship's tactical, decision-making, and weapons delivery capabilities. Classic line-of-sight limitations for surface ships and limitations to underwater acoustic detection, classification, and localisation are thus mitigated through the use of the manned LAMPS aircraft.

LAMPS helicopter flying over USS McInerney

LAMPS is being acquired in two phases. The first, Mk I, involved installation of shipboard equipment and conversion of H-2 helicopters already in the inventory to an SH-2 configuration. Mk I became operational in 1972. The Mk III includes the integration of improved avionics and shipboard systems to be used with the SH-60B Seahawk, a modified version of the Army UH-60A Blackhawk helicopter.

In 1974 the USN selected IBM as the system prime contractor to work with the Naval Air Systems Command in developing LAMPS Mk III. By late 1976, after extensive developmental testing, system capabilities were demonstrated in deep water using two modified helicopters with representative avionic and shipboard electronics. Two open-ocean tests concluded the validation of the LAMPS Mk III mission performance. The first was conducted jointly by the Naval Air Systems Command and IBM. After the data reduction was completed and the technical performance was assessed, the test was judged highly successful. The second test was conducted under the direction of the commander of the operational test and evaluation force to verify the operational suitability and performance of the LAMPS Mk III concept. The Navy was given permission to continue with full-scale development by the Department of Defense in 1978 with IBM as system prime contractor, Sikorsky Aircraft as the air vehicle contractor, and General Electric as the engine manufacturer for the new Mk III air vehicle.

The LAMPS Mk III weapon system embodies the integration of the parent ship (frigate, destroyer, cruiser) and the manned aircraft (SH-60B Seahawk) operating from that ship for both ASW and anti-ship surveillance and targeting (ASST) missions. As an adjunct of the sensor and attack systems of the parent or similarly equipped ships, the aircraft extends the detection, classification, localisation, and attack capabilities where needed to increase line of sight and range capabilities of the parent ship. Radar and ESM sensors extend the ship's line-of-sight against surface threats, whereas sensors that operate relative to the ocean medium (eg sonobuoys and magnetic anomaly detectors) enable the ship to engage the underwater target.

The primary control of aircraft tactics and selection of sensor and weapon modes remain with the parent ship for both the ASW and ASST missions, with an equally important, independent mode of LAMPS aircraft control provided as a backup.

In an ASW mission, the LAMPS aircraft is deployed from the parent ship when a suspected threat has been detected by the ship's towed array sonar, hull-mounted sonar, or by other forces. It proceeds to the estimated target area, where sonobuoys are dropped into the water in a pattern designed to entrap the target. The sounds (acoustic signatures) detected by the buoys are transmitted over a radio frequency link to the aircraft where they are analysed, codified, and retransmitted to the ship for interpretation and analysis. When the location of the threat has been determined with adequate precision, the aircraft descends near the ocean's surface for final confirmation. This may be accomplished using active sonobuoys, passive directional sonobuoys or by trailing a magnetic anomaly detector behind the aircraft. On final confirmation by any of these methods, a torpedo attack can be initiated. The extension of the ship's sensor, tactical control, and attack capabilities is achieved by using a duplex data link that transfers acoustic, electromagnetic, command data, and voice from the Seahawk, and command data and voice to the aircraft. Data is processed and evaluated aboard the parent ship where tactical and command decisions are made, and tactical instructions, weapon delivery information, and transmission of processed data are linked back to the SH-60B Seahawk.

Data transmitted to the parent ship (or other LAMPS-equipped ship) is processed by digital computers and specialised processors, distributed, and evaluated by the parent ship's operators: the LAMPS air tactical control officer, acoustic sensor operator, remote radar operator, and ESM operator. The combat information centre evaluator uses the data in context of the overall tactical situation to determine what actions to take in attacking. Operation of the LAMPS Mk III system was described in detail in previous editions of *Jane's Weapon Systems*.

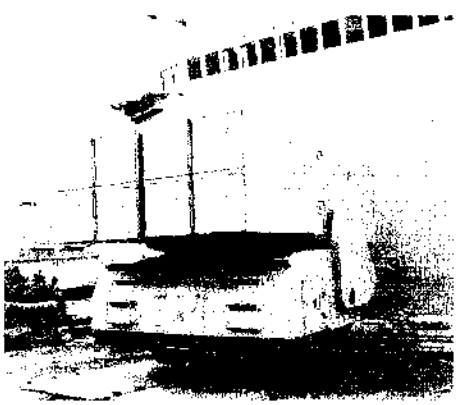
STATUS

Introduction to the US Fleet of the SH-60B LAMPS Mk III began in 1984, when there were plans to deploy such helicopters aboard about 100 US Navy surface vessels, including DD-963 and DDG-993 destroyers, CG-47 cruisers, and FFG-7 frigates. The earlier LAMPS Mk I Seasprite will continue to serve in some older FFG-7s. A stable production rate of 18 SH-60B helicopters per year is planned, 90 being requested in the next five years.

Procurement of 84 SH-60B helicopters between fiscal years 1984-1987 is expected to total $1737·8 million, with procurements of 21 in 1984, 24 in 1985, and 18 annually in 1986 and 1987.

CONTRACTORS

System prime contractor: International Business Machines Corporation, Federal Systems Division, 10215 Fernwood Road, Bethesda, Maryland 20034, USA.



SH-60B Seahawk helicopter: Sikorsky Aircraft.

General Electric Company: Engine contractor.

6001.241

ASROC ANTI-SUBMARINE SYSTEM

ASROC (RUR-5A) is an all-weather, day or night, ship-launched ballistic missile carried as the primary anti-submarine warfare (ASW) weapon aboard USN destroyers as well as some cruisers and frigates. The weapon consists of a Honeywell Mk 46 acoustic homing torpedo (**2822.441**) or a nuclear depth charge (estimated yield one kiloton) attached to a solid-propellant rocket motor. It can be fired from an eight-cell launcher Mk 112, the Mk 26 launching system, or from the Mk 10 Terrier missile launcher (ASROC/Terrier system).

8-round ASROC launcher aboard USS David R Ray (W Donko)

Other major components include a fire control computer and an underwater sonar detector.

OPERATION

After launch the weapon follows a ballistic trajectory. The rocket motor is jettisoned at a predetermined point and the payload continues toward the target. If the payload is a torpedo, it is lowered to the water by a parachute, where its homing mechanism is activated upon submersion. Depth charge payloads sink to a predetermined depth before detonating.

Range of the weapon is classified but has been estimated to be from 2 to 10 km. The missile is 4·6 m long, has a diameter of 32·5 cm, and a span of 84·5 cm. Launch weight is about 435 kg.

DEVELOPMENT

ASROC has been in development since 1955 and entered service with the USN in 1961, becoming widely fitted in anti-submarine vessels of various classes. Plans to develop the ASROC system to utilise a vertical launch system (VLS), initially for some surface ships but later in attack submarines, were at first suspended on grounds of cost and/or a need to merge the project with the ASW-SOW stand-off weapon programme (**4181.441**). However, changing circumstances in the USN's overall ASW requirement and its inventory of weapons in this category led to a reversal of the original cancellation of vertical launch ASROC (VLA), and it is intended that the new version will ultimately replace the original ASROC deployed on surface ships.

STATUS

Users of the ASROC system include: USA (27 cruisers, 87 destroyers, 65 frigates), Japan (15 destroyers, 11 frigates), Spain (five each destroyers and frigates), Greece and Taiwan (four destroyers each), Canada (four frigates), Federal Republic of Germany (three destroyers), Turkey (three destroyers), Brazil, South Korea and Pakistan (two destroyers each), and Italy (one missile cruiser). In the 1985 fiscal year report by the US Secretary of Defense funding for ASROC (VLA) was included for development with $30·8m assigned for 1984, $26·7m in 1985, and $37·4m in 1986 and $38·1 m in 1987. In the last of these years a further amount of $71·7 million was proposed for procurement of 250 ASROC (VLA). Following a request for proposals issued in 1982/83, Goodyear Aerospace was awarded a VLA development contract in November 1983.

The conventional launch ASROC will continue to be supported by Honeywell as prime contractor to the US Naval Ocean Systems Centre, San Diego.

CONTRACTORS

Honeywell Inc, Training and Control Systems Operations, 1200 East San Bernadino Road, West Covina, California 91790, USA (Prime Contractor).

Goodyear Aerospace Corporation, 1210 Massillon Road, Akron, Ohio 44311, USA (VLA development).

1128.441

SUBROC (UUM-44A) ANTI-SUBMARINE MISSILE

This is a submarine launched missile which follows a short underwater path before transferring to an air trajectory for the major portion of its journey to the target area. When this is reached a nuclear depth bomb is separated from the remainder of the missile and then follows a ballistic trajectory to the point where it re-enters the water. The W55 nuclear charge then sinks to a predetermined depth before detonation. Estimated yield of the warhead is about one kiloton.

Principal characteristics of SUBROC are: length 625 cm, diameter 53·3 cm, weight 1853 kg (approximately), range 56 km (approximately), and speed is supersonic. It has a solid fuel motor.

OPERATION

The UUM-44A missile forms part of an advanced anti-submarine system designed for deployment in nuclear-powered attack submarines operating against submerged vessels armed with strategic missiles. This system includes the AN/BQQ-2 Raytheon integrated sonar system and the Mk 113 SUBROC fire control system produced by the Librascope division of Singer-General Precision Inc.

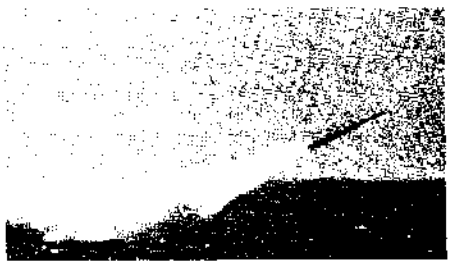
After detection and location of a target submarine, co-ordinate data are fed into the attack submarine weapon system which programmes an optimum missile profile for the SUBROC missile. It is assumed that this can be accomplished in virtually real-time.

The SUBROC missile is launched horizontally from a standard 21 inch (53·3 cm) torpedo tube, by conventional means. At a safe distance from the launch vessel (which need not be directed towards the target area for firing) the solid-fuel missile motor is ignited and the missile follows a short level path before being directed upward and clear of the water. Missile stability and steering is effected by four jet deflectors, which function in both water- and airborne sectors of the trajectory. Guidance is by means of an inertial system (SD-510) produced by Kearfott.

When free of the water, SUBROC is accelerated to a supersonic speed and guided toward the target area. At a predetermined point separation of the nuclear depth bomb is initiated by explosive bolts and a thrust-reversal deceleration system which enables the warhead to continue to the re-entry point on a ballistic trajectory controlled by vanes on the depth bomb.

Impact with the water is cushioned to protect the

arming and detonation devices. A preset depth sensor detonates the nuclear charge when the bomb is in the vicinity of the target. It is probable that the target position will need to be established with an accuracy that will permit the warhead to detonate within its estimated lethal radius of 5 to 8 km from the target.



SUBROC missiles can be carried in torpedo tubes without attention for long periods, and launched with minimal preparation time.

DEVELOPMENT

Development of the UUM-44 began in June 1958 at the US Naval Ordnance Laboratory, White Oak, Maryland, under the management direction of the Bureau of Naval Weapons, with Goodyear Aerospace Corporation as the prime contractor. Technical evaluation was completed in 1964, and production and operational deployment began in 1965.

STATUS

SUBROC is operational on nuclear-powered attack submarines and in 1982 there were about 64 USN attack submarines equipped to use the system. Each ship carries four to six SUBROC missiles. An improvement programme to sustain the effectiveness

SUBROC anti-submarine missile after leaving launch submarine and taking to the air, but before separation of its nuclear depth charge and rocket motor

of this weapon against new threats was initiated in 1976/77.

This would have entailed replacement of the SUBROC analogue guidance sub-system by a digital one and regraining of the weapon's rocket motors, and it was estimated that to extend the operational life of the system by five years would have cost about $41 million. A Congressional decision was taken in 1979 not to update the system along these lines, and as a consequence the USN turned to the ASW-SOW (anti-submarine warfare-standoff weapon) programme (**4181.441**) to meet existing and anticipated operational requirements. The SUBROC system is now considered obsolescent and it is proposed to withdraw the system from the USN inventory during the 1980s. It will be replaced by the ASW-SOW.

CONTRACTORS

Prime contractor: Goodyear Aerospace Corporation, 1210 Massillon Road, Akron, Ohio 44311, USA.

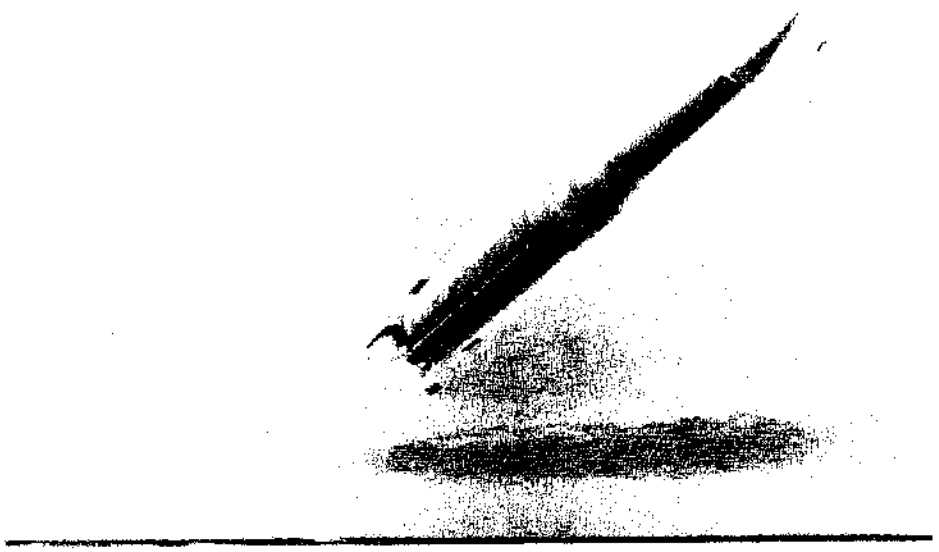
Mk 113 fire control system: Singer-General Precision Inc, Librascope Division, 808 Western Avenue, Glendale, California 91210, USA.

SD-510 inertial guidance system: Singer-General Precision Inc, Kearfott Division, 1150 McBride Avenue, Little Falls, New Jersey 07424, USA.

Nuclear warhead: Sandia Corporation, Livermore Radiation Labs, Livermore, California, USA.

Solid-fuel motor: Thiokol Chemical Corporation, Elkton Division, Elkton, Maryland, USA.

4181.441



ASW-SOW ANTI-SUBMARINE WARFARE STAND-OFF WEAPON

The USN ASW-SOW programme was approved by the US Secretary of Defense in 1980 and is intended to develop a long-range anti-submarine weapon by the late 1980s. The ASW-SOW is required to replace the technologically obsolete SUBROC (**1128.441**) which it is planned to withdraw from the USN inventory during the 1980s. The new weapon is also intended to meet the challenge of new threats such as the latest Soviet 'Alfa' class of submarine, and it will be designed for launching from US nuclear attack submarines, and surface fighting ship vertical launch systems. Specific platform applications of ASW-SOW have not been defined more precisely to date.

In USN attack submarines the weapon will be used with existing torpedo tubes and the Mk 117 digital fire control system. (The latter is planned to be the first type of existing shipboard hardware to incorporate Outlaw Shark capabilities, now in research and development to provide a correlated, computer-formated, all-source data handling facility for forces at sea. A major objective of this project is over-the-horizon targeting.) US attack submarines cannot at present launch a weapon against a target unless it closes to within reach of the Mk 48 torpedo. The ASW-SOW will extend this range appreciably, as well as permitting further attacks on submarines which successfully evade a torpedo attack.

Four separate designs for ASW-SOW were proposed but they have in common a combined underwater/air-flight/underwater path from submarine launch platform to target, similar to that of the SUBROC predecessor system, but variations include the method(s) of propulsion employed. The system as defined so far calls for alternative payloads consisting of either a nuclear depth bomb or a homing torpedo. The former has the advantage of a larger kill radius, thus making lesser demands in terms of accuracy and range performance, but it is hoped that development of the ALWT will prove adequate as a basis for a more precise (non-nuclear) ASW-SOW payload.

As already stated, the proposals made by the various contractors selected to submit concept formulation plans in response to the ASW-SOW requirement differed in a number of respects and all four were described in *Jane's Weapon Systems 1981-2*. The team selected to continue development of the project was that linking Boeing, Gould and Hercules Aerospace. Boeing as the leader with responsibility for the vehicle; Gould for the payload, acoustics and signal processing, and guidance; and Hercules for the single solid-propellant rocket motor.

Drawing of the Anti-Submarine Warfare Stand-off Weapon under development for the US Navy by Boeing

The latter is apparently designed to propel the weapon during its initial underwater trajectory (after clearing the launcher torpedo tube) and during the air flight. On clearing the surface of the water, four small wrap-around fins at the rear of the rocket motor casing deploy automatically to aid stability. After booster burnout, the motor is probably jettisoned, leaving the payload section to follow a ballistic path to the target area, where after deceleration it re-enters the water for the payload/warhead section (nuclear or torpedo) to come into action.

It will be possible to fire the ASW-SOW from surface ships or submarines and rounds will be stored in canisters ready to fire from the vertical launch systems of destroyers (DD 963 class), guided missile cruisers (CG 47 class), and guided missile destroyers (DDG 51 class). From SSN 637/688 class attack submarines, the missile will be carried by capsule to the surface before the solid-propellant rocket motor ignites to propel it to the target area.

Both the surface-launched and submarine ASW-SOW missiles will be able to carry either the US Department of Energy-developed nuclear depth bomb or the advanced lightweight torpedo. Surface ships will have a third payload option in the existing Mk 46 Mod 5 torpedo.

STATUS

The ASW-SOW programme was initiated in 1980 and it was then estimated that the research, development, test and engineering cost would amount to a total of about $550 million. Funding is under Programme Element 63367N of the US DoD budget and the actual funding for fiscal year 1982 was $35·4 million, with $20·2 million in 1983. Proposed development funding in fiscal years 1984-1987 is $27·4 million, $51·3 million, $75·3 million and $113·7 million, respectively. The 1986 fiscal year report by the US Secretary of Defense stated that ASW-SOW will be developed to replace SUBROC aboard USN attack submarines, with provisional entry into service during the early 1990s. One of the first classes to be fitted will be the 688 class of nuclear attack submarines, although the weapon will be compatible with surface vessels equipped with vertical launch facilities.

A second static test firing of the Hercules Aerospace rocket motor for ASW-SOW took place successfully in July 1983. In May 1984 Boeing announced a $95·9 million contract to prepare the demonstration and validation phase of the programme which is due for completion by the end of 1985. A submarine launch of the weapon was expected to take place by the end of 1984.

CONTRACTORS

The Boeing Company, Box 3707, Seattle, Washington 98124, USA; with Gould Inc, Government Systems Division, and Hercules Aerospace.

3629.441

TORPEDO Mk 32

The Mk 32 is an acoustic anti-submarine torpedo which is still in use aboard a number of former USN ships now transferred to other navies in various parts of the world, mostly aboard escort types. They are launched by the Mk 4 rack-type launcher unit in most cases, in which a single torpedo is carried in the ready-to-launch position with two more torpedoes stored nearby on deck. The current version is the Mk 32 Mod 2, which is equipped with an active acoustic homing head. It is also capable of air drop launch.

Propulsion is by electric motor, powered by a silver/zinc-oxide battery which is activated by sea water. After launch, the torpedo descends to a depth of 6 m and the active sonar begins to operate, transmitting 50 kHz pulses while the torpedo follows a spiral search pattern, circling to left or right as

selected. The search pattern is maintained until the sonar obtains a target response and the homing sequence commences. In the event of failure to obtain a target contact, the circular search pattern continues until the battery is exhausted, after which the torpedo dives deeper prior to self-destruction.

CHARACTERISTICS
Length: 2080 mm
Diameter: 483 mm
Weight: 350 kg
Warhead: HE 49 kg
Propulsion: Electric motor
Range: Approx 8600 yards (7864 m) at 12 knots
Max acoustic range: 560 m
STATUS
Operational but obsolescent.

2817.441
TORPEDO Mk 37 Mods 0 and 3

Designed primarily as a submarine-launched anti-submarine torpedo, but suitable for deck launching by the Mk 23 and Mk 25 torpedo launchers, the Mk 37 torpedo is a 19 inch (482·6 mm) weapon that has been described as the first successful high-performance anti-submarine torpedo. The 19 inch diameter of all versions of this torpedo was chosen to enable the torpedo to swim out from a standard 21 inch (533 mm) launch tube, an arrangement with obvious operational advantages.

Mods 0 and 3 are free running torpedoes. After one has been launched on a target interception course it maintains it until it, at a preset range, it 'enables' a process involving arming the warhead and switching in the attack logic circuits. The latter include various preselectable options such as depth limits, search pattern, and type of homing. The final attack is by sonar auto-homing which can be active, passive, or both combined.

Mod 3 is an updated version of Mod 0, the updating consisting of the incorporation of a large number of minor modifications based on operational experience.

DEVELOPMENT
Developed by Westinghouse the Mk 37 Mod 0 torpedo first went into service in 1957. Mk 37 torpedoes have been produced in large quantities by the Naval Ordnance Plant, Forest Park, Illinois, and are still in widespread use in the US fleet.

CHARACTERISTICS
Length: 352 cm
Diameter: 483 mm with guides to fit 533 mm tubes
Weight: 645 kg (warshot); 540 kg (practice)
Warhead: 150 kg HE
Speed: 24 knots (Mod 3)
Submersion: To 270 m (Mod 3)
STATUS
Operational, but replacement by the Mk 48 torpedo (**2823.441**) has now begun

---

2818.441
TORPEDO Mk 37 Mods 1 and 2

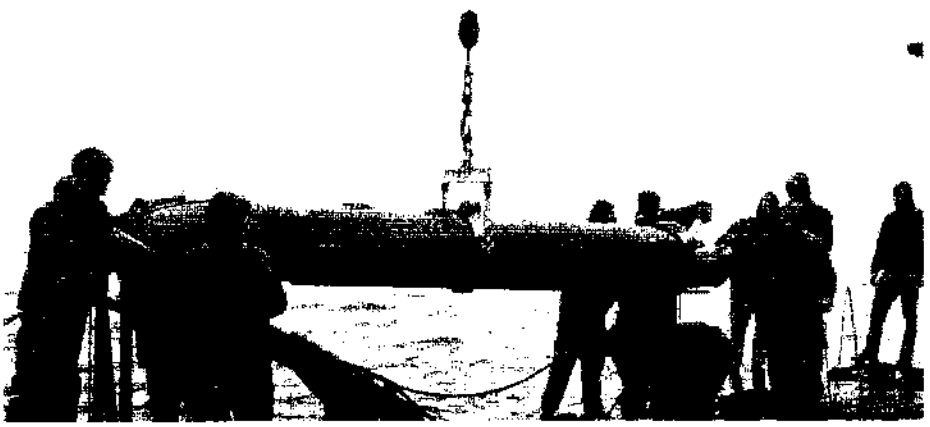
These versions of the Mk 37 torpedo differ from Mods 0 and 3 (**2817.441**) in their size and method of guidance; in other respects they are substantially similar.

Both versions are wire-guided, whereas the Mk 37 Mods 0 and 3 are free-running torpedoes. Both are 4·09 m long and weigh 766 kg (warshot) or 657 kg (practice).

Just as Mod 3 is an updated version of Mod 0 so is Mod 2 a version of Mod 1 updated by the incorporation of a number of minor modifications.

CHARACTERISTICS
Length: 409 cm
Diameter: 483 mm with guides to fit 533 mm tubes
Weight: 766 kg (warshot); 657 kg (practice)
Warhead: 150 kg HE
Speed: 24 knots (Mod 2)
Submersion: To 270 m (Mod 2)
STATUS
Operational.

4762.441
TORPEDO NT 37E MODERNISATION



The NT 37E torpedo is a modernised, improved version of the standard, battery-electric propulsion Mk 37 heavyweight torpedo (**2817.441**, **2818.441**). This dual purpose ASW and anti-ship torpedo can be fired from both submarines and surface ships. Incorporating a standard RS 232 or Harpoon digital fire control interface, the torpedo is compatible with the following platforms and fire control systems: West German 205/206/MSI-70U; West German 209/HSA-SINBADS (later version); RNLN Swordfish/HSA-M8; British Oberon/TCSS-5, TIOS; US Guppy/US Mk 106; US Mk 32 surface launch tubes; or any class equipped to fire Mk 37 torpedoes.

The NT 37E performance improvement kit and hardware, largely installed in the field, completely upgrades existing Mk 37 torpedo inventories. It consists of three major subsystems:

(1) An Otto-fuelled thermo-chemical propulsion system. When compared to the performance of an unmodified Mk 37 silver-zinc battery and electric motor, the new propulsion system demonstrates a 40 per cent increase in speed, a 150 per cent increase in range, and an 80 per cent increase in endurance. The propulsion system utilises existing Mk 37 motor mounting provisions and is compatible with existing Mk 46 fuelling and engine maintenance facilities, engine tools, and engine refurbishment kits.

(2) A solid-state acoustic system and a noise-reduction laminar-flow nose assembly replaces the Mk 37's vacuum-tube acoustic panel and hemispherical nose. The new sonar substantially improves the passive detection range against high speed surface targets and active detection range against small silhouette submarine targets; in most cases, target acquisition range has been doubled. The new SUBTIP self noise reduction nose assembly increases transducer isolation while reducing flow noise effects, reducing the likelihood of self decoying at all depths.

(3) A solid-state computer based guidance and control system with inertial navigation capability replaces the Mk 37's vacuum tube analogue system, resulting in greater system stability, reliability and accuracy. The new system utilises a Honeywell H-737 inertial sensor assembly and a MIL SPEC 8002 microprocessor, allowing fully programmmable tactics and inertial navigation. Should future naval tactics require modified torpedo command and control, changes can be easily implemented by revision of software and replacement of programmable read-only memory units (PROMs).

Sea trials of NT 37E heavyweight torpedo

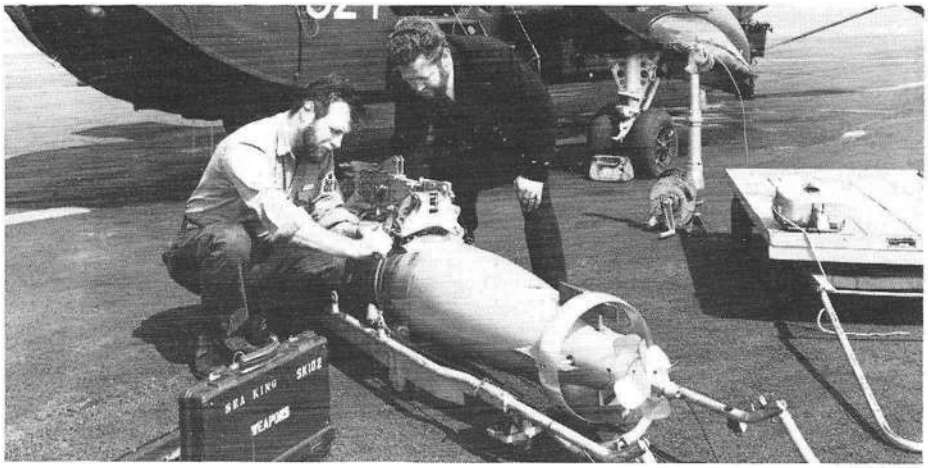
Two speed propulsion and 2 way wire guided telemetry, providing full exchange of data and commands between torpedo and submarine, are also available for the NT 37E as options.

CHARACTERISTICS
Type: NT 37E, wire guided, Mod 2, non wire-guided, Mod 3
Length: 4505 mm (Mod 2); 3846 mm (Mod 3)
Diameter: 485 mm
Weight: 750 kg (Mod 2), 642 kg (Mod 3)
Run modes: (1) Straight run/salvo-anti-ship; (2) straight run with acoustic miss indicator to initiate acoustic re-attack; (3) active snake and circle – ASW; passive snake and circle – anti-ship
Warshot explosive weight: 150 kg HE
Propulsion: Thermo-chemical rotary piston cam engine with Otto-fuel; 2-speed option
STATUS
The original Mk 37 upgraded version was called the NT 37C and included the thermo-chemical propulsion system and anti-ship kit.

Honeywell acquired the rights to the NT 37C from the Northrop Corporation in 1979 and, at the request of principal NATO NT 37C user navies, instituted a development programme to improve the logistic support capability and the acoustic and guidance performance of the torpedo. This effort resulted in the new, supportable, solid state acoustic and guidance system and nose assembly.

Advanced development of the solid-state guidance and control system was completed in 1982. Performance of the NT 37E model was demonstrated on a three-dimensional instrumented range and during sea trials with user navies during the period 1981-1984. The tests demonstrated the following improvements: increased dynamic control and accuracy, complete wire guidance capability, ease of changing tactical software, low sonar background noise levels, low acoustic false alarm rate, long range active and passive acoustic attacks on acoustic targets, increased torpedo reliability and reduced maintenance. The Mk 37 family of torpedoes is used by at least 16 navies.

CONTRACTOR
Honeywell Marine Systems Division, 5303 Shilshole Avenue NW, Seattle, Washington 98107, USA.



2820.441
TORPEDO Mk 44

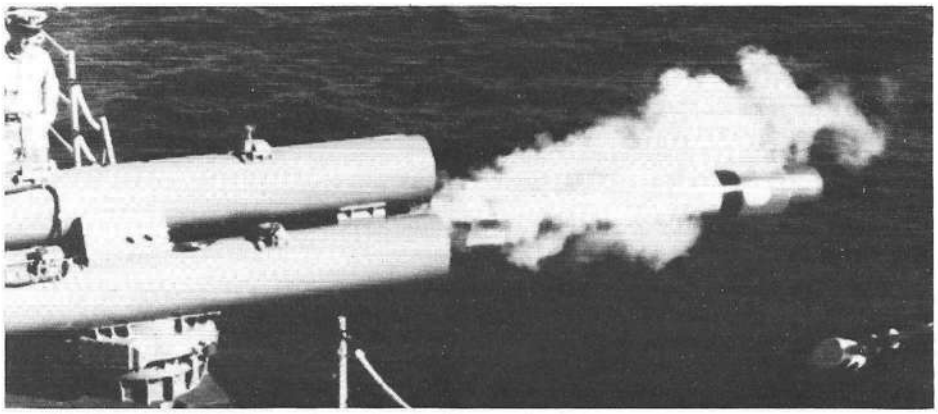
This is a lightweight torpedo designed for launching from aircraft or helicopters, from surface vessels (using Mk 32 tubes), or by the ASROC rocket system (**6001.241**).

Two models have so far been produced but the differences in dimensions are trivial. Both torpedoes are electrically propelled and their calibre is 12·75 inches (324 mm). Approximate length is 2·56 m and the torpedoes weigh about 233 kg with a 34 kg warhead. Active acoustic homing is used. Depth and course settings are entered by umbilical cable. Estimated maximum submersion depth is approximately 300 m. A range of about 5000 m at a speed of 30 knots has been reported. Arming is by seawater scoop.

STATUS

Obsolescent. Licence production was initiated in a number of foreign countries. Replaced by Mk 46 (**2822.441**) in USA and UK service. Some other states are adopting the Mk 46 but the navies equipped with the Mk 44 are those of Argentina, Australia, Brazil, Canada, Chile, Columbia, Federal Republic of Germany, Greece, Indonesia, Iran, Italy, Japan, Netherlands, New Zealand, Norway, Pakistan, Philippines, Portugal, South Africa, South Korea, Spain, Thailand, Tunisia, Turkey, Uruguay and Venezuela.

Mk 44 torpedo being prepared for loading on Sea King helicopter



---

2822.441
TORPEDO Mk 46

Torpedo Mk 46 is a lightweight, 324 mm calibre weapon designed as a successor to the Mk 44 (**2820.441**) for use with several ASW systems. It can be launched from surface vessels, fixed-wing aircraft, or helicopters and can be carried by the ASROC rocket (**6001.241**). Mk 32 tubes are used for surface launching.

The Mk 46 is a deep-diving, high-speed torpedo fitted with an active/passive acoustic homing system and intended for use against submarines. After water entry it searches for, acquires, and attacks its target; if it misses the target it is capable of multiple re-attacks.

Two models of the Mk 46 have been produced. Mod 0 was the first US torpedo to be powered by a solid-fuel motor: it is 2·67 m long and weighs about 258 kg. Immediately it enters the water it starts a helical search pattern. Mod 1 is slightly lighter and is powered by a five-cylinder liquid mono-propellant (Otto) motor. The Mk 46 torpedo also forms the active element of the Captor mine system (**2541.441**, below) in which role it has the designation Mk 46 Mod 4.

Mk 46 Mod 5 (NEARTIP) torpedo produced by Honeywell which succeeded the Mods 1 and 2 Mk 46

CHARACTERISTICS

Type: Mk 46 Mod 1
Length: 2·59 m
Diameter: 32·4 cm
Weight: 230 kg
Max speed: 40 knots
Range: 11 000 m (max)
Acquisition range: 460 m (estimated)
Max depth: Classified
Search patterns: Multiple
Warshot explosive weight: 44 kg
Propulsion: Mono-propellant

STATUS

Mod 1 is operational: the first delivery to the USN was made in October 1965. Following the cancellation of the Mk 31 torpedo a quantity of Mk 46 torpedoes was purchased as an interim measure by the UK MoD for RN use.

