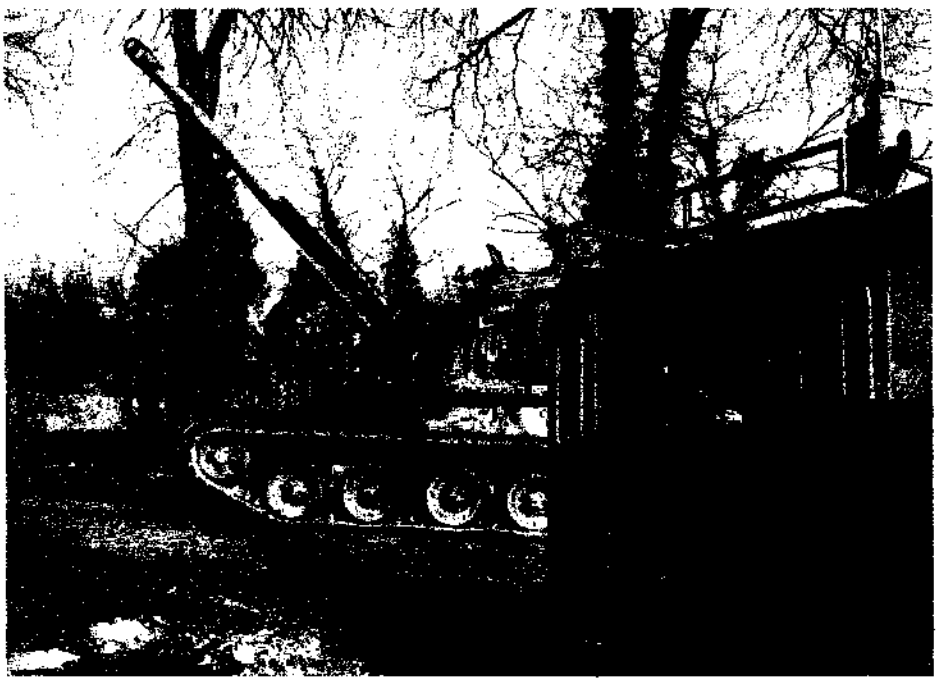
(3) management: decision making is speeded and enhanced by storage of the tactical situation in the computer memory, and by virtue of the facilities provided for man/machine dialogue.

To meet the needs of different organisational structures, ie from the autonomous battery to the artillery group which combines the fire from 18 batteries, CIMSA has organised automation of these units around two types of vehicle both of which are based on the AMX-10 in the French Army system;
(1) fire centre vehicle (fire control post) containing the computer which essentially executes fire calculation functions: this is a technical centre. (AMX-10 PCH SAF)
(2) a command vehicle for the relevant fire unit commander (battery commander, regiment commander, or the group commander): this is a tactical centre. (AMX-10 PCH SAL).



The following elements are linked to these two vehicles:
(A) artillery observers who have artillery tactical terminals (ATT) to send their message coded for fire requests, fire adjustments, intelligence messages. This information is automatically sent to the fire centre vehicle via radio link
(B) the guns receive the fire centre computer-generated fire data on a remote display unit.

Automatic digital data links ensure the reliable and rapid exchange of data between these various elements of the system, using modems and standard radio sets.

If regimental organisation is prevailing, the equipments for a standard regiment are:
(A) 1 Regimental FDC computer
(B) 3 Battery FDC computers

ATILA system battalion fire direction centre computer

ATILA system chain of command extends to individual batteries or guns. Fire direction centre vehicle (right) seen with GCT-155 SP howitzer

(C) 9 Artillery Tactical Terminals (ATT)
(D) 18 Gun Display Units (GDU)

The regimental FDC computer is intended to provide maximum responsiveness for the employment of fire power. It, selects the targets to be attacked; monitors up to six batteries' FDC's; achieves fire planning and allocates fire units and ammunitions; provides tactical information; and deals with any type of target.

The battery FDC is intended to provide: rapid and accurate computation of firing data; secure transmission of fire commands; reception of fire request from the observers or the regimental FDC.

The Artillery Tactical Terminal increases the execution task of the fire mission thanks to a simple and accurate description of the fire request, and conducts fire, thanks to an efficient and complete dialogue with the regimental and/or battery FDC.

The Gun Display Unit is intended to display for the gun section chief all the firing data elaborated by the computer and to send back the gun status.

CHARACTERISTICS

Organisation: Battery - Regiment (3 to 6 batteries) - Group (3 to 6 regiments)

System capacity at regiment level is as follows:

Observers: Up to 36 positions
Recorded targets: 500
Recorded fire plans: 4
Safety zones: 40
Muzzle velocity: 540
Registration points: 20
System reaction time
Transmission of one message: 1s
Battery reaction time: 15s
Regiment reaction time: 35s

Slightly different versions of Atila have been designed for two Middle Eastern customers, variations between these and Atila I include differing organisational structures and the data processors employed at regimental and battery levels. Also offered for export is another developed version known as Atila II.

ATILA II:

In the latter half of 1983 CIMSA revealed a new version of the Atila system configured for use with different artillery organisational structures to those of the original system. Atila II incorporates certain design improvements made possible by experience with operation of Atila I and embodies CABA 11 and CABA 21 processors at battery and command posts, but the basic objectives of both systems are essentially the same.

STATUS

In series production and serving in six countries.

Issue of Atila hardware to French Army artillery units began in 1980. By early 1985, 10 of the 16 French artillery regiments due to equip with Atila were reported to have the system, and the remaining six are expected to receive their equipment by the end of 1986. Work is in progress on a later version which will be known as Atila II.

A version of Atila has been sold to Saudi Arabia for direction of French-built GCT-155 self-propelled guns, and the designation of this export version is Palmier. Exports of the system are reported to amount to about 30 systems sold to two Middle Eastern countries and one South American state.

COMBAT MONITORING SYSTEM

The Combat Monitoring System (CMS) is designed as a tactical command system for target acquisition and identification, threat analysis and target assignment in battlefield combat situations. The equipment can be divided into two functional packages, the weapon system data acquisition unit (WSDA) and the central control and command station (CCS). The data input and output to each participating fire unit is made via a WSDA. These are integrated in each fire unit. The weapon carriers attached to the CMS are monitored and controlled by a central station. This may be installed in a shelter, standard cabin or any armoured vehicle.

The system can be used to monitor or control weapons on the ground or in the air. Data relevant to combat action is transmitted from each weapon system either by FM radio or by cable link, to a central control. After the threat is analysed and the target interrogated by IFF, a target assignment is given to the appropriate weapon system. The tactical situation is presented to the command controller on a colour display unit. A printout of the action is available for analysis.

The CMS can be operated as a tactical training system. Alternatively, it can be used as a range instrumentation system for assessing weapon systems.

4144.161
HEROS COMPUTER-ASSISTED COMMAND SYSTEM

Studies were initiated in the late 1970s by the Federal German Army into the development of a computer-based command, control and information system, known from its German title (Heeres-Fuhrungs-informationssystem fur die Rechnergestutzte Operationsfuhrung in Staben) as HEROS. Background and some details of the system appeared under the above entry number in the 1982-83 edition of *Jane's Weapon Systems*. The following paragraphs summarise information obtained since then.

HEROS is intended to integrate all primary and special staff areas with the German Army. It is designed to:

(1) support army operations
(2) enhance command and control of own forces and deployment of joint reconnaissance systems
(3) provide a fast flow of information to the Joint Staff, to air force and navy staffs, as well as to NATO and Allied Headquarters.

The planned implementation of the programme envisages the following phased system evolution:

Mobile Systems:

(1) HEROS-2/1 Corps, Division and Brigade Staffs
(2) HEROS-4 Home Defence Brigades

Static Systems:

(1) HEROS-3 Army Staff/Army HQ
(2) HEROS-5 Territorial Army Staffs/Traffic Routing
(3) HEROS-6 Additional tasks in case of crisis, tension and mobilisation
(4) HEROS-7 Additional peacetime tasks.

Currently two of the above versions are under development, a testbed version of HEROS-2/1 designated HEROS-2/1-X, and the first phase of HEROS-3 which is known as HEROS-3-1. Brief descriptions of each version follow.

HEROS-2/1-X

This provides for operational testing by the German Army with the following objectives:

(1) test and validation of operational requirements for the final system to support operational command in corps, division and brigade command posts
(2) checking of critical technical elements such as data communications and program-controlled display of tactical situation
(3) collection of decision criteria regarding the lowest data entry level (brigade or battalion)
(4) test facilities for military peripheral equipment or comparable experimental models.

Software was developed initially on a large computer to implement all functions of the system and was then transferred to mini-computers of the testbed system. This comprises the following command post cells at division and brigade level:

(1) Information Cell
(2) Tactical Operations Cell (G2/G3 and S2/G3, respectively)
(3) Support Cell (artillery).

Facilities are provided for simulation of other staff areas of main command posts. Each command post cell is equipped with a computer, disc storage, two alpha-numeric consoles, printer, the command post network interface, and communications equipment. Other hardware and facilities are: a plotter for three-colour hard-copies on paper or foil and interfaces for AutoKo and combat net radio in the Information Cell; a two-colour graphic display unit with laser projection onto maps (1 m × 1 m) in the Tactical Operations Cell G2/G3 (division level); and a graphic plasma display unit with slide projection of maps in the Tactical Operations Cell S2/G3 (brigade level). The battalion level command posts are equipped with input/output devices interconnected with the brigade command post via combat net radio.

Information exchanged between command posts is encrypted and formatted according to NATO standards so that interoperability with other national or NATO systems is possible. During 1983 West Germany and the USA completed a memorandum of understanding to the effect that HEROS and the US Army command and control system SIGMA should be interoperable, and bilateral working groups have been established to implement this agreement. The first task of the SIGMA/HEROS working groups is to develop the necessary interface equipment and procedures, and later to demonstrate interoperability in technical and tactical tests.

As now configured, HEROS-2/1-X provides these functions:

(1) editing of formatted and free text messages
(2) redundant storage of information in a data base
(3) display of command and control information as maps and tabular data
(4) system control
(5) command post internal and external communications.

HEROS-3-1

This represents the first phase of development of the principal static version of the HEROS system and it was decided to gain practical experience by operational use of this evolutionary version in Wintex/Cimex 81 NATO exercise for staff. Feasibility had been demonstrated during Wintex/Cimex 79 with a testbed system.

The hardware configuration consists of a central computer and input/output devices capable of direct dialogue intercommunication via data transmission facilities. The central computer complex (DVA HEROS-3-1) is based on a Siemens 7541 machine together with approoriate storage devices (such as discs or drum memories) and central input/output devices. Separate work stations remote from the Army Staff HQ are equipped with data displays with hard copy and/or punched tape input/output devices, and these are interconnected by a secure data link.

For the graphic display of the situation at the main operations centre, staff are provided with a large-screen (3 m × 3 m, or 2 m × 2 m) four-colour BM 8501 display. Selected parts of the map are projected from a diapositive/slide onto the screen, while tactical information is positioned there directly by the processing system itself. The displayed tactical information can be plotted by an operator as a hard copy either on paper or on foil. The large-screen display and plotter are both linked to a control computer (PDP 11/34) which is connected with the central DVA HEROS-3-1 processor by data link.

For analysis by means of tabular information, there are operator positions with displays having a capacity of 24 lines of 80 characters each, and each display is combined with a printer that can print the screen information as a hard copy. Input/output of messages on paper tape takes place at the Staff centre, in the information centre, the army intelligence centre, and at the corps/territorial commands/divisions by intelligent terminals. These terminals are combined with tape reader/punch units and the hard copy devices.

The HEROS-3-1 central computer complex is based on a Siemens 7541 machine which employs the BS 2000 time-sharing operating system. The BS 2000 supports the time-sharing mode as well as local and remote batch processing, so there is a uniform command language for all classes of operation. The software of the Siemens 9687 data transmission pre-processor performs all tasks such as transmission procedures, and information processing.

Peripheral hardware consists of seven disc sets with a total storage capacity of 882 Mbyte, four magnetic tape units with a speed of 780 Kbyte a second, a high-speed printer, a central console with control screen, keyboard and printer, and the Siemens 9687 data transmission pre-processor which is linked to the distributed peripheral equipment.

The last hardware category comprises the large-screen display and the plotter which are controlled by a PDP 11/34 mini-computer connected to the central processor by a data link, and three PDP 11/03 micro-processors for the processing of data transmission, control of the plotter and of the large-screen display. The PDP 11/34 operates with the RSX 11M (multi-user) real-time operating system, and the PDP 11/03s use the RSX 11S (single-user) operating system. Other distributed hardware consists of two disc units with a total capacity of five Mbyte, a display and a printer connected to the PDP 11/34 and a number of Siemens 8160 displays with report printers as alpha-numeric terminals, Siemens 6610 intelligent terminals with printers and paper tape input/output facilities.

The system manages and supervises a supply file which contains all unchecked input information; a message file containing all formally checked information; the situation file which contains all information checked as far as format and content are concerned; a symbol file with all information available for the graphic display; and a symbol file containing all tactical symbols currently being displayed on the large-screen display.

STATUS

Development of both HEROS-2/1-X and HEROS-3-1 is continuing, with Siemens AG as the main contractor, together with GFS-MIDAS and INFODAS.

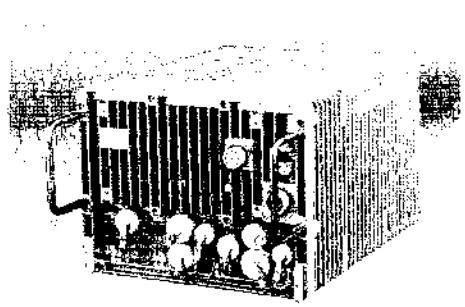
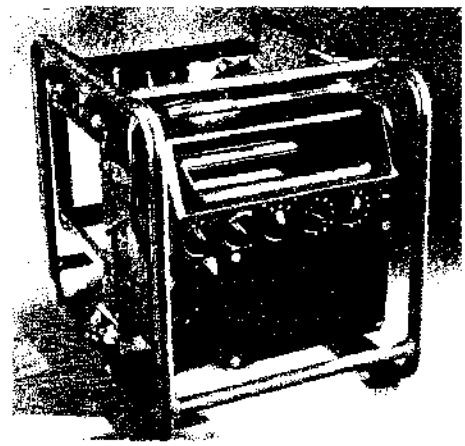
1626.161
FALKE ARTILLERY COMPUTER SYSTEM

Falke is a computerised artillery fire direction system for use at battalion or battery level. The system was developed by AEG-Telefunken for the Federal German Ministry of Defence in close co-operation with the military user. The result of this co-operation is a system which meets the present and most of the future military requirements.



The central unit of the Falke system is the universal military computer AEG 80-20 MARS. This computer is fully militarised, especially designed for mobile operation under rough operating conditions and available in three versions, differing in computing power and memory capacity. It can be run on a 24 V DC power supply. The word length is 16 bits and the maximum main memory capacity is 1 Mbyte. Many standard sed interfaces for different military

peripherals are provided. Special peripherals include a hermetically sealed magnetic tape cassette unit (PLG 38) for program loading (soon to be replaced by a magnetic bubble cassette unit) and a data display and transmission unit (radio and wire transmission) for use by the fire direction officer, the forward observers and as gun display (OAZ 794).



The application programs are: fire direction for various calibres; simultaneous fire control for different firing units; surveying and reconnaissance procedures; and evaluation of meteorological data.

For operating the computer a flexible dialogue principle is used. This means that the computer itself calls for all necessary input data and performs various plausibility checks. Thus the operation of the Falke system is very easy to learn and to execute. Furthermore, since operation is fully programmable, all specific requirements and procedures can easily be realised.