The Mod 0 was produced in limited quantities because the Otto fuel was found to be a more practical propellant. It is used in the US fleet only, for aircraft launch applications.

The Mk 46 Mod 1 was introduced in the US fleet in April 1967 and was followed by the Mod 2 in 1972. Production of the former was completed in February 1971 and conversion of 600 Mod 2 units was completed by early 1975.

Recent efforts have been directed to the NEARTIP (Near-Term Improvement Programme) to improve the acoustic performance and countermeasure resistance of the Mk 46 torpedo.

In particular, this programme was designed to restore the acquisition range of the Mk 46 torpedo which was reduced by an estimated 33 per cent by the adoption of an anechoic coating for some of their submarines by the USSR. Code-named Clusterguard, this paint reduces the effectiveness of the standard Mk 46's acoustic homing head and NEARTIP is meant to restore this aspect of performance to at least the same as the pre-Clusterguard status. Other improvements are to the guidance and control and associated fire control system to achieve improved performance against the more sophisticated threats envisaged. NEARTIP implementation is in the form of modification kits applied on a retrofit basis to existing Mods 1 and 2 Mk 46 torpedoes. Captor Mk 46 torpedoes (Mod 4) will not be fitted with NEARTIP kits; instead there is a different modification kit for this programme (see **2541.441**, below).

As prime contractor for the Mk 46 since 1965, Honeywell has produced more than 9000 torpedoes for the USN and other navies. The fiscal year 1984 report by the US Secretary of Defense included funding for both new Mk 46 (NEARTIP) torpedoes and conversion kits to upgrade older Mk 46s, an estimated 500 of which will be used in the Captor role. Actual and planned procurement of Mk 46 torpedoes in fiscal years 1984 and 1985 were 1200 and 1565 units, respectively, at a combined cost of $446·8 million, while for the two following years (FY 1986/87) procurements of 500 torpedoes each year are proposed with annual costs of $132·8 million and $106·8 million, respectively.

A successor to the Mk 46 Mod 5 NEARTIP torpedo is being developed under the Advanced Lightweight Torpedo (ALWT) programme (**4182.441**). During 1984-85 contracts for the supply of several hundred Mk 46 Mod 5 torpedoes to Canada were disclosed.

Users of the Mk 46 torpedo include: Australia, Brazil, Canada, France, Greece, Indonesia, Iran, Israel, Italy, Japan, Morocco, Netherlands, New Zealand, Norway, Pakistan, Portugal, Saudi Arabia, South Korea, Spain, Taiwan, Thailand, Turkey, UK and USA.

CONTRACTORS

Aerojet Electro Systems Company, Azusa, California, USA, was responsible for the development and early production of both Mod 0 and Mod 1.

Honeywell Inc and Gould Ocean Systems Division have also been involved in manufacture and the former is now prime contractor for the Mk 46 NEARTIP.

4182.441
MK 50 ADVANCED LIGHTWEIGHT TORPEDO (ALWT)

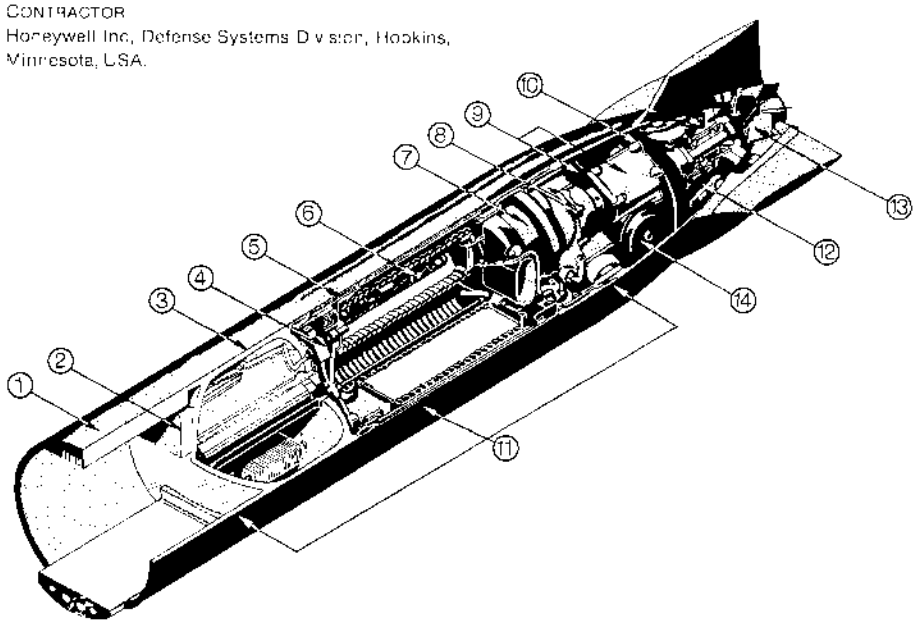
The Advanced Lightweight Torpedo (ALWT), (once designated EX-50, but now the Mk 50) is being developed for use from ships, submarines and aircraft in order to meet the advancing and sophisticated Soviet submarine threat as a successor to the Mk 46 Mod 5 (NEARTIP) lightweight torpedo (**2822.441**). The design objectives include an enlarged target detection envelope embracing faster submarines operating at greater depths, and other desired features are increased speed and endurance, terminal homing, signal processing, and greater destructive effect. The last objective will be attained by a new design of directed energy warhead which it will be necessary to place on its target with high precision to ensure that the directed energy blast penetrates the hull and does not glance off. It will also be advantageous to hit the target submarine amidships. The ALWT is expected to have similar dimensions and weight to those of the Mk 46 and have a speed of about 40 knots with a maximum submersion of some 600 m.

In addition to the ability to operate against fast, deep diving submarines, there is a requirement for capabilities against shallow, slow-moving submarines and surface ships. The most difficult objective to be met, according to the US DoD, is the realisation of reliable terminal homing which is essential if a directed energy warhead is to be used.

Initially two sets of contractors competed under the A-109 procedure whereby each contractor had broad latitude to develop their own unique torpedo so long as it conformed with the Navy's operational requirements. The combination of Honeywell as prime contractor, with Garrett Pneumatic Systems for the propulsion, was selected as sole contractor during 1981. Exhaustive test and evaluation has begun with an engineering development phase to follow. Production torpedoes are likely to come into service in the mid- to late 1980s.

A propulsion test vehicle version of the Honeywell/Garrett torpedo was test launched in the latter half of 1981. It used a closed cycle steam turbine engine in a stored chemical energy propulsion system (SCEPS) with the energy being supplied by a chemical reaction. The command/control system was computer based and software controlled and given reference information by an autopilot on which to base its decisions for steeering and engine control.

Test launch in course of Mk 50 ALWT programme



Seven modified Mk 45 torpedoes are being built as high speed mobile torpedo targets (ADMATT) for ALWT testing by Rockwell International. These run at up to 41 knots and tow a hydrophone/echo repeater array that simulates the spatial extent of a real submarine, and this method was chosen as the only feasible way of developing and testing the ALWT terminal homing system. A three-dimensional instrumented shallow water range has also been developed for ALWT evaluation.

STATUS

Now in full-scale development, the Mk 50 is due to join the US fleet in the late 1990s. Continued development funding budgeting in the four years 1984-87 is $143·3 million, $146·3 million, $168·4 million and $169·9 million, respectively, with projected procurement in the last year of 84 torpedoes at a cost of $124·1 million.

CAPTOR - ENCAPSULATED TORPEDO

Captor, a contraction of 'encapsulated torpedo', is the name given to an anti-submarine system comprising a Mk 46 torpedo (**2822.441**) inserted into a mine casing.

Deployment is in deep water, generally in the vicinity of strategic routes travelled by enemy submarines, and submarines are the intended targets. US officials have stated that Captor has the ability to detect and classify submarine targets while surface ships are able to pass over a Captor field without triggering the Mk 46 Mod 4 torpedo which carries the warhead (43·5 kg PBXN-103 explosive). This capability is reported to have been tested.

The detection and control unit (DCU) that performs these functions is the most costly sub-assembly of the complete Captor weapon and accounts for about 45 per cent of the total unit cost - approximately $130 000. DoD statements imply that the DCU incorporates facilities for turning itself on and off, in addition to its principal operational functions of detecting possible targets, classifying them by their sound signatures, and initiating release of the Mk 46 torpedo when the target is within range of its homing head. It is probable that the turn-on/turn-off system is quite sophisticated in the interests of power conservation to ensure the maximum operational life for deployed Captor mines. Factors which are likely to be taken into account include the levels of traffic (surface and submarine), ambient conditions, sea-state, etc.

Both active and passive sensor modes are employed and the system first operates in a listening (passive) mode which continues for a certain length of time sufficient to identify the target as a submarine and not a surface vessel. The system then switches to an active mode during which it is assumed target ranging is carried out to determine the optimum release time for the homing torpedo.

The detection and control unit is gated to ignore surface traffic and has an estimated range of about 1000 m on submarine targets. There is no IFF capability and friendly units must be warned of Captor minelaying and positions of deployed mines.

There are presumably provisions for some method of self-deactivation or self-destruct for those Captors which are life-expired and which are not capable of retrieval, and other measures to prevent unauthorised salvage or interference may be expected.

The current deployed life of a Captor mine is thought to be in the neighbourhood of six months, but it is not known if this is the USN's target, though it is a fact that considerable effort has been placed on ensuring maximum shelf and operational life.

Captor mines can be sown by surface ships, submarines, and by aircraft. In the former delivery mode, mine rails or other delivery systems are not required, the chosen technique being by means of an over-the-side boom (or yard and stay) with a capacity of 1045 kg. The Captor is brought to a point about 10 m above the surface before release, which has to be at an angle to ensure proper entry into the water. Any submarine equipped with standard 21 inch (533 mm) torpedo tubes can lay Captor mines, these having the advantage of being capable of covert minelaying. Aircraft employ a parachute technique for delivery of Captor.

According to USN statements, there are two main options for Captor delivery: one utilises P-3 maritime aircraft, nuclear strike submarines and surface ships; the other envisages a combination of USAF B-52 bombers and P-3 aircraft, plus surface ships and nuclear strike submarines. Captor has been tested for delivery on P-3C, A-6, A-7 and B-52 aircraft, LKA and other cargo ships, and aboard ten different classes of submarine, including conventionally powered boats.

Most Captor minefields will be barriers located at some distance from possible enemy defences, and in the more highly defended areas Captor mines would be delivered by aircraft or submarines. The unique capability of submarines to plant mines covertly and under ice would be employed selectively.

CHARACTERISTICS

Length: 3·7 m (overall)

Diameter: 533 mm

Weight: 908 kg (with torpedo and mooring)

STATUS

Initial production was started in March 1976, although the US Secretary of Defense's report of January 1981 said the procurement had been at a low level while development and testing were conducted to correct performance deficiencies. In December 1978 reduced performance against shallow water targets had been indicated. Nevertheless initial operational capability was achieved in September 1979. Further procurement was cancelled after fiscal year 1980 by a decision taken in December 1980, and in January 1980 a Captor improvement programme was approved. The weapon was granted approval for service use in February 1980, but no procurement funds were sought in the fiscal year 1981 budget 'because Captor failed to provide the high level of effectiveness we had sought. Subsequent testing has demonstrated that recent modifications have corrected its performance deficiences. The 1982 fiscal year budget requests funds to continue production."

Despite this somewhat chequered history, in spring 1980 Admiral Rowden was able to disclose that about 630 Captors had been procured. The 1986 Report by the US Secretary of Defense, indicated the following procurement and funding for Captor (in millions of dollars and quantities in brackets):

Fiscal year:	**1984**	**1985**
Quantity/amounts:	(300)	(300)
	101·7	122

2823.441

TORPEDO Mk 48

The Mk 48 torpedo is carried by all US attack and fleet ballistic missile submarines. The weapon can be adapted to launch from surface ships. Currently it is operational only on submarines. The torpedo is wire-guided through a two-way communications link in the current Mod 3 version.

The Mk 48 torpedo is propelled with an axial flow pump-jet propulsor driven by an external combustion gas piston engine. This engine, like that in the Mk 46 torpedo (**2822.441**), is a Gould design. The fuel for the engine is a monopropellant, Otto Fuel II.

The Mk 48 torpedo is capable of operation in wire-guided active or passive acoustic and non-acoustic modes. The acoustic modes of operation allow active or passive target detection capabilities.

In the description of the Mk 48 torpedo which follows, the weapon is treated in five distinct sections, known as 'groups', which are from front to back of the torpedo: nose, warhead/exercise, control, fuel tank, and afterbody/tailcone.

The nose group contains units known as functional item replacement (FIR) units which are the transducer Mk 72, transmitter Mk 83, receiver Mk 68, and homing control logic (HCL) Mk 1. The transducer unit occupies the forward portion of the nose shell

and transmits and receives acoustic signals to and from the ocean environment. These signals are generated by the transmitter located directly behind the transducer. The receiver, located in the lower half of the nose shell, processes acoustic signals received from the transducer and determines target position relative to the transducer for the development of steering orders during torpedo homing.

The HCL is located in the aft end of the nose shell directly above the receiver. The HCL contains a computer that directs torpedo manoeuvres in search, homing, and re-attack modes. Other circuits within the HCL unit analyse all acoustic signals for valid target returns.

The warhead group is located immediately aft of the nose group and contains the warhead Mk 107, exploder Mk 21, arming device Mk 2, and electronic assembly Mk 12. The explosive charge is loaded into the warhead shell at an explosives loading facility. The loaded warhead shell, with source and sensor assemblies installed, constitutes the warhead. Arming device Mk 2 and exploder mechanism Mk 21 insert into a cavity in the main explosive charge. The arming device and exploder mechanism are accessible from outside the warhead shell. The torpedo is issued with the exploder and arming device installed. Electronic assembly Mk 12 is a FIR item located in the aft warhead compartment. This unit contains target detection electronics which trigger the explosive.

The control group, located between the warhead and the fuel tank group, houses the command control unit Mk 154 or Mk 168, gyro control unit Mk 155, and power control unit (PCU) Mk 156. The command control unit is mounted in the lower third of the control shell. The command control implements fire control instructions, maintains the torpedo at the commanded speed, and monitors depth to ensure that the torpedo stays between the commanded maximum and minimum depth limits. The gyro control unit is mounted in the centre of the control shell. This unit converts steering commands into fin deflection signals to maintain the torpedo on the commanded course. The PCU is mounted in the upper third of the control group.

The warshot fuel tank group is located between the control group and the afterbody/tailcone group. There are no FIR items in the fuel tank group. The fuel tank group stores fuel for the propulsion system and houses the wire dispenser used for command guidance after launch. At launch, the fuel shut-off solenoid valve in the fuel tank is opened, allowing fuel flow to the engine in the afterbody/tailcone group. The warshot fuel tank group carries a full fuel load.

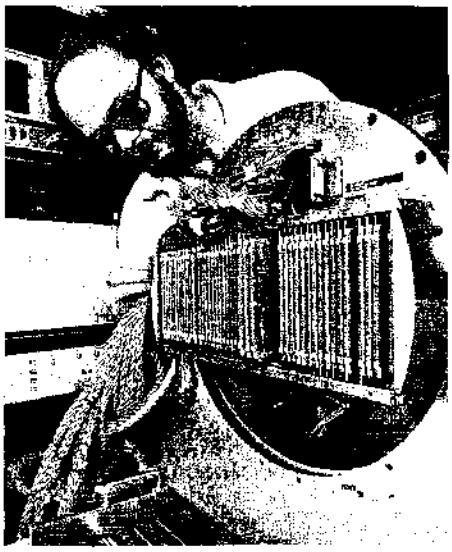
The afterbody/tailcone unit contains the engine, steering control surfaces, and engine accessories, less alternator and chamber and valve assembly. This unit becomes the afterbody/tailcone group when the combustion chamber (grain loaded) and alternator are mounted on the forward bulkhead of the unit. The alternator assembly, mounted on the forward bulkhead of the afterbody/tailcone group, is driven by a power take-off shaft from the engine and provides electrical power required by the torpedo after launch. The chamber and valve assembly is mounted within the water jacket on the forward bulkhead of the afterbody/tailcone group. Fuel is burned in the combustion chamber to provide hot gas to operate the engine.

DEVELOPMENT

Anticipation by the US authorities of impending advances in submarine technology by the USSR noted in the 1960s and 1970s led to studies of the Mk 48's capabilities against likely threats, and in 1975 resulted in an Operational Requirement issued by the Chief of Naval Operations for a programme to develop appropriate modifications to the Mk 48 torpedo to keep pace with anticipated submarine threat developments. The origins of the Mk 48 ADCAP (advanced capabilities) programme lay in this requirement, but the extent and rate of Soviet submarine technology advance hastened both ADCAP progress and another Mk 48 improvement programme.

Recognition (by the USA) of the impressive operational characteristics of the Soviet 'Alfa' class submarine in late spring 1979 resulted in a decision taken in September 1979 to accelerate the ADCAP programme. It was also responsible for an intensive test and analysis programme to determine the true limits of the then current Mk 48 in terms of depth, speed, and acoustic capabilities. This was known as the expanded operating envelope programme, and showed that the Mk 48 was structurally reliable at the depth needed to engage 'Alfa' class submarines; the target speed recognition capability required could be achieved; the vertical coverage was adequate, as was the self-noise at higher speeds with the existing nose and array; and additional speed could be achieved. Laboratory modifications were made to a few torpedoes for tests, and these changes were implemented in the form of a programme to update fleet Mk 48 torpedoes to what is now the Mk 48 Mod 4 standard.

Of the performance requirements demanded by the ADCAP programme, the most important are:



(1) sustained long acquisition range
(2) minimised adverse environment and countermeasure effects
(3) minimised shipboard tactical constraints
(4) enhanced surface target engagement capabilities.

Hardware changes involved in ADCAP entail replacing the entire nose of the weapon housing the acoustics and beam forming circuits and replacement of the signal processing by the latest electronics. The latter will also incorporate the current command and control electronics. Warhead sensor electronics will be improved.

Application of the expanded operating envelope programme findings (see above) to ADCAP has resulted in the upgraded ADCAP, which incorporates: upgraded acoustics and electronics; an expanded operating envelope (depth, target speed, weapon speed options); increased fuel delivery rate and capacity for optimum speed and endurance; improved surface target capabilities.

CHARACTERISTICS

Length: 5·8 m
Diameter: 21 inch (533 mm)
Weight: About 1600 kg
Max speed: 55 knots
Max range: 38 km
Max depth: 500 fathoms (914 m)

Data processor cards which are part of digital guidance and control system being developed by Hughes for Mk 48 torpedo ADCAP programme

STATUS

The Mk 48 has been in production since 1972 and is used aboard USN attack submarines, and strategic submarines for self defence. By early 1980 more than 1900 torpedoes of this type had been delivered to the USN and an estimated 800 plus were in the production and procurement line. It was then estimated that another 1050 might be required to meet inventory objectives and to allow for peacetime training and testing.

In August 1979, Hughes Aircraft Company received a contract for development of digital guidance and control electronics for the Mk 48 ADCAP programme.

The first test run was carried out by the USN at Nanoose Bay in early 1982, using the inertial guidance system developed for the ADCAP programme. About 240 more runs were programmed before completion of this phase of the programme after which it was expected that entry into service will take place in 1983/84. However, the 1985 report by the US Secretary of Defence amended this to indicate anticipated deployment of the system in the mid- to late-1980s.

In the US Secretary of Defense's Annual Report to Congress in February 1985, it was stated that following completion of a successful test programme in 1984, it had been decided to accelerate production of the ADCAP torpedo. The five-year programme calls for production of 1890 ADCAP units, including 123 in fiscal year 1986, at a cost of $433·2 million. In the following year, procurement of 280 units costing $671·4 million is proposed.

The only known foreign users are Australia and the Netherlands.

AMERICAN MINE WARFARE PROGRAMMES

The American mine warfare programme comprises two main elements, mines and mine-countermeasures. The application of mines in weapons against submarines and surface ships has the objective of denying access to and use of ports and to provide offensive and defensive barriers. The current stock of sea mines consists of the Mks 52, 55, 56 and 57 types.

CHARACTERISTICS

Type: Mk 52, aircraft laid bottom mine
Length: 2·25 m
Diameter: 844 m
Weight: Mod 1, 542 kg; Mod 2, 567 kg; Mod 3, 572 kg; Mod 5, 570 kg; Mod 6, 563 kg
Charge: 270 kg HBX-1
Max depth: 45·7 m (Mod 2, 183 m)
Actuation: Mod 1 acoustic; Mod 2 magnetic; Mod 3 pressure/magnetic; Mod 5 acoustic/magnetic; Mod 6 pressure/acoustic/magnetic

Type: Mk 55, aircraft laid bottom mine
Length: 2·89 m
Diameter: 1·03 m
Weight: Mod 2, 580 kg; Mod 3, 992 kg; Mod 5, 992 kg; Mod 6, 996 kg; Mod 7, 995 kg
Charge: 576 kg HBX-1
Max depth: 45·7 m (Mods 2/7, 183 m)
Actuation: Mod 2 magnetic; Mod 3 pressure/magnetic; Mod 5 acoustic/magnetic; Mod 6 pressure/acoustic/magnetic; Mod 7 dual channel magnetic

Type: Mk 56 Mod 0, aircraft laid moored mine
Length: 3·5 m
Diameter: 1·06 m
Weight: 1010 kg
Charge: 159 kg HBX-3
Max depth: 366 m
Actuation: Total field, magnetic dual channel

Type: Mk 57 Mod 0, submarine or ship laid moored mine
Length: 3 m
Diameter: 510 mm
Weight: 934 kg
Charge: 154 kg HBX-3
Max depth: 350 m
Actuation: total field, magnetic dual channel

Also employed by the USN is a range of air deployed munitions based on modified general purpose low drag bombs and which can be released without requiring a parachute. The modification involves the use of a Mk 75 Mod 0 Destructor Modification Kit which can be added to 500 lb, 1000 lb and 2000 lb Mk 80 series bombs to form the Service Destructors (DST) Mks 36, 40 and 41, respectively. These are mostly intended for use in shallow waters such as estuaries etc, against typical coastal targets.

There is also the DST 115A, which can be employed with either aircraft or surface craft for use against surface targets.

CHARACTERISTICS

Type: Mk 36, aircraft laid bottom mine
Length: 2·25 m
Diameter: 400 mm
Weight: 240 kg (with fixed conical fin) 261 kg (with tail retarding device)
Charge: 87 kg H-6
Max depth: 91·4 m
Actuation: Mods 0/3 magnetometer; Mods 4/5 magnetic/seismic

Type: Mk 40, aircraft laid bottom mine
Length: 2·66 m
Diameter: 570 mm
Weight: 447 kg (with fixed conical fin) 481 kg (with tail retarding device)
Charge: 204 kg H-6
Max depth: 91·4 m
Actuation: Mods 0/3 magnetometer; Mod 4/5 magnetic/seismic

Type: Mk 41, aircraft laid bottom mine
Length: 3·83 m
Diameter: 630 mm
Weight: Mods 0/3, 926 kg; Mods 4/5, 921 kg
Charge: H-6
Actuation: Mods 0/3, magnetometer; Mods 4/5, magnetic/seismic

Type: 115A, aircraft laid surface mine
Length: 0·45 m
Diameter: 620 m
Weight: 61 kg
Charge: 24 kg HBX-3
Actuation: Magnetic/seismic

Quickstrike

The Quickstrike bottom mine development programme is funded under PE 64601N and embraces a family of mines using different size cases but with common target detection and classification mechanisms. The four members of the Quickstrike family are the Mks 62, 63, 64 and 65. The last of these (Mk 65 Mod 0) is in the 2000 lb (900 kg) class and was expected to go into production in 1981. The Mk 64 will probably be the next to enter production and this also is in the 2000 lb (900 kg) class, based on a Mk 84 2000 lb bomb and measuring 3·8 m long and 633 mm diameter.

Quickstrike mines are for shallow water deployment (to approximately 100 m) and targets will have to approach to within a few hundred feet for it to act. It will use existing Mk 80 series GP bomb cases as well as a new mine case. Quickstrike mines will be deployed by aircraft, surface ships, or submarines, but principally from the former.

This family of mines is based primarily on conversion of existing ordnance (bombs and torpedoes). An exception is the Mk 65 mine which is not a bomb conversion. It has a thinner case than the equivalent bomb and contains the effective underwater PBX explosive. It is 3·3 m long and 734 mm in diameter. In fiscal year 1982, a procurement of 307 out of the total inventory objective of mines is planned. Also, the target detection device, TDD 57, employing influence mechanisms, will convert Mk 80 series bombs to mines, and procurement of an additional 1701 TDD 57s was planned in 1982. The TDD 58 combination sensor for the Mk 65 mine was due to complete development in fiscal year 1982 and enter production in fiscal year 1983.

The fiscal year 1984 report by the US Secretary of Defense stated that ways were being studied to provide Quickstrike and Mk 67 SLMM mines (below) with a wider variety of target detection devices. Quickstrike funding in the 1986 budget was $32·2, $34·9, $35·7 and $50·5 million, in fiscal years 1983/84/85/86, respectively.

Captor

Captor is a deep anti-submarine mine (Mk 60) intended for use in barriers against enemy strategic submarines. It can be emplaced by submarines, surface ships and aircraft. The kill mechanism consists of a Mk 46 Mod 4 homing torpedo (**2822.441**) which is released by a fire control system contained within the detection and control unit of the main Captor unit. Further details of Captor will be found in **2541.441**, above.

SLMM

The submarine-launched mobile mine (SLMM) Mk 67 is intended to provide the US fleet with a capability for planting mines in shallow water (to approximately 100 m) by submarine, using a self-propelled mine to reach water inaccessible to other vehicles. It is also meant for use in locations where covert mining would be particularly desirable from a tactical standpoint. It measures 4·09 m long × 485 mm diameter and weighs 754 kg.

The Mk 67 SLMM consists essentially of a modified Mk 37 torpedo (**2818.441**); alterations involved include some reworking of the Mk 37 torpedo bodies and replacement of the torpedo warhead with the applicable mine components. Tooling and other plant facilities were installed in fiscal year 1978 for production of Mk 67 sub-launched mobile mines in 1979.

Procurement plans for the Mk 67 SLMM in the 1984-87 period budget were for 242 mines costing $22·1 million in fiscal year 1984, 280 at a cost of $22·6 million in 1985, a similar number in 1986 for $23·7 million, and 273 proposed for 1987 at a cost of $26·1 million.

Mine Countermeasures

In 1983 construction began of the first in a new class of mine countermeasures ships, the MCM-1 Avenger. Ships of this class are intended to match increasing Soviet mine warfare capabilities and to enhance US minesweeping facilities. Five of these ships have been authorised to fiscal year 1984, and nine ships included in the 1985 - 89 shipbuilding plan complete the programme. A second new class of mine countermeasure ship, the MSH-1 will augment the MCM class ships. The MSH-1 minehunters will be equipped with advanced combat systems similar to those in the MCM-1 ships, but will be smaller and less costly. Congress authorised the lead ship of the class in 1984. To complete the 17-ship programme, the five-year building plan contains another 16 vessels.

4425.441

HONEYWELL MNS

The Honeywell mine neutralisation system (MNS) developed by the company's Marine Systems Operations and the US Naval Sea Systems Command, is now in production for the US Navy's new MCM ships. It is the result of more than ten years work to provide a system that surpasses the conventional towed mechanical, magnetic and acoustic sweep techniques. It is designed to detect, locate, classify and neutralise moored and bottom mines, using high-resolution sonar, low light-level TV, cable cutters and mine destruction charges. A special underwater vehicle carries these sensors and countermeasures and is remotely controlled from the parent vessel.

Initial target detection and vehicle guidance information is provided by the ship's sonar and vehicle tracking is aided by a Honeywell RS/900 acoustic position indicator. Vehicle sonar is used during the mid-course search and final homing phases, and high resolution enables operations in poor visibility by sonar guidance alone. Low light TV is used in conjunction with sonar during the precision guidance phase near the target. Underwater launch and recovery of the MNS vehicle assists operations in high sea states.

Vehicle power is provided via a neutrally buoyant umbilical cable which also carries signal and control links between the vessel and the MNS vehicle. Aboard the parent vessel a sonar screen on the control console displays sensor and vehicle status information in digital form. The monitor and control consoles are the focal point for operation and management of the complete system. Display facilities include: sonar, TV, secondary sonar and TV, vehicle control, cutter and dropped-charge actuation.

CHARACTERISTICS

Vehicle endurance: Unlimited
Speed: 6 knots
Weight (in air): 1135 kg
Length: 3·8 m
Propulsion: Hydraulic, twin 15 hp
Thrusters: Horizontal/vertical
Cable length: 1000 m
Total system weight: 11·7 t
Power requirements: 60 kW (peak)

STATUS

In production.

CONTRACTOR

Honeywell Marine Systems Division, 5303 Shilshole Avenue NW, Seattle, Washington 98107, USA.

LAND-BASED AIR DEFENCE SYSTEMS

3215.181
AIR DEFENCE SYSTEMS NOTE

This section is concerned principally with national air defence systems, and systems for the command and control of air defence forces comprising a mixture of weapons (eg guns, missiles, and aircraft) intended for deployment in a mobile or semi-permanent fashion in support of an expeditionary force abroad. Within the constraints imposed by what is, by nature, one of the more sensitive areas of defence technology, the aim is to concentrate upon the infra-structure of such systems and the hardware associated with this aspect of air defence. Sensors and weapons are covered elsewhere in this volume. Land radars are also treated in the Equipment section.

The distinction between 'air defence command and control systems' above, and certain army fire control systems is clearly a fine one in some instances: the reader is therefore directed also to that sub-section, which follows this one.

As already observed air defence is a particularly sensitive subject and consequently information on some nations' systems and equipment is often severely limited. Political, as well as military reasons frequently are the cause of manufacturers' reluctance to divulge the destination of equipment such as radars or computers, which might otherwise enable assessments of particular countries' air defence provisions. There is an increasing tendency for long- and medium-range radars to be employed for both air defence purposes and air traffic control (ATC) functions. Up to a point, the demands of both services are almost identical and there is much to be said for combining the requirements in terms of sensors, data handling and display equipment, as far as is possible. Where it seems appropriate, therefore, we are giving some details of certain examples of this practice in this section. Such instances will be clearly identified in the text. In other cases air defences are being freshly constructed and may as yet be incompletely defined. In the following paragraphs brief details are given of what is known of some of these programmes.

Argentina

In the early 1970s Argentina was known to have expressed an interest in a new national network, and later the French Thomson-CSF concern undertook a similar programme to that completed for Brazil, namely an integrated ATC/defence network.

In 1978 an $8·79 million US contract for the supply of three AN/TPS-43 air defence radars to Argentina was announced, and later it was reported that a number of Cardion-built AN/TPS-44 radars had been supplied. No status details of either sale was obtained subsequently and no official information has been disclosed, but it is probable that these radars were sited to afford cover for the main naval and air bases near Buenos Aires, Puerto Belgrano, Commodoro Rivadavia, Santa Cruz, Rio Gallegos, and Rio Grande and Ushuaia. In 1982 one of the AN/TPS-43 radars was deployed to the Falkland Islands in support of Argentinian forces landed there. This equipment was captured by British forces when the Islands were reclaimed and subsequently returned to the UK. It seems likely that early steps were taken to replace this item of lost equipment following withdrawal from the Falkland Islands, either with another TPS-43 or a broadly similar type such as the Thomson-CSF TRS 2215 or TRS 2230.

Egypt

Egypt is unusual in that it has four armed services, one of which is dedicated to air defence. To what extent this peculiarity is a result of the period when Egypt relied mostly on the USSR for her defence equipment and consequently absorbed much of the military thinking of that state is not known. However, the fact remains that much of the essential hardware for air defence, particularly anti-aircraft artillery, and surface-to-air missiles, was initially of Soviet origin despite the severance of the Egyptian-Soviet link in successive stages in 1972 and 1975. Since that time military equipment procurement has tended to reflect the various phases of Egypt's evolving relationship with differing friendly nations willing (or anxious) to provide arms or to avail themselves of one or other aspect of Egypt's resources or situation. Examples of such countries which have a capacity in the air defence sphere are Italy, France, UK, China, and the USA.

As a consequence of this somewhat chequered background, it is understood that the present inventory comprises an extremely varied total of hardware. There are almost certainly still examples of Soviet radars associated with missile systems previously supplied, such as the SA-2 Guideline, SA-3 Goa and SA-6 Gainful, various French types and Egypt has also consistently been reported as one of the unidentified Middle Eastern states said to have been supplied with Plessey's AR-3D three-dimensional radar although this cannot be confirmed.

In 1980 four General Electric AN/TPS-59 3-D radars and, later, eight Westinghouse AN/TPS-63 air defence radars were ordered for Egyptian use at a combined cost of about $154 million. In the same period 12 AN/TSQ-143 mobile automated operations centres, which interface with the TPS-59 and TPS-63 radars, were ordered from Westinghouse, for operation of Hawk missile batteries. Each operations centre has four OJ-560 display consoles, two main computers, 12 high-density micro-processors and an audio/video recorder that files all track data, displays and operator actions. The first of these centres had been completed by May 1984.