For the acquisition of meteorological data, a fully mobile and militarised meteorological system, based on a 120 km balloon tracking radar, a one-, two- or three-channel radiosonde system and a computerised evaluation system, is available. Radar, radiosonde system and evaluation system (also using the military computer AEG 80-20 MARS) together are installed in a single standard two-wheel trailer, so avoiding any external connections.

Military computer AEG 80-20 MARS

Display and transmission unit OAZ 794

STATUS

The Falke system is in production and systems have been delivered to the German Bundeswehr in quantity, as well as to different customers abroad.

AEG-Telefunken, Anlagentechnik, Geschäftsbereich Hochfrequenztechnik, Postfach 1730, 7900 Ulm, Federal Republic of Germany.

4829.181

ARMY COMMAND AND CONTROL SYSTEM PROGRAMMES (FRG)

The German Federal Government has embarked on a comprehensive improvement plan for the Army's command and control facilities. This involves several distinct development programmes for new systems to replace or complement existing C^2 systems. The major examples of such programmes are briefly summarised in the following paragraphs:

ADLER

Between 1985 and 1988 a new artillery C^2 system known as Artillerie-daten-lage und Einsatz-Rechnerverbund (ADLER) is planned for introduction, and this will provide for the rapid collection and dissemination of recce/target information between regimental HQs and individual batteries via data link. The objective is to facilitate immediate transfer of information, fire orders, reports etc. to ensure optimum fire concentration with minimum reaction time and expenditure of ammunition.

MR80/20 computers with RDS-80 disc memories will be employed, and other equipment includes: DEA-64 data I/O units and SEM 80/90 radios by SEL, the PLG-39 program loader from ATM Computer, and MT-120 commercial teleprinters from Mannesmann/Tally. The computer (MR80/20) has been selected as the standard machine for German Army C^2 systems. A main contractor for the ADLER system has yet to be nominated.

ARES

Dornier is developing a new fire control system for use with the multiple launch rocket system (MLRS) (**4060.111**) when this is deployed by the German Army, and it will perform the same function for the 110 mm LARS, light artillery rocket system (**5577.111**). The Artillerie-Raketen-Einsatz-System (ARES) functions will include:

(1) battlefield surveillance
(2) target identification and location
(3) calculation of fire data
(4) production of fire orders
(5) launcher site survey at battery level
(6) data communications management.

ARES will be compatible with the ADLER network (above), and with allied NATO forces operating with MLRS.

IFAB

Thyssen-Henschel, as main contractor, has developed an integrated fire control system for artillery batteries (Integrierte Feuerleitmittel fur Artillerie - IFAB) to fulfil similar functions for tubed artillery as does ARES for rocket batteries. The principal sub-contractor for the electronics is ESG, with ATM Computer supplying VDUs and SEL input/output devices.

3797.161

LEMSTAR TANK FIRE CONTROL SYSTEM

The LEMSTAR integrated fire control system has been designed to meet the demand for a fire capability on the move. The basic concept and the philosophy of LEMSTAR is equivalent to the fire control systems of the latest Western tanks, for instance the German Leopard 2 and the American XM1. Most of the system components of LEMSTAR are field proven hardware and already produced in series for various tank applications.

The original intention in proposing the LEMSTAR was not only to equip the West German tank Leopard 1, it was also the intention to make it available for various retro-fitting programmes of, for example, the M48, M60, Centurion etc. Firing on the move will be possible by means of a primarily stabilised gunner's sight with integrated laser rangefinder, a ballistic computer, and a slaved main weapon. In order to meet fully these requirements even on the move, the system comprises the following main components:

(1) combined laser rangefinder aiming sight, primarily stabilised (LV/2 Stab or RZG Stab)
(2) standard fire control computer (FLER-H or FLER-M)
(3) weapon stabilisation system which is slaved to the primarily stabilised gunner's sight
(4) position data transmission between sight and weapon by synchros of high accuracy.

A simple block diagram is shown in the diagram. The most essential asset of the system philosophy is the combination of a primarily stabilised line of sight (LOS) with the slaved weapon. This is an essential prerequisite for achieving high overall performance. Further, this is the most important feature, which is claimed to distinguish LEMSTAR from other fire control systems for tanks.

By use of a primarily stabilised gunner's sight with an integrated laser rangefinder, the aiming and tracking of the target is more precise, even on the move. The stabilisation accuracy of the LOS is essentially higher against that of the gun due to the lower mass, the smaller size and mechanical tolerances of the sight. In order to achieve highest hit probability, the computer receives various inputs by special sensors such as air pressure, air temperature, crosswind, powder temperature, and cant angle; further input signals are: gunwear, jump and droop, target range, vehicle velocity, target angular velocity, terrain slope, ammunition selection, and turret position.

All these inputs are automatically processed for computing the super-elevation and lead angle which are affecting (again automatically and directly) the gun without influencing the LOS. This means that the gunner keeps the LOS continuously on the target. The gun will be kept in the exact fire position via the synchro chain. After pushing the fire button firing will be released when coincidence between LOS and gun bore sight occurs. Because of the high coincidence frequency, the time gap is very low.

Thus, a high first round hit probability, even on the move and against moving targets is achieved. The functions described above belong to the gunner. The tasks of the commander depend on the tactical requirements of the user. Therefore, the possible equipment starts with a simple panoramic periscope up to a primarily stabilised one which is able to take similar functions as the proposed gunner's sight. If night fighting capability is required, AEG-Telefunken recommends the LLL-TV night sight type PZB 200. This is a rugged proven unit for gunshield mounting with separate monitors for gunner and commander. Both sights can be easily incorporated into the LEMSTAR system.

The stabilised rangefinder aiming sight (**3580.193**) serves the gunner as his main sight for observation, aiming and tracking, and ranging the target. It contains the optical periscope with two magnification steps, the integrated Nd-glass laser rangefinder and the stabilisation equipment. The moving range of the stabilised LOS is ±4° in azimuth and in elevation in accordance with the main weapon allowing for the correction angle of super-elevation. The three optical paths, laser-transmitter, low power and high power sight channel combined with laser receiver are deflected by one common mirror, which is fully stabilised to ensure the constant optical alignment under all dynamic conditions. The sight is monocular. The range is digitally displayed in the eyepiece and in case of multiple echoes there are indication lamps for one, two and more echoes. In total, three different ranges can be detected and stored from one laser transmitter pulse.

The Type FLER-H fire control computer (**1619.161**) consists of the following sub-assemblies: sensors; vertical gyro; control panel; central computer unit; 400 Hz inverter. The computer sensors can be extended to maximum performance by adding a complete line of sensor units such as crosswind, ammunition temperature etc. Later versions of LEMSTAR may incorporate the FLER-M fire control computer.

The objective of the computer as a part of an integrated fire control system is to improve the firing capacity by increased hit probability, increased effective range, and reduction of the time between target acquisition and firing.

The computer calculates the super-elevation and the lead angle in azimuth (due to the curved trajectory) from the ammunition selected, the target range, internal and external ballistic data, trunnion cant and the terrain slope. Correction angles in azimuth and elevation are calculated taking into account the laying speed during target tracking. The computer controls the setting of these angles at the

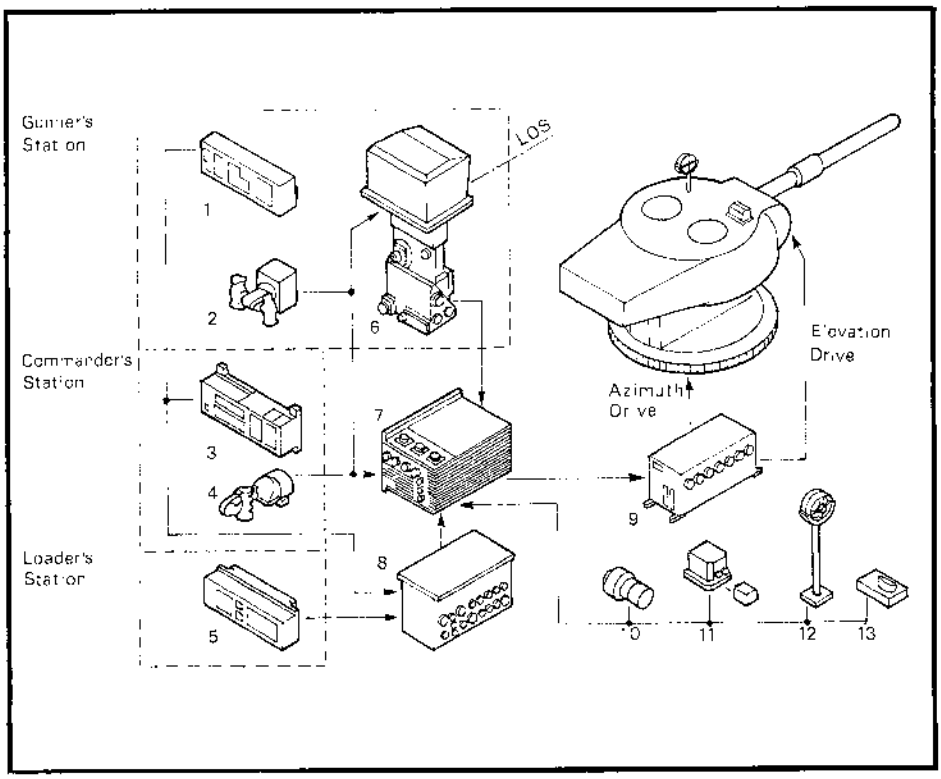
sights and weapon. The inputs are measured automatically and fed into the computer, and alignment of weapon and sight is corrected automatically.

The weapon stabilisation system (WSS) is slaved to the gunner's stabilised sight and its task is to slave the gun to the LOS allowing for the correction angles generated by the computer. The LOS is guided by the gunner's handle. Furthermore, the WSS compensates for the disturbance of the gun caused by the moving hull in such a way that the gun is kept stabilised during travel.

The WSS contains the two sub-system components: hydraulic weapon drive pack, and WSS-electronics including the sensors.

The hydraulic weapon drive pack is a field proven hardware with respect to performance and reliability and has been produced in several thousands of units (eg for the West German Leopard 1).

The position of the gun in elevation and azimuth is sensed by gyro units. The electrical synchro chain links the stabilised gunner's sight with the gun. It contains precision resolvers as input elements at the sight and as receptor elements at the weapon and both elements are selected as a pair to ensure the high accuracy required.



STATUS

LEMSTAR is proposed for refit applications in MBTs such as the M48, M60 and Centurion. No specific programmes have yet been identified officially.

In early 1981, LEMSTAR had been tested by the West German Army in a Leopard 1 tank and the possibility of refitting all Federal Republic Leopard 1s with the system was under consideration. It is understood that LEMSTAR has also been proposed for Italian Leopard 1 tanks and the system was being fitted to an Austrian Steyr-Daimler-Puch Panzerjaeger, an M48 and an AMX-30 tank for trials. A total of four pre-production systems had been completed.

CONTRACTOR

AEG-Telefunken, Anlagentechnik, Fachbereich Flugwesen und Sondertechnik Steuerungs und Regelungssysteme, Industriestrasse 29, 2000 Wedel (Holst), Federal Republic of Germany.

1619.161

FLER-H TANK FIRE CONTROL COMPUTER

The FLER-H is a hybrid computer of modular construction, principally designed and developed for use in tank fire control systems, but capable of other military applications such as anti-aircraft and artillery systems. The main elements of the computer are the computer core store and the computer control unit, plus a number of peripheral units. These include a vertical sensor for trunnion cant and terrain slope, an air data sensor, and a powder temperature measurement unit. The store is largely composed of integrated circuits, and the processing of non-linear data such as elevation angle and correction data is effected by hybrid multipliers and using polynomial approximation. Modular ballistic units provide for the known parameters of the various types of ammunition used. Other input data apart from that previously mentioned consists of range, target tracking in azimuth and elevation, crosswind component, gun tube wear, departure error, and parallax. Outputs of the FLER-H cover the correction angles in the form of AC electrical signals to control the sights and the weapon to within 0·5 mrad. These correction angles are inserted into the commander's and gunner's sights and into the weapon system so as to create an independent line of sight without disturbing elevation and azimuth.

Block diagram of FLER-H tank fire control system

The improvement in weapon accuracy resulting from the use of the computer system depends on the weapon and ammunition used and the range of the target. A factor of improvement in first-round hit probability of three or four is by no means an impossibility.

The modern successor of FLER-H employs current digital technology. Various types are stated to be available of differing performance, but no details have been received.

CHARACTERISTICS

Ammunition types: Choice of 4 ballistics

Distance range: 400 – 3000 m

Calculation accuracy: ≤0·1 mrad

Target velocity: Azimuth 40 mrad/s; elevation 15 mrad/s

Air pressure: 810 – 1215 mbar

Air temperature: –35 to +65° C

Crosswind: –20 to +20 m/s

Powder temperature: –30 to +45° C

Trunnion cant: –12 to +12°

Terrain slope: –20 to +20°

Test circuits: BITE

Power supply: 28 V DC, 90 W
26 V DC, 400 Hz, 10 W

Weight and dimensions

Core: 21 kg, 360 × 272 × 240 mm

Vertical sensor: 4·5 kg, 250 × 190 × 190 mm

Air data sensor: 6·8 kg, 345 × 220 × 178 mm

Powder temperature sensor: 4·1 kg, 205 × 130 × 160 mm – (125 × 65 × 75 mm)

Control unit: 3·2 kg, 180 × 215 × 105 mm

STATUS

The FLER-H computer is in series production for use in Leopard 1 A4 tanks. It also forms part of the LEMSTAR tank fire control system proposed for modernising programmes for other types such as the M48, M60 and Centurion (see **3797.161** in this section).

CONTRACTOR

AEG-Telefunken, Anlagentechnik, Fachbereich Flugwesen und Sondertechnik Steuerungs und Regelungssysteme, Industriestrasse 29, 2000 Wedel (Holst), Federal Republic of Germany.

4858.161

FLP 10 TANK FIRE CONTROL SYSTEM

The FLP 10 tank fire control system is designed for the control of main and secondary armament in main battle tanks such as the Leopard A1A1, A2 and A3, providing facilities for the engagement of fixed and moving targets under day or night conditions. It is understood that FLP 10 is to be retro-fitted to a large number of FRG Leopard 1 tanks.

The system contains the thermal imaging sight assemblies of the Leopard 2 MBT, with the same performance. The laser rangefinder is also identical with that of Leopard 2, and there are a number of other elements that are common with that vehicle's FCS. Among the major features of the FLP 10 are the following:

(1) Primary stabilised line of sight for the optical and thermal imaging sight.

(2) Integrated thermal imaging sight.

(3) Facilities for the commander to monitor the image presented in the gunner's primary sight, and to input range data obtained passively from the commander's periscope, laser rangefinder or manually.

(4) Six main gun ammunition types, and ballistics for the machine gun.

(5) Dynamic lead angle

(6) No separate parallax processing is needed for the daylight channel, thermal imaging sight or laser.

(7) Facilities to input ballistic parameters.

(8) Common temperature compensated angle transmission mechanism for daylight channel, thermal sight and laser.

(9) Cant angle sensor.

All the principal components of the FLP 10 are housed within the tank turret. They are: (a) gunner's primary sight (GPS), (b) computer control unit, (c) commander's GPS eyepiece assembly, (d) commander's thermal imaging control unit,

(e) gun stabilisation electronics, (f) laser electronics, (g) loader's control unit, (h) vertical sensor, (i) gunner's control unit, (j) thermal imaging electronics, (k) interface/test/operating mode control assembly, (l) fire control computer.

In the fire control system, several optical, electro-optical, electronic and mechanical subsystems operate together. A single mirror that is stabilised in azimuth and elevation is used for the daylight visual channel, laser transmission and reception, and thermal imaging. This ensures synchronisation of the optical axes. This mirror enables the gunner and commander to aim at the target using daylight or thermal imaging, and perform laser rangefinding. Identification and tracking of the target in daylight are by means of a high quality day telescope. A reticle, range value and system status information are superimposed on the telescope image. At night or in poor visibility identification and tracking are performed with the thermal imaging sight. Target markers are superimposed on the thermal image which is injected into the daylight channel optical path. After aiming at the target, it is possible to measure range with the laser rangefinder; the line of sight is not affected by changes in the ballistic values.

The gunner, or commander if the latter's GPS eyepiece is being used, controls the line of sight with the aid of hand controls. Utilising the vertical sensor, the effects of cant error is eliminated from the aiming process. The resulting target data are fed automatically into the fire control computer which continuously calculates the superelevation and lead angles according to selected ammunition type and preset parameters. These include: target speed, cross-wind, grain temperature, height above sea level, air temperature, correction values and control signals.

CHARACTERISTICS

Gunner's primary sight: Integrated unit with 4 channels, daylight, laser transmit/receive, night vision (thermal imaging)
Magnification: ×12
Field of view: 5°
Commander's GPS eyepiece
Exit pupil: >5 mm diameter
Transmittance: >10%
Superimposed data: Range, ammunition type, ready to fire
Fire control computer
Ballistics: 6
Max processed range: 4000 m
Rangefinder: Nd:YAG laser
Wavelength: 1·06 μm
Receiver FOV: 0·35 - 0·4 mrad
Measuring range: 200 - 9900 m
Resolution: Less than 20 m
Measurement accuracy: +10 m
Pulse rate: 10 pulse/minute
LOS aiming and stabilisation
Aiming sector: ±3° (azimuth); −10° to +20° (elevation)
Stabilisation precision (channels): Less than 0·1 mrad

STATUS

It has been reported that the FPL 10 will be retrofitted to a considerable quantity of Federal German Leopard A1A1, A2 and A3 main battle tanks, but contract details are awaited.

CONTRACTOR

Krupp Atlas Elektronik GmbH, Sebaldsbrücker Heerstrasse 235, D-2800 Bremen 44, PO Box 44 85 45, Federal Republic of Germany.

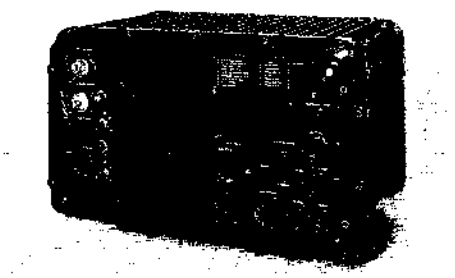
BC81 (Re 83)/(FARGO) ARTILLERY COMPUTER

The BC81 artillery computer is a battery level digital computer for calculating firing data for guns of various calibres, taking into account the usual meteorological, ballistic and other parameters. Entering service with the Swiss Army, for which the Fargo system was developed, the computer is designated Re 83. The processor is a version of the British Aerospace 1412A (formerly Sperry 1412A), which is used in a variety of other military applications, among them co-ordinate conversion for the Exocet MM38 anti-ship missile system (**1156.221**). The standard software package provides for firing calculations for nine different types of guns and ammunition, as well as a number of targets and observer positions, and has a full survey capability. Input data includes meteorological information, target co-ordinates (including altitude), and ballistic characteristics. In view of the system's intended operating environment (the Swiss Alpine region) elaborate provisions have been made for insertion of crest clearance data, target zones and other restrictions due to the nature of the terrain.

DEVELOPMENT



Began in 1977 at Bracknell, in co-operation with the Swiss company Zalliweger Uster AG. Extensive Swiss Army trials and evaluation preceded production decision in 1982/83.

STATUS

Production for Swiss Army confirmed in 1983; large order placed with estimated total value £14 million. Production deliveries due to start 1985.

CONTRACTOR

British Aerospace Dynamics Group, Bracknell Division, Downshire Way, Bracknell, Berkshire RG12 1HL, England. (Formerly Sperry Gyroscope).

BC81 artillery computer incorporates 1412A digital processor. The Swiss Re 83 version differs in minor details

4755.181
KOLLMORGEN CVFCS

The Kollmorgen combat vehicle fire control system (CVFCS) is an advanced computer-based fire control system for fitting in existing MBTs, such as the M41, M47 and M48, without major vehicle modification. Development was carried out jointly by the Electro-optical division of Kollmorgen of the USA and Ferranti Computer Systems Ltd in the UK.

Although primarily designed for American M-series tanks, compact dimensions, low cost and ease of operation make the system suitable for use in a wide range of AFVs, including fire support and infantry combat vehicles. The system is modular in concept and consists of a small number of compact units which are located in various parts of the vehicle.

Data from external sensors is fed to the fire control computer which calculates the correct lead and super-elevation angles required to hit the designated target during the gun-laying sequence. The system generates an aiming mark which is automatically injected into the gunner's sight. Parameters inserted into the computer also include: charge temperature, barrel wear, wind speed, and air temperature and pressure. There is automatic compensation for certain variable factors.

Inputs to the FCS computer which performs ballistic calculations, are accepted from the gunner's control panel, a laser sub-system, and other system sensors. All computations are performed under program control. The gunner's control panel combines the functions of a system control module, data entry terminal, and visual display, and this is the main interface between the vehicle crew and the system. The gunner uses the controls to conduct system tests, insert crosswind values, and also to select the back-up mode in the event of a malfunction. An ammunition selector panel is used by the loader to inject the ammunition type into the computer so that appropriate ballistics are employed in calculation.

A turret displacement unit and a trunnion tilt sensor also form part of the FCS. The former provides basic data for the lead angle correction, and the trunnion tilt sensor measures deviations from the horizontal directly and inputs the data to the computer automatically, allowing the system to compensate for vehicle attitude during the firing sequence.

The primary sensor of the complete FCS is the sight, a modular monocular day/night instrument equipped with a laser rangefinder and unity vision periscope. Sight modules include the optics block, head module, laser, electronics junction box and vehicle mount. The head module incorporates a 2:1 motion reduction transmission which links the gun elevation position arm to the sight upper mirror. The optics module comprises the main body of the sight, and boresight adjustment is by means of fine azimuth/elevation rotation within the head module.

The laser module is made up of four replaceable units, including a sealed optics unit containing the laser resonator and receiver telescope, a ×2·5 beam expander telescope, a receiver unit with an avalanche photodiode and preamplifier, and a power supply unit.

Other options that can be accommodated include: thermal imaging, sight stabilisation and the incorporation of a third-generation image intensifier.

CHARACTERISTICS

Range: 400 - 9995 m
Trunnion tilt: ± 30°
Crosswind: ± 25 m/s
Charge temperature: −40° to +65°C
Air temperature: −40° to +65°C
Air pressure: 700 - 800 mm Hg
Gun jump correction: ± 5 mil
Ammunition types: 6
MV correction: ± 100 m/s
Computation accuracy: 0·2 mil
Sight
Magnification: ×8
Field of view: 8° (day); 7° (night)
Exit pupil diameter: 6 mm (min)
Boresight adjustment range: ±8 mils
Direct vision FOV: 8·5° (elevation) × 18° (azimuth)
Elevation LOS rotation: +22/−18
Image intensifier tube: 25 mm
Laser rangefinder
Wavelength: 1·064 μm
Range accuracy: ±5 m
Pulse rate: 1/s (cont)
Output energy: 20 mJ (min)
Pulse width: 12 ns
Laser divergence: 0·45 mrad
Receiver FOV: 0·56 mrad

DEVELOPMENT

Development was undertaken jointly by Kollmorgen and Ferranti Computer Systems Ltd.

STATUS

Production. No contract details have been disclosed.

COMBAT ARTILLERY C³ SYSTEM

Combat is the name given by Elbit Computers Ltd to the artillery command, control and communications (C³) system they have designed to meet the needs of artillery formations at battery and battalion levels. The basic configuration is of a modular design which allows the addition of more units to increase the performance and range of facilities. The basic version of Combat provides for C³ functions necessary for operation at battery level. It consists of a battery C³ unit, a section chief display and communication unit for each gun, and a sight display unit for each sight. By the addition of an artillery computer the system will perform functions such as storing up to 30 positions, 100 targets, 15 simultaneous fire missions and handling of two meteorological telegrams. By adding modems various additional functions can be incorporated to bring the above facilities to forward observers and enable forward observers to undertake tasks such as re-positioning of sights etc.

Artillery tactical command unit of Elbit Combat artillery C³ system

Combat hardware at the fire direction centre (FDC) is based on an artillery tactical command (ATC) unit, and this includes the ballistic computer and a measurement remote terminal (MRT). The FDC sub-system performs simultaneously on three networks (guns, battalion level, fire control) and displays updated status data on the battery in real-time. It carries the requested artillery computations itself or receives them from the artillery computer when incorporated in a larger system. Messages received or transmitted are printed automatically. At the gun level, the hardware consists of the gun central unit (GCU), sight control monitor (SCM), the elevation sight monitor (ESM) and various other sensors and actuators. The gun sub-system receives and displays firing data and other command information sent by the FDC. Elevation and bearing sights are automatically set to the requested firing data. Data from sensors is reported via the gun sub-system to the FDC; for example, the gun sub-system receives measured muzzle velocities and transmits the mean values back to the FDC. Forward observers are equipped with a Mini-SACU (**4278.161**) which interfaces with a digital goniometer, a laser rangefinder, and a gyro north-seeker.

Conventional cable, or digital burst transmission radio links, can be used to interconnect the various elements of the complete Combat artillery C³ system.

STATUS

Production.

CONTRACTOR

Elbit Computers Ltd, PO Box 5390, Haifa 31053, Israel.

4278.161
SACU COMMAND AND CONTROL

The Israeli electronics concern, Elbit, produces a range of stand-alone digital communications units (SACU) for the transmission and management of most kinds of battlefield communications via line (twin conductor) or radio channels. The latter may employ FM and AM in the VHF, UHF or HF bands.

The basic SACU provides simplified, two-way high-speed burst data transmission in standard message format or as free text. The display incorporated in the unit leads the operator through the message entry sequence. Entries are made via the keyboard in accordance with a pre-stored list. Received messages are stored in a memory and displayed on operator request. The system provides for automatic message acknowledgment, and special purpose computations, such as ballistic or navigation calculations are optional. SACU interfaces with standard communications equipment. Optional interfaces include: printer, central processor, tape cassette, and teleprinter. A microprocessor controls the SACU operation and performs data processing functions. The keyboard is a sealed, flat surface, pressure activated device which is self-luminescent for night operation. Characters are formed by 5 × 7 dot arrays in the display which can present up to 256 characters.

CHARACTERISTICS

Data transmission: FSK at 300 or 1200 bits/s; DPSK at 2400 bits/s
Height: 355 mm
Width: 406 mm
Depth: 355 mm
Weight: 24·9 kg

SACU family with Mini-SACU on left and Micro-SACU on right

Mini-SACU

This is another member of the SACU family which provides similar facilities to those of SACU (above) but which is packaged for use by forward observers and at observation posts. A touch-panel keyboard is provided for operator access to the system, and the unit has message coding facilities as well as error detection and correction. Other features include: high-speed burst mode transmission; radio network management; automatic message acknowledgement; microprocessor control; long- and short-term memory.

Micro-SACU

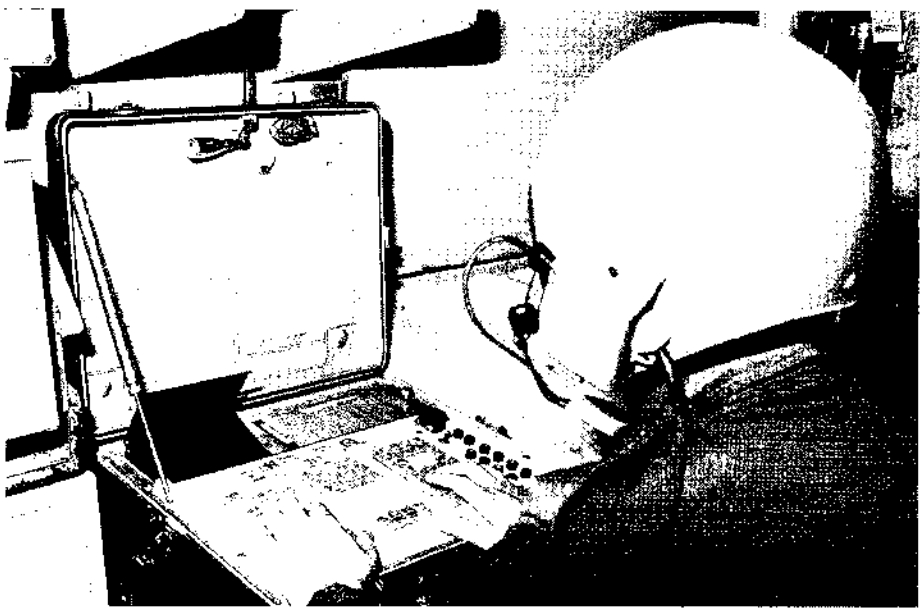
This small, hand-held version of Elbit's SACU serves the isolated soldier. It interacts with other components of the SACU family and central computers for integral C³ capability. Powered by an internal battery, power consumption is very low and a touch-panel keyboard operates in conjunction with a 96-character display.

CHARACTERISTICS
Data transmission: FSK at 75, 150, 300 or 1200 bits/s
Height: 220 mm
Width: 105 mm
Depth: 85 mm
Weight: 1·5 kg

Other members of the SACU family of equipment are:

TI-100: an interface unit for linking a teleprinter to SACU
GI-100: an interface for linking special-purpose equipment to SACU
LRCS 100: a long range communication SACU-based system for complex HF networks
PDI 100: a plasma display interface for major command and control centres

STATUS
In production and thought to be employed by the Israeli Defence Forces.
CONTRACTOR
Elbit Computers Ltd, PO Box 5390, Haifa 31053, Israel.



3192.161
DAVID ARTILLERY BATTERY COMPUTER

The DAVID artillery computer was developed to be used by the technical assistant at the battery level. Using LSI technology, a small and low-cost unit has been designed which performs all the calculations required at this level: firing data, adjustments, fire for effect, corrections, survey, etc, as well as functional checks of data and procedures to prevent operator errors.

Based on experience gained since the system was introduced into IDF service in the 1970s, the David artillery computer has been developed and has now reached the Mk III version. As before, the David performs all the calculations at the battery level, replacing all the traditional tables and charts. Calculations under fire are much quicker and much more accurate and effective.

The new David replaces the old software with a microprocessor programmed in an Elite language and a 104K memory. This means that it can now store up to 120 targets and handle five simultaneous missions, quicker than ever. Maintenance is simplified through increased modularity. Power consumption is lower. Externally, no change was made in the computer. It is still compact, lightweight and rugged, adaptable to a wide variety of guns. The system is easy to operate, requiring only minimal training.

Data can be transmitted from the computer to a hard copy recording device as well as to gun display units and higher level systems such as battalion Field Direction Centres. Direct data transmission from the forward observer to the computer is also provided. The complete David system includes a David Field Artillery Computer in the battery fire direction centre, and a Gun Display Unit and Slave Unit for each gun. Connections between the display units at the guns and the fire direction centre are via regular field telephone wires.