In early 1985 it was anticipated that arrangements for co-production and assembly of AN/TPS-63 radars at the Bahna Electronics plant in Egypt would soon be completed. A quantity of 34 sets was mentioned as a possibility at that time.

Hughes received a $210 million contract in December 1983 for the first phase of a new Egyptian national air defence system, and this called for integration of all existing radars, missile batteries, air bases, and command centres into an automated command and control system. Also to be integrated are E-2C Hawkeye airborne early warning aircraft, the first of four so far planned is expected to arrive in July 1986. The US Congress proposed the sale of a fifth E-2C to Egypt in February 1985.

India

In early 1974 an Indian Air Defence Ground Environment System (ADGES) programme was revealed when it was announced that indigenous production of equipment was to start in January 1974 at the Bharat Electronics Ltd plant at Ghaziabad, east of Delhi. The system is being installed along the Indian northern and western borders (with Pakistan and China) and a communications system for use in the air defence of a limited area along the northern borders was built with American equipment.

The current air defence system is understood to rely on a miscellaneous assembly of radars of varying origin, reflecting India's changing international associations and allegiances since gaining independence. This includes British, French, Soviet and possibly other types of equipment.

Between 1962 and 1978 at least 24 long- and medium-range radars of Italian design were installed ostensibly for ATC use, but clearly so that target data from some of them at least would be useful for air defence/surveillance. Most of these radars are D-band equipments, eight of them ATCR-2 systems and the remainder ATCR-4Ts (**2248.153**). Licensed production of the latter type was undertaken in India from 1971 onward, more than 10 being provided in this way. It is very probable that the Soviet-built SA-2 Guideline air-defence missiles used by the Indian Air Force rely on a number of Soviet radars.

In 1978/79 the second high-power radar of the ADGES plan was installed and installation of the remainder was in progress. The first phase of the associated communications network had been completed, and development of a computer-based ADP system had been completed by the Tata Institute of Fundamental Research. Evaluation under simulated environmental conditions preceded its removal to radar sites for integration and user trials.

Thomson-CSF revealed in February 1984 a contract to supply four 3-D military radar stations to India, and the construction under licence of five more stations.

Indonesia

Following the earlier updating of the previous air defence/ATC network (largely provided by Decca in the late 1950s and early 1960s) by the French Thomson-CSF concern, it was revealed in late 1978 that a further modernisation was in progress. At the same time the ordering of two three-dimensional air surveillance radars was announced. These are TRS 2215 equipments (**3272.153**), the transportable version of the TRS 2230 static E/F-band system. More recently, certain equipment of Dutch origin is thought to have been acquired for short-range air defence purposes.

On completion of a contract, announced in June 1984, to provide four new ATC centres, Thomson-CSF will have installed over a period of ten years coverage for most of the Indonesian archipelago with TA 10 or TA 23 primary radars, RS 770 or RS 870 secondary radars, and 10 regional control centres. In mid-1985 Thomson-CSF revealed a further contract to extend the coverage of the eight primary, and 11 secondary surveillance radars then serving Indonesian airspace.

Jordan

Jordanian air defence is based on F-5 and F-104 aircraft and Improved Hawk SAMs (**2640.131**), supported by AA guns. The main command and control element is the AN/TSQ-73 air defence missile control and co-ordination system (**2835.181**, later in this section). It can now be expected that the radars of western origin (probably including Westinghouse TPS-43 equipments) associated with these systems will have been joined by some Soviet equipment following Jordanian procurement of the SA-8 Gecko SAM and ZSU-23/4 air defence systems from the USSR.

Kenya

In June 1985 Thomson-CSF reported the award of a contract to provide complete air coverage for Kenya by means of a system comprising a central control facility supplied with data from four radar sites. This will probably be an integrated civil/military system with the main centre at Nairobi and with an ancillary control centre at Mombasa in the SE of the country.

Kuwait

In recent years Kuwait has significantly increased its air defence forces with acquisitions of Mirage F1 interceptors and Hawk surface-to-air missiles, of which seven or eight battalions have been ordered. Recently acquired sensors include the ITT-Gilfillan TPS-32 mobile three-dimensional radar (**2516.153**). Kuwait is also reported to have been the recipient of one or more Plessey AR-3D air defence radars (**2484.153**) although this has not been confirmed. For command and control of the Hawk missiles two TSQ-73 systems (**2835.181**) were ordered and are thought to have been operational since 1982.

In June 1982, ITT Gilfillan was paid more than $5·3 million by the US Army Missile Command for support of two AN/TPS-32 radars in Kuwait. In November 1983 Thomson-CSF was awarded a contract to modernise the low-altitude air defences of Kuwait and to set up an integrated command system for the entire air defence infrastructure. Gradual implementation over the next three years may involve the supply of TRS 2230 3-D radars.

During 1984 and 1985 various projects were implemented with the aim of further improving Kuwait's air defence. In mid-1984 steps taken with US assistance included: certain radar improvements; AN/TQS-73 Missile Minder system for use with PIP Hawk SAMs; and arrangements for data link facilities to allow Kuwait to share data obtained from Saudi Arabian E-3A AWACS aircraft, and use the information for direction of Hawk missile batteries. In March 1985, Thomson-CSF announced a Fr 1·2 billion contract for the KAFAD command, control and communications programme to modernise Kuwait's air command and control system. This includes a series of radar stations around the country's borders and a central command post.

Libya

For several years plans to expand and modernise the

Libyan air defence network have been hampered by political obstacles. US, UK, Italian and French companies and consortia competed for the task, but it is now thought that Libyan air defence is modelled on Soviet principles and heavily reliant on equipment from the same source.

Malaysia
Following the British withdrawal from the Far East in 1971, the Malaysian Government purchased two Marconi S600 mobile radar units (**2426.181** and **1168.153**) to meet the country's immediate air defence needs and to support the two RAAF Mirage squadrons based in Malaysia. About a year later a third S600 system was procured. In early 1983 it was learned that a Hughes air defence radar, HADR (**3721.153**), had been ordered for MADGE (Malaysian Air Defence Ground Environment) for which Hughes Ground Systems Group is the prime contractor.

This system is now operational, providing air surveillance and identification services for civil and military aircraft in airspace of interest to Malaysia. It uses modern data processing equipment, large screen displays, new communications and the Hughes 3-D radar which is probably used in conjunction with earlier existing radars to provide target data for the entire country. Control of radar sensors, aircraft and other air defence assets is exercised from a number of control centres.

Morocco
A series of contracts, collectively assessed as worth about $100 million, for the provision of an air defence network was announced in June 1977. The principal contractors named were Westinghouse, Burroughs and Ford Aerospace. Westinghouse provided the primary radars and integrated the entire system, while Burroughs supplied large-scale B-6700 series computers for processing tracks, ATC data, identification, plot extraction, etc. Ford Aerospace provided microwave communications links under a contract worth about $8 million. Value of the Burroughs contribution was approximately $30 million.

The complete system is based on 16 AN/TPS-43 radars at early warning and coastal sites. A centralised control facility directs Moroccan air defence aircraft.

Nigeria
In 1984 Nigeria continued its programme of refurbishment and upgrading of the national infrastructure, including the airspace control services. It was reported in October 1984 that a 3-D surveillance radar (probably a Selenia RAT-31) was to be procured for civil/military ATC purposes at Lagos. This is understood to be intended for control of nearby AA units, most likely guns and Roland SAM units. Elsewhere in Nigeria, ATC radars that had been shut down for many months are being reactivated. These include: Enegu radar installed in 1980 but only commissioned in 1984; Kano and Kaduna airport radars.

Philippines
Although independent since 1946, the Philippines has relied almost entirely on the USA for its defence, and this is reflected in the inventory of the Philippine forces. Under the terms of the treaty between the two countries, the USA enjoys important base facilities in the Philippines, notably the Subic Bay naval base and Clark AFB, and over the years there have been appreciable supplies of equipment of US origin. The Philippine forces operate Hawk surface-to-air missile batteries, and F-5 fighter aircraft are also available for air defence. In addition to the target detection and designation radars associated with the Hawk missile batteries, two Italian-built ATCR-3T radars supplied for ATC purposes at Manila and Mactan in 1972 could also serve a supplementary surveillance role. In 1980 the first of four ITT-Gilfillan Series 320 three-dimensional air defence radars was delivered under the terms of a $13 million contract given to the US company by a Dutch contractor.

Saudi Arabia
On to an original air defence network based on radars of American and British origin dating from the 1960s, a succession of improvements have been grafted, either for their overall system enhancement potential or as adjuncts or essential elements of a new weapon system acquired for the Saudi Arabian defences. Examples of the latter process might be the radars associated with US Hawk surface-to-air missile batteries, or with French air defence weapons such as Crotale, and Shahine. In the case of the Hawk system, a contract covering the supply of an AN/TSQ-73 air defence control system (**2835.181**) for Hawk batteries, and to be integrated with the existing air defence network was revealed by the US in 1978. At a time of unrest in the Middle East, America rapidly supplied one AN/TPS-43 3-D radar (**2517.153**) to strengthen the region's defences, and at the same time deployed AWACS aircraft to serve as an airborne control post based in Saudi Arabia. Four of these aircraft were used in this way, and at that time there were already two AN/TPS-43 radars in the country in addition to the one flown out from the USA in October 1980.

Defence ministers from six Arab states in the Gulf area agreed in principle to establish a joint air defence system based on Saudi Arabian airborne warning and control system aircraft to be supplied by the US. The states concerned are Saudi Arabia, Kuwait, United Arab Emirates, Bahrain, Qatar and Oman. The Royal Saudi Arabian Air Force is also seeking a command, control and communications (C^3) complex to be supplied by the US. The system will consist primarily of a command operations centre (COC); five sector command centres (SCC), co-located with sector operations centres (SOC) at the main operating bases; two base operations centres, one co-located with an SCC/SOC; 17 combined long-range radar and remote-controlled air/ground radio sites; and associated communications for an operational command and control system.

The overall project became known under the programme name Peace Shield and was finalised to include five E-3A AWACS aircraft, eight KC-135 tanker aircraft, the C^3 system with its underground command centres, data processing facilities and communications links, and a new ground network of 11 AN/FPS-117 long range radars, similar to the North American Seek Igloo radars and also supplied by General Electric. Work on the estimated $8500 million programme started in 1981, and by 1985 the centralised COC had been constructed and work was in hand on connecting and building the five sector command and operations centres to be linked to the centralised facility.

Plans to link Saudi Arabian air defence systems, and those of some neighbouring countries (eg Kuwait, UAE etc) with the AWACS aircraft by data link were completed during 1984-85 and implementation started.

In February 1984 an agreement was reached between the French and Saudi Arabian Governments to integrate new versions of the Shahine missile system with the national air defence network. Estimated value was $4 000 million. Westinghouse also received contracts in 1984 for improvements to TPS-43 radars, communications and troposcatter links.

Singapore
During 1980 a joint civil/military integrated ATC system based on Signaal LAR II long-range surveillance radar and data handling equipment by the same manufacturer, under the name LORADS (long range radar and display system) was commissioned. Most of the hardware, including the radar antenna, is located at Changi International Airport, and the data stored in this computer-based system is available to both civil and military authorities. In a move, in late 1982, that was seen in some quarters as a preliminary to the formation of a regional air defence system embracing five ASEAN states (Indonesia, Malaysia, the Philippines, Singapore and Thailand), Singapore requested approval for the purchase of two E-2C airborne early warning aircraft from America and contracts were awarded to Grumman in 1984. In addition to these machines, which are expected to be delivered in September and December 1986, the USA has reportedly agreed to supply improved Hawk air defence missiles, and there is a possibility that Singapore may acquire the Mirage 2000 fighter aircraft or the American F-16A.

South Korea
South Korea is being supplied with Improved Hawk surface-to-air missile systems and will probably procure the related TSQ-73 system (**2835.181**) for command and control. A new overall air defence system to provide for target assignment, early warning, and co-ordination of other air defence forces such as interceptors will probably be developed. One aspect of this is the likely procurement of E-2C Hawkeye airborne early warning aircraft, possibly in 1988.

Taiwan
It is believed that Taiwan is engaged in the development and implementation of an automated air defence network similar to those provided by Hughes for Japan, Switzerland, Spain, and Israel. In February 1981 the US Government indicated an offer to supply five Hawk missile batteries, with a total of 280 Improved Hawk missiles. Taiwanese plans then envisaged four Improved Hawk battalions, of which three had already been purchased. These are almost certainly operated by AN/TSQ-73 automated air defence systems supplied by Westinghouse who may also have provided TPS-43 radars. It was reported in February 1985 that Congress had proposed the sale of the TPS-43 to Taiwan.

Thailand
Air defence assets operated by this state include two AA artillery regiments armed with 40 mm guns and other weapons, two air defence squadrons of F-5 aircraft, and miscellaneous AA weapons operated by other units. The volatility of the potential threats facing Thailand, and its geographic circumstances, pose difficulties in arranging for appropriate air defence command and control. However, based on two TPS-43 3-D radars delivered by Westinghouse in 1980, and a new TPS-70 ordered from the same company in 1985, a new automated air defence system is to be established. This will be the first phase of a larger, more elaborate scheme.

United Arab Emirates
It was reported in early 1985 that the UAE was examining the possibility of acquiring an E-2C AEW aircraft to supplement the existing ground-based radar surveillance facilities in the Gulf States.

Venezuela
The Venezuelan forces include a number of weapons specifically intended for anti-aircraft applications, and although no details of a dedicated air defence network have been received, two Italian-built ATC long-range radars supplied in 1973 do have the useful advantage of being sited at virtually the western and eastern extremities of the country. A Selenia ATCR-2 with computer-based display system is located at Maracaibo, while in the east there is a Selenia ATCR-3. Westinghouse is known to have supplied air defence equipment, which probably includes the TPS-43 air defence radar. A tri-service evaluation committee was set up in 1980 to consider the development of a national air defence system.

Yugoslavia
This communist state, though relying to a marked degree on Soviet and Warsaw Pact sources for much of its military equipment, nevertheless manifests a stoutly independent line in certain areas of its defence procurement. Thus, although there is a marked preponderance of Warsaw Pact systems, such as SA-2, 3, 6, 7 and 9 SAMs, various AA artillery and the ZSU-57-2 self-propelled AA gun in its air defence inventory, Western hardware does find a place in the Yugoslav order of battle. One such instance, reported in 1982, was a Westinghouse contract valued at $39·1 million for six AN/TPS-70 surveillance radars.

AUSTRALIA

3521.181
AUSTRALIAN AIR DEFENCE

Australia's sparse population in conjunction with its continental size combine to make a conventional static air defence organisation along the lines of that of the USA an unrealistic proposition. Instead, an effective compromise is achieved by the combination of Hub Cap air defence systems (two) (**2016.181**) with the search radars and part of the infra-structure needed for the control of civil and military air traffic serving the main population centres of Australia. In this way the costs of fixed installations are minimised while operational flexibility is maintained.

Hub Cap was described in detail in this section of *Jane's Weapon Systems 1979-80* and in previous editions, but a short summary of the salient features is retained in this entry for convenience. The main air defence forces available consist of Mirage III-O fighter aircraft, Rapier surface-to-air missiles (some equipped with the DN181 Blindfire radar), and AA guns, but the Bloodhound long-range surface-to-air missiles originally deployed with Hub Cap have since been withdrawn from service.

The Hub Cap system provides three-dimensional airspace surveillance and control of fighters to intercept hostile targets over a wide area from fully mobile air-conditioned shelters designed for deployment by C-130 aircraft.

The use of digital computing permits automatic tracking of targets from the primary radar while plot extraction from the secondary radar returns is used to reinforce the primary radar auto-tracking. For the RAF requirements, the computer is programmed to take account of the Mirage III characteristics, perform an assessment of an interception situation when supplied with the relevant data on weapon availability, and provide a number of alternative intercept solutions for selection by a controller. The computer can be re-programmed to enable the system to operate equally effectively with other types of fighter. Comprehensive communication facilities are provided with Hub Cap enabling operational personnel to communicate with each other, with aircraft under control, and with units external to the system.

The Australian Defence White Paper of November 1976 revealed that the radars of the two Hub Cap systems were to be replaced, and at the same time it was confirmed that obsolescent air traffic control radars at RAAF and RAN bases were being replaced. Tactical radars capable of being carried in C-130 transport aircraft entered service in 1979. These radars are Westinghouse AN/TPS-43 equipments (**2517.153**) of American origin and both systems are thought to have been commissioned in 1982. This programme was known as Project Recap. At the time of completion (mid-1982) a further contract award to Westinghouse Corporation was announced for the provision of a tactical air defence system. The system to be delivered in late 1983 allows for radar-directed control of defensive fighter aircraft operations wherever the system is deployed.

Construction of a back-scatter over-the-horizon (OTH) radar for the detection of both aircraft and ballistic missiles was first revealed in 1974. Code name for the project is Jindalee and the site is near Alice Springs, close to the US satellite facilities there.

Promising results from the experimental narrow-beam Jindalee OTH radar indicate that future surveillance of the Australian coast and surrounding offshore regions will be undertaken by this technique. By 1978, about $A6 million had been spent on Jindalee research and development. Ranges of more than 1000 miles (1600 km) against civil airliner targets had been obtained with the Jindalee installation, and in late 1978 approval was given for a larger and more powerful version to have a much wider coverage arc (Stage B). Construction started at Alice Springs, with an anticipated total cost of $A24 million. This installation has greater transmitter power and a larger receiving antenna, and will provide for surveillance cover of airspace to the north of Australia. The new Stage B receiving station was constructed at Alice Springs, next to the original Stage A site on Bond Springs Station. The new reception antenna array is 2·8 km long. Much of the large transmitter complex at Harts Range, about 160 km from Alice Springs, had been completed by early 1982 and it was necessary to build a new 3 MW power house and building to house the additional transmitter equipment. A number of advanced items of new equipment developed at the Australian Electronics Research Laboratory, South Australia, was moved to the Stage B sites in 1981. When the new computer equipment becomes available, it is hoped that it will be possible to track targets while the beam continues to scan the whole surveillance area.

At a later date additional OTH radars might be needed to provide all-round surveillance. It is also hoped that OTH radar will provide a surface target detection capability for the oceanic areas around the Australian coast.

AUSTRIA

3326.181
AUSTRIAN AIR DEFENCE (MRCS-403)

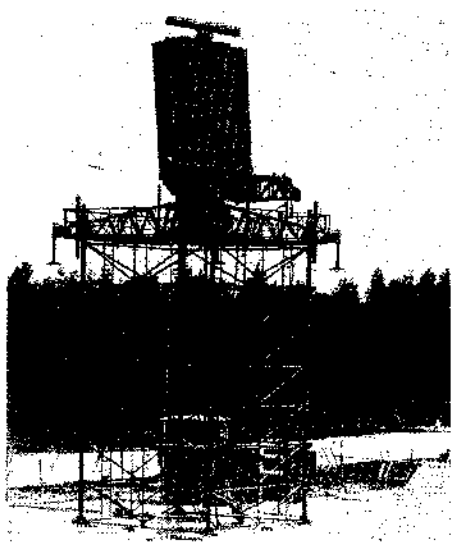
Under contracts awarded to Selenia in 1976 and 1977 by the Austrian Ministry of Defence, the Italian company is supplying a number of mobile and fixed air defence systems for incorporation in the nation's overall defence network. The systems being supplied by Selenia are designated MRCS-403 mobile automatic reporting and control system, and are based on static and transportable versions of the RAT-31S three-dimensional radar (**1953.153**) in conjunction with a data processing and display sub-system.

The radar's main characteristics are simultaneous range, azimuth and elevation measurements of targets at all altitudes, sophisticated ECCM performance, and high resistance to ground and/or weather clutter.

The MRCS-403 produces an air situation picture which is transmitted back to superior command centres via a narrow-band data link. This is performed together with functions such as automatic track initiation, automatic tracking, automatic and/or manual height measurement and automatic track reporting. The system can process three-dimensional low- and medium-altitude air situations, and is also able to perform autonomous control functions such as identification, interceptor and air defence missile control. In its basic configuration it comprises a shelter-housed RAT-31S radar and data processing and display shelter. For expanded operational capabilities, additional shelters are used on a modular basis to provide more operator and communications facilities.

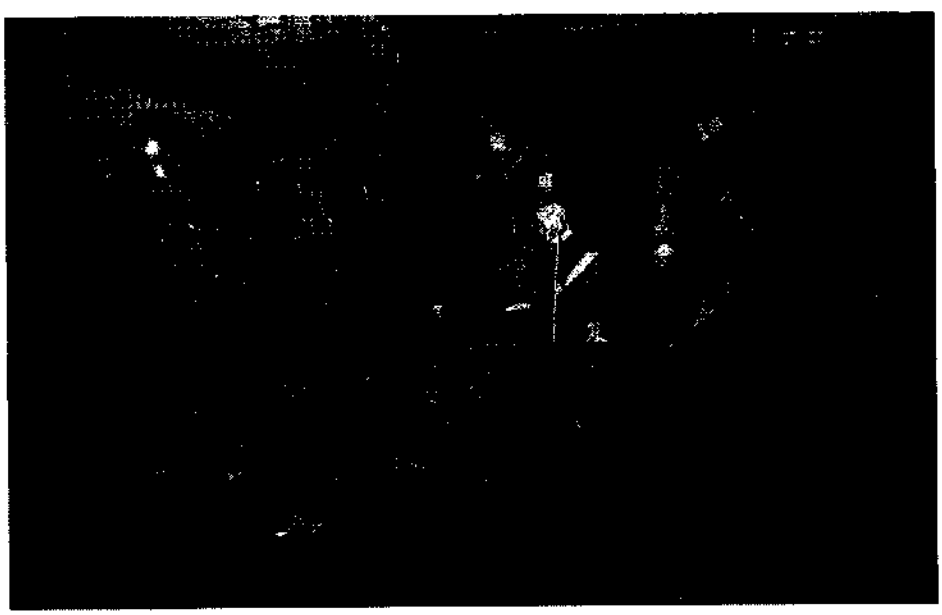
The operations shelter contains a dual NDC-160 computer complex, three display consoles, a communications control unit, and ground-to-air facilities. The computer is integrated locally with the three-dimensional surveillance radar, and for remote IFF/SSR inputs the system is equipped with a data link interface for receiving plots. The computer processed information is fed to the display sub-system as synthetic/alert track information and to remote centres as track information via a data link.

Typically there are five operator positions: master controller, track controller positions (2), manual input operator, and the radar supervisor. Track capacity is 60 (expansible) and three intercepts can be handled simultaneously. The displays employ synthetic video presentation and there are two video maps for each unit.



The Austrian MRCS-403 systems probably interface with other Austrian air surveillance facilities, including the national civil ATC network, and there is known to be a requirement for a number of low-level radars for gap-filling purposes. The Selenia Pluto equipment (**3277.153**) is probably under consideration for this function.

STATUS



The first systems have been delivered and are now operational.

CONTRACTOR

Selenia, Industrie Elettroniche Associate SpA, Via Tiburtina 12 400 Km, 00130 Rome, Italy.

The first Austrian site to be equipped with Selenia's MRCS-403/RAT-31S air defence radar. Operational test and evaluation was completed in 1979

BRAZIL

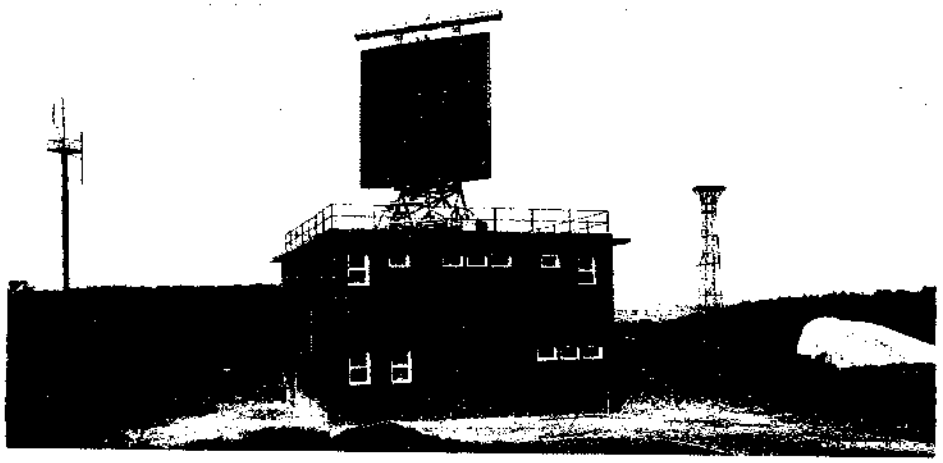
4898.181

SISCEA INTEGRATED AIRSPACE CONTROL SYSTEM

The integrated civil/military airspace surveillance and control system now being implemented in Brazil is the culmination of a series of predecessor systems representing stages of evolution of the complete system that were known as DACTA I, II and III. These were described under entry number **2166.181** in earlier editions of this book. The successor system is called Siscea.

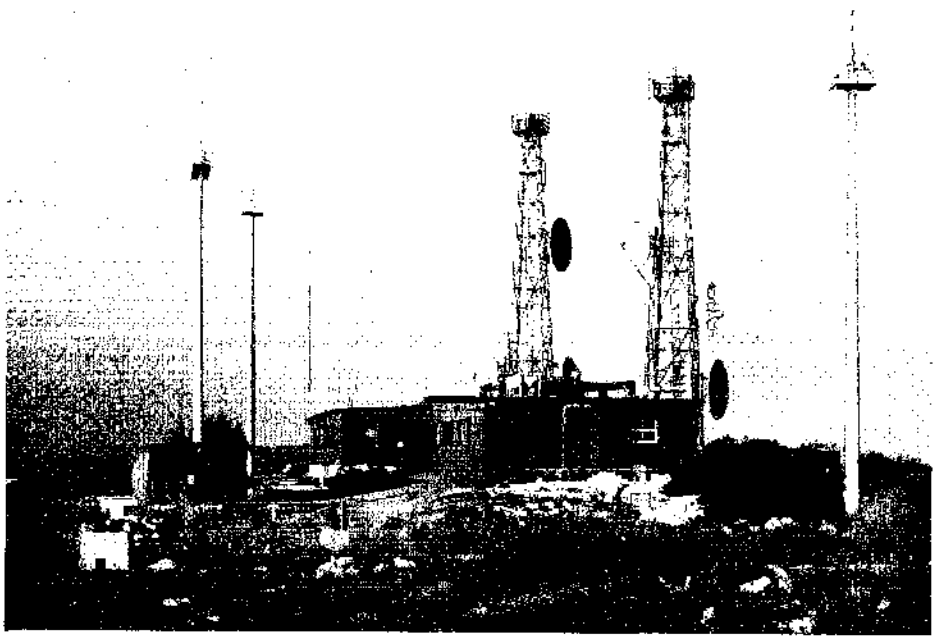
Of the forerunners DACTA I was initiated in 1972 and became fully operational in 1976, covering the central part of Brazil. This led to a series of phased extension and upgrading programmes (DACTA II, DACTA III and Amazonia) which expanded the coverage and facilities, together with a modernisation at a later stage of the original DACTA I.

The updated DACTA I uses LP-23 M long-range surveillance radars (**3099.153**) and RS 870 SSRs supplying data to the Brasilia regional control centre which provides radar control over the Rio/São Paulo/Brasilia triangle within which most of Brazil's civil air traffic is concentrated. The DACTA II phase relates to the introduction of TRS 2230 3-D radars (**3272.153**) and more RS 870s to provide radar coverage and control over the entire southern part of the country from the Curitiba centre, including the extensive military needs of this area. The completion of DACTA I and II will give unbroken coverage of about four million square kilometres. The continuation, DACTA III extends this cover over the whole north eastern region of Brazil, with a new regional control centre to be built, probably at Recife. Two-dimensional primary surveillance radars with SSR will be used in this phase of the programme. In total, the DACTA II and III phases will entail the supply of 11 3-D long-range radars and four approach radars, as well as operations centres equipped with between 20 and 30 consoles.



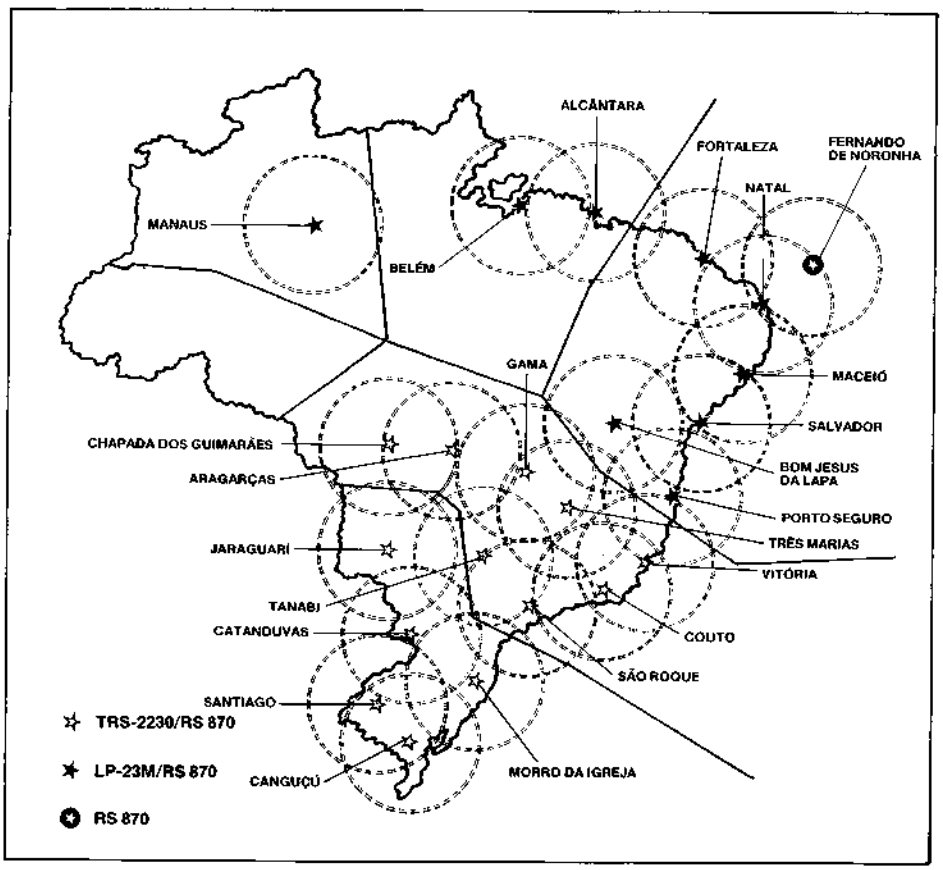
The final stage of the Siscea project will be the implementation of the Amazonia phase which includes the provision of two new autonomous regional control centres with LP-23 M surveillance radars and RS 870 SSRs at Manaus and Belem. The ultimate phase of the programme will result in there being five regional control centres, the main ones being Brasilia, Curitiba and Recife.

Concurrently with, and no doubt closely interconnected with the Siscea system (although to what exact extent is not known in detail) are numerous other radars (civil and military) which have been installed or ordered in recent years. Among such items are a number of Selenia RAT-31 3-D surveillance radars (**1953.153**) and various airfield surveillance and terminal area radars of French and Italian manufacture. A number of French height finding radars were also supplied and installed during the earlier years of the DACTA stages of the programme and it is likely that a significant proportion of these are still operational.



At the Brasilia integrated detection and control centre, target data from search, height finder and SSR sensors are received via microwave links and processed by two automatic data processing systems. The computer programming is fully integrated and its functions include tracking of military and civil aircraft, interception for air defence, and flight plan processing for ATC purposes. The centre consists of separate operations rooms for ATC and for air defence, and there is also an automatic switching centre for message management and communications.

STATUS



Implementation of the Siscea programme began in 1972 and in its DACTA I format the system has been operational for more than ten years. In 1985 DACTA II was nearing completion and work on the upgrading

TRS 2230 three-dimensional surveillance radars and RS 870 SSRs like this will cover the entire southern Brazilian airspace when the Siscea ATC/air defence network is completed

A comprehensive radio, telephone and microwave link system co-ordinates the extensive radar and communications network needed for Brazilian ATC/air defence control purposes

Map showing the full extent of the Brazilian integrated air defence/ATC radar network when the Siscea programme is completed. The six air defence zones, with headquarters at Belem, Recife, Rio de Janeiro, São Paulo, Porto Alegre and Brasilia, will be served mostly by LP-23 M surveillance radars in the north and TRS 2230 3-D radars in the south of the country

of DACTA I and construction and installation for the DACTA III extensions was well under way. These phases involve the replacement of some of the originally installed radars, for example, the LP-23 M and Volex 3-D radars at the Tres Marias site have been or will be replaced by a TRS 2230 3-D radar. The original LP-23 M and Volex radars could be used elsewhere such as the regional control centres at Manaus and Belem in the Amazonia phase of the programme. Completion of the Amazonia phase and implementation of the full five-centre system is estimated to require several more years.

CHINA (PEOPLE'S REPUBLIC)

2052.181

CHINESE AIR DEFENCES

No detailed information on Chinese air defences is available, but there are some known statistics on their magnitude.