DAVID artillery computer equipment in use

CHARACTERISTICS
Microprocessor: 8085A
Memory size: 104K (96K EPROM, 8K RAM)
Computation time: 0·5 - 0·7 s (fire data); 0·2 s (chart data); 1·0 - 1·5 s (corrections)
Guns handled: 6 (in one sequence)
Targets and/or alternate positions stored: 120 (expandable to 200)
Fire missions: 5 (expandable to 15)
Corrections stored: 18 (expandable to 30)
Safety measures: crest clearance; no-fire areas (optional)
Warning measures: visual - error message; aural - buzzer
Peripherals: output to GDU, input/output to/from TDM-326, printer (optional)
Temperature: -30 to +52°C (operation); -40 to +71°C (storage)
Accuracy: 20 m (range); 15 m (deflection); 0·1 s (fuze setting); 1 m or 1 mil (survey calculations)
Dimensions: 500 × 440 × 270 mm
Weight: 27 kg
STATUS
In production and operational since the late 1970s. Now in Mk III version.
CONTRACTORS
RAFAEL, Armament Development Authority, Israel.
Ministry of Defence, Haifa, PO Box 2082, Israel.

3524.161
GUN DISPLAY SYSTEM

The Gun Display System (GDS) is designed to transfer essential data between the DAVID artillery battery computer (**3192.161**) at the fire direction centre (FDC) and individual guns of a battery. The system addresses each gun separately so that the pertinent information is passed only to the relevant gun, with the single exception that in the registration process, all the guns receive the firing data of the ranging gun. Each new command displayed at the gun activates an audio warning to draw the gun crew's attention to the new orders.

The GDS consists of three main sub-systems:
(1) the display units located at the guns
(2) the message centre for generating and receiving messages in the DAVID artillery computer
(3) a communication system.

A main display unit is mounted in front of each gun crew commander, and an additional display unit can be located near the gun sights. This slave unit will display only the relevant information for the particular gun layer. The GDU receives firing commands issued by the message centre and displays them to the crew commander and individual gun layers. It receives and displays the following data:
(1) preparation for engagement: projectile and fuze types
(2) firing data: deflection, elevation, fuze setting, propellant and charge number
(3) range adjustment data: ranging gun and ammunition type for range adjustment (the ammunition type is displayed only to the ranging gun)
(4) fire for effect data: number of projectiles, firing mode and fire interval.

GDU transmits the following reports back to the message centre:
(1) acknowledgement of a new command (push-button)
(2) transmission error (by means of error detection techniques in the data transfer system)
(3) READY signal (push-button)
(4) FIRED signal (push-button). This also operates the count of rounds fired
(5) MISFIRE signal (push-button)
(6) number of rounds remaining for completion of the mission (automatic)
(7) last round fired signal (operates automatically when round remaining reaches zero).

The numeric data, the projectiles and firing mode data appear on seven-segment indicators. The unit is also provided with a test button and an ON-OFF switch.

The message centre is packaged in the DAVID computer container, and uses spare keys of the DAVID keyboard, and no hardware or software changes are required in the DAVID system to add the gun display system. The communication system is based on normal telephone line communications techniques.
STATUS
Production.

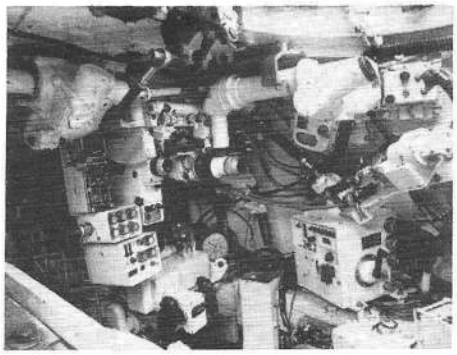
RAFAEL, Armament Development Authority, Israel.
Ministry of Defence, Haifa, PO Box 2082, Israel.

3870.161
ELBIT FIRE CONTROL SYSTEM

After a two-year development effort, Elbit Computers Ltd began production of a digital tank fire control system based on a microprocessor central processing unit (CPU) in 1979. Although designed primarily for the Merkava tank, Elbit's concept was to produce a modular system that was flexible enough to permit expansion to meet future requirements and advances, and at the same time to be basically suitable for use in all existing types of tank. Currently Elbit is manufacturing systems (known as the Matador FCS) for M-60, Centurion and other MBTs, based on its successful programme for the Merkava. In addition, the company has designed a low-cost system (Lancelot **4786.161**) for retro-fitting in light tanks as well as for use on new AFVs.

In addition to the CPU, the system consists of three operation units (gunner, commander, and loader), control and feedback servo loops, and sensors. The system is capable of operation without power in an emergency. The gunner's unit is the main operation unit and it provides all manual inputs necessary for the ballistic computation. This unit also incorporates a logistics panel which enables bore-sighting and system built-in test as well as display of pre-selected inputs and computed outputs. The gunner's unit also



includes controls for the selection of ammunition (any one of six types), and jump compensation for each type of ammunition in elevation and deflection. The commander's unit provides readout of the system's display, range and ammunition inputs and the loader's unit provides ammunition inputs. An integral facility for firing the gun at night is provided, based on the use of a second generation image intensifier.

The Matador system includes the following automatic sensors: laser rangefinder, turret cant angle sensor, target velocity sensor and a meteorological mast with crosswind velocity, air temperature and pressure sensors. The control loop transfers the computed super-elevation information to the hydraulic gun elevation servo and to the ballistic drive. In addition, deflection data is transferred to the moving reticle. The feedback loop ensures that the actual gun super-elevation and reticle deflection data are identical to the computed data and will correct any error accordingly. Thus, the gunner's aiming reticle remains on target (full autolay capability) throughout the entire firing preparation process.

Parameters taken into the elevation and deflection compensation calculation typically include range, type of ammunition, cant angle, parallax, ammunition drift, gun jump, gun wear, moving target angular velocity, crosswind, barometric pressure, air temperature, charge temperature, and options such as muzzle reference system, line-of-sight angle, and gun resolver.

CHARACTERISTICS

Operating range: 400 - 5000 m
Elevation compensation: -1 to +99 mils
Deflection compensation: +25 mils
Cant angle range: ±15°
Jump compensation: ±5 mils (for all ammunition types)
Bore-sighting range: 400 - 5000 m
Ammunition selection: 6 types
Electrically inserted range: 300 - 5000 m
Computer memory: EPROM; 16 K total, 5 K utilised
Dimensions
Gunner's unit: 210 × 220 × 220 mm
Commander's unit: 85 × 115 × 134 mm
Loader's unit: 80 × 72 × 134 mm
Cant angle indicator: 100 × 160 × 190 mm

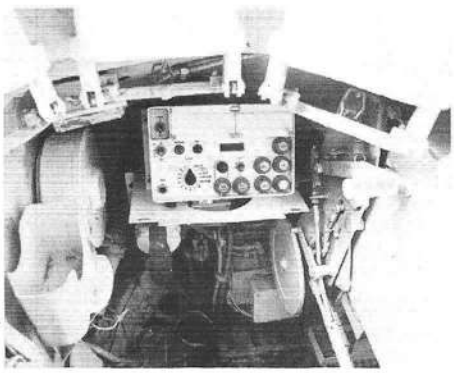
LANCELOT TANK FCS



Lancelot is a tank fire control system designed for retrofitting in existing tanks such as the AMX-13, M-41, M-47, and newer light AFVs. It has been evolved from experience gained by Elbit in the development of the Matador FCS (**3870.161**) for the Israeli Merkava main battle tank programme.

The Lancelot system consists of a Nd-Yag laser rangefinder, a second generation image intensifier, a digital computer with a built-in cant angle sensor, control units for both commander and gunner and a moving target velocity sensor. Although based on the digital system developed for the Merkava, Lancelot is more compact enabling it to be fitted in the turrets of a wider range of smaller vehicles.

The system corrects the aiming reticle for the same parameters as the MBT FCS (range, ammunition type, cant angle, parallax, ammunition drift, gun jump, gun wear, moving target velocity, crosswind, barometric pressure and air temperature).

Component units of Lancelot AFV FCS

Elbit Lancelot FCS fitted in AMX-13 tank

STATUS

The Lancelot FCS has been fitted into various armoured vehicles and tanks, and the accuracy and ergonomic features proved. No details of production or series fittings have been released.

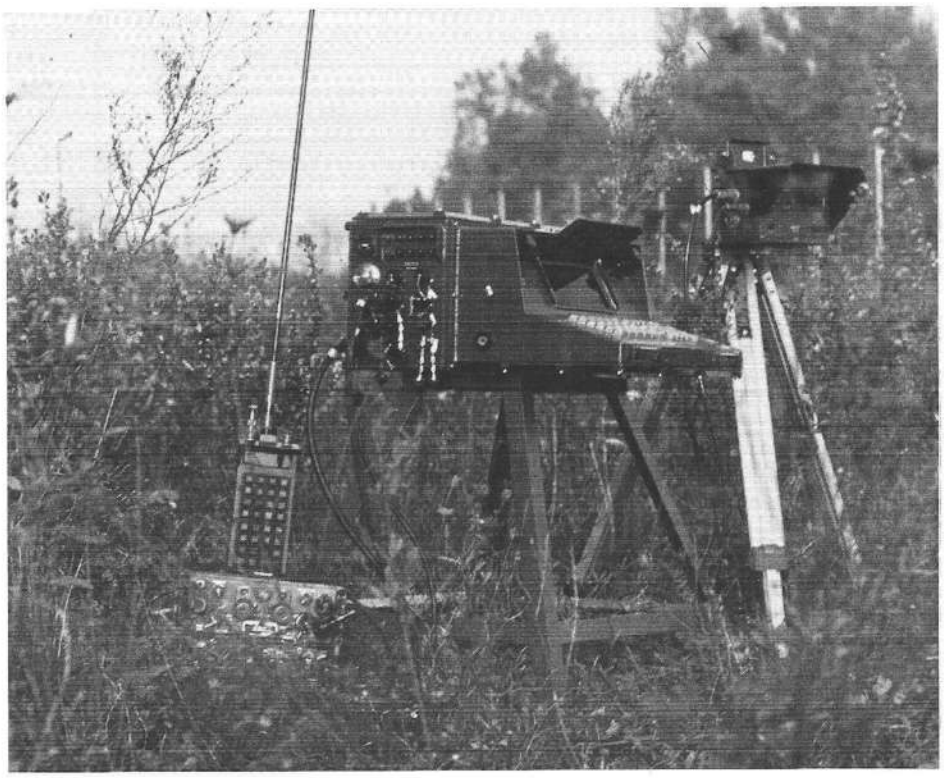
ITALY

4490.161
SEDA AND SEDAB ARTILLERY AUTOMATION SYSTEMS

The SEDA is a field artillery automation system which performs the management and process of field artillery information at battalion level and carries out all the procedures needed to compute firing data for the battalion (up to six batteries each composed of up to eight guns).



The most important functions performed automatically by SEDA are:

(1) automatic data transmission and reception among different units of the battalion
(2) fire preparation
(3) evaluation of the fire possibility
(4) evaluation of the targets and the consequent definition of the fire characteristics
(5) firing data computation and fire distribution
(6) fire planning
(7) target recording
(8) ammunition management

The SEDA basically consists of:

(a) one battalion computer at the battalion command post
(b) one battery computer at each battery command post
(c) one man portable terminal (DMT) for each commander and observer
(d) one gun commander display unit (GDC) for each gun

Using the DMT, observers and commanders send target reports, fire requests and adjustments to the battalion and battery computers; the transmission is performed in a fully automatic way through fixed

Elements of the SEDAB artillery automation system

format messages digitally coded by DMT and sent on voice channel of a frequency modulation radio-set. The battalion computer exploits all the information stored in its memory to coordinate the fire among the different batteries. It sends these data digitally coded to the battery computers which compute firing data for each GCD. The battalion computer can be directly linked to various peripheral units of the battalion, such as a meteo station or a muzzle velocity meter.

Compared with calculation by conventional methods or with other digital systems, SEDA offers the following advantages:

(1) A fast and reliable transmission of information among the different battalion elements, also when the voice communication link becomes particularly weak.
(2) The system can use radio sets already available at the battalion
(3) The computers fulfil fast and accurate calculations of firing data because they perform a numerical integration of the projectile trajectory taking into account point by point all the meteorological and ballistic conditions.
(4) All the information coming from the observers can be introduced also manually into the computers.

The SEDAB, artillery fire control system at battery level, is a part of the SEDA. It can operate autonomously as a separate stand-alone system to provide fire computations and transmission management for a battery of up to eight guns. SEDAB includes: one computer at the battery command post; one man portable terminal (DMT) for each observer; one gun display unit (GDC) for each gun.

STATUS

In production

CONTRACTOR

4855.161

CMB8 MORTAR COMPUTER

The CMB8 is a military, hand-portable computer which automates the procedure needed to compute firing data for a mortar battery, composed of six mortars.

It makes use of all the information stored in its memory to compute firing data for the different mortars of the battery, and it can be connected to a Galileo military, hand-portable printer for the recording of the executed procedures. An internal rechargeable battery and the possibility of a connection to an external power supply give the CMB8 a long combat autonomy.

Compared with conventional methods, the CMB8 offers many advantages:

(a) A drastic reduction of time in calculation, together with an increased precision.
(b) A reduction in preparation time and crew members, because a menu sequence directs the operator step by step, to achieve the completion of the procedures.
(c) The recording, by a printer, of the executed procedures.
(d) A possible automatic data transfer through a digital link with other units of the battery (observers) or with upper levels.

The most important functions performed by CMB8 are:

(1) The fire preparation, including:
  (a) Survey preparation with several programs such as: polar coordinates replot, close traverse replot, shift from known point, intersection replot, reverse intersection.
  (b) Introduction of the position data for all the mortars of the battery.
  (c) Ballistic preparation with the introduction of meteo message, charge temperature and weight, muzzle velocities, etc.
(2) Evaluation of the fire possibilities taking into account friend troop positions, (not fire areas and crest clearances) to evaluate the possibility of fire against a target
(3) Firing data computation and fire distribution for efficacy for each mortar (convergence, smoke, parallel, barrage)

STATUS

In production for the Italian Army.

Officine Galileo SpA, Via Einstein 35, 50013 Campi Bisenzio, Florence, Italy.

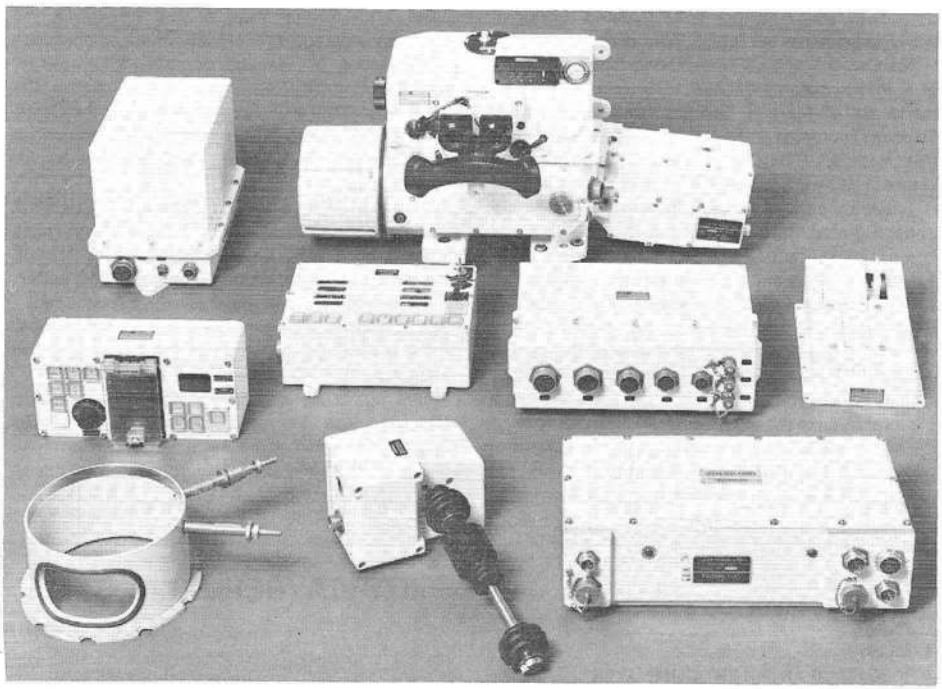
4232.161

OG 14 L2B TANK FIRE CONTROL SYSTEM

The OG 14 L2B modular fire control system is designed for use in the new Italian OF 40 and Leopard medium tanks. It comprises an optical sight with a laser rangefinder, a digital ballistic computer, control panels for the gunner, commander and loader. With the additional sensors the ballistic computer can carry out lead angle computation with the tank and target in motion and integrate data for meteorological conditions, powder temperature and gun wear. The computer is designed also, to accept 120 mm gun ballistic data.

Optional dedicated software permits crew training.

CHARACTERISTICS



Laser rangefinder
Max range: 10 000 m
Max pulse rate: 1 pulse/s
Ballistics computer
Max computation distance: 4000 m
Max elevation correction: ±80°
Max traverse correction: ±30°

STATUS

In production.

4856.161

OG14L3 (TURMS) LASER TANK FIRE CONTROL SYSTEM

The TURMS OG14L3 is a third generation LTFCS for battletanks characterised by a fire-on-the move capability, owing to the primary stabilised gunner sight, master with respect to the slaved gun.

TURMS is specially conceived for tanks of new production (in particular for a recently started programme for the Italian Army) but, thanks to its modularity, offers high flexibility of installation, also for upgrading existing tanks.

The system consists of: periscope gunner's laser sight, integrating in a single housing four main modules (ie primary stabilised head mirror, visual unit, laser transceiver and thermal imaging unit); commander's panoramic sight, primarily stabilised, for daylight surveillance; ballistic digital microprocessor computer; meteorological, tank attitude and gun wear sensors; muzzle reference system; gunner's, commander's and loader's control panels.

As a result of the very high quality and accuracy of line of sight stabilisation and firing computation which takes into account all the parameters affecting the ballistic trajectory, the TURMS OG14L3 features a very high first hit probability even on the move against moving targets in day and night conditions.

CHARACTERISTICS

Gunner laser sight
Monocular: 10×
Stabilisation accuracy: Better than 0·15°
Laser rangefiner: Nd:YAG ranging up to 10 km
Thermal imaging unit
Spectral band: 8÷14μ
FOV: 1·1×2·2° (narrow); 3·3×6·6° (wide)
Commander's sight
Binocular: 2·5× - 20°; 10× - 5°
Stabilisation accuracy: Better than 0·5°
Ballistic computer
Ballistic computation range: 300 to 4000 m
Ammunition types: choice of 5 ballistics
Integrated autotest (BITE).

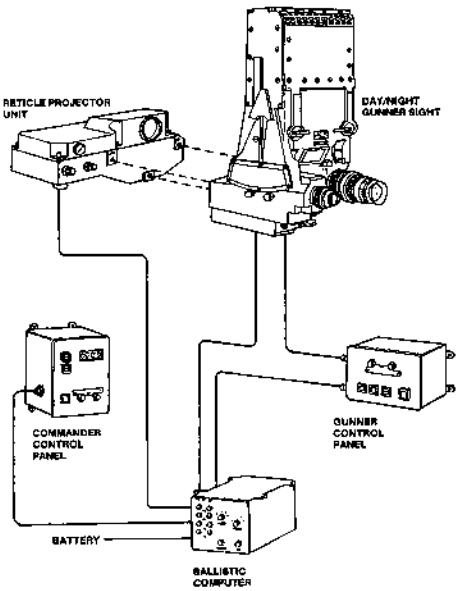
4857.161
ATREOS LASER TANK FIRE CONTROL SYSTEM



ATREOS is an austere LTFCS, specially suitable for armoured vehicles and retrofitting of existing tanks, in a minimal configuration to provide very good performances at a reasonable cost.

The major units, linked as shown in the nearby schematic system layout are:

(1) Day/night gunner sight comprising: laser visual unit, passive night elbow, periscope assembly with ×1 window
(2) Reticle projector unit
(3) Ballistic computer
(4) Gunner control panel
(5) Commander control panel

The day/night gunner sight is assembled in a self-contained periscope housing, interchangeable with the M32 existing periscope. The laser visual unit and the passive night elbow directly and respectively replace the M32 daylight elbow and the M32 active IR elbow to add day/night range finding and firing capability. Bulk absorption laser filters, one integral with the eyepiece and the other for the ×1 window, provide safety to gunner's eye. The ballistic computer, usually attached to the turret ceiling above the gunner, is a digital computer which generates the traverse and elevation lead angles according to the selected ammunition and the measured range.

CHARACTERISTICS
Telescope
Magnification: ×8
True field of view: 7°
Data and signals displayed in the eyepiece
Laser rangefinder
Passive dye Q-switch Nd YAG
Range: 350 m – 9995 m
Passive night elbow
Intensifier tube: Second generation
Magnification: ×5
True field of view: 10°
Tube gain: ×25 000 (min)
Ballistic computer
Target range: 400 to 3500 m
Ammunition choice: 4 types
Computation accuracy: 0·5 mils
STATUS
Preproduction.

4532.181
CATRIN

CATRIN (Sistema Campale Trasmissioni Integrato) is an automatic communication system intended for Corps area operations. It functions in the same way as other field communication systems being developed in Europe, such as the British Ptarmigan.

The CATRIN project is based on a feasibility study prepared between 1970 and 1975 by a consortium made up of Marconi Italiana, Selenia, IBM and Telettra. Technical and operational specifications in line with EUROCOM recommendations were established by the Italian Staff in 1978 and the project is presently carried out by the Italian Army with a consortium of Italian industries. The consortium, composed by Italtel, Face Standard, Telettra, GTE, Fatme and Marconi Italiana, is now working on various components of the system, in particular the central software and hardware. By 1983 the Army expects to have completed the study of the central software, of the supervision sub-system and of the single-channel radio access control, and procured a pre-prototype of the main switch.

The CATRIN network consists of trunk-nodes, whose equipment is mounted on shelters for maximum mobility, connected to one another by 32-channel UHF radio-links. Each trunk node may be linked by 16-channel radio relays to Corps and Division access nodes. More mobile users have a radio-access sub-system connected to a radio central.

The grid configuration of CATRIN gives the redundancy necessary to ensure continued operation in the event of damage or failures. A central supervision sub-system continuously checks the operativity of the entire system and gives the Corps signal commanding officer relevant information on the status of the network and instructions for redeployment.

Channels selected for CATRIN are 16 kb/s and 32 ko/s with speech digitally encoded by Delta modulation. Traffic security is obtained through integral ciphering of all communications. A super-cipher is provided to the most sensitive subscribers.

Each user is identified by a seven-digit number which is retained anywhere in the Corps area, no matter how many times he moves.

More mobile users, such as battlegroups or brigade HQs, can use the single-channel radio access (SCRA) sub-system. It gives a subscriber on the move the same local and trunk communication facilities as static users.

The SCRA equipment will be compatible with the new single-channel radio-net family being developed by the Italian Army. This will allow a radio-net user to become a CATRIN subscriber simply by coupling its radio to an SCRA adapter.

A typical Corps network manages 1276 speech users, 248 telegraph and 204 radio users.

The whole system is installed on class 1 and 2 UEO shelters, while terminal equipment is normally mounted on armoured vehicles.

CATRIN network can directly communicate with EUROCOM compatible systems, like the British Ptarmigan. It can also be connected to NICS, national civil and military networks and integrated with the combat-net radio use on the field by lower echelons units.

STATUS
Operational tests of the full system should start in 1986 and series production of the whole range of sub-systems will be possible by 1988, although many elements of CATRIN will be put into production much earlier.

Radio links and Delta multiplexer, for example, are already in production by Marconi Italiana for use in the Hawk anti-aircraft missile regiments.

PYK-80 FIELD ARTILLERY COMPUTER

The PYK-80 field artillery computer is a digital microprocessor-based system which performs ballistic calculations and related computational tasks for the direction of various field artillery weapons. It is produced in a number of versions appropriate to specific types of weapons, as denoted in the following list:

PYK-80(V)1 – 105 mm howitzer
PYK-80(V)2 – 155 mm howitzer
PYK-80(V)3 – 8 inch howitzer
PYK-80(V)4 – 4·2 inch mortar
PYK-80(V)5 – multiple rocket launchers

The configuration of the computer can be seen from the illustration which shows the operator keyboard hinged from the front of the unit and the LED display. The unit is adaptable to any type of gun by means of interchangeable plug-in units which carry the necessary program and parameter changes. Calculations performed include firing data, firing adjustment, target data storage and checking, error checks and built-in test. Optional functions include firing data transmission and display using a gun display unit, and target data transmission by means of a data message device.

PYK-80 field artillery computer unit

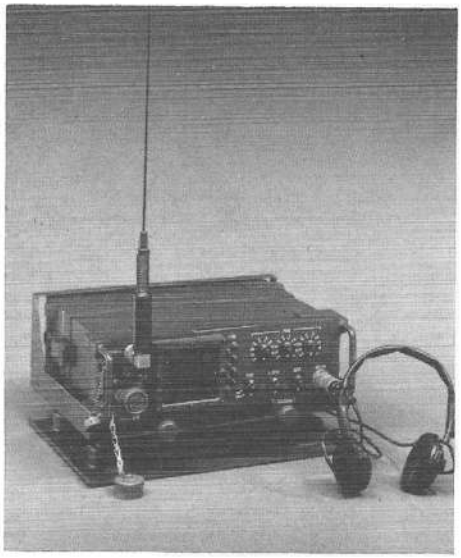
Input data to the system consists of target information, artillery data, and observer positions, FO information such as target position and adjustment data, meteorological data, and battery information including centre of arc bearing, gun position(s), and minimum elevation. Output data includes: firing data, quadrant elevation, charge number and fuze time.

The PYK-80 computer is connected to the FOs, higher command, a survey team for survey data, a met team and the gun batteries.

CHARACTERISTICS
Type: PYK-80 (V)
Width: 390 mm
Depth: 210 mm
Height: 360 mm
Weight: 16 kg
ROM: 16K bytes
RAM: 4K bytes
Cycle time (instruction): 1·2 microsec
STATUS
Production.
CONTRACTOR
Gold Star Electric Co Ltd, 27-2, Yeoeuido-dong, Yongdunpo-ku, Seoul 150, Republic of Korea.

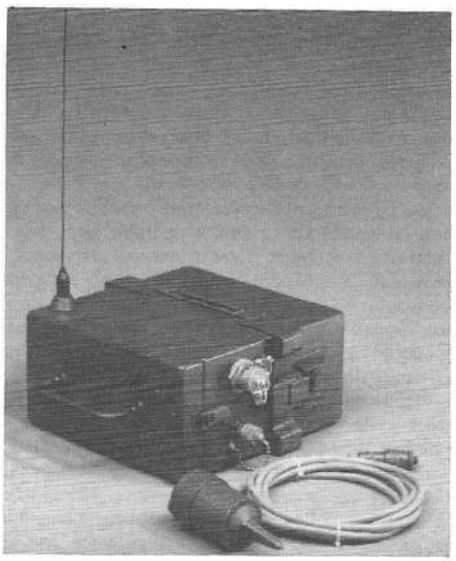
4752.181
GSQ-250K REMOTELY MONITORED SENSOR SYSTEM

The GSQ-250K remotely monitored sensor system consists of a radio frequency monitor (RFM), miniaturised seismic detector (Minisid), audio add-on unit (AAU), and magnetic intrusion detector (Magid). The Minisid, AAU and Magid are implanted in the area to be observed, where they detect vibration, sounds and magnetic disturbances that might indicate human and/or vehicular activity. This information is sent back to the monitoring site in the form of VHF radio signals. The RFM, which can be installed in a monitoring station, a mobile unit or used as a portable unit, receives, analyses and displays the data gathered.



The main elements of the system are:
(1) USQ-46A radio frequency monitor
(2) USQ-154 miniaturised seismic intrusion detector
(3) DJ-382 audio add-on unit
(4) DJ-509 magnetic intrusion detector
(5) geophone, microphone and auxiliary equipment.

This equipment is combined in various ways to suit the environment and the specific operational requirements of the system. Possible configurations include:
(1) using the Minisid alone, with its built-in transmitter, to monitor vibration
(2) using the Minisid with the AAU to monitor vibration and sound
(3) using the Minisid with the Magid main solenoid only to detect seismic vibration and magnetic field changes
(4) using the Minisid with the Magid's main and auxiliary solenoids to detect magnetic field changes only.



USQ-46A

The USQ-46A RFM consists of a main unit, an antenna and a headset, and is supplied complete with power supply and mounting base. It may be operated in a man-pack, vehicle-mounted, or fixed station configuration. It receives signals on any one of 840 channels. When a signal from a Minisid is received, the RF monitor displays the remote sensor's identity number on its front panel and relays the received audio to the headset.

CHARACTERISTICS
Frequency range: 160 - 176 MHz
Number of channels: 840
Modulation: FM/FSK
Channel spacing: 18·75 kHz
Identity codes: 64 (max)
IF: 21·4 MHz
LO frequency: 3·75 MHz
Dimensions: 333 × 263 × 103 mm
Weight: 8 kg (approx)

USQ-46A radio frequency monitor unit

USQ-154 Minisid

DJ-382 audio add-on unit

USQ-154

The USQ-154 Minisid consists of a main unit, antenna, and a geophone. When the geophone detects vibrations in the ground, such as those caused by troops or vehicles passing within range, it transmits an alarm signal on a frequency suitable for reception by the RFM. The AAU or Magid can be connected to the Minisid for use as supplementary sensors.

CHARACTERISTICS
Transmitter Power: 2 W (min); 4 W (nominal)
Frequency range: 162 - 174 MHz
Transmission: Digital FSK
Spurious emission: 40 dB minimum
Frequency response: 40 - 2000 kHz
Detection range: 50 m dia (troops); 300 m dia (vehicles)
Dimensions: 210 × 210 × 105 mm
Weight: 5 kg (approx)

DJ-382

The DJ-382 audio add-on unit consists of a main assembly containing a microphone and is used as an ancillary device connected to the Minisid, from which it draws its power. The AAU is activated by three successive occurrences of ground vibrations and sends out audio signals within its range of audibility via the Minisid. An optional daylight sensor permits operation at night only if desired.

CHARACTERISTICS
Audio output: 0·3 to 1·0 V rms
Voltage gain: 80 dB
AGC range: 50 dB (keyed AGC)
Detection range: 3 - 4 m dia (troops); 10 - 20 m dia (vehicles)
Dimensions: 135 × 76 mm (dia)
Weight: 1 kg (approx)

DJ-509

The DJ-509 Magid consists of a main solenoid and is used as an ancillary device attached to the Minisid to detect disturbances to the Earth's magnetic field associated with the passage of magnetic material through the area being observed.

CHARACTERISTICS
Voltage gain: 138 to 141 dB
Detection range: 3 m dia (troops); 10 m dia (vehicles)
Dimensions: 310 × 65 mm (dia)
Weight: 1·4 kg (approx)

STATUS
Production.

CONTRACTOR
Gold Star Electric Co Ltd, 27-2, Yeoeuido-dong, Yongdunpo-ku, Seoul, Republic of Korea.

VERDAC/FIST ARTILLERY FCS

A replacement for the US-supplied FADAC (Field Artillery Digital Automatic Computer) used by Dutch forces since 1967, has reached the prototype stage and is expected to begin Army trials in 1985. This is the Signaal VERDAC/FIST equipment, which has entered initial production and awaits a full production contract expected in early 1986.