Until comparatively recently the Chinese were reported to have in service about 50 surface-to-air missile sites and some 4500 anti-aircraft guns of various types. An interceptor aircraft force of over 4000 aircraft is maintained, consisting of MIG-15, MIG-17, MIG-19, and MIG-21 types. A new all-weather fighter of Chinese design recently entered service. Associated with all of these were about 1500 air defence radars, but little is known of the detailed deployment of these systems or their organisational structure beyond the general information that the radars constitute a network for air surveillance and control and a missile early warning system for the detection of ICBM launches against China. More recent information, while still leaving much open to question, suggests that the country's defences are being substantially modernised; new radars, it seems, have been designed, and improved versions of the SA-2 Guideline missiles (**2942.131**) which the Chinese originally acquired from the Soviet Union are being produced as the HQ-2J. However a recent American assessment still considers the Chinese air defence system to be subject to major weaknesses, such as an outmoded command and control system.

In February 1984 it was reported that a French company has, or will have, supplied six long-range radars, three terminal area radars, and control centres for airspace management of the Shanghai/Peking region.

It should also be noted that at least one very large phased-array radar has been constructed in Western China, presumably as part of the missile warning system. However there is still no indication of any Chinese effort to develop an ABM system. Instead there are fairly widely publicised and comprehensive civil defence precautions, which include large air raid shelters, grain storage, and similar measures.

FRANCE

4571.181

T.ACCS

Thomson-CSF Air Command and Control Systems (T.ACCS) is the designation of the improved MIDAS (**2106.181**) range of systems that the company designed and developed for such purposes. There are three basic types of station.

All these stations are implemented using the same line of versatile modular equipments, based on the latest data processing and display techniques. In addition to the radar and telecommunications equipment not described below, these equipments include radar plot extractors, data processing systems, and display systems. Compared with the original MIDAS systems, increased computer facilities make possible significantly greater track capacity and data handling capabilities with little if any increase in manning requirements.

The company range of radar plot extractors includes models matched to 2- or 3-D radars, taking into account the importance of low-altitude surveillance and the possibility of enemy ECM actions. They may be specific sub-assemblies incorporated with the radars in new equipments, or programmable assemblies which can be matched to previously installed radars.

Thomson-CSF air defence systems use general-purpose computers belonging to the MITRA range. This range includes computers and peripherals designed and packaged for various environments: standard environment, aboard transportable cabins or aboard armoured vehicles. This computer family is fully compatible from a software point of view, and all models use the same basic software (assemblers, compilers, real-time operating systems). For the specific air defence software, Thomson-CSF has developed a full set of packages devoted to the various functions: automatic and rate-aided manual tracking, threat evaluation, weapons allocation, automatic interception, missile designation, simulation. Operational software for each station is then built up by linking these various modules.

Visual display systems now used by Thomson-CSF for air defence centres are of the autonomous type; each display console includes its own refreshing memory and a programmable processor, which digitally performs various functions connected with the display, such as scaling and off-centring, synthetic information selection, etc or gives tactical assistance to the operators. These local functions performed by the console processor can be adapted to various requirements, for example for rate-aided manual tracking and to remote these tracks, without having a local data-processing system. These autonomous consoles are also used for displaying mixed raw and synthetic video signals.

The range of autonomous consoles now in production includes two basic models:

(1) the TVT 3540 display console is specially designed for minimum volume and can therefore be installed in small-size cabins.

T.ACCS AMC 900 operations console

(2) the AMC 800 and AMC 900 consoles feature an important modularity: besides the 41 cm (or 53 cm) PPI, they can be fitted with TV monitors driven by the console processor for displaying alpha-numeric information. Moreover, by using removable function keys which are interpreted by software, the consoles are standardised; their operational use (for tracking, identification, weapons selection, interception etc) can be modified at any time, giving a multi-console system the possibility of creating a configuration adapted to the current situation.

Three types of station developed by Thomson-CSF using these families of equipments differ mainly in their operational assignments, sizes, and their fitness for mobility.

These three types of station are classified as:

(1) Fixed Operations Centre: air defence operations centre, sector operations centre and control and reporting centre
(2) MCRC: mobile control and reporting centre
(3) LARP/FACP: mobile low altitude reporting post/forward air control post.

FIXED OPERATIONS CENTRE

Functions of a fixed operations centre include:

(1) automatic establishment and updating of the general air situation
(2) identification of detected aircraft
(3) evaluation of the threat
(4) allocation of targets
(5) assignment of weapons
(6) activation and automatic guidance of interceptors
(7) co-ordination between fighters and surface-air missile units
(8) control of military air traffic
(9) complete simulation for the training of military staff.

A typical centre will include MITRA computers with peripherals (typewriter with cassette reader, mobile-head magnetic disc, card reader, printer), for:

(1) local tracking (automatic)
(2) conversion of co-ordinates
(3) track correlation with automatic transmission to other stations
(4) trial intercept identification
(5) automatic interception computations
(6) simulation for the training of controllers.

Other items are AMC 800 and AMC 900 consoles, and possibly a large screen display, for general air situation presentation.

A centre can be easily adapted to each specific need, by varying the number of autonomous consoles and the central memory size of the computers. If necessary, a second similar computer complex can be added to the system, allowing various degraded modes in case of a computer's failure.

MCRC

This configuration is inherently capable of operating in various roles, either on an autonomous basis, or linked to a fixed operations centre and to other mobile centres. Its operational capacity is less than that of a fixed centre, but it nevertheless affords wide

possibilities which make it usable as an addition to an operation centre in territory air defence for an army corps to provide aerial protection. The MCRC is used to complement the fixed air defence organisation and to carry out the control of tactical air defence missions and battle corps cover missions.

It allows the following functions: automatic initiation and automatic following of tracks from local radar data. Both functions can also be performed in rate-aided manual mode; transmission and automatic or manual correlation of tracks in connection with higher and subordinate levels; identification of tracks; automatic control of up to six simultaneous interceptions; recovery of fighter aircraft; co-ordination with surface-to-air missile units; simulation of eight moving targets, of which four are piloted fighter aircraft.

Typical operational capacities are: 90 tracks; automatic two-way communications with six air defence centres; up to six simultaneous automatic interceptions; eight simulated moving targets of which four can be piloted in real time from pilot consoles.

The MCRC includes MITRA computers, adapted for use in a cabin, with a mini-tape for program loading and data recording, and a teletype. There are three AMC 800 consoles, also adapted for use in a cabin by a master controller and two interception controllers.

This typical configuration, which can easily be extended with additional modules, meets the requirements of the operations centre normally associated with the Thomson-CSF mobile 3D radar TRS 2215 (**3272.153**).

LARP/FACP STATION

This configuration has a dual operational role: it allows an additional radar coverage, in particular at very low altitude, with minimum personnel and material; and it is designed to carry out control of tactical missions, mainly in aerial support and to aid aerial penetration operations. To fulfil these missions the LARP/FACP makes use of data from a radar adapted to low altitude detection, such as a TIGER radar (**2156.153**), the associated secondary IFF radar, and possibly, visual observation posts. Additionally, it is connected through automatic data link with a fixed or mobile centre.

The LARP/FACP is equipped, for processing and display, with two autonomous consoles TVT 3540.

The main functions are detection of targets; building up of tracks by rate-aided manual tracking of targets; identification (IFF/SIF); introduction of visual observation data into the system; transmission of tracks to the higher level; reception of tracks from the higher level; control of tactical missions.

STATUS

In production and in service with several overseas countries probably including Saudi Arabia and other gulf states.

2161.181
STRIDA AIR DEFENCE SYSTEM

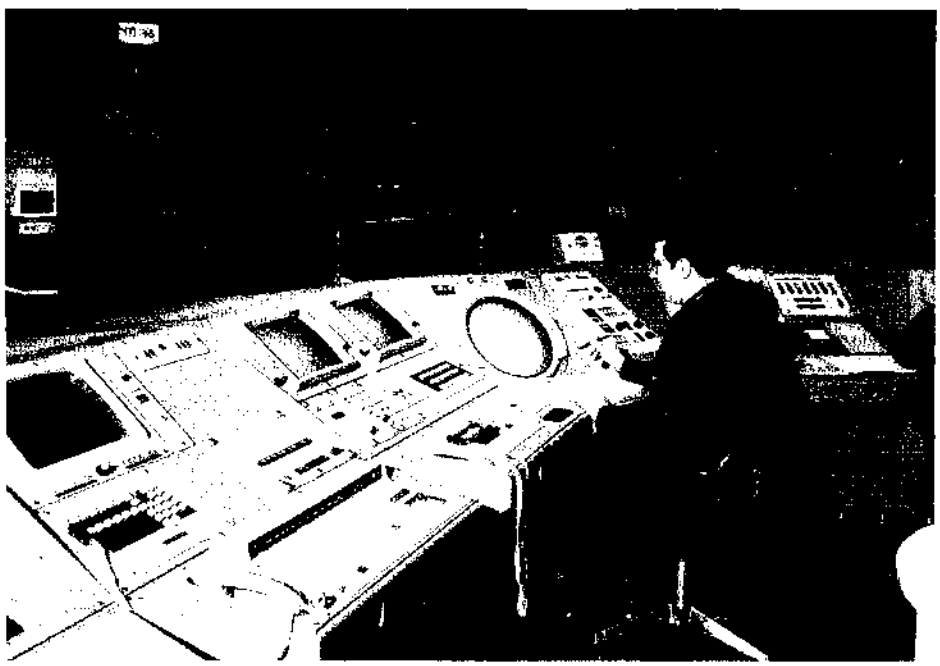
STRIDA (Système de Traitement et de Representation des Informations de Défense Aérienne) is the French air defence data handling system. The system consists of a network of stations covering French territory with the following main functions:

(1) detection and identification of aircraft moving in French airspace
(2) threat evaluation and dissemination of early warnings. The air situation is centralised and synthesised in the air defence operational centre (ADOC)
(3) updating of active means (aircraft and missiles) status in every sector operational centre (SOC)
(4) weapons selection, engagement and automatic intercept guidance
(5) aircraft recovery to air bases
(6) control of military operational and training flights
(7) co-ordination with the air traffic control system to ensure identification and spacing of operational military flights with respect to general air traffic
(8) progressive integration of the information reported by air base radars for improving the low altitude coverage.

STRIDA consists of different types of operational centres (ADOC, SOC/CRC, CRC, ARP) which exchange digital messages by a special telecommunication network, the Air 70, associated with electronic switching stations.

At ARP and CRC levels, signals coming from 2-D and 3-D long range radars (Palmier) and height-finding radars (SATRAPE with phased-array antenna) are used for providing the labelled air situations needed at SOC/CRC and ADOC levels. All information and orders to be exchanged between these different centres for command and control purposes are transmitted through the Air 70 network.

The STRIDA network is connected to the NADGE network (**1181.181**), to the 4F2L (**2533.181**) system and to Combat Grande (**2322.181**) to provide total coverage of western continental Europe. It is also connected to the French ATC CAUTRA system for co-ordination of military and civil air traffic control.



The data handling equipment of a typical latest generation CDCS station mainly consists of:

(1) an EVIR radar data extractor using a programmed extraction concept
(2) a high power processing system using IBM 370 series computers
(3) a display sub-system including from 20 to 30 operational positions (see below).

In some centres, special equipment is found: in the air defence operational centre, a large screen display and in a centre for intercept controller training a piloted aircraft simulator (SACHA) generates a video signal corresponding to up to 12 simulated aircraft. This signal can be mixed with the live video of the radar for a transparent simulation.

Each operator position or console designed for one controller and his assistant is composed of:

(1) a plan view display for presenting raw video (local radar raw video) and data generated by the processing system (synthetic view of the air picture - mainly tracks). A 40 cm diameter screen is used

VISU IV consoles produced by the Sintra subsidiary of Thomson-CSF for the STRIDA air defence system

A STRIDA air defence reporting centre and communications node co-located with a 3-D radar in the Alps

(2) one or several monochrome or colour screen(s) (diagonal from 13 to 35 cm and capacity up to 4000 characters) for presenting detailed information on certain subjects (tracks, intercepts) or data received in alpha-numeric form (operational status, flight schedules)
(3) several keyboards and a rolling ball (or a joystick) for selecting the data presented and entering functions and data
(4) control keyboards and panels for communications (radio, telephone, interphone) and secondary radar.

STATUS

The research and development programme for the STRIDA system began in 1956 under the responsibility of Service Technique des Télécommunications de l'Air (STTA). The first stations were fitted with specialised IBM/CAPAC real-time computers and Sintra VISU II display sub-system. They became operational in 1963. Since this date, there has been a continuous programme of improvements for software and hardware during the implementation of the whole military programme, every new centre having to be interoperable with the others. The medium and high level coverage main centres are now near completion. The last ones are equipped with IBM 370/158 computers and Sintra VISU IV display sub-systems. The next step entailed the extension of the low-level coverage of the system by the integration of recovery and tactical operations radars. In 1978, Sintra was chosen to supply the STRAPP (STRIda-APProach) limited to the low-altitude radar at each approach centre. Data to and from STRIDA main centres are automatically processed and transmitted by the STRAPP.

SILLACS LOW-LEVEL AIR DEFENCE SYSTEM

The Siemens low-level air defence control system (SILLACS) evolved from the West German TMLD system (**3607.181**). The latter system was enhanced by adding more functions and improving its effectiveness. In the new system, SILLACS, extensive use is made of automatic data processing, multiple radar tracking and the support of control operations. SILLACS therefore forms a mobile autonomous low-level air defence control system for sensitive areas that can be interfaced with any nation-wide air defence system for the upper airspace.

Low-level radars are available with ranges of 45, 60 and 90 km for optimum coverage configurations. They combine very high clutter suppression with high ECM-resistance. Two versions of the Siemens pulse doppler radar family are specially designed for use in SILLACS:

(1) the fully mobile DR 151/DR 161 with detection ranges of 45 and 60 km, respectively, consisting of one vehicle with a mast erectable up to 18 m and the radar/operator shelter
(2) the transportable DR 172 with a detection range of 90 km, consisting of two shelters: an antenna unit and an operator shelter. The Siemens IFF interrogators DII 211, DII 111 or DII 511 are integrated in the primary radars. Up to eight of these radars may be connected to the SILLACS Control and Reporting Centre (CRC) which contains the data processing and display equipment as well as the communication facilities for interceptor guidance and data exchange to higher ranking command and control centres.

The CRC consists of one equipment shelter, one display shelter and separate power generators mounted on trailers. The equipment shelter houses all sub-systems for automatic data processing, data and voice transmission and switching. The display shelter contains four operator work stations for air situation display and control and two assistant's positions. This equipment is connected to the CRC equipment shelter via cable link.

Incoming target reports from the radars first undergo a validity check. They are then fed into the multiple radar tracker, which generates a consistent unambiguous picture of the air situation. New tracks are initiated automatically. Non-automatic initiation areas can be defined by the operator. Processing and display of target reports can be performed independent of track processing. Thus even in case of computer failure an air situation picture can be obtained from the system. Mission data, eg speed, heading, bearing, distance are provided by the computer for the support of intercept control operations. The operator work stations consist of:

(1) 22-inch (56 cm) diameter air situation displays for target reports and tracks, symbols and vectors
(2) alpha-numeric readouts for status information and track data
(3) function keyboards
(4) alpha-numeric keyboards
(5) rolling balls.

The display control panel incorporates the facilities to select the displayed area, ie to adjust its centre or to off-centre it by means of the rolling ball, to choose the proper scale to switch the output channel of interest to the connected air situation display and to connect the display unit to any input channel. By means of additional push-buttons the operator can combine and adjust the display of video maps, grid lines, plots and tracks as required. Each operator position in the CRC display shelter is supplied with an IFF remote-control panel to specify mode and expected reply code of IFF interrogations. At this panel the actual, remotely-controlled status of the IFF interrogators of up to eight associated radar sites can be indicated simultaneously. The operational program system and the video map are stored on tape cartridges.

Exchange of information between the four operators and two assistants in the CRC and several subscribers is provided. By means of a communication system containing radio link and multiplex equipment, external communication paths are set up. Furthermore, connections to the operators in the associated radar sites and remote-controlled ground-to-air radio link facilities are installed.

SILLACS CRC operator's position

STATUS

The system is in full operation with an unspecified number of customers.

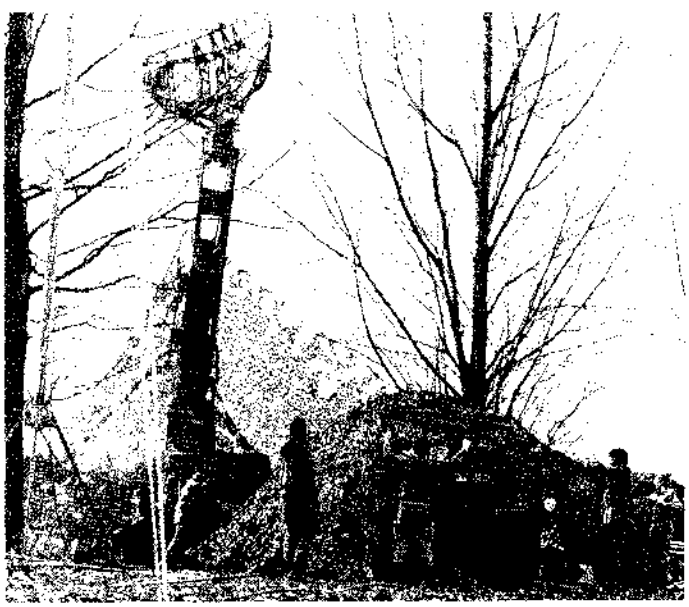
TMLD LOW-LEVEL REPORTING AND CONTROL SYSTEM

The air defence of the Federal Republic of Germany is intimately bound up with the overal. NATO air defence ground environment (NADGE) system of radars, communications and data processing and control centres (**1181.181**), and to varying degrees with systems employed by allied nations present in Europe, such as the American 407L air weapons control system (**2533.181**). However, because of limitations in the low-level cover of parts of the former systems and because the AFCENT sector of the Central European NATO area is particularly subject to the threat of low-flying surprise attacks, the Luftwaffe has set up the TMLD (Tiefflieger-Melde-und-Leitdienst) low-level reporting service, additional and supplementary to the other radars.

This is part of the combat operational system of air defence and is designed particularly for the monitoring of low-level airspace. The TMLD radars are located in the area near the border, the individual sites being chosen to ensure continuous surveillance. When the radar detects a target, the information is converted into data messages and immediately transmitted to the low-level reporting centres TMLZ (Tiefflieger-Melde-und-Leitzentralen) and on to the user. The whole TMLD is completely mobile so that changing tactical and operational circumstances can be accommodated. The main tasks of the TMLD are:

(1) monitoring the lower levels of airspace in selected areas
(2) processing the low-level air situation in the control centres (TMLZ) and passing the information on to the air defence control centres (eg NADGE, GEADGE)
(3) preliminary warning and target forecasting for Hawk SAM units
(4) control of air operations.

The TMLD units are combined into two sections, and are employed in the 2 ATAF and 4 ATAF areas. In each case they come under the command of the commander of a Type B signals regiment. It is planned to assign them as a NATO command force. The main elements of such a unit are:



(1) a radar crew to operate the radar equipment
(2) an evaluation crew to man the control centre
(3) a radio relay crew for setting up communications links
(4) a maintenance crew for the maintenance and repair of equipment.

In peacetime the TMLD mainly limits its activities to monitoring the area in the immediate vicinity of the border, in a quasi-static role. At other times, however, monitoring of airspace must be extended to a greater area, making use of the system's mobility and flexibility. In this it will be supported by the Army's AAD command and control systems, which will be employed in monitoring the airspace over the combat area.

The principal hardware used in the TMLD system comprises: MRDR 30/1 mobile pulse doppler radars (**3286.153**); TM control centre; CRC TM display unit; radio link set. The radar consists of two 5-ton trucks, each with a 1½-ton trailer containing a generator, with one truck serving as an equipment carrier and the other as the antenna carrier. In the TM centre all the information provided by all the radar equipment within one sector is processed and displayed. Linked users include: the NADGE/GEADGE air defence control centres and Hawk SAM batteries.

OPERATION

Information on air targets supplied by the TM radar is converted into messages for transmission to the TMLZ. The data transmitted contains the positions of the target as X/Y co-ordinates and the target

A Siemens MPDR-30 radar of the Federal German Republic's low-level air defence system deployed in the field

identification. Two operating modes are planned for the preparation of this information: automatic, and semi-automatic.

Automatic Operation: This is regarded as the normal mode for peace time. Targets detected are automatically evaluated on the basis of whether or not they emit a valid IFF/SIF code, and they are reported accordingly. In addition, the operator in the radar truck (acting on instructions from the control centre) can insert further symbols manually in order to give prominence to certain targets of particular significance.

Semi-automatic Operation: This mode is of special importance when automatic operation with the radar signal processor is not possible for techincal or tactical reasons. In this mode the operator can mark targets identified on the radar display with the aid of a rolling ball, using symbols that he can superimpose on the target blip. Transmission of targets to the TMLZ or the user is again performed automatically. For this purpose various types of symbol are available, to each of which a particular meaning is assigned to assist the responsible air defence officer in reaching decisions.

STATUS

The system has been fully operational since 1977.

In the meantime work has begun on a successor system for the 1990s, HFIaA FiiSys, the German Army Air Defence surveillance and Command and Control System. Following the design and definition phase, development started in early 1983 with Siemens acting as prime contractor and AEG-Telefunken, ESG, IDAS and SEL as sub-contractors.

Development will be carried out in two phases. Phase 1 comprises the radar together with radar data processing and broadcast, the fire co-ordination tank and the adaptation of the AA gun tank Gepard and the surface-to-air missile system Roland. In Phase 2 the units for on-line radar and combat vehicle deployment and frequency planning will be added.

3945.181

GEADGE

GEADGE is the acronymic title of a programme to develop and install a new air defence network for the southern part of the Federal Republic of Germany, and is derived from 'German Air Defence Ground Environment'. The new system, for which Hughes Aircraft Company was nominated the prime contractor in 1979 under a contract worth more than $150 million, will replace the 20-year old 412L radar network (**2533.181**) operated by the West German Air Force. The new system integrates new and existing long-range surveillance radars into a single network based on four centralised command centres, and it will embrace manned and unmanned fixed and transportable radar systems. Eventually GEADGE will receive radar data directly from E-3A AWACS early warning aircraft. The southern portion of West Germany was not included in the original NADGE system (**1181.181**), but GEADGE fills the gap left in that system and connects directly with it. In addition to fixed and transportable gap-filler radars, the new system will utilise two of four new permanently located radars known by the manufacturer's name of HADR (Hughes air defence radar) (**3721.153**), which is an advanced three-dimensional, multi-role radar that will automatically detect, classify, and report on targets intruding into their coverage area.

In the GEADGE system, Hughes is also supplying HMP-1116 minicomputers, H-5118M central computers, and HMD-22 display and control consoles, as well as being responsible for software, installation and integration.

STATUS

The first of two sites became operational in 1983 and 1984, and the final two centres were expected to become operational in 1985.

SIEMENS BATTERY CO-ORDINATION POST (BCP)

Site defence against low flying aircraft is generally dependent on the use of more or less autonomous short-range AA weapons such as machine guns and surface-to-air missiles. This new system by Siemens is meant to increase the effectiveness of such existing weapon systems. Depending on the topographical features of the site to be defended, on the available defensive weapons, and particularly the anticipated threat, the battery co-ordination post (BCP) optimises air defence.

Equipped with an acquisition radar and command and control equipment, the commander is able to control up to 12 fire units deployed around the site. An integrated digital computer evaluates threat and status information. Data link and weapon terminals are provided to connect the BCP with the fire units for the transmission of aiming and firing instructions and for the exchange of data.

STATUS

Siemens have conducted system tests which have demonstrated increased weapons effectiveness. This system is integrated in the Artemis 30 AA gun air defence system being produced for the Greek armed forces, and in the CORAD (Co-ordinated Roland Air Defense) system.

ISRAEL

2226.181

ISRAEL AIR DEFENCE SYSTEM

A computer-controlled air defence system has been installed in Israel. No official details of the equipment are available, and it is believed that no public statement regarding the existence of the system has been made by either the Israeli authorities or the prime contractor, but it appears to be generally accepted that Hughes Aircraft Company were awarded the contract after completing a study for the new system and it is also understood that the system is based on main control centres situated near Tel Aviv and in the Western Negev in the southern part of the country. There are possibly subsidiary centres elsewhere, and the existence of a tactical operations centre with a PPI display of the entire Israeli airspace for viewing by the Cabinet has been claimed.

There are thought to be many similarities with the USAF 407L tactical command and control system (**2824.181**), and Hughes 4118 digital computers as employed in this system are reported as providing the data processing facilities for the Israeli air defence system. Sensors are understood to include two Westinghouse AN/TPS-43 three-dimensional radars (**2517.153**), several FPS-100 radars, and there are almost certainly other radars of British, French, and Israeli origin which have been incorporated into the system.

In January 1976 the sale of four Grumman E-2C early warning aircraft to Israel was reported and these

were delivered between November 1977 and mid-1978.

The E-2Cs have either APS-120 or APS-125 long-range airborne early warning radar (**1783.353** and **1965.353**) and Grumman had a study contract to make the E-2C data link compatible with the Israeli air defence network to enable the exchange of data between ground and air sensors, as well as integrating the AEW element into the overall system.

The original Israeli defence network is thought to have been completed and handed over by Hughes some time during 1973.

In 1981-82 a major communication control system for air defence sites was supplied to the Israel Defence Forces by the Electronics Corporation of Israel Ltd (ECI) in co-operation with Elbit Computers Ltd. The multi-function communication control system (MCCS-800) is a computer controlled system that provides a large number of operators with access to remotely located equipment and it includes a secure switching matrix and associated radio and crypto equipment. The system is operational and a mobile version is under development; an airborne system is planned.

ITALY

3324.181
MARS AIR DEFENCE SYSTEM

Current air defence concepts call for an integrated system with a primary centralised mode of operation and a back-up decentralised secondary mode whereby each peripheral sub-system is provided with a limited autonomous capability. Therefore, by introducing a cost-effective redundancy criterion, the vulnerability factor of the total system is notably reduced, resulting in an overall reliable and responsive air defence network.

A peripheral sub-system, such as a reporting post of a total air defence network as mentioned, requires a certain level of additional capabilities over and above the normal reporting role. These are mainly in the control area, meaning identification and interceptor control functions.

Selenia is offering such a system known as the Automatic Reporting System (ARS), in a mobile (MARS) configuration, which amply fulfils the requirement of a low cost system performing a considerable level of autonomous control as well as the main reporting functions. It is basically capable of producing an air situation and transmitting this situation to superior command centres via narrow band data links. This is performed with the aid of functions such as automatic initiation, automatic tracking, automatic and/or manual height measurement and automatic track reporting.

The identification and the airborne interceptor support-functions are also available for the back-up autonomous mode of operation. The system is able to process low and medium-high coverage air situations and can be easily upgraded to a multi-radar configuration. It can also be upgraded to a reporting and control system (ARCS) which performs the full-scale autonomous control functions such as identification, interceptor and SAM control.

MARS can be integrated with a variety of 2-D plus heightfinders and 3-D radars. It is provided with auxiliary functions such as data recording and data collection.

In the mobile version the system is most suitable for tactical use in forward battle areas, performing in the low cover surveillance and close air support role, or in a more extensive air defence system, where it performs a high/low cover gap-filling and back-up interceptor/SAM control role.

In this basic configuration it can be housed in one data processing and display shelter. For expanded operational capabilities, additional shelters can be added in modular form to satisfy requirements for increased operator and communications facilities. The system is transportable by helicopter, C-130/C-160 aircraft, road and rail.

The automatic reporting system consists of an extractor/combiner unit, a GP-160 computer, a display sub-system consisting of a central unit and three display consoles, peripherals consisting of a magnetic tape cassette unit integrated with the computer, paper tape reader, teletype and line printer units and a communications unit.

The system may be integrated locally either with 2-D surveillance radar, secondary surveillance radar and associated heightfinder, or a 3-D surveillance radar and secondary surveillance radar. For surveillance radars integrated at video level, the system is equipped with a SR/SSR extractor and combiner unit. For surveillance radar integrated at SR plot/message level, the system is equipped with a SSR extractor and combiner unit. For remote SR/SSR radar inputs, the system is equipped with a data link interface for receiving plots.

The heart of the system is the GP-160 computer or NDC-160 for the mobile version, which processes various inputs coming from the local or remote radar via the extractor/combiner unit, operator orders via the display sub-system and cross-tell information from remote centres. The computer process information is then sent to the display sub-system as synthetic/alert information and to remote centres as track information via a data link.

The digital cassette is utilised for operational program loading and for data recording, the line printer for data reduction, the teletype unit for data introduction and the paper tape reader for back-up loading. Communications facilities are provided for intercom, ground to ground and ground to air functions and are tailored according to the customer's requirements.

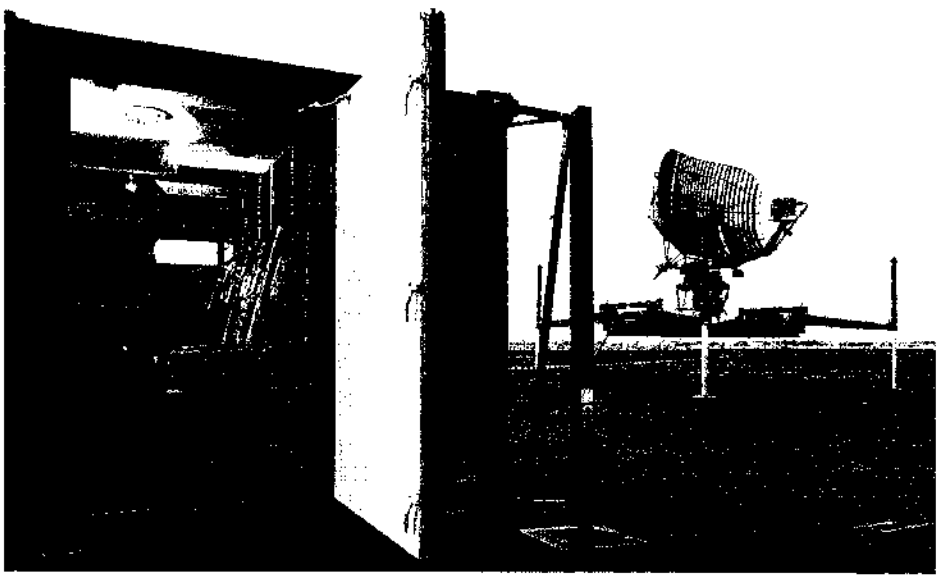
The system includes three operational areas (surveillance, command and fire co-ordination) each requiring different types of equipment.

OPERATION

Operational roles are:

(1) 2-D multiple radar input
(2) early warning surveillance with single or multiple radar input
(3) airborne interceptor support
(4) mobile or static applications
(5) local or remote radar input

Specific functions include:



(1) automatic target detection and initiation
(2) automatic tracking
(3) multi-radar processing (with optional multiple radar configuration)
(4) rate-aided manual tracking
(5) data link for exchange of track data, command messages, etc with automatic and manual facilities
(6) identification by computer assisted SIF active/passive decoding, automatic data link, or manual input
(7) search radar/IFF video display
(8) synthetic video display.

CHARACTERISTICS

Track capacity: 40 (expansible)
Simultaneous intercept vectoring: 2 (expansible)
Data link: Up to 4 sites
Video maps displayed: 2
Operator orders: 42
Computer: NDC-160, mobile
Core store: Up to 16-bit, 32 K words, with 4 K increments
Instruction set: 84 (121)
Cycle time: 0·8 μs
I/O channels: 62
Displays: MDJ-03, mobile

CONTRACTOR

Selenia, Industrie Elettroniche Associate SpA, Via Tiburtina 12 400 Km, 00130 Rome, Italy.

Selenia Pluto SIR (search and interrogation radar) with operational control centre cabin of Spada/Aspide air defence system. Closely integrated with the overall national Italian air defence system, 12 of these systems are being deployed by the Italian Air Force and there are plans for at least 20 systems. Each SIR is normally associated with two or three missile firing sections with its own tracking radar and three 6-round SAM launchers although there can be four firing sections

JAPAN

2254.181
BADGE AIR DEFENCE SYSTEM

BADGE (Base Air Defence Ground Environment) is a computerised air defence system designed to provide the information gathering data processing and display functions required for umbrella protection against aerial attack on Japan. The system comprises radars that will automatically detect, track, and identify airborne targets over Japan and a large area of the surrounding ocean, computers to process the radar data and evaluate threats, and other computers to process and furnish data on weapon availability, intercept geometry and related measures, all of which is displayed, together with the processed radar data on complex displays to the appropriate interceptor or missile controllers.

The $56 million system was largely built in Japan for the Japan Self Defence Force. The prime contractor was the Hughes Aircraft Company of the USA and they supplied much of the equipment of the first installation as well as being responsible for system and equipment design. Most of the subsequent manufacture, however, was carried out by Japanese manufacturers.