VERDAC/FIST is to equip the Dutch corps in West Germany with five major terminals to each battalion (one per battery, and two at battery level). Each terminal has several microprocessors, a keyboard and a VDU, and is employed to calculate firing data at battery level and to exchange data between battalion and battery via burst transmission (to avoid countermeasures).

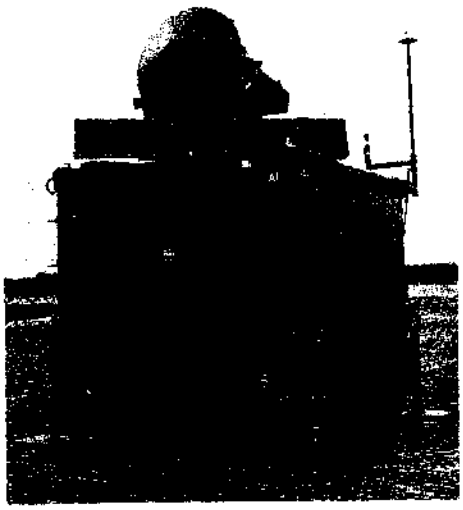
The battery computer is able to store data (such as ammunition levels, gun status and characteristics etc) for up to four batteries, information on up to 150 targets, accept and process information from forward observers and the fire direction officer, carry out aiming calculation for up to eight guns, and the average time between receiving a fire order and displaying firing data is less than 25 seconds for the first seven rounds.

STATUS
Undergoing field trials and awaiting full production contracts for deployment from mid-1986 onwards.

CONTRACTOR
Hollandse Signaalapparaten BV, PO Box 42, 7550 Hengelo, Netherlands.

2301.181
FLYCATCHER (VL4/41) AA WEAPON CONTROL SYSTEM

Flycatcher is a versatile AA radar weapon control system designed to detect, identify, and automatically track aircraft flying at low to medium altitudes. It can be used to control either guns or missiles, or any combination of both.



Main elements of the system are a dual retractable search and track antenna system, two radar transmitter/receivers, a radar display and control assembly, a fire control assembly, and a digital computer. The whole system is housed in a transportable military container. Power consumption is about 11 kVA. Up to three different weapons can be controlled independently by the computer.

The radar operates in the I-band, and features track-while-scan, a high data-renewal rate, and a multiplicity of ECCM and anti-interference facilities. An additional K-band facility provides high tracking accuracy with anti-image performance. The search antenna is a slotted waveguide; the tracking antenna is parabolic with a cassegrain reflector and a monopulse feed horn. TV tracking is incorporated as a complementary system.

The general-purpose computer, which can handle targets with speeds up to Mach 2 performs the ballistic computations for medium calibre guns and data processing for missile guidance and a number of other functions.

CHARACTERISTICS

Function: All-weather point and area defence with AA guns and S/A missiles against medium- to low-level air attacks

Signaal Flycatcher radar installation

Sensors: I-band search and track radar, K-band anti-image tracking radar, TV, IFF

Weapons: Up to 3 weapons, being either all guns (30, 35, 40 mm) or any combination of guns and short-range surface-to-air missiles; parallax distance up to 1000 m

Search coverage: Up to 20 km (1 m² target) track-while-scan

Display: PPI, north-oriented, clutter- and interference-free, scales 10/20 km

Target engagement: Joystick indication, automatic acquisition and tracking, automated weapon control

System design: Container construction, retractable antennas, self-contained diesel-driven power supply, removable wheel-train, micro-miniaturised solid-state electronics

Dimensions: Length 2·73 m; width 2·12 m; height (antenna in) 2·13 m, (antenna out) 3·65 m

System weight: 3000 kg (approx)

Environmental: Operating temperature −40 to +52° C, storage temperature −55 to +71° C, others according to MIL-STD-201A, ground equipment, world-wide, vibration and shock capabilities based on MIL-S-52059A

STATUS

The equipment is in service for the defence of Netherlands air bases and in several other countries.

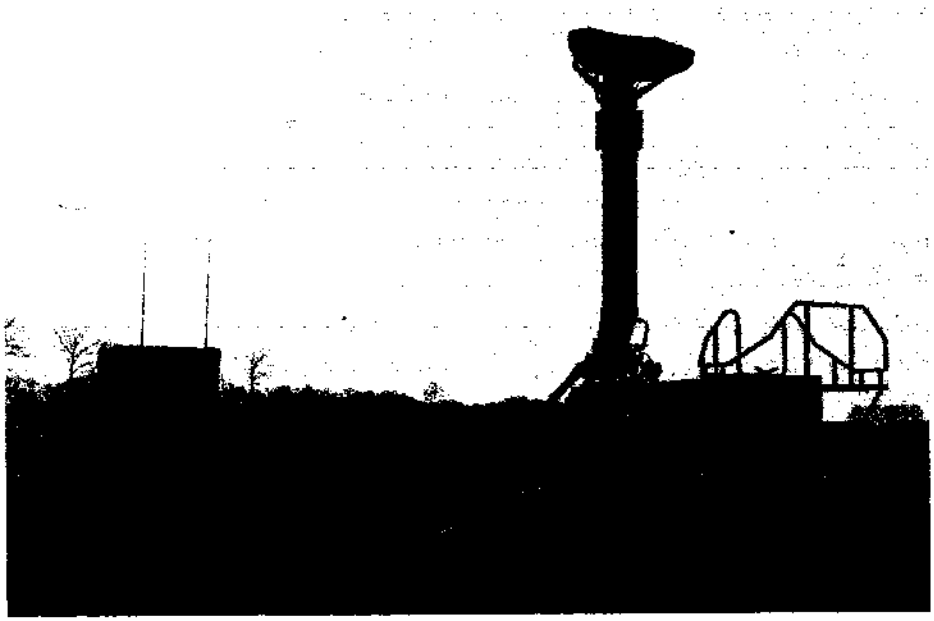
CONTRACTOR

Hollandse Signaalapparaten BV, PO Box 42, 7550 Hengelo, Netherlands.

4489.181
REPORTER AIR DEFENCE SYSTEM

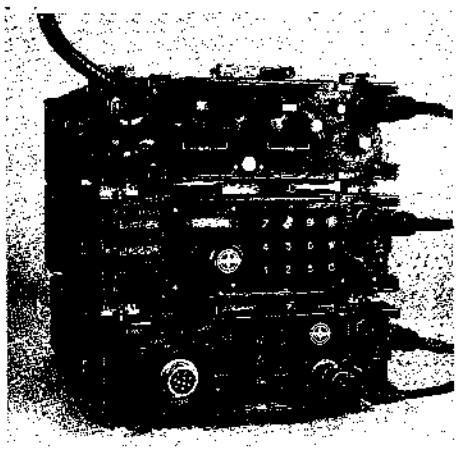
The Reporter (radar equipment providing omni-directional reporting of targets at extended ranges) is designed to provide early warning of unknown air targets, flying at altitudes of 15 to 4000 m and ranges of up to 40 km. An integrated IFF system enables the target to be identified by the operator, and after target indication by the operator, target parameters are automatically transmitted in broadcast fashion via VHF/FM radio or by line communications to the terminal equipment. An unlimited number of firing units lacking early warning/alerting systems, eg light AA guns and weapons with target tracking devices may use this information if they are equipped with the appropriate portable terminal equipment. Weapons with associated surveillance radars are able to maintain radar silence by utilising information from the Reporter system. Each terminal equipment displays the data of the highest priority target, with reference to their own position. The firing units are free to change location at short notice without the need to inform the Reporter unit, as the latter does not need to know weapon positions. Every fire unit is equipped with a terminal equipment set. This set consists of an FM radio, a target data receiver (TDR) and as an option an interface for automatic aiming. The TDR can be programmed to various criteria such as the allocated defence sector and the position of the firing units.

Reporter consists of the following main items of equipment:



(1) an I-band search radar with integrated IFF
(2) equipment for the control, data handling, transmission (one-way data link) and power supplies
(3) any number of lightweight portable terminal equipment sets for use by the fire units in the field. This equipment receives data on all targets but displays only targets which are significant to each fire unit. The TDRs receive data via a voice channel of a VHF/FM radio, and interface units are available to convert the information into control signals for automatic aiming of weapons.

The system's main features are: immediate detection of pop-up targets due to a fast scanning rate; simultaneous high quality clutter and ECM suppression; automatic range and bearing tracking of up to 12 targets; one-man operation.



The radar is carried on a two-wheel trailer which carries a mast-mounted antenna. The operator's console and the associated communications, computer and electronics equipment are housed in a standard shelter.

CONTRACTOR

Hollandse Signaalapparaten BV, PO Box 42, 7550 Hengelo, Netherlands.

BODIL COAST ARTILLERY FCS

BODIL is an electro-optical fire control system for coastal artillery applications developed for the Norwegian Coast Artillery by Kongsberg.

Few details have been revealed but the BODIL FCS includes mini-computers, electro-optical sensors, data transmission links, and gun displays. The system requirements are based on reliability and ease of operation. Only one sensor operator and one system operator are required.

The system is flexible, and can easily be expanded to cater for larger batteries and fortifications, for example, by adding more sensors and tactical and tracking displays. The design allows for the transmission and reception of data from other batteries.

STATUS

Operational.

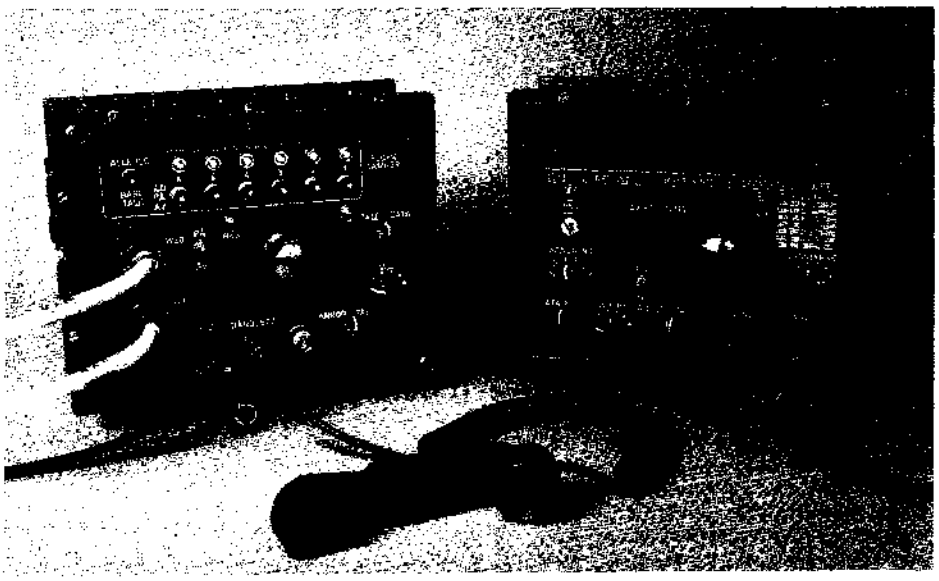
CONTRACTOR

A/S Kongsberg Vapenfabrikk, PO Box 25, 3601 Kongsberg, Norway.

BODIL fire control system in operation with a Norwegian coast defence battery

2645.161
ODIN ARTILLERY FCS

Odin is the name given to a computer-based battalion-level artillery fire control system which is currently in service with the Norwegian Army.



The basis of the system is the Kongsberg NM90 – a special fire-control version of a general-purpose computer. One of these is located at each battery command post, and there is a further computer of identical pattern at battalion command post. Each computer has a field artillery panel, a combined control and display panel for entering information and displaying data. The important feature of this arrangement is that, in association with programs stored in the computer, the panel not only accepts and displays data but also instructs the operator, by various display devices, leading him through the sequence of actions required by the fire control procedure. Firing data are presented at each gun by means of the gun-display unit NO/VGG-20.

Target data inputs will in general be provided by forward observation posts, each of which is equipped with a Simrad LP3 laser rangefinder (**1804.193**) and the NO/VGC-30 data transmission system produced by Siemens A/S in Norway. Other inputs accepted by the system are meteorological data, muzzle velocity measured by, for example, the Nera Bergen doppler radar chronograph, and survey data from standard survey equipment. In addition the computer can store gun ballistic data (up to three types of gun simultaneously) and ammunition calibration data.

The computer comprises a central processing unit, a memory unit, the field artillery panel referred to above, and a power supply unit, all contained in one cabinet. General specification details of the computer are set out below.

CHARACTERISTICS

Type: General purpose, digital, 16-bit word
Organisation: Parallel, negative numbers in two's complement. Floating point arithmetic performed in hardware
Instructions: 96 total (32 basic)
Addressing: Any combination of relative, register modified, and indirect
Main memory: 16 K. Asynchronous operation with CPU. Power failure memory protection. Expansible to 64 K
Memory cycle time: 1·5 μs
Input/output: 16 bits in parallel under program control to/from 256 devices. 1 channel for direct memory access

NO/VGG-20 gun intercommunication unit and gun display unit used with the Kongsberg Odin artillery FCS to provide automatic data transmission from computer to individual guns

Data words: Single word 16 bits
Double word 32 bits
Floating point number 48 bits
(33 mantissa 15 exponent)
Interrupt: Standard single-level interrupt system
Power requirements: 24 V DC (18 – 32 V)
Power consumption: Approx 400 W (16 K memory)
Dimensions: 630 × 410 × 470 mm
Weight: 70 kg
Environment: DEF-133 Table L-3
Temperature: –40 to +55°C (operating); –55 to +80°C (non-operating)
Vibration: 1*g*
Shock: 50*g* – 10 ms
Humidity: 0 – 100% (with condensation)
RFI: MIL-STD-461A
Peripherals: Interface for paper tape reader digitronics 2540 EP. Other peripherals may be connected via the general I/O channel. There is spare space for introduction of special interfaces according to specifications

DATA CAPACITY

Grid co-ordinates: 9 battery points
18 guns organised in 3 batteries with 6 guns in each battery
36 forward observer locations
100 targets or survey reference points
10 safety zones
2 obstacle points for each of 5 obstacle sectors
Calibration data: 18 guns; 8 ammunition lots
Ballistic data: 3 types of gun at the same time.
Programs are available for the following artillery pieces:
US 105 mm M2A1 or M2A2 howitzer
US 155 mm M1 howitzer
US 155 mm M109G SP howitzer
Other programs are being developed and can be produced for any gun, subject to the availability of ballistic data

STATUS

In production and in service with Norwegian forces and under consideration by several others.

CONTRACTOR

A/S Kongsberg Vapenfabrikk, PO Box 25, 3601 Kongsberg, Norway.

4493.161
AS80 ARTILLERY FIRE CONTROL SYSTEM

The AS80 fire control system has been developed to fulfil the need for a decentralised autonomous system which requires minimal operator training while maintaining fast, reliable and accurate fire control computations.

The system consists of a digital computer; a terminal unit with keyboard, visual display keyboard and visual display facilities; a printer and a gun display system. All units have been fully militarised to ensure survival of the system in vehicles. Low power consumption is achieved by automatically reverting to a standby state during inactive periods. All programs and data are non-volatile, and are retained even when the power is switched off. Communication between the user and the system is achieved by means of an interactive dialogue, using menu selections, which guide the user through the correct sequence of operation. The procedures implemented in the dialogue correspond to the manual artillery procedures for the gun. These procedures may be adapted for other weapons or procedures. Approval for the entry of data into the system may be controlled by the officer in charge by use of the confirmation switch.

Currently available software caters for four simultaneous engagements using fire units of up to eight guns. However, with limitations, a total of up to 32 guns can be accommodated. The main facilities offered by the system are:

(1) entry of data
(2) handling of engagements
(3) performing survey calculations
(4) printing of data
(5) hardware check-out.

On having entered the necessary data for the deployment, engagements may be undertaken using the four phases which are provided. These are:

(1) initial orders for the definition of the fire mission
(2) adjustment of fire on the target
(3) fire for effect
(4) end of mission and registration of targets.

During the adjustment and fire for effect phases gun data is calculated and is immediately available for transmission by either radio or landline to the gun display units, which may be either tripod or gun mounted. In addition to the ability to compute ballistic firing data, the system offers several additional features which include: retention of records; ability to perform survey calculations at battery level; warnings of infringements in 'no fire' areas and crest violations; preparation of fire plans; derivation of meteorological conditions (eg from an S700 met system, **4494.161**); maintenance of target, weapon and ammunition records.

Inside a fire control post container of the South African AS80 system showing the terminal (with keyboard lowered), digital computer and interface unit on lower shelf

The principal hardware items of the AS80 system are shown in adjacent illustrations, and most are generally housed in a standard transportable container which also serves as accommodation for the fire control officer and staff. They include a 16-bit minicomputer, a customised terminal offering protection of the CRT during transportation, a printer using standard teleprinter paper, a gun display unit interface with associated line distribution box and interface to data entry terminals. Up to 32 gun display units may be driven by one interface unit. Communication with the self-contained gun display units may be achieved either by the internal radio or by a landline.

CHARACTERISTICS

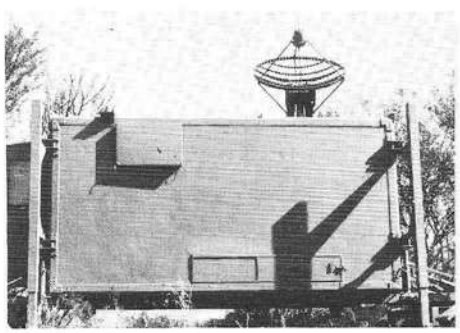
Computer: 16-bit; 64 K words, expansible to 256 K words; programs and data non-volatile
Terminal keyboard: 56 characters (36 alpha-numeric, 4 symbols, 11 specific function keys, 5 unspecified function keys); remote 'confirm' switch for FCO
Printer
Line length: 80 characters/6 lines/in
Speed: 30 cps (max)
Character set: 58 characters from ASCII standard code
Interfacing: 20 mA single current loop

STATUS

Operational and in production.

CONTRACTOR

ESD (Pty) Ltd, PO Box 35, Halfway House, 1685, Republic of South Africa.



AS80 printer unit in its protective case

4494.161
S700 METEOROLOGICAL STATION

The S700 meteorological system provides a simple method of gathering meteorological data for ballistic computations and related battlefield applications. The system is completely mobile, being fitted in a standard military shelter, and offers automatic tracking of a radiosonde from the launch until termination of a flight. The data received from the radiosonde, together with its position, is fed to the digital computer which calculates wind speed and direction, at the various altitudes, together with a pressure, temperature and humidity profile. The results may be presented in formats suitable for direct use in artillery fire prediction calculations. The deployment of the system is simple, requiring only a single vehicle for transportation and a crew of two for operation.

The man-machine interface is by means of a dialogue, the first operation undertaken being the calibration of the radiosonde in a ground check chamber included in the system. Calibration is performed for temperature, pressure and humidity. On completion of the calibration process, the radiosonde is attached to a balloon and the antenna is aligned for tracking by means of a CCTV monitor. Ground meteorological conditions obtained from the monitor unit are fed into the computer system. On releasing the balloon, the antenna automatically tracks and data containing temperature, barometric pressure and humidity are received and recorded, being used in conjunction with the tracking antenna position to produce the required meteorological data as a hard copy print-out. The ground receiver antenna automatically tracks the sonde, using the latter's transmissions, thereby eliminating any need for radar tracking of the balloon/sonde. This has the operational benefit of making the ground station passive in use and thus immune to counter-measures.

Tracking and reception unit of S700

The hardware consists of a monitor unit, a receiver unit, a tracking unit and a processor unit which offer the following:

MONITOR UNIT

System power conditions, flight clock, CCTV for initial antenna alignment and ground weather conditions.

RECEIVER, TRACKING AND PROCESSOR UNITS

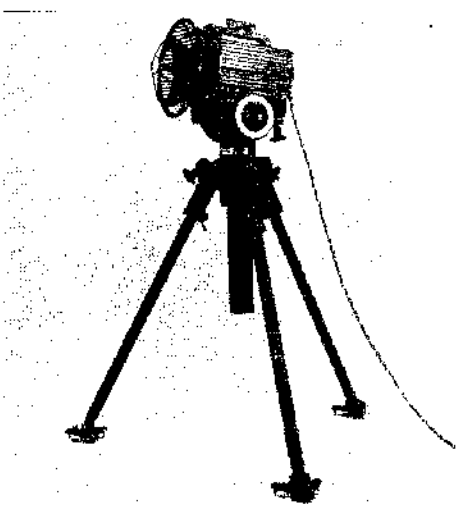
Receiver frequency range: 1680 MHz ± 20 MHz
Tuning: Manual + AFC
IF: 30 MHz
Sensitivity: 100 dBm
Noise figure: 9 dB max

COMPUTER

The digital processor used is a 16-bit mini-computer, understood to be of South African design and manufacture. The system operates from standard lead acid batteries, the supply voltage being 24 V DC. Power consumption is nominally 170 W with a peak requirement of 320 W. Fully militarised, the system conforms to DEF 133 Table L2 (as applicable) and can operate in the temperature range of -10 to +50°C.

DIMENSIONS AND WEIGHTS

Shelter: 419 × 227 × 228 mm (without wheels or legs)
Operating console: 825 × 510 × 400 mm (excluding computer terminal)

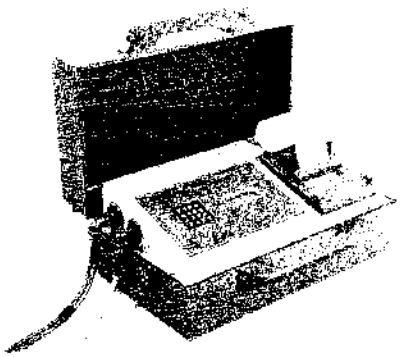


Radiosonde ground check chamber: 406 × 400 × 360 mm
Antenna unit: Height (max) 1·7 m (excluding raising mechanism); turning radius 0·96 m; disc diameter 1·2 m

STATUS
The system has been extensively deployed under operational conditions and is in regular service.
CONTRACTOR
DIEL (Pty) Ltd, PO Box 228, Plumstead, 7800, Republic of South Africa.

4495.161
EMVA MK 10B MUZZLE VELOCITY ANALYSER
The EMVA Mk 10B muzzle velocity analyser is a doppler radar measuring instrument capable of measuring projectile velocities over the range 30 to 3000 m/s. Results are presented in metres per second for direct application in fire control calculations. It is suitable for use with gun calibres of 20 mm and above. The instrument consists of an antenna head suitable for mounting on the gun, or on a tripod adjacent to the gun, and a processor unit. The processor unit contains a liquid crystal display and printer for data recording. A single 50 m or optional 100 m shielded cable connects the antenna head to the processor. Power can be obtained from standard lead acid batteries. No warm-up time is required and the equipment is ready to operate immediately after the brief automatic self-test sequence has been completed.

Provision of interactive operator dialogue minimises incorrect data entry, and informs the operator of incorrect procedures. It also enables potential operators to be trained in a matter of hours. The dialogue is currently available in two languages.
OPERATION
The operator enters the expected velocity range, and any other relevant data that may be required to be recorded in hard copy form, into the processor via the keyboard. The measurement process is entirely automatic from the time the system commences measurement until the final hard copy print-out. The antenna head ceases to radiate the moment the projectile is beyond instrument range. The instrument is self triggered by the doppler signal. However, an external trigger unit which operates on gun flash or projectile shadow is also provided. When plugged into the antenna head it automatically overrides the self-trigger circuit.



From the instant the measurement commences until the projectile leaves the range of the instrument approximately 100 individual velocity samples are taken and stored. The exact number depends on the velocity and cross sectional size of the projectile. These samples are then evaluated, processed and used to calculate to two decimal places, the velocity of the projectile as it left the muzzle of the gun.

Doppler radar head for EMVA Mk 10B muzzle velocity measuring analyser

This velocity value, which is presented on the liquid crystal display, and printed out within seconds of the round being fired, is the non-standard instrumental velocity. Readout of the standard instrumental velocity may also be obtained provided that the gun tables for any particular gun or guns are known and are pre-programmed by the factory into the processor memory. Similarly the effect of gun wear, elevation and meteorological conditions may also be taken into account. In the rapid fire mode the operator need only press a single key to instruct the processor to assume that all the data entered for the previous round will be the same for the next and to automatically increment the round number.

The complete system consists of an antenna head, processor and tripod as well as a transport box for the antenna head, cables, external trigger unit and optional charge temperature thermometer. This box also doubles as a field operating bench for the processor. The processor is in its own fully rugged-ised box.
CHARACTERISTICS
Velocity range: 30 - 3000 m/s
Accuracy: ±0·05%
Power requirements: 24 V DC: 2 A average
Dimensions
Antenna head: 305 × 145 × 165 mm
Processor unit: 650 × 380 × 290 mm
Accessory box: 720 × 520 × 270 mm
Tripod: Adjustable height from 600 - 1500 mm
Weight
Antenna head: 9 kg
Processor unit: 30 kg
Accessory box: 20 kg
Tripod: 25 kg
DEVELOPMENT
Developed in the Republic of South Africa.
STATUS

2378.181
BOFI ANTI-AIRCRAFT FIRE CONTROL SYSTEM
BOFI is an all-weather fire control instrument of multi-sensor type developed by Bofors for their 40 mm L/70 gun (**5528.103**) of which large numbers have been produced. The equipment is fully integrated with the gun and each gun will become an autonomous firing unit that can combat its targets individually.

The equipment consists of a computer, an operator's panel with joystick, sights for day and night use, laser rangefinder and a tracking radar. The major portion of the equipment is installed in the operator's cab. The main sensor of the multi-sensor fire control is the Ku-band (J-band) radar, using the MTI function during acquisition and frequency agility during automatic tracking to increase the accuracy. Tracking observation can be done on an A-scope or by using the sights. The optronic sensors consist of a 10 Hz neodymium laser rangefinder, a day sight and a night sight with a three-stage light amplifier. The sensors can be used redundantly to give maximum performance and resistance to jamming.

The computer is of hybrid type which calculates the target co-ordinates continuously as well as the target's future position in a cartesian co-ordinate system. External ballistic corrections are set on the operator's panel and are compensated for in the computer's calculation of super-elevation and wind drift etc.

A central search radar is used acting as a combat control centre for a battery of BOFI guns. An optical target indicator is incorporated in the system for designation of targets visually detected at the gun site. The BOFI equipment is designed in such a way that it can also be used on existing 40 mm L/70 field guns.
DEVELOPMENT
Development work and system tests of the all-weather equipment were completed in 1979 and further details will be found in **2349.131** in the Mobile Gun and Rocket Systems section of this volume.
STATUS
The basic version without tracking radar was tested during 1972-73 and put into series production in 1976. The system has been exported to several customers.

FIELD ARTILLERY FIRE CONTROL COMPUTER 9FA 302
The 9FA 302 is a design development of the 9FA 301 already in quantity service with the Swedish Army for use with the new FH 77 155 mm field howitzer. The design of the new 9FA 302 incorporates experience derived from field trials of the 9FA 301 as well as up-rated performance specifications requested by other customers. The most important changes, apart from software improvements, are: improved temperature range, extending from tropical conditions to arctic environment; higher capacity solid-state memory application for greater target range and increased number of projectiles and propellant charges.

The 9FA 302 is a field artillery computer designed for battery-level operations. Its main application involves the computation of azimuth, elevation, fuze settings and propellant charge for a battery emplacement of up to eight guns.

Discrete firing parameters are computed for each gun and normally transmitted directly via a data link to the RIA gun sight (**3144.193**). Firing parameters can also be transmitted directly to a gun display unit (GDU) placed on or in the immediate vicinity of the gun. All guns receive firing parameters less than five seconds after input of the complete set of target condition data.

The computer can also operate as a back-up system for two additional batteries. There are three basic operational modes for the computer, one for each battery. It is possible to switch between these

three modes and always to return to the original operational status. Thus firing data can be computed in sequence for three batteries while a return to the battery which has highest priority is possible at a given instant. Calculation of firing data is performed by solving differential equations. This method gives high accuracy while requiring only a small amount of data to characterise the ballistic behaviour of the projectile. Ballistic data for numerous different projectiles can be stored simultaneously.

Besides calculating firing data, the computer is also capable of:

(1) storing 100 target/registration systems
(2) storing five safety zone limits
(3) storing, automatically counting and displaying current ammunition stock
(4) store and display of current corrections
(5) automatic/manual selection of propellant charges
(6) selection of high or low angle trajectory
(7) selection of calibres, shells, charge system and charges
(8) continuous systems diagnostic program
(9) artillery survey routine
(10) final protective fire target; firing data for this target is automatically transmitted to guns in End of Mission mode
(11) UTM Co-ordinates Handler mode can be used worldwide, using current spheroid and zone cross-overs.

PEAB 9FA 302 fire control computer

The 9FA 302 is housed in a single enclosure consisting of the following modular units: a general-purpose digital computer with a CPU micro-processor, input/output stations, a 128 Kword solid-state memory, and ergonomically designed control and display panels.

Normally the 9FA 302 is mounted in a vehicle but it can be set up separately. Only one man is needed to operate the equipment. The computer has a built-in, continuous self-test program. A special diagnostics program quickly localises faults. The modular system configuration promotes ease of service and maintenance.

CHARACTERISTICS
Width: 580 mm
Height: 420 mm
Depth: 750 mm
Weight: 45 kg
Power: 21 - 30 V DC approx 200 W
Operating temperature range: -30 to +60° C
Operational data
Battery emplacements: 3
Guns per battery: 8 (max)
Projectile types: 8 (max)
Charges: 10 (max)
Target memory: 100
Firing zone limits: 5 areas

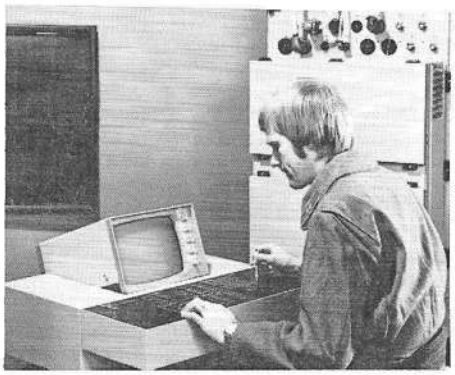
9AA/100 FIRE CONTROL SYSTEM



The 9AA/100, formerly KALLE (**2468.181**), is a light anti-aircraft gun control system developed by Philips Elektronikindustrier AB, as main contractor, in partnership with the Aerospace Division of Saab-Scania who are responsible for the optronic technology. It is intended for fixed or mobile installations controlling typically, two guns of 30 to 40 mm calibre.

The basic system comprises a combined TV director and laser rangefinder assembly, a computer, a display and control unit, and data transmission circuits and adaptors for the guns. The TV director is manually laid for target acquisition, after which it tracks automatically by contrast tracking and with the laser rangefinder provides full target co-ordinates for the computer. The computer is a general-purpose mini-computer and is the same as that used in other PEAB fire control systems, 9 LV 200 Mk 2, 9KA 400 etc.

Controls on the display and control unit include director controls for acquisition and tracking modes and provision for gun supervision and control. Displays include a TV monitor for presentation of the picture and target data in alpha-numeric form. System options include an IR-camera and associated tracking circuits to give night-time capability. It is also produced in a shipboard version, called 9 LV 100 (**3185.281**).

STATUS
In service.