BADGE sites extend from the northernmost tip of Hokkaido to the southern extremity of Okinawa Island and there are believed to be at least 28 surveillance radar locations. The computers belong to the Hughes H330 series. Japanese airspace is divided into four air defence sectors with a direction centre for each: Western Air Defence Force Control Centre (ADFCC); Central ADFCC, Iruma; Northern ADFCC, Misawa and Okinawa ADFCC. The system became operational in 1969.

BADGE is similar in many respects to ADGE (**2211.181**) and Florida (**2373.181**) and reference may be made to the latter for more detailed information.

Three years ago, Japan initiated an extension and upgrading programme called BADGE-X which would both increase its coverage and provide for the integration of the Japanese Hawk surface-to-air missile batteries with the existing defence systems.

It was then understood that there were likely to be five phases to this operation, although the precise order was not known. The phases were:

(1) updating and expanding BADGE to improve coverage of the main Japanese islands
(2) linking BADGE to the Nike/Hawk batteries via the JAN/TSQ-51B distribution systems then being built by NEC Corporation under licence from Hughes
(3) developing an airborne early warning system
(4) further extending BADGE to cover other key areas such as Okinawa
(5) introducing improved (three-dimensional) radars for BADGE to replace the FPS-20 surveillance radar (**2528.153**) and FPS-6 heightfinders (see **2523.153**) then used.

STATUS

We first reported this programme in the 1972-73 edition of this book, and late in 1972 an official of Hughes Aircraft estimated that there was a potential of $20 million of business in computerised air defence radar systems for Okinawa. Since then it has been learned that the BADGE system's computers have all been duplicated, thereby greatly enhancing reliability, ease of maintenance and repair, and improving training facilities. Prime contractor for this work was Nippon Avionics Company Ltd. Additional computers and peripheral equipment, designed to work in parallel with the original hardware were added, and another feature was the addition of a number of magnetic drum memories upon which all operational data are stored automatically. In the event of a malfunction demanding a computer change-over, the drums have all operational data that were contained in the failed system and they will be available for use in the standby system.

In its fiscal year 1979 budget the Japan Defence Agency announced that after evaluating eight possible airborne early warning aircraft types, it was decided to procure four E-2C AEW aircraft to provide the low-flying target capability and extended range facilities not possible with the existing ground-based air defence radars. The first patrol area designated for coverage by the E-2C is expected to be operational in 1983. The Defence White Paper also alluded to other measures to renew and modernise BADGE equipment as well as research and evaluation in support of this.

Although it is not known under which particular segment of the improvement plans outlined above present efforts are being conducted, certain details of progress in the modernisation of the Japanese air defence arrangements are summarised below:

Older early warning and fighter control radars are in the process of being replaced by modern three-dimensional radars. The equipment selected has the JASDF designation J/FPS-2 but is also known as the F3D. Produced by NEC Corporation it is probably either one of the equipments described in entries **2298.153** and **3701.153** or a near derivative. It is understood to have been based on a mobile radar known as the M3D (J/TDS-100) and the first example of the new radar was installed at the Oominata radar site in 1979. The FPS-2 is an electronically scanned array radar which uses mechanical rotation for azimuth scan, other features including dual transmitter/receiver, MTI, digital processing and SIF. The display arrangements employ the same symbols that are used in the BADGE semi-automatic air defence system and six bearing lines and two targets can be displayed simultaneously for GCI. Special ECCM facilities are incorporated.

The contract for development of the J/FPS-2 was awarded in 1977 and manufacture started in May 1978. Tests were commenced in November 1978 and the first radar was installed at Oominata, 42nd Warning Group of the Northern Air Warning/Control Force. The JASDF is believed to have at least seven F3D radars installed and the second modernised J/FPS-2 was installed at the Sado radar site, off the coast of Niigata in the Japanese Sea during 1980. Two mobile J/TDS-100 3-D radars were installed in the North and Centre Air Warning Control Force regions, and it was planned to install an improved TDS-100 in the Western Air Defence District.

In March 1982 it was reported that the air defences of Chitose air base and the Tobetsa radar site were to be upgraded and the 1982 budget allowed for three Toshiba Type 81 air defence missile systems. It was also decided to start development of a new long-range air defence radar system to replace the FPS-20, the new equipment to be an active phased array system with a longer range than the 300 km of the FPS-20.

In early 1983 the Japanese NEC concern was selected as prime contractor to undertake the BADGE-X expansion programme, with Hughes Aircraft Company as a major sub-contractor (for systems design, management and licensing of hardware).

It was revealed in early 1984 that funds for the second phase of the XJ/FPS-3 air warning and control radar development will be allocated in the 1984 Defence Budget. This new equipment will be the main air defence/interceptor control radar of the BADGE system.

Installation and construction of the BADGE system expansion was due to start in the second quarter of fiscal year 1985. First system will be installed at the HQ of the Middle Air Defence Force, followed by Northern ADF, Air Defence Command, Western ADF and SW Composite Air Division. Completion expected in March 1988.

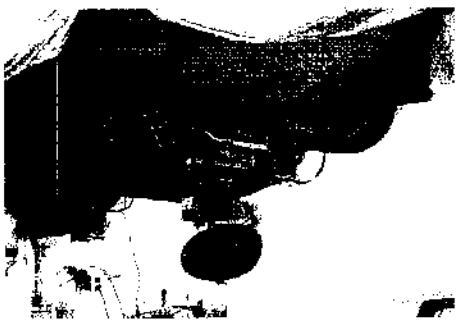
Nippon Avionics, NEC Corporation.

NATO

1181.181
NADGE - NATO AIR DEFENCE GROUND ENVIRONMENT

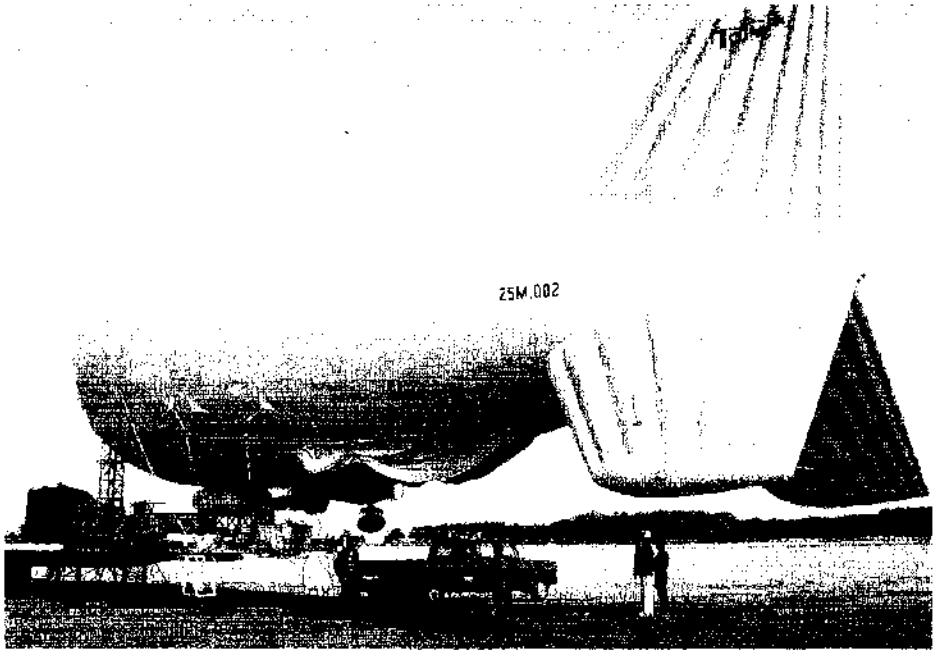
This is a multi-national programme involving 14 NATO countries (so far as funding and contracts are concerned) in the updating and co-ordination of the air defence systems of nine European members of NATO. They are Norway, Denmark, West Germany, Netherlands, Belgium, France, Italy, Greece, and Turkey. The British air defence network interfaces with NADGE. French participation is limited to use of, and contribution to the reporting and control functions, and that country's defence forces will not be directed against hostile targets by NATO.

NADGE, which is now fully operational, was conceived not as an entirely new air defence installation, but rather as an overall plan for the improvement of some existing hardware and the provision of new equipment in certain areas either to fill gaps in the pre-existing systems or to improve their performance. The original cost was an estimated £120 million. The history of the programme and details of the system and elements of the equipment have been described under this entry number in previous editions of *Jane's Weapon Systems*. The following notes summarise the most significant of the latest detail improvements and system enhancements.



STATUS

Improvements to individual national air defence networks are in train in several NATO countries (or are planned) and these will all be engineered to complement and enhance the overall NADGE capability. In April 1984 it was announced that Portugal is building a new NATO radar station on the Algarve coast. Transportable or mobile three-dimensional radars, are being added to the NADGE network. Norway is to acquire HADRs to enhance the NADGE facilities in that country and by the end of 1985 two of the three radars ordered in 1981 will have been delivered to Norway. The third will follow in early 1986.



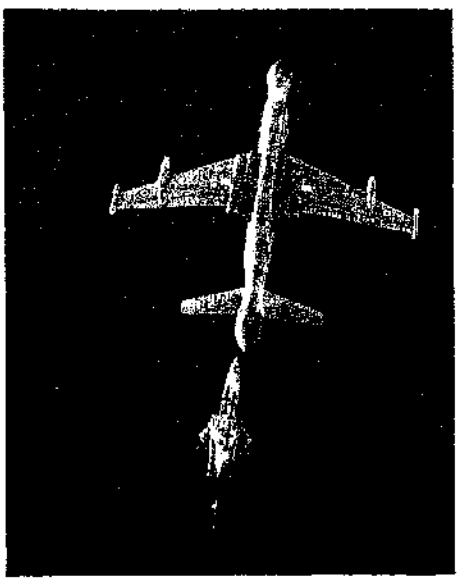
In February 1984 a contract was awarded to Hughes and Kongsberg for 18 TPQ-36 derived Low Altitude Surveillance Radars to form a low-level acquisition radar and control system (ARCS) of air defence. The computer-based ARCS will be used with the Hawk missile system where it will replace three radars and multiple control centres. The ARCS radar is a mechanically rotated derivative of the phase-scanning mortar locating radar. Norway has also agreed to allow NATO AWACS aircraft to operate from its Orland Base on Trondheim Fjord. A new NATO AWACS base at Konya in Turkey was opened in October 1983. This is a part of a network of AEW bases.

From 1987 onward the Nimrod AEW will join forces with NATO AWACS E-3A aircraft, and special communications equipment will enable Nimrod aircraft to exchange data with ground stations, ships and other aircraft. The combined NATO airborne early warning aircraft force will consist of 11 Nimrod AEWs and 18 E-3As. The first E-3A aircraft was delivered to the main operating base at Geilenkirchen, West Germany in February 1982 and the Nimrod AEW-3 enters service in 1987. In 1982 Boeing delivered three AWACS aircraft to NATO, the last of the 18 being due mid-1985. As noted elsewhere Saudi Arabia will receive the first of five AWACS in 1986, and the USAF has ordered 34, with an eventual total AWACS fleet of 46.

The Airborne Early Warning/Ground Environment Integration Segment (AEGIS) programme provides for the controlled exchange of air surveillance data between the NADGE system and the NATO AEW aircraft by augmenting existing ground facilities. This will enable NATO commanders to direct air defence weapons against enemy aircraft intruding into Western European airspace at any altitude. When fully implemented AEGIS will process in-flight

RASIT radar mounted on underside of TCOM balloon for low-level gap-filling air defence role in West Germany

LMT RASIT battlefield surveillance radars mounted below TCOM tethered balloons have been ordered by West German Army to avoid terrain masking of low-level air surveillance radars used for air defence



AWACS radar data for dissemination to command and control installations throughout Europe from Scandinavia to Turkey. The award of a $285 million contract in October 1982 for installation of AEGIS equipment at 36 NADGE sites brings the total AEGIS contract value to about $400 million, and the number of equipped sites to 42. Hardware includes the improved terminal version of JTIDS and the Hughes 115118 ME computer. With this facility, ground controllers will be able to watch targets detected and tracked by AEW radars, thus extending the former's operational range. The first two AEGIS ground stations (in Denmark and West Germany) became operational in October and November 1983, and the complete system is expected to be operational later this decade (1980s).

Denmark awarded contracts to Hughes Aircraft Systems International, the Belgium-based subsidiary of Hughes Aircraft Company, to provide an automated command and control information system (CCIS) for NATO's northern Europe command. The system is designed to give NATO commanders current information on the disposition and readiness of their forces in the field and provide information on enemy air activities through the use of high speed computers. Commanders will also be able to use the CCIS to plan deployment of their forces and to speed transmission of order. Four Scandinavian subcontractors will be used by Hughes and the system was due to be fully operational by the mid-1980s. In a similar programme, in April 1981, Britain embarked on the project definition phase of UKAIR CCIS to meet ASR 1300, which has as a major function linking the C-in-C UKAIR (as local NATO air forces commander) with UK-based air commanders. In late 1982 the UK MoD announced development contracts for JTIDS for British air defence requirements. The CCIS is to be connected to the existing NADGE system.

To improve detection of low-flying intruders Denmark instituted, in March 1984, the Coastal Radar Integration System (CRIS) which links data from Danish coastal radars that survey the Kattegat and the western Baltic, a corridor that intruders might seek to use. A £2 million contract was awarded to Thorn EMI with completion due by 1986. Data from CRIS will be passed to NADGE.

In mid-1984 it was reported that 40 LMT RASIT battlefield radars (**2141.153**) had been ordered for use by the West German Army for mounting beneath tethered balloons. These will be flown at an altitude of about 800 metres to eliminate shadow zones in low-level radar cover for air defence purposes. Deliveries were to start in February 1985.

There is a NATO requirement for a number of S-band 3-D surveillance radars to be located at sites in Italy, Greece, Turkey and Portugal to upgrade the cover in the so-called Southern Flank of the NADGE network, and competitive bids were sought from qualified contractors in the early 1980s. The estimated total value is in the region of $300 million and bids were submitted by Hughes, Selenia/Sperry, Thomson-CSF, and Plessey/ITT-Gilfillan. Hughes proposed a transportable version of the HADR (**3721.153**) ordered for West Germany and Norway; the Selenia/Sperry team offered the RAT-31S (**1953.153**); Plessey/Gilfillan suggested the AR320 (**3649.153**) which has been sold for use by the RAF; and Thomson-CSF a new derivative of the TRS 2230 known as the TRS 22XX. The status of the contest had not been confirmed in July 1985 despite the fact that the Plessey bid had been reported as 'non-compliant' (this disputed by the contractor) and in June Hughes had unofficially intimated that it had secured the contract. Although unable to make an official statement, Hughes nevertheless felt confident enough to claim that eight variants of the HADR 3-D radar known as the H 3000 had been ordered for the Southern Flank sites. The total package is believed to contain options for a further six of these radars.

From 1987, RAF AEW3 Nimrod aircraft are due to join NATO E-3A AWACS patrols as part of the NADGE air surveillance facilities. NIMROD is here accompanied by Tornado F2 armed with Sky Flash AAMs

CONTRACTORS

The members of the original six-nation consortium and their main equipment contributions to NADGE are listed below. There are also numerous other subcontractors from the other participating countries which are receiving orders in relation to their own country's contribution to the funding of the project.

Hughes Aircraft Company, Fullerton, California, USA: Computers, systems design and specialised software.

GEC-Marconi Electronics, Chelmsford, Essex, England: Height-finder radars, improvements to existing radars, height-strength measuring consoles, manual tracking posts, and reporting posts.

AEG-Telefunken, Ulm, Federal Republic of Germany: Video link equipment for Norway, Denmark, and Turkey, part of the medium-power radars under sub-contract from Thomson-CSF.

Thomson-CSF, Paris, France: Medium-power radars.

Selenia, SpA, Rome, Italy: Data displays and video link equipment for Italy.

NV Hollandse-Signaalapparaten, Hengelo, Netherlands: Gap-filler radars, two-dimensional extractors, display system modifications.

OMAN

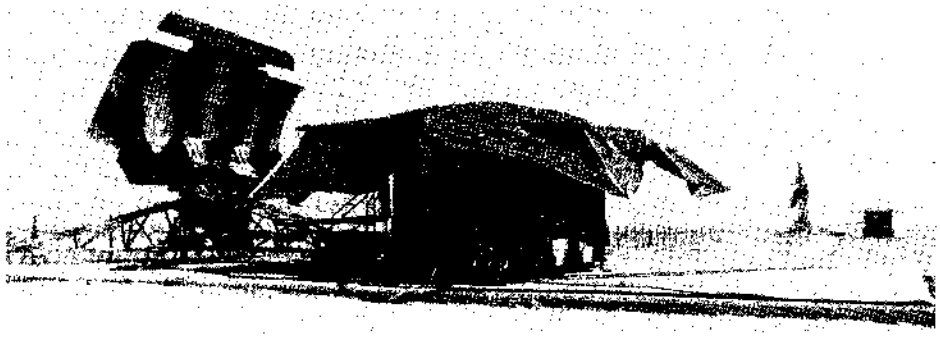
3325.181

OMAN AIR DEFENCE

The air defences of the Sultanate of Oman have undergone a major modernisation and improvement programme instituted in the early 1970s. The ruler, Sultan Qaboos-bin-Said, engaged BAC, now part of British Aerospace, to undertake the task, with advice and assistance from the British Government. The basic requirement was for a highly mobile and accurate integrated air defence system capable of defending civil or military installations from ground or air attack and able to intercept any intruders anywhere within the Sultanate or its surrounding waters. The hardware selected for these tasks comprised two and one-third batteries of Rapier low-level surface-to-air missiles (**2424.131**) and 12 Jaguar tactical strike and fighter aircraft. To make the most effective use of these forces, a master communication and control network was required urgently to provide the necessary early warning and tactical control and command link to the defence force. Marconi provided the bulk of the radar and communications equipment needed.

The communications system has two main centres, connected by strategically-sited terminal and repeater stations. These link the air defence operations centre with the two sector operations centres, each of which has its own surveillance radar station.

Defence centres in the vicinity of Muscat in the north and along the border with Yemen in the south are linked by a tropospheric scatter system running the length of the country and fed by short haul line-of-sight radio links. This network is used to convey processed data and high priority communications from radar sites and sector operations centre to the main operations centre. One of the Rapier squadrons and the Jaguar aircraft are based at Thumrait, a military airfield 700 km south of Muscat and where



there is also a radar and communications installation. There are also other units, including the Rapier Squadron HQ at Seeb on the coast to the west of Muscat.

STATUS

Operational. In mid-1985 it was revealed that Marconi Radar had received a £38 million contract to extend and update the Oman Integrated Air Defence System. The major items of new equipment are two Martello S713 long-range 3-D radars (**3491.153**), their associated MACE display and data handling systems. Part of the contract involves updating and expansion of existing Sector Operations Centres (SOCs) and Control and Reporting Centres (CRCs), as well as the provision of a new CRC.

CONTRACTORS

British Aerospace, Dynamics Group, Six Hills Way, Stevenage, Hertfordshire SG1 2DA, England.

Marconi Radar S600 series search and heightfinder radars deployed in the desert

Marconi Radar Limited, Writtle Road, Chelmsford, Essex CM1 3BN, England.

SPAIN

2322.181

COMBAT GRANDE AIR DEFENCE SYSTEM

Combat Grande is the name of the programme of automation of the Spanish air defence system by the USAF for the Spanish Government and supplied by a jointly owned Spanish-American company registered in California.

The new programme (coded 451D) was designed to automate Spain's manual air defence system by providing a computerised capability for aircraft surveillance and tracking. It includes the development of a combat operations centre and a sector operations centre and modernisation of seven existing long-range radar and ground-to-air transmitter radio sites located throughout the Spanish peninsula. The programme also calls for the improvement and enlargement of an existing microwave system to tie in to the new defence system.

Included in the radar enhancements were the provision of new IFF/SIF facilities, video extractors, and modems. A capability for remote operation of the radar site ground/air communications from sector operations centres for aircraft control was also provided. The existing microwave links between the various stations forming the network will have their capacity increased and redundant routes will be added where alternatives do not exist at present to ensure reliability and security of communications.

The system employs the Hughes H5118M computer, and the Radex system – developed by Hughes in an earlier air defence programme – provides video extraction and signal processing facilities.

The H5118M is a medium-scale, militarised computer specifically designed for command and control systems. It is smaller, less costly, and more reliable, says the manufacturer, than its predecessors. It has the same maximum capacity as the H3118M, developed 10 years earlier, yet is only one-fifth the size. Software packages developed for a number of other computers may be used interchangeably with the new H5118M, including the H3118M of NATO's air defence ground environment (NADGE) system (**1181.181**), the H4118M used in the USAF 407L system (**2824.18**), and the Mk 156 employed in the USN improved point defence target acquisition system (IPD/TAS) (**1928.281**).

In its basic configuration, the H5118M consists of a processor, buffered input-output channels, and 16 384 words of core memory, housed in a refrigerator-size cabinet, along with power supplies, maintenance-control panels, and cooling mechanism. It is categorised as a modular, 18-bit, binary, parallel, synchronous system with a 2 microsecond add time and a 4·6 microsecond multiply time. A building-block design enables the H5118M to be expanded to a dual-processor system and a maximum of 131 072 words of core memory, with no increase in cabinet size.

The Radex equipment provides automatic tracking of target returns from primary radars. When other modifications are added, tracking performance will be improved by increasing the number of tracks that can be handled by an individual console operator; track accuracy on non-co-operative tracks; the operator's ability to detect valid targets by providing better recognition than with current narrow pulse video display. Radex was recently bought by the USAF for integration into the 407L system.

It is expected that the modernisation techniques will resemble those applied to some of the older systems which were updated during the NADGE development programme (**1181.181**) and although, so far as is known, there is no definite intention to link the Combat Grande system with NADGE at present, it is a near-certainty that the new system will be so designed as to make such a linking-up operation a simple matter if and when the need is established.

STATUS

Under a new programme, unofficially known as Combat Grande II, additions are being made to the radar facilities and new microwave communications are being installed to improve air defence network data exchange services. In June 1980 the first delivery of Collins data transmission equipment was made. This was to replace outdated hardware at five of 44 sites being modernised under the programme to improve data transmission from radar sites to Torrejon Air Base, near Madrid, for use in the combat operation centre. Completion of this part of the programme is due by mid-1982. The contract awarded to Rockwell International Collins Transmission Systems Division was worth $15 million.

In an award of $2·37 million announced in July 1980, General Dynamics Corporation was given the task of modification, test and installation of a search radar at Barbanza in the north-west of the country. The equipment will include an antenna array measuring about 12 × 5·4 m and dual transmitter/receivers. A US-built heightfinder radar will also be installed at the site. The new Barbanza Mountain radar station was handed over to the Spanish Air Force by USAF Electronic Systems Division in April 1984, making a total of eight Spanish air defence radar sites modernised by ESD.

One of the seven long-range radar sites in the Combat Grande Spanish air defence system. Also known as SADA, Sistema Semi-Automatico de Defensa Aerea, it was produced by a jointly-owned Spanish-American company, COMCO

With the formal entry of Spain to NATO, the closer linking of the Combat Grande system with the NADGE air defence system (**1181.181**, above) can be expected. There may also be certain new installations as a result of this development also but at this stage details of Spain's admission to NATO and the operational and hardware implications of this event have not been specified.

The Spanish Air Force was considering the development of an AEW aircraft based on the Casa CN-235 medium freighter aircraft to enlarge the scope of the national SADA (Sistema Semi-Automatico de Defensa Aerea) network, it was revealed in early 1985.

CONTRACTORS

Prime contractor is COMCO Electronics Corporation, a company jointly owned by Hughes Aircraft and the Compañia de Electronica y Comunicaciones SA (CECSA). Each of the two parent companies has a 50 per cent holding in COMCO.

Hughes built the computers and designed the communications equipment for the new system. CECSA manufactured the communications subsystems and managed the civil engineering construction.

SWEDEN

2358.181

STRIL AIR DEFENCE SYSTEM

STRIL is a fully automatic air surveillance and operations control system operated by the Swedish Air Force.

Inputs to the system come mainly from high and low level air surveillance radars, but a back-up visual reporting service is included to supplement the radar data and to replace it if the radar input is blocked. Information from all these sources is fed into a central data store whence it is extracted for selective presentation to controllers having specific territorial assignments.

OPERATION

When a threat is detected the STRIL controllers, who also have available to them state-of-readiness information on available forces and weapons, decide with what kind of available weapon the threat can best be countered and assign that weapon to the task. In appropriate cases, eg surface-to-air missiles, they will also control the operation. Currently the forces controlled by the system are the SAAB Draken and Viggen interceptor aircraft, AA guns, and a diminishing number of Bloodhound surface-to-air missiles (**2406.131**). Most of the control and reporting centres, and the display and computing equipment at the local operations rooms at radar sites have been delivered by Datasaab, which also participated in the overall system development of STRIL.

The STRIL centre is also linked up to the civil defence organisation, and can both alert them and warn industry or the civilian population.

If the threat cannot be countered by the forces under the control of one centre but can be countered by those of another centre, the system provides both voice and transmission links for giving information to other centres. Both narrow- and broad-band microwave links are employed for the exchange of data between centres.

Although primarily an air defence system STRIL is linked to coastal as well as to anti-aircraft artillery.

The original STRIL-60 system has been the subject of sustained development and improvement throughout its operational life. The most recent, and so far as is known, the most extensive modernisation programme is now in progress. Recently Datasaab supplied new advanced computerised display systems with such facilities as automatic tracking, etc, and in late 1975 it was confirmed that 16 three-dimensional primary radars are to be installed to supplement and/or replace existing older radars. The radars selected after an international competition were an improved version of the ITT/Gilfillan AN/TPS-32 (**2516.153**) which will be installed in rock shelters and with 'pop-up' antennas. The display equipment, including ECCM control and display processing, will be developed and manufactured in Sweden by Datasaab.

A contract worth SKr35 million has been placed by Svenska Radio AB for a quantity of Marconi multiprocessors and display sub-systems. These will be installed in cabins for use as transportable operations rooms by the Swedish Air Force.

The two main examples of the Datasaab family of transportable air defence operations centres (TADOC) are the TADOC 311 and TADOC 431. The latter is the more sophisticated with regard to operational functions, computing power etc. These transportable centres can be moved to new locations easily if strategic plans are changed or if it becomes necessary to replace other centres which have been destroyed by enemy action. Another advantage of this technique is that buildings or bunkers in stationary centres can be simplified or even eliminated by housing equipment in TADOC cabins. The general configuration of TADOC units employed in the air surveillance and combat control system is shown diagrammatically nearby. Up to three TADOC 311s can be collocated, and up to four TADOC 431s. Each cabin can contain from two to four operational consoles, and it is possible to exchange data between cabins within a collocated group.

TADOC 311

Normally, the TADOC 311 interacts with radars in the ASCC system. Data from the radars is sent automatically to the CRC without any operator intervention. The primary radar can be of the 2-D or 3-D type and automatic transmission ensures fast target detection within the entire ASCC system and thus a short system response time (essential in modern air defence systems). However, since systems that may have to be used in wartime must have fall-back modes of operation, the TADOC 311 can exercise a certain amount of control in addition to its normal reporting role. This permits independent operation, should the CRC or its ground-to-ground communication fail. In addition to its 'own' local radar, the TADOC 311 can make use of a remote radar (either a military gap-filler radar or a civil radar). This remote radar delivers extracted radar data via a narrow-band, telephone-type channel such as a radio link.

The TADOC 311 can also serve as a centre for visual reporting posts (VRP). Their data can be filtered by the centre and transmitted to the CRC.

Main operational tasks of the TADOC 311 include:

(1) Producing target information and transmitting it to the CRC. This is normally automated for radar data (transmission of extracted radar data or plot messages). There is, however, a manual back-up function that can be used if the radar or extractor function is degraded. The manual back-up function can also be used to filter and transmit target information obtained from VRPs

(2) ECCM control, which entails evaluation of the ECM situation and the taking of appropriate countermeasures to eliminate or alleviate the consequences of jamming

Secondary operational tasks include:

(3) Autonomous airspace surveillance, which is carried out within the area covered by the connected radar station(s) in the event that ground communication to the CRC or the CRC itself is out of action

(4) Weapons control, primarily, control of fighter aircraft in the situations cited above

(5) Producing target information and transmitting it to nearby SAM/AAA units. This can be performed using the manual back-up function mentioned earlier.

TADOC 431

Normally the TADOC 431 serves as a tactical operations centre such as a CRC in the ASCC system. The TADOC 431 is responsible for all tactical operations within an air defence sector. Sensor information from radars and control and reporting posts (CRP) is transferred automatically to the TADOC 431 which can also receive information from visual reporting posts (VRPs) either directly or via a CRP (in which the information is filtered to some extent). The received airspace information forms the basis for weapons control. The TADOC 431 also reports the airspace situation to a co-ordination centre (CC). This reporting is automatic so that the CC will receive an accurate and up-to-date airspace situation picture of the sector in question. However, since systems that may have to be used in wartime must have fall-back modes of operation, the TADOC 431 can take over some CC functions should the CC or its ground-to-ground communication fail.

The main operational tasks of the TADOC 431 include:

(1) Airspace surveillance: this is carried out utilising information obtained from connected sensors of different kinds and from subordinate centres. An airspace situation picture of the air defence sector is compiled and presented in the TADOC 431 itself and can be reported to a superior centre such as a CC

(2) Weapon control, which involves: evaluation of the threat situation; assignment of the appropriate weapon system (fighter, SAM or AAA); allocation of specific fighter aircraft or SAM/AAA unit and weapon controller; interception and recovery control of fighter aircraft or allocation of targets to SAM/AAA units. Weapons control is exercised throughout the air defence sector and is based upon the airspace situation picture

Operational console in a TADOC 311 air defence control cabin

(3) Civil defence telling and base alerting. This is carried out by issuing warnings to threatened civil targets, such as highly populated areas, industrial areas etc. Warnings are also issued to threatened air bases. Moreover, general airspace situation information is distributed to different 'customers'

(4) Co-ordination of military and civil air traffic control by co-ordinating military and civil air traffic activities in the air defence sector to ensure safety and facilitate identification of civil flights

Secondary tasks include:

(5) Close air support and reconnaissance supervision: for the most part, this entails supervision of reconnaissance flights and supervision and/or direction of close air support aircraft. The objectives are to keep track of these aircraft and be ready to warn them of hostile aircraft

(6) Naval support and co-ordination by co-ordination of naval and air force activities in the air defence sector to minimise the risk of inadvertent firing on friendly units. This can also include the exchange of selected target information between the TADOC 431 and a naval command centre.

CONTRACTORS

Prime contractor for the STRIL system is Datasaab AB (formerly Stansaab Elektronik AB), 175 86 Järfälla, Sweden. Datasaab is also responsible for the creation of similar systems in Denmark and elsewhere.

SWITZERLAND

2373.181
FLORIDA AIR DEFENCE COMMAND CONTROL SYSTEM

FLORIDA is the name given to a computerised air defence command and control system that was accepted and declared operational by the Swiss military authorities in April 1970. General contractor for the system was the Hughes Aircraft Company.

DEVELOPMENT

The system consists of several military radar stations with 3-D radar and air defence direction centres, including computers, display consoles, and associated equipment. Information from the radar station is fed into conversion equipment in underground air defence direction centres and processed in turn by a high-speed general-purpose computer.

This computer automatically establishes speed, heading, and altitude of an unidentified intruder. Display consoles present a constantly updated picture of the aircraft's flight track as well as information on the various weapons available, their launch ranges, velocities, armament, restrictions, and time-to-kill.

Should the target be identified as an immediate threat, the air defence commander can electronically request all-weather interceptor aircraft or surface-to-air missiles to intercept and destroy, and can alert the civil defence organisation.

SYSTEM COMPONENTS:

The radar used is a long-range three-dimensional radar, with a planar array antenna using the Hughes elevation frequency scanning technique. This provides simultaneous range, bearing, and altitude data. An IFF system is associated with the radar.

The system includes video extractors that analyse radar returns, with the help of a real-time computer, and extract actual aircraft tracks from spurious returns such as clouds and ground returns. Track acquisition and updating is automatic.

This processed information is fed to air defence direction centres where it is accepted by a computer. This takes in information from the missile sites, airfields, and other military installations and stores it for use in selecting defensive measures.

It can also simulate air battles for training and instruction, and can be used as a general-purpose data processing centre.

The computer may be required to provide information on weapons available, their launch ranges, velocities, armament, restrictions, and time-to-kill. Numerals and symbols are used to provide this intelligence to the controller and to depict the battle area, the threat and the defences, the problems, and their solutions. The computer, the Hughes H-3324, is of the same type as those associated with the radars but has a much larger storage capacity. Typically it might be called upon to execute between 50 000 and 550 000 instructions in a second.

In the direction centre the display consoles are arranged to display only that information which is pertinent to the tasks of the operator concerned. The principal functions are:

Identification officer – responsible for designating radar tracks as friendly or hostile aircraft.

Interceptor director – interested in his own controlled interceptor and the assigned hostile aircraft. To him, specific data about this intercept is presented including attack geometry, altitude, speed, time to intercept, etc.

Air traffic co-ordinator – concerned with military aircraft requesting clearance to cross civilian airways.

Missile officer – (surface-to-air) in close contact with the missile batteries and assigns targets to the appropriate site.

Chief of air defence – concentrates on deployment and the threat. Total composite air situation and threat boundaries are important to him.

Aircraft and missile forces currently under control are two Mirage IIIS interceptor squadrons and two Bloodhound 2 surface-to-air missile battalions (**2406.131**). There are also 22 battalions armed with 20 mm and 35 mm AA guns. The first batch of Contraves Skyguard fire control systems (**2377.181**) for the 35 mm AA gun defences was being procured in 1979, and a second quantity of Skyguard systems was due to be requested in the 1979 ordnance procurement programme. It was also expected that approval would be sought for further Skyguard and mobile air defence systems incorporating missiles under the air defence bill.

STATUS

The system officially became operational in April 1970. In the 1979-80 period the Swiss authorities studied competing equipment as a means of providing air surveillance and ground control of interceptor aircraft in the lower airspace. Field tests and evaluations were held of competing systems, among them the Hughes VSTAR (**4080.153**), and the Selenia MRCS-403 mobile air defence system (**3326.181**) and its 3-D radar RAT-31S (**1953.153**). In early 1982 it was announced that under a Swiss air defence programme called Taflir a prototype Westinghouse AN/TPS-70(V)2 radar (**4319.153**) was ordered for delivery in late 1983.

CONTRACTOR

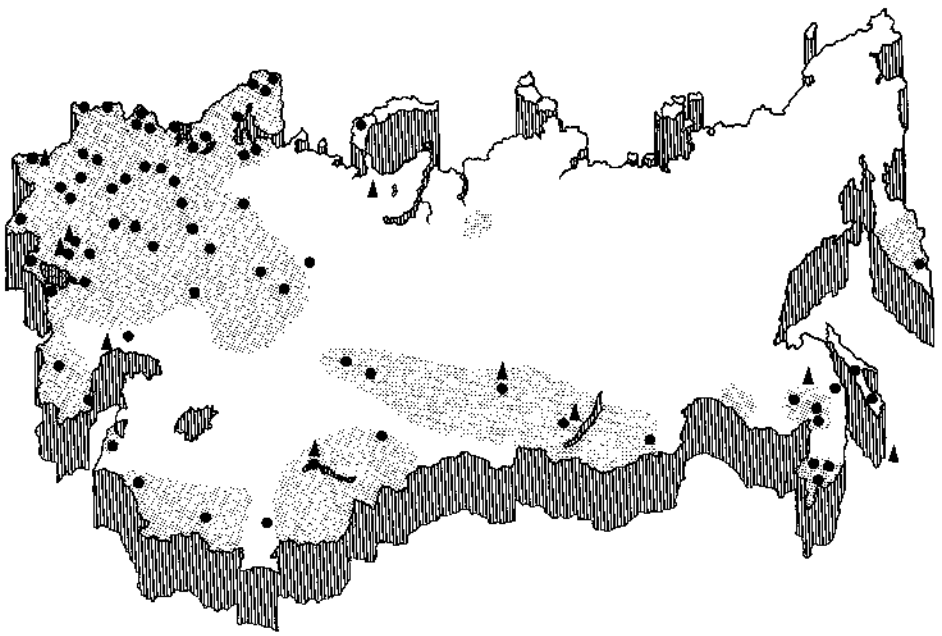
System contractor: Hughes Aircraft Company, Fullerton, California 92634, USA.

UNION OF SOVIET SOCIALIST REPUBLICS

3214.181

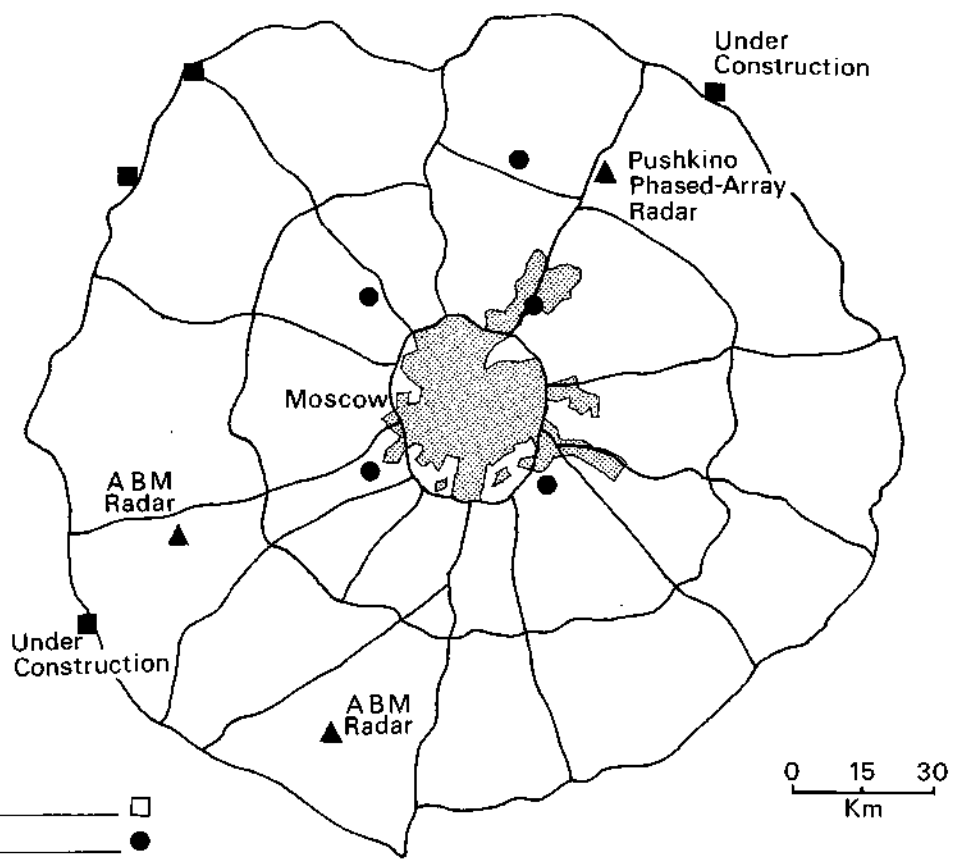
SOVIET AIR DEFENCE

The Soviet Union maintains and operates an elaborate and extensive air and space defence network consisting of a variety of organisational levels equipped with a multiplicity of sensors, systems and control and command levels which are frequently interdependent and overlap to provide operational redundancy. This ensures maximum protection from equipment failures or other interruptions in service due to hostile action or accident.



Early Warning. What is claimed as the world's most comprehensive early warning system provides separately for detection and alerting to both ballistic missile attack and conventional air attack by missiles and aircraft within the atmosphere. The current ballistic missile early warning system consists of a launch detection satellite network, over-the-horizon (OTH) radars, and a series of large phased array radars on the periphery of the Soviet Union.

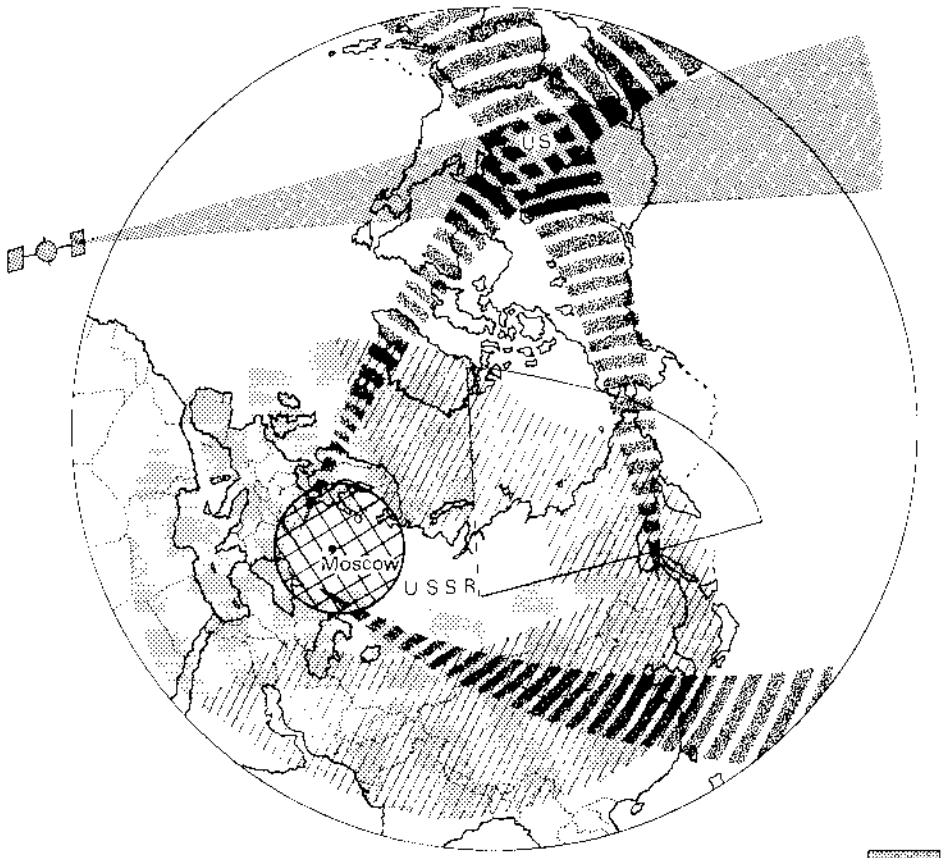
The launch detection satellite system can give a warning of any American ICBM launch, as well as determining the area from where it was launched. Two large OTH radars, which have been set up to face the US ICBM fields, could provide up to 30 minutes warning of an ICBM attack from the USA. The two systems combine to give more reliable warning facilities than would either on its own.



The next layer of ballistic missile early warning facilities consists of 11 Hen House large detection and tracking radars located at six sites on the Soviet periphery, and these can confirm the warning of an attack given by the satellite and OTH radar systems and give an indication of its scale. The Hen House radars are also able to provide certain target tracking data in support of ABM deployments.

Since 1983, an additional large new phased array radar, claimed to be for ballistic missile early warning purposes, has been detected under construction in Siberia, at Abalakova. This would bring the total of radars of this type in use or being built to six. This new radar closes the gap in the combined Hen House and new phased array radar early warning and tracking radar. Together, this radar and the five others like it form an arc of coverage extending from the Kola Peninsular in the northwest, around Siberia, to the Caucasus in the southwest. Hen House radar coverage completes the circle. In the US viewpoint, the new phased array radar probably violates the 1972 ABM Treaty in that it is not located on the Soviet periphery nor does it point outward from Soviet territory, as required by the Treaty. The complete network provided by these radars, which could provide target tracking data for ABM deployments beyond Moscow, are expected to be operational by the late 1980s.

It should be noted, however, that the Abalakova radar is in the region of the Soviet Baikonour space centre and the Plesetsk missile test range, and that its single face is oriented to provide an arc of cover that embraces the missile down-range area. Other observers have advanced the alternative theory that the new radar may be related to Soviet ASAT researches, rather than forming part of the USSR national defence network.



Soviet territorial air defence

Moscow ballistic missile defence

The latest Il-76 Soviet AWACS aircraft is known to NATO as Mainstay

Coverage of ballistic missile detection and tracking systems

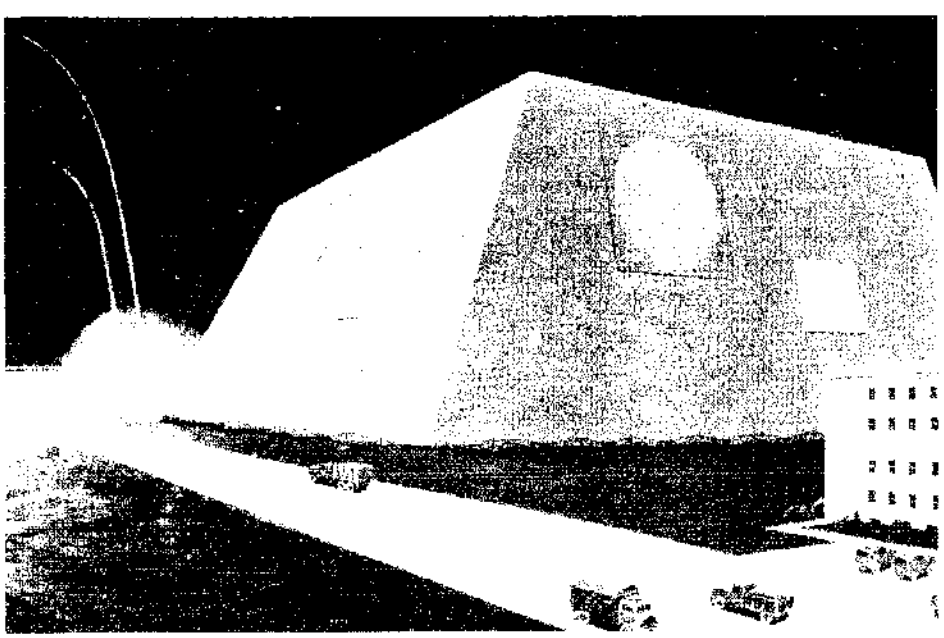
Ballistic Missile Defence. Throughout the 1980s the Soviet Union has been working to upgrade the Moscow ABM system, which is intended to give a measure of protection for the city itself and for the significant civil and military command installations that exist in and around Moscow. The original single-layer ABM system included 64 reloadable launchers above ground at four complexes for the Galosh ABM-1B, six Try Add guidance and engagement radars at each complex, and the Dog House and Cat House target tracking radars to the south of Moscow. The Soviet authorities are now thought to be upgrading this system to the 100 launchers permitted by the 1972 Treaty. When complete it will be a two-layer system consisting of silo-based long-range modified Galosh interceptors designed to engage targets outside the atmosphere; silo-housed high-acceleration interceptor missiles designed to engage incoming targets within the atmosphere; associated engagement and guidance radars; and a new large radar at Pushkino designed to control ABM engagements. It is believed the ABM silos may be reloadable. Full operational status is predicted for the late 1980s.

In 1985, US authorities expressed the view that the SA-X-12 surface-to-air missile (**4774.131**), which is nearing operational status, also has a ballistic missile defence capability.

Air Surveillance. There are an estimated 7000 or more air surveillance radars deployed in the USSR at about 1200 sites. These provide virtually complete coverage at medium to high altitudes of the airspace over the USSR, and in some areas extending hundreds of kilometres beyond Soviet borders. Limited cover against low-altitude targets is concentrated in the west of the Soviet Union and certain high-priority areas elsewhere. From 1983 onward the Soviet authorities have begun to deploy two new air surveillance radars which will aid the early warning of cruise missile and/or bomber attacks, and will enhance air defence electronic warfare capabilities.

Existing air surveillance radars are also being improved and US officials estimate that more than 20 types are under development. Additionally, the programme to deploy improved air surveillance data networks is continuing, to enhance the exchange of target data throughout the surveillance network to radar outstations to surface-to-air missile sites, and various levels of control posts. This is one aspect of a major overhaul that is thought to be under way, which involves provision of improved capability against low-level threats such as cruise missiles. The programme is understood to embrace the partial integration of strategic and tactical air defences, upgrading of early warning and surveillance facilities, and the installation of the improved data network mentioned above. Other facets are new aircraft and air-to-air missiles, surface-to-air missiles and a Soviet Union AWACS.

The estimated present strength is in the region of 1200 air defence interceptors and approaching 10 000 missile launchers at about 900 sites, dedicated to strategic defence. There are believed to be another 2000 interceptors within the USSR that could be drawn upon, plus 1800 tactical SAMs.

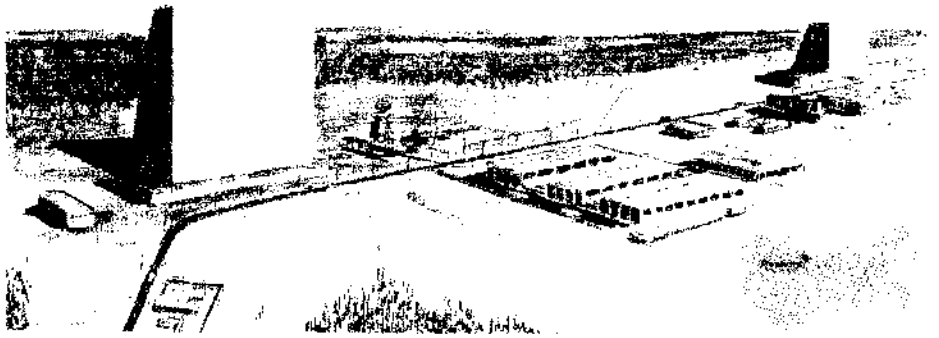


PVO Strany (*Voiska Protivovzdushnoy Strany*) is the national air defence command of the Soviet Union, with an underground headquarters on the outskirts of Moscow. There are four operations/systems commands:

(1) RV-PVO (*Radio tekhnicheski Voisk-PVO*) radio-technical troops
(2) ZA-PVO (*Zenitnaya Artilleriya-PVO*) anti-aircraft artillery
(3) ZRV-PVO (*Zenitnaya Raketmye Voiska-PVO*) anti-aircraft missile troops
(4) IA-PVO (*Istrebitel 'naya Aviatsiya-PVO*) fighter aviation forces.

The 7000 or so air defence radars are the responsibility of the RV-PVO, while missile systems and AA guns are in the hands of the ZA-PVO and ZRV-PVO commands. Fighter aircraft are managed by IA-PVO.

Operationally the Soviet air defence network is divided into four levels of command responsibility: Air Defence (AD) Districts or Rayons, AD Zones, AD Sectors, and 'frontal' AD sub-units defencing specific point targets. The rayons are sub-divided into at least two AD zones and these are in turn divided into SAM defence sectors. Each level has a particular command function and operational mission. At rayon level these include search and entry, long-range target identification, designating air threats to lower command echelons, and authorisation of fighter intercepts or missile engagements. Twenty two rayons cover the USSR from the eastern border with China to the Warsaw Pact states of Eastern Europe.



The AD districts are divided into AD zones, some districts having as many as four zones and these are under IA-PVO operational command. The command responsibilities at this level embrace target identification friend or foe (IFF), GCI radar operation, and fighter intercept of hostile/unknown aircraft.

Artist's impression of the Pushkino ABM radar on the outskirts of Moscow

An AD sector is a specific, relatively small scale section of airspace under the control of Air Defence Launch Command Centres, and their defence is based on SAMs and their associated target tracking and guidance radars.

Passive defence: The Soviet Ministry of Defence controls the nation-wide civil defence programmes of the USSR. The Chief of Civil Defence is a Deputy Minister of Defence and General of the Army. Full-time civil defence staffs exist at each echelon of the Soviet administrative structure. Civil defence staffs also exist at significant industrial, utility and other installations. In wartime, the civil defence administrative structure, assimilated into an integrated command system, would play a significant role in maintenance of the government and the economy. This goal is supported by the protection provided for the leadership through deep, hard, urban sheltering and an extensive network of hardened relocation sites outside the cities, with redundant communications systems. The programme also provides for continuity of support for the economy in wartime through the protection of the essential workforce by sheltering at work and by the dispersal of off-shift workers to areas away from work sites.

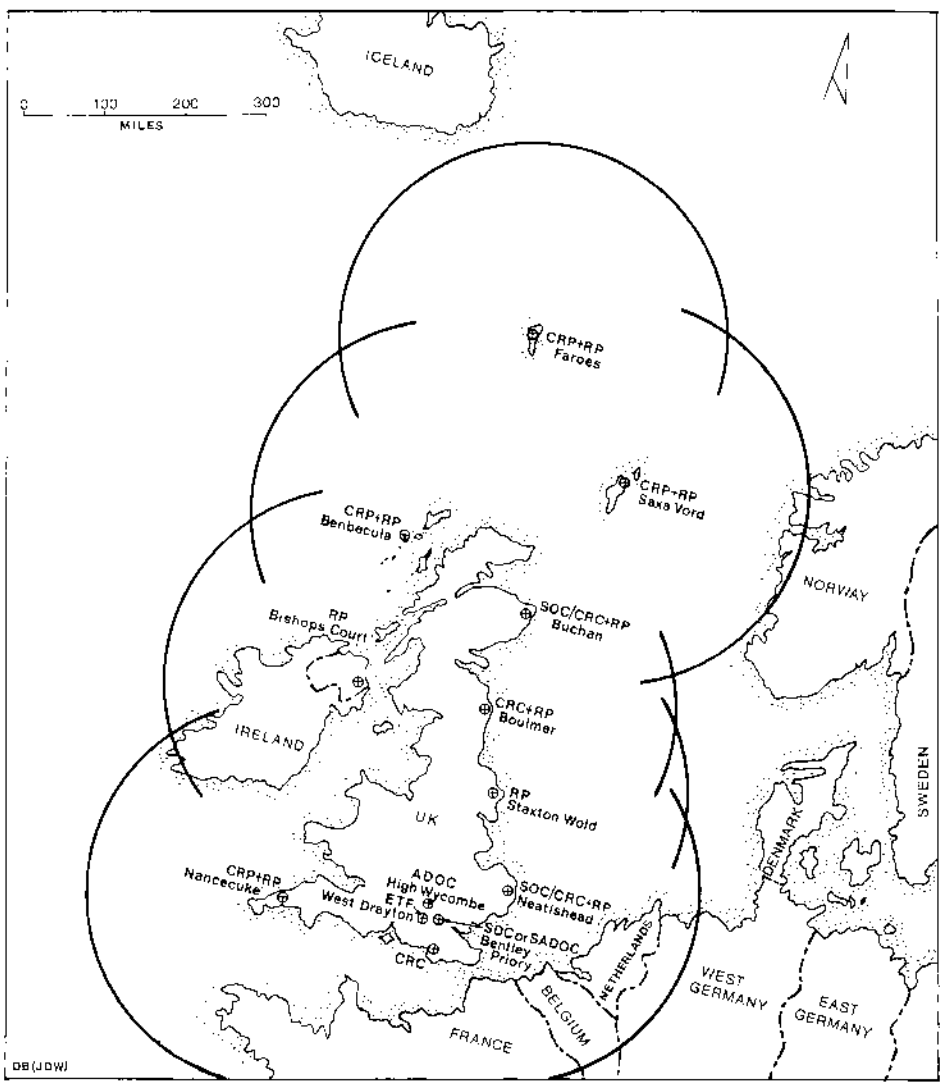
UNITED KINGDOM

2444.181
UK AIR DEFENCE SYSTEM

The United Kingdom Air Defence Region (UKADR) forms one of four regional commands of the NATO Integrated Air Defence System and stretches for about 1000 nautical miles in an arc from north of the Faeroe Islands to the western flanks of continental Europe. The systems for warning of attack on the UK are BMEWS (**2525.181**), one station of which is sited in the UK, and the UK Air Defence Ground Environment (UKADGE), the former being concerned with missiles (ballistic) and the latter with aircraft. UKADGE is also linked with NADGE (**1181.181**).



The UK air defence system is coupled into the continental air defence systems by its links with six NADGE stations. The UK data terminal for these links is the West Drayton complex which was originally intended as the heart of Linesman. Incoming data is relayed from West Drayton to the Air Defence Operations Centre (ADOC) at High Wycombe and thence to the sector operations/control reporting centres (SOC) at Buchan, Boulmer, and Neatishead.

Each SOC consists of a radar system and a control and reporting centre, and each is capable of operating independently of other elements of UKADGE.

The 1984 Statement on Defence Estimates stated that a programme of qualitative and quantitative improvements to UK air defences was underway, and this involves the replacement or modernisation of virtually all the RAF's air defence assets. The UKADGE network of ground radars and command and control and communications systems are being totally modernised. In the 1983 Statement it had been confirmed that as part of the programme, 12 transportable 3-D radars had been ordered, and the first of the RAF's 11 Nimrod Mk 3 AEW aircraft is now expected to enter operational service in 1987. This project has become known generally as Improved UKADGE or IUKADGE.

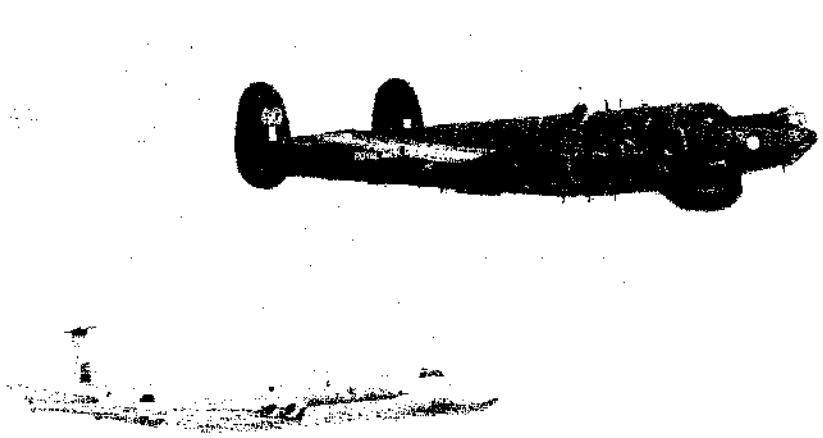
The structure of the new system is illustrated in the nearby map. Centralised command of air defence operations in the UK air defence region is exercised from the ADOC at High Wycombe which is linked to four combined sector operations centres and command and reporting centres (SOC/CRC), with, in turn, links to four command and reporting centres (CRP), and there are a number of reporting posts (RP). Other significant installations are the standby ADOC (SADOC) at Bentley Priory, where there is also a software development centre (SDC), and an engineering training facility (ETF). Comprehensive high capacity data links exist or are being established to ensure rapid and secure interchange of data between these sites, as well as to other neighbouring air defence facilities with which interoperability is essential.

The latter include links with the French STRIDA air defence network at Tours and Doullens, NADGE at six sites, NATO AWACS and Nimrod AEW3 aircraft, certain naval vessels and various defence assets such as fighter aircraft bases, SAMs etc. Each SOC is responsible for tactical control of operations within its designated region and for the associated CRCs in charge of tracking and interceptor control. The CRPs give a certain degree of back-up fighter control and the RPs represent the detection front line. Each of the RPs has or will have modern 3-D radar(s). Also to be implemented is a supporting network of passive sensors (employing ESM and infra-red detection techniques in all probability).

Map of major IUKADGE sites in the British Isles (Courtesy Jane's Defence Weekly)

To manage the vast quantity of data gathered by this array of sensors, ensure its reliable and rapid distribution in a flexible manner, and display it in a better fashion than was possible with the predecessor systems such as Linesman, demands greatly enhanced data processing facilities. Each SOC/CRC incorporates five VAX minicomputers, two for input/output processing, one for radar tracking, one for passive sensor (EW/ESM/IR) tracking, and one for system 'housekeeping': any single computer failure can be tolerated without impairing system performance.

The first of the new ground radar contracts to be awarded was for two D-band American General Electric AN/TPS-592 variants (see below) to meet ASR 887. This requirement called for transportable sets capable of setting up at a pre-surveyed site and going into operation within six hours of arrival. ASR 1585, met soon afterwards, called for E/F-band radars for the UK East Coast chain and this requirement was met by three Plessey-UTT Gilfillan AR-320 equipments, and also included two Marconi Martello D-band radars. A later requirement, ASR 1586 calls for another two Martellos and three more AR-320s. The original contracts are reported to have also included certain decoy equipment to divert, confuse or frustrate any Soviet anti-radiation weapons that might be deployed against the radars.



A chain of passive sensors is to be established to meet ASR 1584, and in July 1984 a contract was announced by Thorn EMI Electronics who were awarded a £5 million contract for the development of

a short range air defence alerting device (ADAD). It has not been confirmed at this stage that the Thorn EMI contract relates to ASR 1584, but the relevance will be clear to readers of this book.

Both E/F-band and D-band systems are required for the UKADGE radar updating programme and four radars, all D-band, have been ordered to date. The first two systems, for installation at Buchan and Benbecula in Scotland, are GE592 radars which are a variation of the US AN/TPS-59 (**3282.153**), a powerful solid-state 3-D equipment, a version of which has been selected for the USAF Seek Igloo programme (**2567.181**) in Alaska. This radar has also been supplied, in GE592 form, to Belgium for incorporation in the NATO air defence network of that nation. For the UK, the GE592 is being supplied as two air defence systems, each mounted on five trailers. The antenna is carried on one of these, the other four being for the radar electronics, IFF, simulation, communications and support equipment. This purchase was funded by NATO.

The next two systems to be ordered, this time under UK funding, were the Marconi Martello (**3491.153**) long-range, transportable, 3-D radars.

Initially RAF AEW Nimrods will employ Link 11 communications for the exchange of early warning data, while existing NATO AWACS aircraft will at first use Interim JTIDS before all European AEW aircraft use the full JTIDS format. To enable the UKADGE to play its part in this programme, construction and installation of a network of UK data link stations has been started, comprising five receiver stations stretching from the Faeroes in the North to Norfolk. The first of these is for AWACS operations only, to collect information gathered by US AWACS aircraft based in Iceland, while three other stations at Scottish locations will be for use with Nimrods only and will operate Link 11. The fifth station in Norfolk will be able to handle data from both ACS and Nimrod sources. Thorn EMI Electronics is producing and integrating data link terminals, known as data link buffers (DLB) at these five sites under a programme called Project Cheek.

A delay in entry to service of the Nimrod AEW3 airborne radar aircraft will mean that No 8 Squadron's Shackleton AEW2s will have to serve until 1987 at least

The DLBs will enable local Command Reporting Centres (CRC), which use a standard NADGE message format, to communicate with the two (later three) message standards of the various types of AEW aircraft and other units.

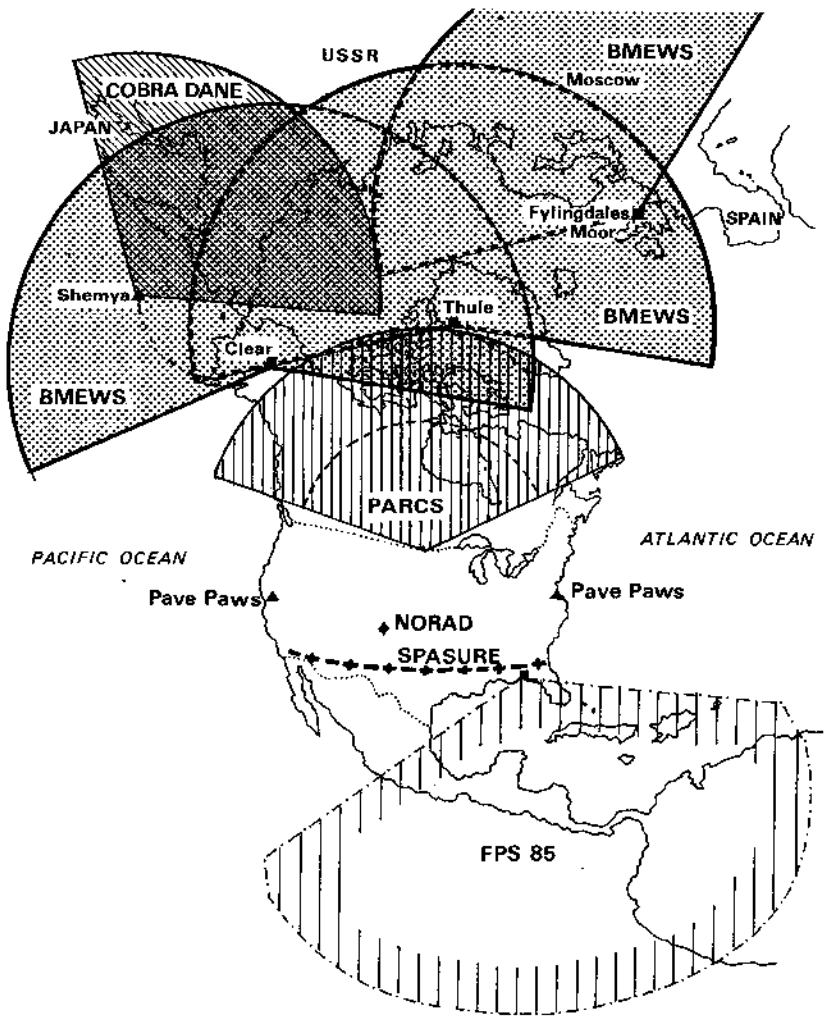
The withdrawal of Bloodhound from West Germany enabled the number of Bloodhound sites in the UK to be increased so that there are now seven: Barkstone Heath, Bawdsey, Coltishall, North Coates, Wattisham, West Raynham and Wyton. This weapon is expected to remain viable until well into the 1990s, and an update programme is to be carried out to improve serviceability.

In May 1985 bids were made public for the competition to provide a new computer-based command, control and information system (CCIS) for the headquarters of the C-in-C RAF Strike Command (UKAIR). This system is intended to appreciably improve the ability to control the strategy of air operations in NATO's UK air region in times of war. The project will be jointly funded by NATO and UK MoD. CCIS will link UKAIR HQ, and a standby HQ, to major RAF and USAF sites in the UK with facilities to enable UKAIR CCIS to interoperate with other UK and NATO systems including the Central Region CCIS, UK Maritime CCIS and IUKADGE.

UNITED STATES OF AMERICA

2525.181
BALLISTIC MISSILE EARLY WARNING SYSTEM (BMEWS)

The BMEWS (system 474N) comprises a small chain of very large radars for the detection of a ballistic missile attack on North America from the general direction of the USSR. There are three operational sites: Site I in Thule, Greenland, Site II in Clear, Alaska, and Site III on Fylingdales Moor in England.



Three types of radar are used. At Sites I and II there are AN/FPS-50 radars (**2511.153**) which are described in the Equipment Section but it may briefly be noted that they use large static arrays that are scanned by an organ-pipe scanner. At Sites I and III there are AN/FPS-49 radars (**2509.153**) which are large tracking radars with parabolic reflectors. At Site II there is an AN/FPS-92 which is similar to the FPS-49 but is a more modern version.

Information on BMEWS targets is transferred by a communications network to the North American Air Defense (NORAD) Combat Operations Center.

STATUS

The BMEWS sites in Alaska, Greenland, and England have been in operation since 1962, and are reported to have proved extremely reliable. In conjunction with two early warning satellites in the western hemisphere and one in the eastern hemisphere, the BMEWS radars comprise the principal means of warning of a ballistic missile attack. Improvements are planned for both types of warning system, ie the BMEWS radars and satellite infra-red sensors. Additional warning of SLBM attack was provided by six System 474N coastal radar stations (**2810.181**), all but one of which have been replaced by the two Pave Paws phased array radars (Project 2059). (The AN/FSS-7 SLBM detection radar site in Florida has been retained to provide additional cover for the south-eastern approaches to the USA.) The SLBM detection system will be further expanded by two additional Pave Paws radars in the south east and south west United States, at Robbins AFB Georgia and at or near Goodfellow AFB Texas. These are due to enter operational service in 1987. Until all four Pave Paws radars are operational, the AN/FPS-85 at Eglin AFB, California will be kept in service.

In early 1978 RCA was awarded a $4 million contract for upgrading of BMEWS Sites I and II by replacing the 15-year-old tactical operations rooms

Main elements of the American ICBM warning facilities protecting North America, showing the coverage of BMEWS stations, PARCS (Perimeter Acquisition Radar Attack Characterisation System), and the FPS-85 phased array radar and SPASUR network in the south. Two more Pave Paws radars are under construction to give better coverage to the SE and SW of the USA. These are due for service in 1987

installed there. An option to carry out the same modification at Site III was included in the contract. The work was expected to take two years. A $1·9 million contract in respect of Site III, Fylingdales Moor, tactical operations room modernisation was awarded to RCA in June 1979. In November 1980 the USAF announced plans to update the Site I, Thule, BMEWS radar to improve its resolution and data processing capability. A $2·5 million contract was awarded to Raytheon in May 1982 for a definition and design study to improve the tactical warning and assessment capabilities of the Thule site. By early 1983 the updating programmes for the BMEWS stations at Thule and Fylingdales were officially expected to be completed in 1986.

By early 1985, the plan to replace obsolete radars at the Thule site by new phased array systems similar to Pave Paws was nearing completion and initial operational capability is expected in 1986, and in that year work will start on a similar replacement programme at the Fylingdales site. The new phased array radars will be more accurate, have a larger track capacity, and provide better prediction facilities.

In addition to its ICBM-related functions, the latter BMEWS site in the UK will improve warning of missile attacks on NATO territory and of SLBM attacks against the USA, while enhancing surveillance of objects in space.

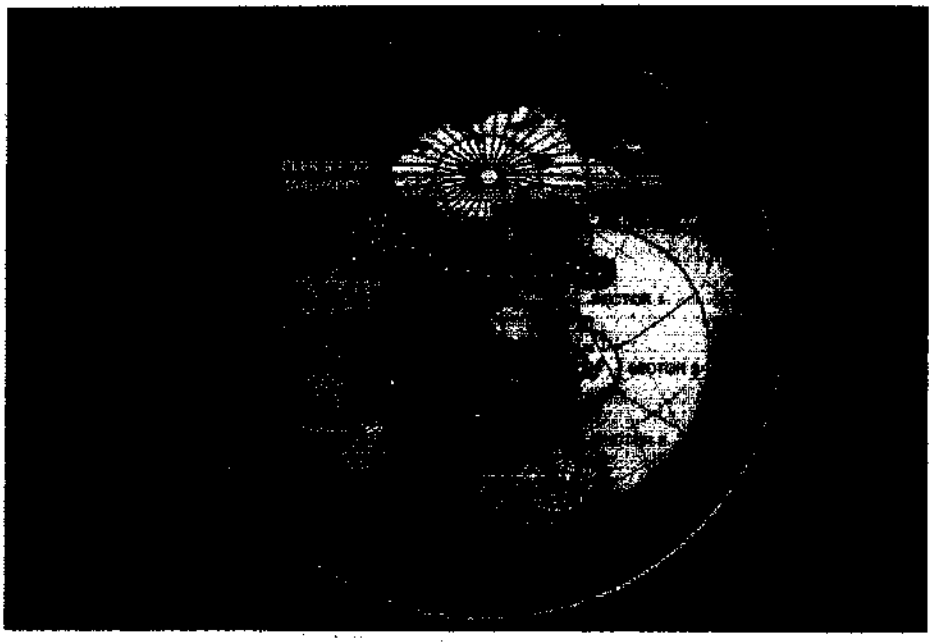
CONTRACTORS

Main contractors for the BMEWS radar systems were RCA, General Electric, and Western Electric.

2750.181

OVER-THE-HORIZON (OTH) RADAR SYSTEMS

Under Programme 414L the USAF Electronic Systems Division is planning to deploy an over-the-horizon backscatter radar suitable for defence of the continental USA against bomber attack (CONUS OTH-B). Such a system will increase the warning of attack by air-breathing air threats by extending US surveillance coverage by more than 1000 nautical miles (1850 km) from the American coasts, and will provide all-altitude detection capability.



Development is continuing of a prototype OTH radar in Maine and test transmissions by this radar began in December 1979. This limited coverage radar has been used to establish the magnitude of some of the technical risks known to be associated with the OTH programme. These are primarily related to the data handling capacity required to deal with the large volume of air traffic in the North Atlantic airways, and the problems associated with the adverse effects on OTH radar of ionospheric disturbances such as auroral effects.

Results with the prototype installation were evidently sufficiently promising for the US Secretary of Defence to state in February 1984 that it is planned to deploy eight 60° sectors of OTH-B radars for all-altitude surveillance of the eastern, western and southern approaches to the continental USA (see illustration). Funds requested for fiscal year 1985 will permit the procurement to complete the east coast segment and buy the first of three radars needed for the west coast segment.

An original interest in OTH radar to provide long-range surveillance in a northerly direction to replace the DEW Line radar chain (**2567.181** above) has now virtually disappeared following the experimental programmes in Canada described in the 1976 edition of *Jane's Weapon Systems*. However, the deployment of a south-looking OTH radar to complete North American surveillance coverage is now proposed.

The prototype CONUS OTH-B was built by General Electric under a $39 million contract awarded in March 1975. The transmitting antenna includes four arrays covering a total aperture of 690 metres, and the receiver antenna array aperture is 1190 metres. The experimental OTH-B radar uses FM/CW transmissions on frequencies between 6·75 and 21·85 MHz. The transmitting array is at Moscow/Caratunk in Maine, and the receiver antenna site is near Columbia Falls, Maine. An expanded operations centre and support facility will be located in Bangor, Maine. Testing began in early 1980 and all testing and validation of system concepts were due to be completed by 1981, by which time total cost could have amounted to about $50 million.

The $66·7 million contract awarded to General Electric in June 1982 to continue trials with the experimental East Coast OTH-B radar was progressing toward an initial operating capability (IOC) with a 60° sector planned for mid-1986. The remaining two East Coast sectors were expected to follow after that date, funding for sectors having been approved in 1983 and planned for 1985, respectively.

North American air surveillance systems, showing OTH-B sectors for east, west and southern cover and improved DEW Line to north. Pine Tree Line is to be phased out

Diagrammatic illustration of OTH-B operation, and DEW Line radar coverage

In July 1984 it was reported that tentative advanced planning was in hand for northern (?) and southern OTH-B installations to complement the eastern and western sites previously funded. The new Operations Centre building at Bangor, Maine, was virtually complete at that time and hardware installation was expected to be completed by the summer of 1985. The west coast OTH-B transmitter is to be located at Christmas Valley, California, with an Ops Centre at Mountain Home AFB, Idaho. Funding provides for a start on the first west coast sector in fiscal year 1986.

CONTRACTOR

General Electric Company, Electronic Systems Division, Syracuse, New York 13201, USA.

2567.181

DISTANT EARLY WARNING SYSTEM (DEW LINE)

One of the earlier parts of the complex of radar systems designed to warn the US military authorities of the approach of enemy aircraft or missiles, the DEW Line, is an array of radars that stretches across the northern areas of North America from Alaska to Greenland. The project was implemented as Programme 413L.

Main radars of the line are the AN/FPS-19 and AN/FPS-30. The number of radars in the DEW Line has been reduced in recent years and is now 31 and by fiscal year 1982 the number will be reduced further to a total of 13. This figure will be maintained until a decision on the best method of improving north-facing detection facilities is taken. Information from these radars is conveyed by way of a communications network to the North American Air Defense (NORAD) Combat Operations Center, together with data from the other warning networks described in this section.

STATUS

It is planned to improve the existing DEW Line chain of radars and to fill some of the gaps in it. This new approach is one result of an American re-appraisal of its continental US air defence requirements, a Canadian review, and the newly defined Joint Surveillance System (see **3213.181** below), being implemented under Programme 968H. New radar signal processing techniques developed for the FAA

(Federal Aviation Administration) and which offer considerable performance improvements, are under consideration for addition to existing DEW Line radars.

The USAF is testing one of two General Electric AN/FPS-117 pre-production radars, initially at its test range and subsequently at King Salmon Air Force Base, Alaska, for the Seek Igloo programme. If successful a further 12 may be obtained to replace radars in Alaska, where they will be operated as MARS (Minimally Attended Radar System) under control of a new regional centre at Elmendorf AFB, Alaska.

This programme has evolved into the CONUS MAR (Continental United States Minimally Attended Radar) system that will eventually replace the DEW Line and the CADIN Pinetree system in Canada to provide a northern radar fence for N America. This will involve a network of about 50 long-range radars that will form the North Warning System. Contracts are expected to be let in 1986.

CONTRACTORS

Many manufacturers were involved in the supply of equipment for and the construction of the radar chain. Prime system contractor was Western Electric. Radar main contractors were Raytheon, Budd and Sperry.

3213.181

JOINT SURVEILLANCE SYSTEM

Under USAF Programme 968H the Joint Surveillance System (JSS) was developed as a successor to the SAGE/BUIC (semi-automatic ground environment/ back-up interceptor control) system (**2803.181**) which had been the mainstay of the North American air defence surveillance and warning complex for some 25 years. The expression 'joint' in the title stems from Canadian participation and also by virtue of the fact that in the USA there is joint provision of sensors and data on the parts of the civil and military air authorities (Federal Aviation Administration and the USAF).

Some hardware from SAGE/BUIC is incorporated in JSS but the latter essentially replaces the former system in performing the peacetime air sovereignty mission.

JSS centres (ROCCs) are located at Griffiss, March, McChord and Tyndall AFBs, and they receive data from 46 radar sites. Fourteen more sites feed data to another ROCC in Alaska at Elmendorf AFB, and two radar sites supply data for another ROCC in Hawaii. Twenty-four air surveillance radar networks in Canada feed data to two ROCCs located at North Bay, Ontario.

The function of the ROCCs is to accept data from multiple sensors, automatically process this data, and display data for detection, tracking, and identification of air targets, and the assignment and direction of interceptor aircraft to ensure peacetime air sovereignty. In time of war or emergency, JSS ROCCs serve as the means of transferring the command and control functions to E-3A AWACS aircraft (**1585.353**), and would continue as a back-up to AWACS. In peacetime, six of these aircraft will be assigned to co-operate with the JSS.

The North American Air Defense Command (NORAD) Combat Operations Center (COC), to which ROCC information is passed, is also undergoing modification under PE 12311F, which provides for command control and communications support to HQ NORAD. Within this PE is the NORAD Cheyenne Mountain Complex Improvement Programme (427M), and acquisition programme to update the data processing, display, and communications elements of the NORAD COC (former 425L system), and the Space Defense Center part of the Aerospace Defense Command (ADCOM) Spacetrack system (**2825.181**), the old 496L system.

STATUS

The first region of the JSS to enter operation under the USAF Tactical Air Command was in March/April 1983 and the remaining regions were due to become operational at intervals of a few months until by March 1984 all seven continental US ROCCs were operational with Hawaii, the eighth, following later that year.

Under the SAGE system, 34 radar sites in the USA were operated exclusively by the USAF and 10 jointly with the FAA. With JSS, there are nine solely USAF radar sites and 36 joint sites. Operation and maintenance cost savings amounting to $100 million per year are expected.

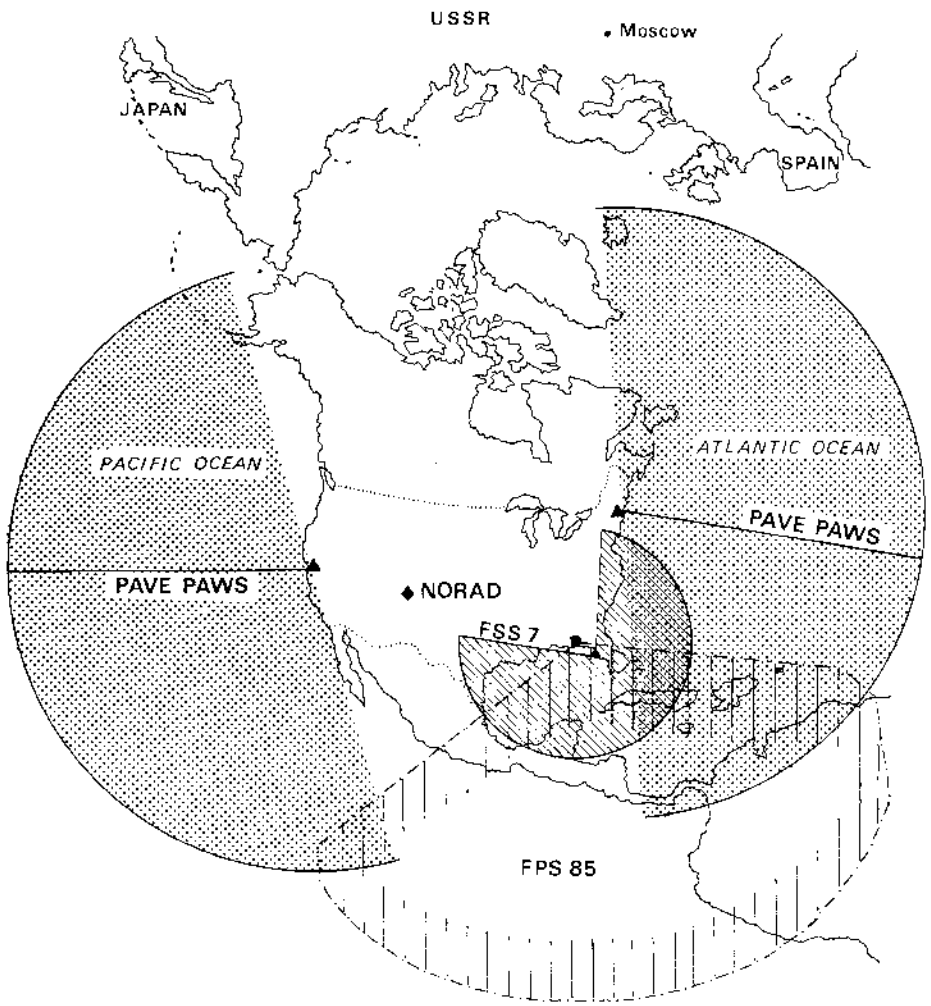
2810.181

SLBM DETECTION SYSTEM – SYSTEM 474N

This system, which became operational in 1971, is designed to detect missiles launched by submarines operating either in the Atlantic or in the Pacific Ocean. It consisted of seven radars located three on each coast of the USA and one in Texas. The main radar used was the AN/FSS-7 (**2538.153**), made by Avco; in 1972, however, it was decided to supplement these radars with about 20 per cent of the surveillance capacity of the AN/FPS-85 radar (**2546.153**) which is otherwise assigned to the Spacetrack programme (**2825.181**) and which can provide coverage over most of Central America and the Caribbean.

With the entry into service of the East and West Coast Pave Paws phased array radars in 1980 it was possible to shut down all but the Florida AN/FSS-7 radars.

STATUS



Operational with AN/FSS-7 radars since 1971. Operational with the AN/FPS-85 from mid-1974.

In April 1976 Raytheon was awarded a contract to build the East and West Coast Pave Paws SLBM warning radars (AN/FPS-115) (**3174.153**) which now replace the 474N system. The two selected sites are Otis AFB, and Beale AFB, on the East and West Coasts, respectively. Each includes a dual-faced array about 30 metres high. The SLBM detection and warning system now comprises these two Pave Paws radars, the FPS-85 radar in Florida, and one FSS-7. In response to a growing SLBM threat, two additional Pave Paws radars will be provided, one in the south east and one in the south west United States, one in Georgia and one in Texas. These four, with the PARCS radar in North Dakota will complete a planned five-site phased-array radar SLBM warning network, and will allow removal of the aging FPS-85 and FSS-7 radars.

A $61·2 million contract was awarded to Raytheon in early 1984 for further Pave Paws work. On 13 January 1984, the USAF allocated $57·7 million for construction of the fourth Pave Paws site, at Schleicher County, Texas, and later that month Raytheon received an $11·2 million contract for the power generators for the third and fourth Pave Paws sites.

The four Pave Paws sites are Beale AFB, California; Otis Air Guard Base, Massachusetts; Robins AFB, Georgia; and Schleicher County, Texas. Site three (Robins AFB) is expected to be operational by late 1986, and the fourth a year later.

Warning data is passed to the NORAD Cheyenne Mountain Complex, SAC, and the National Command Authorities. Software is being developed by IBM. The Otis AFB Pave Paws radar officially became operational in April 1980 and the second of these radars, at Beale AFB, entered service later that year. The Otis installation is operated by the 6th Missile Warning Squadron of SAC and as it became active two older radar stations manned by detachments of the 14th Missile Warning Squadron, at Fort Fisher and Charleston Air Force Stations were de-activated. The latter, close by Fort Fisher, remains in use as the home of Tactical Air Command's No 701 Radar Squadron.

Only one AN/FSS-7 SLBM detection radar needed to be retained after the Pave Paws phased arrays on the East and West Coasts of the USA entered service. Previously there were three FSS-7s on each coast. As two additional Pave Paws radars become operational in the late 1980s, the last FSS-7 and the FPS-85 may be phased out

2825.181
SPACETRACK

Spacetrack is the system code-name for System 496L, the USAF world-wide system for the detection, tracking, and identification of all objects in space. It is composed of large radar optical and radiometric sensors located around the globe and its control centre maintains a catalogue of all objects in space.

Main sensors of the system are the AN/FPS-85 radar (**2546.153**), Cobra Dane (**1949.153**) and the AN/FSR-2 passive optical sensor. The FPS-85, of which the FPS-46 was the prototype, is an electronically steerable array radar (ESAR) operating in the UHF band and giving three-dimensional information on all satellites and similar objects passing over it. FSR-2 is a passive optical surveillance system.

The complete network of four Spacetrack radar sites, in addition to the FPS-85 at Elgin AFB in the USA, and the Cobra Dane at Shemya AFB, includes the BMEWS sites at Thule, Greeland; Clear, Alaska; and Fyilingdales, England.

The current Spacetrack optical system is a four-site, Baker-Nunn camera system with sites at San Vito, Italy; Sand Island in the Pacific; Mount John, New Zealand and Edwards AFB, California. It is capable of tracking and identifying satellites out to synchronous orbit altitudes of 22 300 miles. A USAF spokesman has stated that communications, research and development, and other types of satellite have been observed by this system. Spacetrack data form part of the input to SPADATS - the NORAD space object detection system.

NAVSPASUR

This system, with the USAF Spacetrack system, forms the NORAD space detection and tracking system (SPADATS) and is the USN contribution to the latter. The NAVSPASUR detects and tracks satellites which pass through a detection 'fence' consisting of a fan-shaped radar beam extending in an east-west direction from San Diego, California, to Fort Stewart, Georgia. A central transmitter is located at Lake Kickapoo, Texas. There are a total of nine stations, six receiving and three transmitting. The beam cannot be steered and detections are made when a satellite passes through a stationary beam. There is a single Baker-Nunn camera at Cold Lake in Canada. The NAVSPASUR HQ and Computation Center is at Dahlgren, Virginia and nine field stations extend across the southern part of the US along a great circle inclined at about 33° to the Equator. The largest transmitter is at Lake Kickapoo, and the two smaller ones at Gila River, Arizona, and Lake Jordan, Atlanta. The six receiver stations are situated at San Diego, California; Elephant Butte, New Mexico; Red River, Arkansas; Silver Lake, Missouri; Hawkinsville, Georgia and Fort Stewart. Other sensors feeding into the system are all three BMEWS radar stations, the USAF Eastern Test Range radar on Ascension Island, the Space and Missile Test and Evaluation Center radar at Vandenberg, and the UK's Malvern radar.

STATUS

Under PE 12424F, funding of $4·2 million for fiscal year 1978 was allocated for several projects concerned with providing improved sensors for the 496L Spacetrack system. One, code-named Seek Sail, is a radar development intended to fill a critical gap in the present low altitude (low elevation, rather than height) surveillance coverage. One or more of these radars may be built, possibly at overseas sites. If implemented, Seek Sail radar(s) would be able to provide data on new satellites during their initial orbit.

Another project of the Spacetrack Augmentation programme is GEODSS (ground electro-optical deep space surveillance system). An experimental prototype developed by Lincoln Laboratory has been in operation at White Sands Missile Range since August 1975. It consists of two sophisticated telescopes, a 3' in surveillance and a 14 in tracker, operating in tandem; associated electro-optics; a digital computer; and ancillary electronics and communications equipment. Five sites are planned, with procurement starting in fiscal year 1977. Full operational capability will be achieved in the early 1980s. Algorithms to aid in providing satellite attack warning and software are under development for incorporation in the NORAD Cheyenne Mountain Complex.

The computer provides for on-line analysis and initial presentation, and it also activates an automatic alarm upon detecting unknown space objects. The telescope can detect objects in space which are 10 000 times below the detection threshold of the human eye. A form of MTI is used to control the movement of the telescopes, this being arranged to correspond with either the motion of the target or the star field. The net effect in either case is to isolate the desired target. Five GEODSS sites are planned, of which three have been nominated: Hawaii, Korea and White Sands. The other two will probably include Middle East and Eastern Atlantic locations.

The fiscal year 1984 DoD budget stated that efforts were continuing to complete the required world-wide network of five GEODSS sites, and plans were in hand to modify several existing radars to provide additional high- and low-altitude surveillance coverage. Work is in progress on data processing improvements to track and target enemy satellites more accurately, presumably to assist in designating targets for the developing US anti-satellite (ASAT) capability.

CONTRACTORS

Numerous. Some of the principal ones have been Bendix, Cutler-Hammer, General Electric, Philco-Ford, RCA and SDC.

3073.181
TACTICAL AIR DEFENCE SYSTEM - TADS

The Westinghouse Tactical Air Defense System (TADS) is an integrated, flexible air surveillance and control system for mobile, semi-permanent, or fixed installation. Irrespective of the type of installation, the electronic equipment is identical. TADS can operate autonomously in a manual, semi-automatic, or completely automatic mode, and it can also provide inputs for higher level operations/command centres. Various combinations of equipment can be configured to meet a range of operational requirements in a cost-effective way.

A typical TADS deployment might comprise:

(1) An AN/TPS-43 long-range three-dimensional radar (**2517.153**) complemented by a medium-range 2-D radar such as the AN/TPS-63 (**3475.153**)
(2) One or more operations centres
(3) A communications centre
(4) Cable pallet
(5) Maintenance and storage shelter
(6) Primary power sources
(7) Troposcatter or line-of-sight microwave communications equipment.

A TADS unit can be deployed and fully operational in two hours, and to achieve this mobility, generators, radar antenna, and cable reels are mounted on transportable pallets. All other major units are housed in S-280 shelters. All items can be moved by helicopter, cargo aircraft, or the various land transport techniques.

The communications centre can be adapted to suit a wide variety of air operations and requires only primary electrical power and interfacing with the operation centre to provide ground-air-ground and point-to-point transmission and reception facilities. It typically includes two 28 000-channel HF/SSB transmitter/receivers, interface with line-of-sight microwave equipment, and 24-channel troposcatter interface equipment.

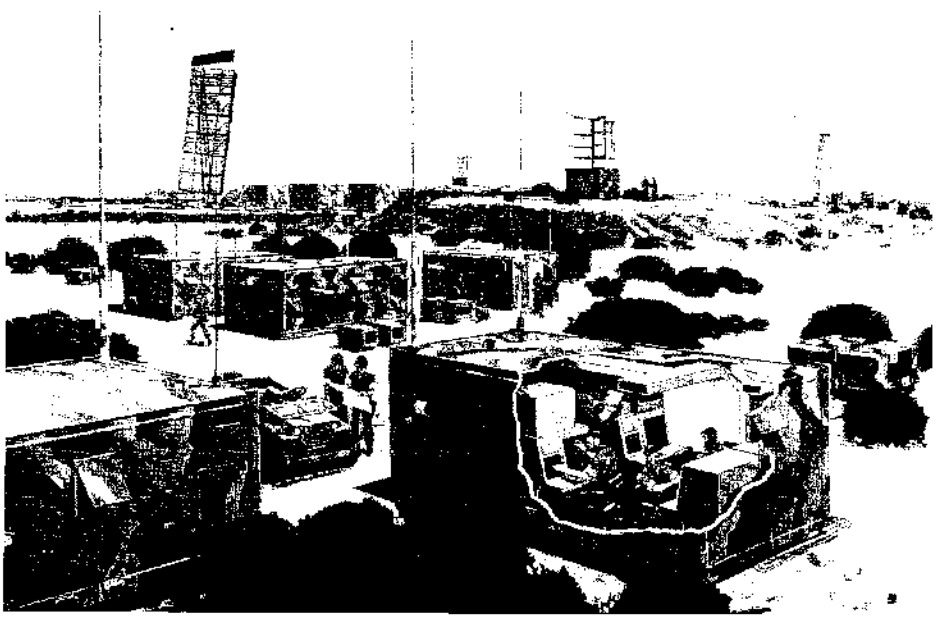
Each operations centre is housed in a standard S-280 shelter, and two or more of these units can be linked to the radar to provide increased operational capability. Equipment in the operations centre includes a radar/IFF signal distribution unit, plotting boards, a video map generator, IFF defruiter, air-conditioning/heater units (operated externally), and associated furnishings and is able to handle up to 100 tracks in a fully automated mode.

STATUS

The configuration was conceived in the early 1970s, and the manufacturers state that TADS is being acquired and deployed by countries in all parts of the world.

Operations centres and communications centres have been custom-manufactured for 13 countries world-wide. They vary in complexity to provide manual, semi-automatic, or fully automatic capabilities. TADS, or related Westinghouse systems, have been ordered for the following countries: Argentina, Australia, Egypt, Federal Republic of Germany, Greece, Iran, Israel, South Korea, Morocco, Singapore, Spain, Taiwan, Thailand and Venezuela.

CONTRACTOR



Westinghouse Defense and Electronic Systems Center, Baltimore, Maryland 21203, USA.

4214.181
TAOC-85 TACTICAL AIR OPERATIONS CENTRAL
1985

The TAOC-85 modular control equipment (MCE) is a transportable automated air command and control system for controlling and co-ordinating the employment of a full range of air defence weapons, interceptors, and surface-to-air missiles.

The basic system element is the operations module (OM). A single OM housed in a standard 20 ft ANSI ISO shelter, contains all the air command and control equipment with the exception of search radar, IFF and prime power requirements needed to perform the air defence function. Four operator consoles are located in each OM. Each console is fitted with a multicolour display with radar/IFF video, graphics and alpha-numerics, and a monochrome alpha numeric display. Full system functional capability is provided by a single shelter which weighs approximately 4500 kg with all the OM equipment, including signal and power cables, installed for transport.

Operations modules are used at the Marine Corps Tactical Air Operations Center (TAOC) and within the

TAOC using five operations modules

USAF Tactical Air Control System, and provide facilities for:

(1) accepting inputs from search radar and IFF systems
(2) performing automatic track correlation, acquisition, identification, classification, tracking, threat evaluation, and weapon selection, assignment and control
(3) receiving and processing track information, orders, commands and status data received via digital data links from other command and control systems and from controlled weapons systems with digital data link capabilities. These data links are TADIL A, TADIL B, TADIL C (one- and two-way), ATDL-1, NATO LINK 1, MTACCS, and JTIDS
(4) processing inputs from operator consoles for the entry, deletion or modification of stored information and initiating the appropriate action both within the operations module and for transmission external to the OM
(5) displaying, on operator consoles, the real time tactical air situation based on all system inputs, manual and automatic.

The required system capacity of a particular centre is determined by its operational employment. Tailoring a centre to a particular requirement is achieved through the use of one or more operations modules within the TAOC. The present system design permits the interconnection of up to five OMs through the use of fibre optic cables. Cables of 500 metres lengths allow the dispersion of OMs for tactical considerations or because of terrain constraints. Interfacing radars may be located up to 2 km from the OM when connected by fibre optic cables. Radar/OM separation of up to 40 km is achieved through the use of a narrow-band secure radio link.

In addition to the use of wide-band inter-shelter communications via fibre optics, advanced technology is used throughout the system implementation and includes features such as multicolour, touch-entry consoles and a high degree of distributed processing which provides automatic reconfiguration when equipment failures occur. The system is software intensive and can easily be modified to perform additional functions.

STATUS

Under joint development for the US Marine Corps and USAF, the TAOC-85 programme will replace equipment developed under the Marine Tactical Data System (MTDS) programme. MCE will replace equipments developed under the USAF 407L programme. The TAOC-85 equipment was scheduled to be introduced into service in mid-1985 with USAF delivery six months later.

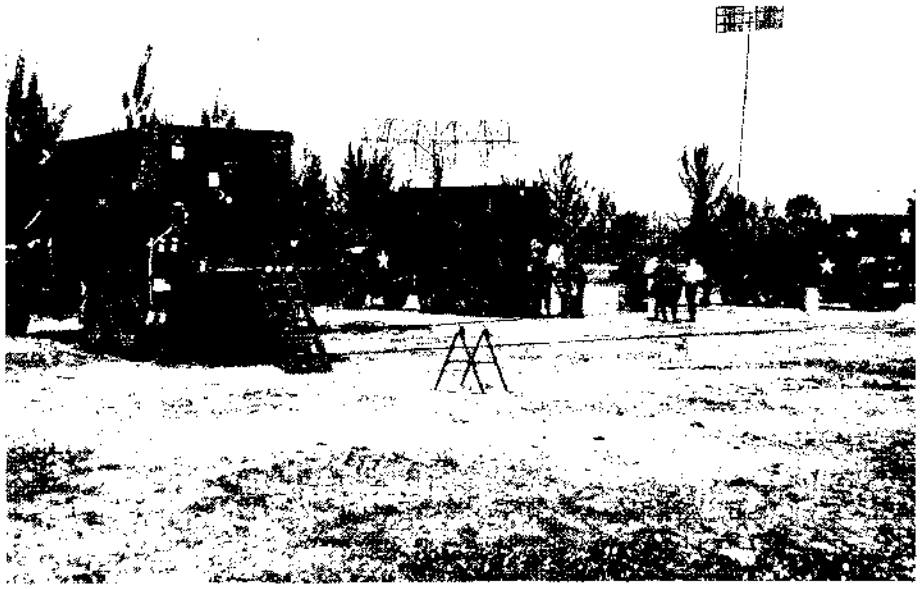
Litton Data Systems, 8000 Woodley Avenue, Van Nuys, California 91409, USA.

2835.181

AN/TSQ-73 AIR DEFENCE MISSILE CONTROL AND CO-ORDINATION SYSTEM



The AN/TSQ-73 is a command and control system for the fire co-ordination of Nike Hercules, Hawk, and improved Hawk missiles. Developed and produced by Litton Data Systems under contract to the US Army, this 'Missile Minder' system incorporates a dual-processor AN/GYK-12 computer tailored to real-time control and co-ordination requirements. Two multipurpose display consoles provide PPI formats for the presentation of radar, track, fire unit, map, and other real-time data. Auxiliary tubular display readouts on the same display surface provide amplifying data on tracks, fire units, operator alerts, and other items. In addition, a light emitting diode (LED) status panel presents fire unit, mission, and system status data.

Radar interface equipment simultaneously and automatically extracts airborne targets from 2-D or 3-D radar and IFF and validates the IFF codes. The integral communications equipment provides for digital communications over missile battery, intra-Army, and TADIL-B data links. Facilities for multiple net voice communications are also provided. Built-in simulation equipment provides realistic training of operators through the simulation of complete air defence scenarios. The AN/TSQ-73 utilises a proven 'repair-by-replacement' maintenance concept consisting of automatic fault detection, semi-automatic fault isolation, and self-contained spares to provide greater system availability and reduced maintenance cost.

In its mobile configuration, the AN/TSQ-73 is housed in a single S-280 type shelter 467 cm long, 203 cm wide and 186 cm high. The system is transportable by cargo aircraft, helicopter, or truck, and is powered by either a 400 Hz diesel generator or a local 50/60 Hz supply.

Processing sensor data provided by a wide variety of currently operational local radars and IFF sets, the two-channel radar interface sub-system automatically detects and acquires the targets sending position reports to the automatic data processor. Special features of the radar interface include an integral IFF beacon decoder and an automatic clutter-mapping function by which extraneous radar returns are removed from consideration as targets.

Each multipurpose console presents situation (PPI) and auxiliary readout (ARO) data on a single cathode ray tube (CRT). Situation information occupies a 37cm diameter circle at the top of the CRT, while auxiliary data is presented in a rectangular area near the bottom. The former includes track symbols position and identification, track number, raid size, height, velocity, extended vectors, and source code. Two area maps selectable from a list of ten, may be displayed simultaneously, with up to three air-defence-safe corridors. Defence weapons status is also presented for total operational control and includes site position, engagement positions, site number, status, commands, and pairing lines. Using computer-generated alpha-numeric data, the ARO presents more detailed track and fire unit information and permits the console operator to edit the displayed data.

AN/TSQ-73 system (left foreground) operating in field test deployment with radar and communications equipment

The arrangement of display console controls optimises operator effectiveness and minimises operator training. Operator entry is made by action switches, a full 36-character alpha-numeric keyboard, and a control stick for entering position co-ordinates.

Much of the AN/TSQ-73 equipment is the same as that used by the US Army's TACFIRE artillery command and control system so that there will be significant savings in training, support, and procurement costs. The general-purpose nature of these systems also makes many of them readily adaptable to other electronic command and control systems. The AN/GYK-12 computer is also used in Tactical Operations System Operable Segment (TOS-OS) and the Tri-Service Tactical Switch (TRI-TAC TTC-39). The general-purpose nature of the display console controls takes full advantage of an alterable processor which can be easily programmed to meet the specific requirements of other applications. Both of these systems are suitable for application to requirements like those of the Air Traffic Management System, control of SHORAD, and SAM-D command and control group.

STATUS

Type classified 'Standard'. In full-scale production for the US Army. Deliveries include systems for numerous other countries. In 1981 a co-production agreement covering the manufacture of 11 AN/TSQ-73 systems for NATO was established. Under this agreement a contract valued at $103 million was awarded to Litton, with co-production in France by Sintra and in Italy by Litton Italia.

CONTRACTOR

ARMY FIRE CONTROL SYSTEMS

2642.181
INTRODUCTION

This section deals with a number of more or less elaborate assemblages of equipment whose functions are primarily concerned with the control of guns or gun-missile combinations for the engagement of surface or airborne targets.

There are some systems described here that are always associated with the same weapon, simply because they have never been used with any other. The section does not include systems designed specifically for use with a particular weapon. In such instances the control arrangement is generally covered in the relevant entry for the complete weapon system.

However, this section does include some items which are not complete fire control systems but are major adjuncts to such systems – a good example being the British AMETS system (**2400.161**).

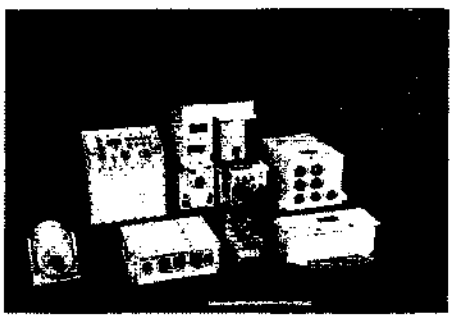
Comprehensive control and reporting and similar systems are dealt with in the section on Land-based Air Defence Systems. The main distinction between systems described in that section and anti-aircraft systems described in this section is essentially one of size; the air defence systems cover sensors and weapons deployed over a wide area extending upwards to sub-continental size; those described below are in general associated with only a few weapons – from a single tank gun to an anti-aircraft battery – although major field artillery systems such as TACFIRE (**2827.161**) and BATES (**2644.161**), while providing a service at battery or regimental level, can cover a wider field.

Readers may find it helpful to consult the companion reference book, *Jane's Military Communications*, which deals with closely related topics to those in the following pages of this section, and *Jane's Armour and Artillery* for additional information on some of the weapons controlled by these systems.

BELGIUM

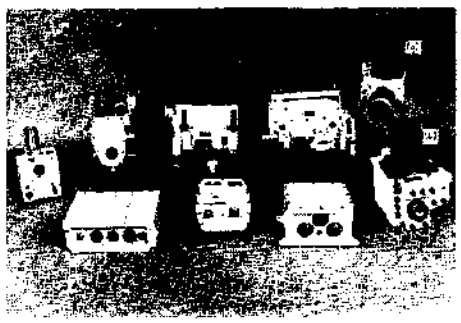
2598.181
SABCA TANK FIRE CONTROL SYSTEMS

SABCA has designed and manufactured over a thousand Laser Tank Fire Control Systems (LTFCS) for Leopard 1, Centurion, Vijayanta, M48, M60 and Belgian JPK tanks.



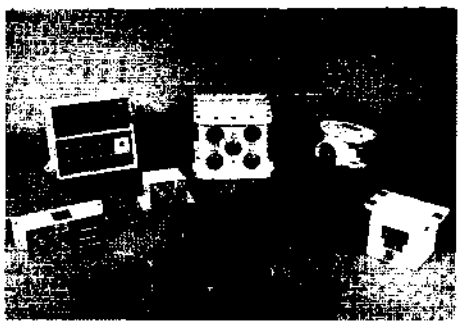
Leopard

The Leopard LTFCS is fully integrated and uses high accuracy computation techniques in the ballistic computer and automatic sensors. The reticle of the laser/optical sight is always centred by a gimballed mirror drive and the laser and optical axes are perfectly aligned.



Centurion/M48/M60

The Centurion LTFCS and M48/M60 LTFCS are basically identical. They consist of two main groups:



(1) an integrated day/night laser sight group including a laser visual unit and a second-generation image intensifier equipment (a) (see illustration) or an all weather day-and-night thermal imaging system (b) (see illustration)

Universal Laser Tank Fire Control System

Integrated day/night laser sight sub-system for Centurion, M48 or M60 MBT

Ballistic computer sub-system for Centurion, M48 or M60

(2) a ballistic computer group including controls and ammunition selection units, automatic or manual corrections for standard and non-standard environmental conditions (see illustration). An extensive built-in-test system controls at all times the performance of the system and identifies faults through line replaceable units, thus doing away with the need for tank level test equipment.

UTFCS

The new Universal Tank Fire Control System is a full solution fire control system designed to meet current threats and operational requirements as well as those of the next decade (see illustration). The system is equipped with a fully stabilised sight (director system). This approach provides a greater scene stability and continuous tracking of targets. It thus provides a full shoot-on-the-move capability and minimum reaction time. The integrated day/night sight is associated to a muzzle reference mirror to compensate gun droop.

The fire control computer, besides ballistic computation, includes interfaces to gun/turret stabilisation system and the sight head electronics; an extensive built-in-test capability; a gunner training mode whereby the gunner can aim and track simulated targets while his performance is monitored permanently.

The major components of the Universal LTFCS are:

(1) an integrated gunner's sight including a stabilised head mirror unit, a laser visual unit and a passive night sight (image intensifier or thermal imager)
(2) a digital micro-computer based on a high performance 16-bit microprocessor
(3) a vertical sensor unit
(4) a gun position sensor
(5) a wind sensor
(6) gunner and commander control units
(7) a muzzle reference unit
(8) a commander's stabilised sight.

CANADA

3937.161
MILIPAC ARTILLERY COMPUTER

The MiliPAC is a portable artillery computer initially designed for the Canadian Department of National Defence to carry out the calculation of firing data for a battery of six guns of 105 mm or 155 mm calibre, as well as a number of related functions such as field and unit survey and fire control.

Since the original development in 1976-79 MiliPAC has been expanded to the battalion level where it is used as a Tactical Fire Control Computer System. This includes the expansion of the data communication capability for the units used at both the battalion and battery Fire Direction Centres and expansion of the capability to receive digital information from the Forward Observers.

The MiliPAC is built as a single unit which is light enough to be carried easily by one man but is meant for installation in a vehicle or other transportable shelter used as the battalion or battery fire control post. The processor used in MiliPAC is the Intel 8086 microprocessor. The memory is a combination of CMOS RAM and EPROM with battery back-up for the RAM memory. The battery can maintain the contents of the RAM for three months with no recharging. The EPROM memory contains all of the program code and is non-volatile. The combination of memory used is 12 K words of CMOS RAM and 128 K words of EPROM, expandable to 448 K words. The light emitting diode display used on the Canadian configuration has the capacity of 8 × 48 character lines and provides input and output data, as well as cue messages to assist the operator. An alternative 512 by 256 dot matrix electro-luminescent (EL) panel has been developed to display the Arabic script. In addition to data entry input from the keyboard, provision is made for teleprinter input and output, and gun display system.

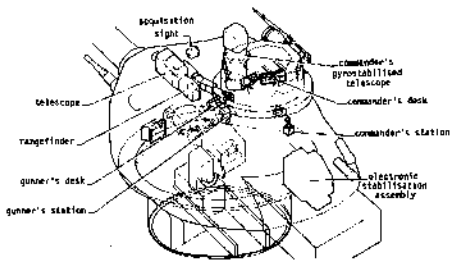
MiliPAC artillery fire direction computer

The standard software package includes routines for calculation of firing data for up to six guns at up to three positions, a combination of 120 target and observer records, each observer being a protected safety zone, an additional five independent safety zones, five fire support lines, five crest clearance zones, two air corridors, minimum firing elevation for each of the firing positions, 12 non-standard muzzle velocities for each gun/projectile combination, 27 lines of meteorological data, ten sets of registration corrections, and ballistic data for four weapons.

CHARACTERISTICS

Computer: Intel 8086 microprocessor
Memory: 12 K words CMOS RAM and 128 K words of EPROM; expandable to 448 K words
Display: 380 character LED (512 × 256 dot matrix EL panel optional)
Weight: 20 kg
Power supply: 20 to 33 V DC or 10 to 16 V DC
Consumption: 50 W

STATUS
Three prototypes were delivered to the Canadian Department of National Defence in 1979 for evaluation and a production order was placed in 1982 for 66 systems. Deliveries against this order started in August 1983 and the system is now in service. Several other countries are studying this system and a major export order for battalion level MiliPAC systems is expected in 1985. Egypt is among the export orders reported.



CONTRACTOR
Computing Devices Company, a Control Data Company, PO Box 8508, Ottawa, Ontario, Canada K1G 3M9.

FRANCE

4147.181
COTAC FCS
Tank fire control systems for French vehicles are produced in several versions forming the COTAC (Conduite de Tir Automatique) family of systems. The principal known examples are outlined in the following paragraphs.

COTAC APX M401
COTAC M401 is the automatic fire control equipment developed for the AMX-10RC tank. It permits daylight engagement of fixed or moving targets. The equipment comprises the APX M504-04 gunner's sight for observation, fire correction data display by M421 optical compensator, laser rangefinding by APX M550 rangefinder, automatic harmonisation of sight and weapon, and emergency firing using a stadiametric ranging scale. Other items are tachometers on both axes; an automatic cant sensor; automatic displays of wind, temperature and altitude; and a computer for calculating fire corrections.

CHARACTERISTICS
Range measurement: 400 – 10 000 m
Target speed measurement: 0 – 25 mils/s (azimuth); 0 – 5 mils/s (elevation)
Cant measurement: +0·2 to –0·2 rad
Crosswind setting: +10 to –10 m/s
Outside temperature range: –15 to +45°C
Altitude setting: 0 – 1500 m
Firing correction computation
Bearing: –30 to +30 mils
Elevation: 0 – 50 mils

Main components of COTAC APX M581

COTAC APX M581
The COTAC APX M581 is an integrated automatic fire control equipment consisting of day/night optical sight units, a laser rangefinder and associated items for installation in the turrets of AMX-30B2 or AMX-32 tanks equipped with 105 mm or 120 mm guns. The sight tube is a 110 mm diameter unit with ×10 magnification, and is equipped to allow harmonisation of the visible and IR beams. There is also an electro-optical unit and computer for fire corrections and aiming calculations. The laser rangefinder is an APX M550.

CHARACTERISTICS
Range measurement: 400 – 10 000 m
Target speed measurement: 0 – 30 mils/s (both planes)
Slant measurement: +200 to –200 mils
Crosswind setting: +10 to –10 m/s
Outside temperature setting: –15 to +45°C
Altitude setting: 0 – 1500 m

STATUS
The APX M401 COTAC has been in series production since 1979 and the APX M581 COTAC since 1981.

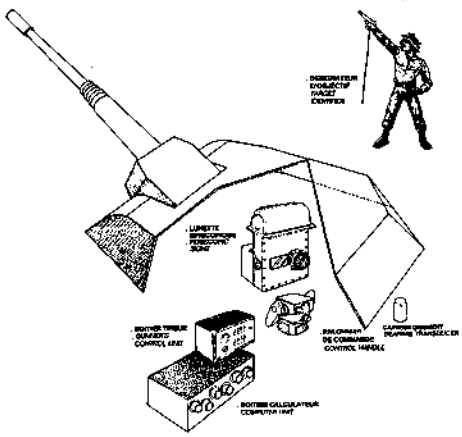
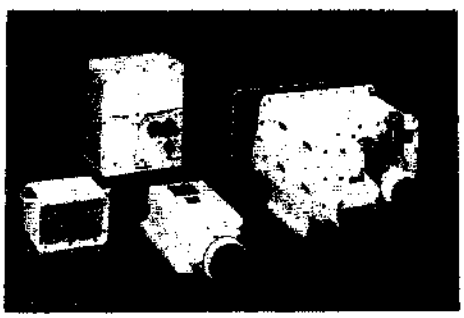
4268.181
SOPTAA FCS.
The SOPTAA anti-aircraft fire control system is designed for the direction of weapons in the defence of ground targets against attack from aircraft or helicopters. The operating principle of the system can be applied to a variety of AA weapons, but the SOPTAA 19 version has been designed for use with vehicle-mounted turrets armed with 20 mm cannons. Operation requires two men: an observer/fire director who detects and designates the target; and a gunner who subsequently tracks it and operates the gun.



The observer is equipped with a designator 'gun', such as the CSEE ELDO (**4248.193**), which automatically calculates the necessary parallax corrections for the distance between observer and weapon, and provides for automatic alignment of the turret onto the target. The turret is provided with a periscopic gunner's sight, derived from the M 371 and with the elevation aiming prism mechanically linked to the gun; an electronic control unit incorporating the computer; and angular transducers or tachogenerators mounted on the cannon. Power is derived from the vehicle's 24 V supply.

The turret sight has a projected aiming graticule, and separate optical channels for ground targets (×6 magnification and 10° field), and for anti-aircraft fire (×1 magnification and a field of 26° vertical × 71° horizontal). The elevation aiming range is from –15 to +55°.

An engagement sequence time of five to six seconds makes it possible to intercept an aircraft designated at 2000 metres at a range of 1000 metres with an accuracy of ±5 mil.



STATUS
Prototypes have been produced.

SOPELEM, 102 rue Chaptal, 92306 Levallois-Perret, France.

Principal elements of SOPTAA anti-aircraft FCS

3979.181
SOPTAC FCS
SOPTAC is a modular range of day/night fire control systems designed for application to AFV gun turrets such as the various 90 mm turrets (by Hispano, SAMM or GIAT) or the FL 12 by Fives-Cail Babcock. The system provides aiming parameters automatically in accordance with the main ballistic parameters: range, three-axis speed of moving targets, ammunition type, meteorological conditions, tank slope, cant angle etc. Various configurations to suit specific turret types have been designed employing different equipment combinations, but mostly based on use of a version of the TJN2 day/night sight (**3754.193**) and the TCV-107 laser rangefinder. The SOPTAC systems applicable to specific turrets are listed below, and main equipment complements and characteristics of each are summarised individually in the paragraphs which follow.

Turret Type	FCS
FL 12 (Five-Cail Babcock)	SOPTAC 18-02, SOPTAC 18-03, SOPTAC 18-04
TS 90 (GIAT)	SOPTAC 10-A, SOPTAC 11-A, SOPTAC 13-A, SOPTAC 21-A, SOPTAC 22-A
Lynx 90 (Hispano-Suiza)	SOPTAC 10-B, SOPTAC 11-B, SOPTAC 13-B, SOPTAC 21-B, SOPTAC 22-B
AR 90 (SAMM) (equivalent to TS 90)	SOPTAC 10-A, SOPTAC 11-A, SOPTAC 13-A

Elements of SOPTAC tank fire control system showing TJN2-90 day/night sight, commander's control unit, computer and CILAS laser rangefinder

The base model for the FL 12 turret is the SOPTAC 18-03 day system comprising the current M213 aiming sight, a module which projects the graticule of the automatic elevation display (with associated electronic unit), a TCV-107 laser rangefinder fitted with a device projecting the sight graticule. A TN_2-i night sight may be added to the system to provide a night sight vision capability.

The SOPTAC 18-03 may be upgraded to the SOPTAC 18-04 version, which permits automatic engagement of moving targets, and slope compensation up to ±10°. A turret rotation sensor is needed for this version.

The SOPTAC 18-02 version is similar to the SOPTAC 18-03, but without the automatic elevation display.

There is a wider range of versions available for the GIAT TS90 turret, offering four day/night models and four day-only types. The SOPTAC 11-A day/night version comprises a TJN2-90-A2 sight fitted with automatic elevation presentation (linked to a TCV-107 laser rangefinder located behind a window in the turret), and with slope compensation and moving target capability. A tacho-generator measures turret rotation, and other data is inserted manually on the commander's control panel. With the TJN2-90-A1 sight and without the slope compensation and target speed measurement facility this system is designated SOPTAC 10-A. The SOPTAC 22-A is a simplified version consisting of the TJN2-90-A sight (without slope compensation, automatic elevation display, or tachometry) and an unlinked TCV-107 laser rangefinder. Day-only SOPTAC systems for the TS 90 turret are the SOPTAC 13-A, SOPTAC 06-A, and SOPTAC 21-A which correspond to the SOPTAC 11-A, 10-A and 22-A except that the sights incorporated are the daylight equipment M563-A2 (with automatic elevation presentation, slope

compensation and tachometry), M563-A1 (with automatic elevation only), or the APX M563 with manual elevation control.

There are four day/night and four day-only SOPTAC versions for the Hispano-Suiza Lynx 90 turret also. The most comprehensive day/night model is the SOPTAC 11-B which comprises a TJN2-90-B2 sight, a TCV-107 laser rangefinder mounted on the gunshield, and in other respects very similar to the SOPTAC 11-A for the TS 90 turret. By replacing the TJN2-90-B2 sight with the TJN-90-B1, which does not have slope compensation or tachometry facilities, the SOPTAC 10-B fire control system is produced. A simplified version is the SOPTAC 22-B which incorporates the TJN-90-B sight and does not include linking of the TCV-107 laser rangefinder. Day-only equivalents of the SOPTAC 11-B, 10-B and 22-B models are available as the SOPTAC 13-B, 06-B and 21-B versions, in which the M198/1-A2, M198/1-A1 or APX M198/1 day sights are substituted for the day/night sights.

SOPTAC 36

The latest version of the SOPTAC series of FCS is the SOPTAC 36 which is a universal day/night periscopic system designed for incorporation in all types of AFV. Like the similar SOPTAC 11, it is a modular system.

The main elements are:

(1) sight module with a third-generation light intensifier tube with day magnification of ×8 (night ×8) and a day field of 7° (night 6°)
(2) an eyepiece arm adaptable to different turret configurations
(3) laser rangefinder, TCV 186, derived from the TCV 107
(4) fire control mobile graticule giving a set of projected graticules with automatic elevation selection and lateral deviation with deflection correction
(5) electronic units used to control the graticules on acquisition of target range, speed, vehicle deflection, atmospheric temperature and pressure, crosswind, ammunition type
(6) automatic muzzle reference module.

STATUS

The SOPTAC II system is in production. Prototypes of the SOPTAC 18 and SOPTAC 36 models have been built.

CONTRACTOR

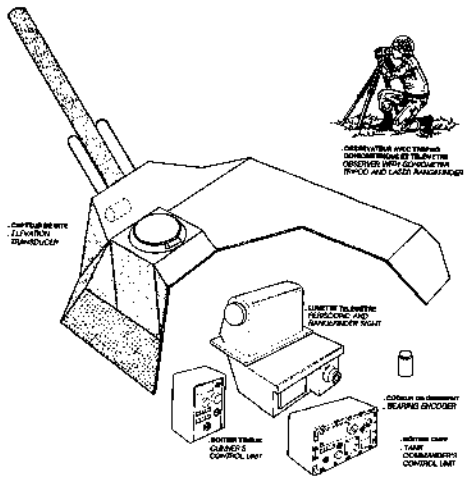
4267.181

SOPTAM FCS

SOPTAM fire control systems have been designed for the operation of mortars from armoured fighting vehicles. Two versions of the system have been identified; the SOPTAM 30 intended for use with turrets equipped with the French DE 81 mm mortar, and the SOPTAM 26 for the Hispano-Suiza Serval mortar turret.

SOPTAM 26

This system is for the operation of mortars from vehicles operating on sloping ground, and the gunner can make the appropriate corrections to bearing aim, resulting from the attitude of the vehicle, according to the horizontal. The system comprises: the Type M 447-03 sight (derived from the APX M371); an electronics unit measuring 212 × 58 × 250 mm and weighing 2·5 kg; an inclinometer weighing 1 kg; and a 24 V power supply. Its performance characteristics are tabulated below:



CHARACTERISTICS

Elevation angle measurement: Up to 70°
Accuracy: 0·8 mil
Deflection and slope correction: Up to 10°
Max error in bearing correction: 5 mil for a level angle of 1100 mils

SOPTAM 30

This was designed for incorporation in lightweight turrets equipped with the DE 81 mortar, and it provides the following functions:

(1) storage of mortar elevation tables

Layout of major components of SOPTAM mortar FCS

(2) turret attitude correction
(3) acquisition of aiming corrections between rounds
(4) acquisition of data from a remote observer (high-angle trajectory indirect firing), for the various alternative firing configurations (flat or high-angle trajectory, direct or indirect fire).

The system comprises: a monocular periscopic observation sight with a slaved head prism; TPV 89 binocular rangefinder, integrated in the sight and providing a laser rangefinder function, and the binocular sight channel also being used for aiming; the gunner's electronic control unit; tank commander's control unit incorporating the computer; all these being powered from the vehicle's 24 V supply.

CHARACTERISTICS

Observation sight
Magnification: ×1
Instantaneous field: 10° (vertical) × 17° (horizontal)
Total field: 26° (vertical) × 60° (horizontal), with displacement of both eyes
Elevation aiming range: -15 to +45°
Mortar/sight servo accuracy: ±0·3 mil
Rangefinder/aiming sight
Magnification: ×6
Field of view: 7°
Laser wavelength: 1·06 micron
Measurement field: 15° at 9990 m, accuracy ±5 m
Max calculation time: <3 s
System accuracy: ±0·3 mil (flat trajectory modes); ±1 mil (other modes)

STATUS

The SOPTAM 26 has been produced in small batches and prototypes have been manufactured of the SOPTAM 30 system.

CONTRACTOR

SOPELEM, 102 rue Chaptal, 92306 Levallois-Perret, France.

APX M586 TANK FCS UPDATE

The APX M586 is a tank fire control improvement equipment intended for the updating of earlier MBTs such as the M48, AMX-13 etc. The equipment comprises an external unit positioned in front of the original firing sight tube, and a control console for use by the tank commander. There is also a TCV-107 laser rangefinder and an electro-inertial sensor unit which contains all the necessary elements for parameter measurement and fire correction calculations.

By the addition of Thomson-CSF Canasta low light-level television equipment a complete day/night capability can be obtained.

CHARACTERISTICS

Range measurement: 300 - 10 000 m
Target speed measurement: 0 - 30 mil/s (both planes)
Cant measurement: +200 to -200 mils
Crosswind setting: ±10 m/s
Altitude setting: 0 - 2000 m
Automatic setting of firing corrections: ±30 mils (azimuth); 0 - 60 mils (elevation)

The afocal module is adaptable to the gunner's sight of T 54, T 55, T 59 battle tanks and is fitted at the forepart of the daylight aiming sight. It enables both daylight and night aiming without any mechanical modification on the turret. Night aiming is performed by using a second-generation micro-channel light intensifier tube whereas daylight aiming requires the retraction of a swivel mirror. The module is housed in a sealed water-tight casing and can be removed and reset without having to be boresighted again.

CHARACTERISTICS

Magnification: ×1
Field: ≥70°
Resolution: >0·5 mrad at 10^{-1} lux
Operating temperature: -40 to +50° C
Performance
Daylight aiming: unchanged
Night aiming: 1000 to 2000 m according to atmospheric conditions

The afocal module incorporates an optical plate for combining the images from the visible light and infra-red beams, a deviation display collimator and a laser rangefinder.

STATUS

Prototype.

CAC 101 FIELD ARTILLERY COMPUTER

The Thomson Brandt Armements CAC 101 field artillery computer was designed principally for the preparation of firing data for 105 mm and 155 mm guns and howitzers and for heavy mortars. The main operational characteristics of the CAC 101 include storage in the computer memory of six gun positions, 10 targets, 10 observation posts, and 10 protected areas in addition to meteorological data (standard STANAG 4082 message up to line 21). Protected memories are provided. Ballistic data are carried on plug-in modules, each module carrying the data relating to one type of projectile and the weapon firing it. Using this information, the computer calculates the firing data for the main reference piece as well as the subordinate pieces. A built-in test program carries out self-checking of the system.

Data are entered into the computer by means of a keyboard in accordance with the dialogue between the machine and the operator, assisted by an alpha-numeric display panel. In addition to the standard computational routines, there are possibilities for optional calculations, such as the ballistic co-ordinates of a given round during fire adjustment, computation of the residual correction at the end of a registration, and calculation of the correction for muzzle velocity. Others are topographical

Thomson Brandt Armements CAC 101 field artillery computer

computations such as conversion of rectangular co-ordinates to polar co-ordinates and vice versa, direct and inverse bearings, direct and inverse intersections, triangulations, change of grid system, or goniometric network.

Various peripheral equipments may be connected to the computer, including a teleprinter, telex reader, remote data display etc. The CAC 101 can be rapidly changed from one weapon type to another by the simple expedient of exchanging the plug-in ballistic module.

CHARACTERISTICS
Dimensions: 370 × 355 × 313 mm
Weight: 15 kg
Power supply: 19 - 32 V DC (24 V nominal)
Consumption: 60 W

STATUS
Series production. Believed to have been supplied for export.

ATAC ARTILLERY COMPUTER

A field artillery firing aid (ATAC) is under development by Thomson Brandt Armements, and is expected to be available for delivery in 1985. The system comprises a small hand-held digital computer and an optional console. The computer will perform all calculations for the firing operations of mortars, howitzers and cannon, and is particularly designed for use in autonomous operations where centralised control facilities are not available.

When the lightweight computer unit is fitted to the console, it becomes a system capable of integration into an automated artillery network. The ATAC system can be adapted to any particular weapon (and ammunition type) in the above categories by means of appropriate plug-in modules. Each of these modules carries eight ballistics. The computer has a semi-permanent data memory that can store nine gun positions, 99 target locations, 20 observer locations, ten datum positions, safety data, meteorological information (sounding data Stanag. 4082) and prevailing conditions, and other data such as powder temperature and muzzle velocity.

The main functions performed include firing preparation using the arc method, fire control, fire for effect, special firing missions (eg moving targets), and survey. ATAC can be linked to other ATAC computers by cable or radio links, as can the gun remote data display equipment and observers' terminals. Built-in test facilities are incorporated.

CHARACTERISTICS
Dimensions: 230 × 165 × 85 mm (with batteries)
Weight: 3 kg (approx) with batteries
Display: LCD 160-character screen
Power supply: 24 V DC
Endurance: 1 week normal use
Environmental: Military -25 to +55° C

ATAC portable field artillery computer

STATUS
Development.

Thomson Brandt Armements, 52 avenue des Champs-Elysées, 75008 Paris, France.

3187.161
SIROCCO METEOROLOGICAL RADAR STATION (QR-MX-2)

The Sirocco system comprises an I-band tracking radar for tracking meteorological sounding balloons, and associated telemetry system, processing equipment, and provisions for the transmission of meteorological data for use by artillery units. The last of these may or may not be equipped with an Atila computing system (**3188.161**).

The complete system is built as a self-contained land-mobile unit, the tracking radar being mounted on a two-wheeled trailer, and an air conditioned SH 17 shelter is carried on the towing vehicle. The latter houses the operating crew, the radar and telemetry operating console, a radio-telegraphy system with built-in modem, and stowage for the sondes and radar reflectors. In addition to the radar, the trailer carries the telemetry receiver and two electric generators.

The Sirocco system produces standard met messages, on-line, for transmission by teleprinter or via a radio-telegraphy link for use by artillery units. The messages provide wind speed and direction, and air temperatures at a series of standard altitudes. Maximum range is in excess of 130 km and angular accuracy is better than 0·05° SD. Range can be measured to within 5 m and windspeed can be determined with an accuracy of better than one knot (0·5 m/s).

Sirocco mobile meteorological station deployed

CHARACTERISTICS
Radar: I-band
Peak power: 80 kW
Receiver: 2-axis monopulse
Ranging: Digital in 5 m increments
Angular tracking limits: -8 to +160° elevation; unlimited azimuth
Max range: >130 km
Angular accuracy: Better than 1 mil
Range accuracy: Better than 5 m
Windspeed accuracy: Better than 1 knot (0·5 m/s)

STATUS
In series production and ordered for French and foreign forces.

CONTRACTOR
Electronique Serge Dassault, 55 quai Carnot, 92214 Saint-Cloud, France.

3934.161
ATIBA ARTILLERY FIRE CONTROL SYSTEM

The ATIBA system has been derived from the French Atila (**3188.161**) artillery automation system and is designed to provide fire calculations for artillery units at battery level. However there are provisions for integrating ATIBA systems into a larger overall system such as Atila when appropriate and if required.

The ATIBA artillery fire control system provides for control of a battery of up to eight guns of any calibre, performs firing calculations for each gun using data provided by up to ten observation posts, ballistic data for any calibre, charge, shell and fuze, and standard STANAG 4061 meteorological message inputs. Trajectory calculation time is less than five seconds for six guns. The system also performs related functions such as survey calculations and mobile target engagement.

The equipment consists of the central processor and control unit which can be fitted in any type of vehicle, such as a Jeep or truck, a number (up to eight) of gun display units (GDUs) located at each gun position, and a 1200 baud radio link (wire or radio) connecting the central battery unit to the GDUs and observer positions. The observer posts are equipped with radio sets and modems permitting the exchange of data in digital form. The battery unit and the GDUs are provided with display panels for the presentation of firing data, command orders and other relevant data. At the central battery unit these facilities extend to man/machine interface facilities such as a plasma display screen, keyboard and printer. The plasma display screen capacity is 256 characters.

The central processor is based on CIMSA military computers and it performs the following functions:

(1) calculation of the firing data for each gun
(2) determination of the charge with respect to the battery target-range
(3) processing of any targets, including point and linear targets, in regard to the best distribution of rounds on the target, and the number of rounds per type of shell required

CIMSA gun display unit (GDU) is used at individual gun positions in ATIBA and ATILA artillery automation systems

(4) possible mixes of ammunition types to achieve engagement objectives
(5) fire adjustment
(6) determination of registration firing corrections for each charge
(7) dividing the battery into two sections to engage two different targets.

All the programs needed for the various survey functions exist in the standard software package.

The input data at the battery unit is aided by grids displayed on the screen which list the parameters required appropriate to the function selected. A check is made to indicate to the operator any errors he may have made. By means of the keyboard he is able to insert meteorological data, ballistic data, logistic information, gun co-ordinates, observer and target co-ordinates. Fire requests are entered in a similar fashion. Computed firing data is transmitted to individual guns where the GDUs present data on type of shell and fuze, number of rounds, the charge, bearing(s), elevation(s), fuze time, and triggering mode. Status of guns is returned to the battery unit over the same data link.

A group of ATIBAs can be combined to form one regiment or division Atila without modification other than the addition of a fire co-ordination centre. The latter facility enables the following additional functions to be performed:
(1) centralisation of fire requests at a higher level (regiment or division)
(2) evaluation of the tactical situation and the threat
(3) management of six ATIBA systems from a single co-ordination centre
(4) division of targets among batteries to achieve better concentration of fire on a given target
(5) improved management of ammunition.

STATUS

Adopted by the French Army and in service in six countries. Series production had started by the latter part of 1982.

CONTRACTOR

CIMSA - Compagnie d'Informatique Militaire Spatiale et Aéronautique, 10-12 avenue de l'Europe, 78140 Vélizy, France.

3188.161
ATILA ARTILLERY AUTOMATION SYSTEM

The Atila (artillery automation) system is a data processing system designed to fulfil three major operational requirements of artillery regiments:
(1) computing: this is concerned with the rapid and automatic calculation of ballistic data taking into account such parameters as topography, meteorological conditions, sizes and locations of targets, and locations of gun batteries
(2) transmission: the communication of calls for fire by individual forward observers to the command post, and the transmission of firing data to guns is performed by the system. Automatic inter-command post links provide for the mutual exchange of information