9AA/200 FIRE CONTROL SYSTEM

The 9AA/200 is a combination of the optronic system 9AA/100 and PEAB's Ku-band tracking radar. It is a frequency agile radar, also capable of operation in MTI-mode. The same radar is also used for the Bofir system and for updating of Super-Fledermaus.

The system has been constructed so that the director can be equipped with any combination of the following sensors: TV-camera, laser rangefinder, Ku-band tracking radar and IR-camera. The automatic TV-tracker, which can also be used together with the IR-camera, is a PEAB developed combined tracker, based on centroid tracking.

In the basic version the director is mounted on a lightweight trailer and the control and display units are installed in a shelter.

STATUS
Under development, and possibly intended for use with Greek Artemis air defence system (**4511.131**).

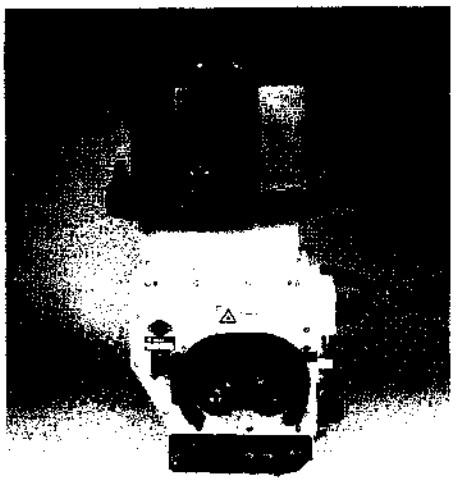
BOFORS AFV FIRE CONTROL SYSTEM

The latest Bofors Aerotronics fire control system for armoured fighting vehicles originates from the FCS developed for the Swedish Ikv-91 tank destroyer, described in **2399.181** in earlier editions of *Jane's Weapons Systems*, and evolved through the Type FV FCS series (**3318.181**).

One system comprises a day/night optical sight with a passive image intensifier and a laser rangefinder; and an independent line-of-sight for the gunner and an accurate ballistic and lead-angle digital computer give the system the necessary high technical and performance characteristics needed for the engagement of moving targets from a moving vehicle. This version is suitable for retro-fitting to existing AFVs and can be modified for use in updating many tanks. As an alternative, the gunner's sight can be specified as a day laser sight.



The system has been configured to accept an integrated stabilised commander's sight and provisions for the commander to align the gunner's line-of-sight with his cupola position.

CHARACTERISTICS
Gun sight
Magnification: ×8·5° (night); ×7 (day)
Field of view: 5·3° (night); 9° (day)
Input pupil diameter: 150 mm (night); 50 mm (day)
Exit pupil: 7 mm
Computer
Range: 200 - 6000 m (laser and manual)
Number of ballistics: 5
Air pressure range: -300 to +100 mm Hg
MV range: ±50 m/s
Air temperature: -30 to +50° C
Powder temperature: ±40° C
Crosswind: ±20 m/s

Computer/control panel of Bofors Aerotronics tank FCS

Head wind: ±30 m/s
Max superelevation and negative lead angle in elevation: +70 mrad/–10 mrad
Lead angle: ±40 mrad
Max lead angle and wind correction: ±45 mrad
Jump max: ±5 mrad
Powder temperature: –30°/+50° C
Trunnion tilt, max: ±14°
Control System
Max azimuth speed: ±300 mrad/s
Max azimuth speed of target: ±80 mrad/s
Max elevation speed: ±80 mrad/s
Max elevation speed of target: ±20 mrad/s
Laser Rangefinder
Wavelength: 1·06 μsm
Pulse power: 1·8 MW
Pulse duration: 15 – 20 ns
Time between measurements: 2 s
Effective input pupil of laser receiver: 130 mm
Maximum range: 6 km (typically)
STATUS
In series production.

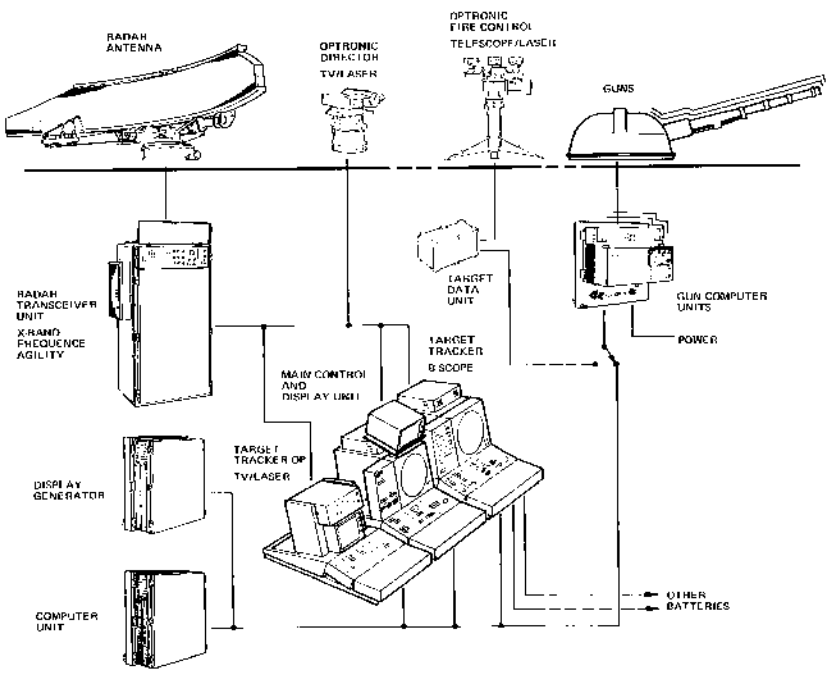
1548.181
9KA 400 COAST FIRE CONTROL SYSTEM KASTELL

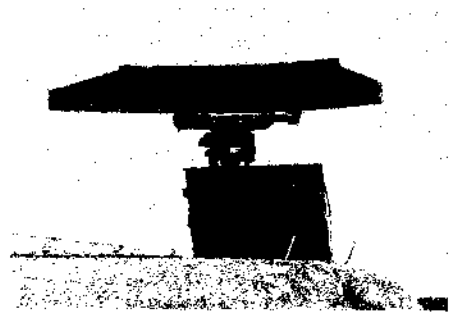
The 9KA 400 is the modern, digital version of the well-proven coast artillery fire control unit MARELD. It is primarily intended for fixed coast artillery or missile batteries. It can also be used as a sensor in the 9CSI 600 STINA naval command system (**4027.281** and **4028.281**).

Sensors are an I/J-band frequency agility radar with a continuously scanning antenna, and a combination TV-camera/laser rangefinder on a separate pedestal. The radar antenna has a very narrow horizontal beam, 0·6°, to give high resolution in azimuth for fall-of-shot observation, and high jamming resistance. Multiple targets are tracked by track-while-scan methods using digital extractor and Kalman filter techniques.



The TV/laser sensor is remotely controlled by the operator and the information is displayed on a TV-monitor and a digital read-out for the rangefinder. The digital computer is of the same basic type as in the 9 LV 200 Mk 2 (**3127.281**) naval fire control system.

Target data, position, and speed vector are generated and fed to ballistic computer units for calculation of gun-laying data. The guns can be dispersed over a large area remote from the fire control unit, and can also receive target data from other fire control units in the vicinity.



The 9KA 400 Kastell can be supplemented with a self-contained electro-optical fire control director using telescopes and a laser for high accuracy computer-aided tracking of one target. Infra-red or image intensifier sensors can be added to obtain all-weather capability.

STATUS
The original 9KA 400 has been operational in large numbers in Sweden, and other countries, since the mid-1960s. The new version entered service in late 1976 and is now in operation and a newer generation Mk 2 version is now in production. At least 70 systems have been ordered for use in Sweden and several other countries.

CONTRACTOR
Philips Elektronikindustrier AB, 175 88 Järfälla, Sweden.

Coast artillery system 9KA 400 Mk 2

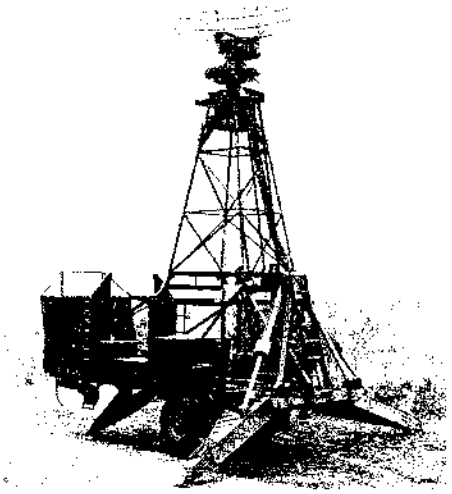
4318.281
9KA 500 COASTAL FIRE CONTROL SYSTEM KARDINAL

The 9KA 500 Kardinal mobile coastal artillery fire control system is derived from the well-proven 9KA 400 (**1548.181**) which has been operational in Sweden and other countries since the mid-1960s. All operational functions of the 9KA 400 are retained and many operational and technical features are added. The major new ones are:

(1) higher mobility through reduced weight
(2) greater deployment flexibility through separation into a sensor unit and an operations unit
(3) additional combat control functions, ie improved presentation of the tactical situation and automatic tracking of multiple targets
(4) the 9KA 500 Kardinal can easily be supplemented with functions for engagement with missiles and some of those functions are already implemented.

The sensor unit is a single-axle trailer with a hydraulically-operated mast. The top of the mast houses the radar antenna and, below the antenna, an optronics unit. The optronic sensors are: a TV-camera and a laser rangefinder. The turning gear for the optronics is an 'around the mast' design giving both the radar and the optronic sensor a full 360° field of view. Also mounted on the sensor trailer is the radar T/R unit, a hydraulic pump, and a motor-generator, making the trailer a self-contained unit, remotely controlled from the operations unit. The mechanical design of the trailer is very rigid in order to achieve the stability necessary for fire control purposes, ie fractions of a milliradian even in strong winds.

Two versions of the radar, transmitting in the X- and the Ku-band respectively, are available. In both versions the well-known spin-tuned magnetron is used, giving wide-band frequency agility with the same benefits as in the 9KA 400. The Ku-band version gives the high angular resolution as in the 9KA 400, ie 0·6°, and yet is lightweight and highly mobile. This particularly high resolution is valuable in applications where separation of targets and fall-of-shot observations ('splash-spotting') is required.



The transmitter power at Ku-band (65 kW) is lower than the power at X-band (200 kW) but the shorter wavelength at Ku-band suffers less from the 'beam-lift' due to multipath effects. Thus the detection and tracking ranges against ship targets are the same for the two radars when deployed at such altitudes, and they are both effectively limited by the curvature of the earth.

The sensor unit and the operations unit can be separated by a distance of some kilometres. Transmission of radar and TV video, data, commands, and logic signals between the two units takes place over a lightweight fibre optical link, which greatly facilitates cable laying compared to conventional cables. Furthermore, the fibre can be used in full duplex in both directions by the use of dual wavelength transmission with dichroic prisms in the terminal equipment.

The set-up of displays and control consoles in the operations unit is similar to the 9KA 400. Like that, the number of consoles and their functions can be easily tailored to suit various operational doctrines and functions, and the weapons to be controlled, either guns and/or missiles.

STATUS
In production.

9KA 500 Kardinal coastal artillery fire control system deployed

SWITZERLAND

3314.181
FIELDGUARD ARTILLERY FIRE DIRECTION SYSTEM

Fieldguard is an all-weather fire direction system for cannon and rocket artillery. It tracks fully automatic projectiles, provides near real-time corrections for meteorological and weapon errors, and computes best firing data for surprise fire for effect individually for all weapons. The system calculates in real-time an accurate total ballistic correction of the firing data by the use of radar tracking.

Compact and modular design allows Fieldguard to be assembled in a shelter for mounting on any wheeled or tracked vehicle. The system is self-contained and consists of tracking radar, computer, operator console for man-machine dialogue, data transmission with weapon display units and power supply. It operates either at battery level or battalion level and needs no weather messages. Fieldguard communicates with different kinds of sensors for target acquisition and target location such as drones, battlefield radars and forward observers.

The system receives fire order and target co-ordinates. The computer calculates the firing data for the basic gun or the ground launcher, based on the stored ballistics, and transmits it automatically to that weapon display unit. The so-called pilot firing now starts. Up to three pilot rounds will be fired, tracked by radar and destroyed in flight in order not to warn the target.

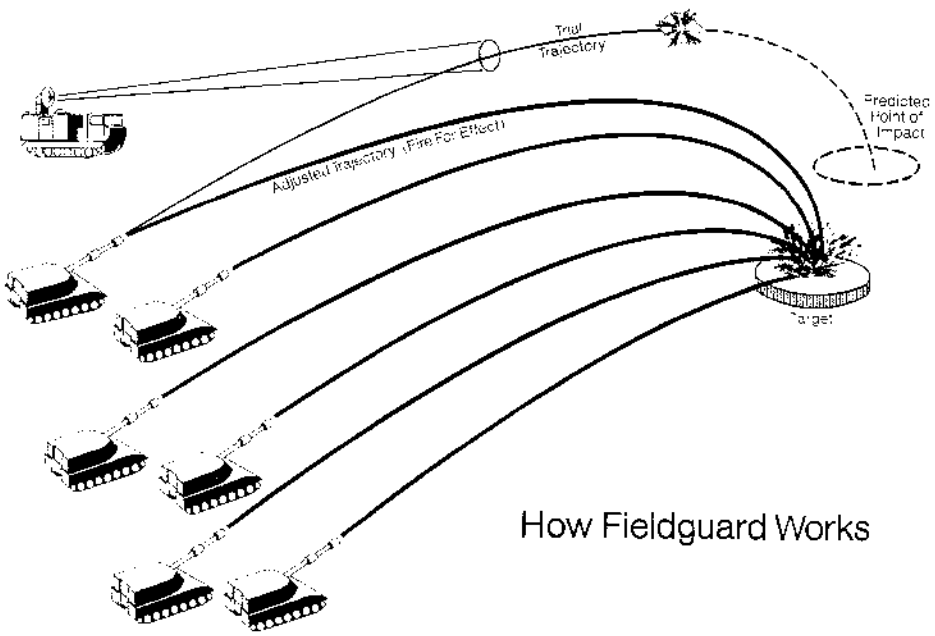

Diagram of Fieldguard pilot firing technique

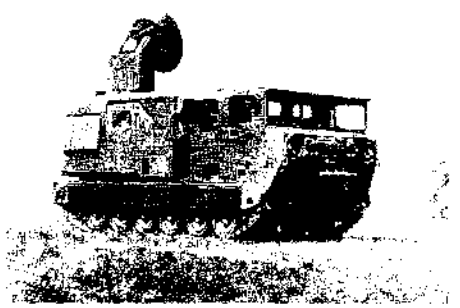

Fieldguard extrapolates the remainder of the trajectory, predicts the fictitious point of impact and computes the firing data of the adjusted trajectory individually for all weapons. The massed fire is released and the target is under accurate and surprise fire for effect. Without foregoing pilot firing, Fieldguard can check and update corrections by tracking one round within a volley of fire for effect.

Forward observers are equipped with portable target locating equipments and connected to Fieldguard by radio. The target co-ordinates will be determined by the laser-goniometer and transmitted to Fieldguard by the Artillery Tactical Terminal (ATT).

Fieldguard advantages summarised by the manufacturer are: operation under all-weather conditions; improved accuracy of fire for effect; improved accuracy of unobserved counterfire; maximum surprise effect on enemy; renders considerable savings in time; minimises ammunition consumption; it operates without meteorological information; and allows considerable savings in personnel.

STATUS
Fieldguard has demonstrated reliability, accuracy and effectiveness in extensive tests and is now in series production. Fieldguard is fielded in several countries and the armed forces of NATO.

CONTRACTOR

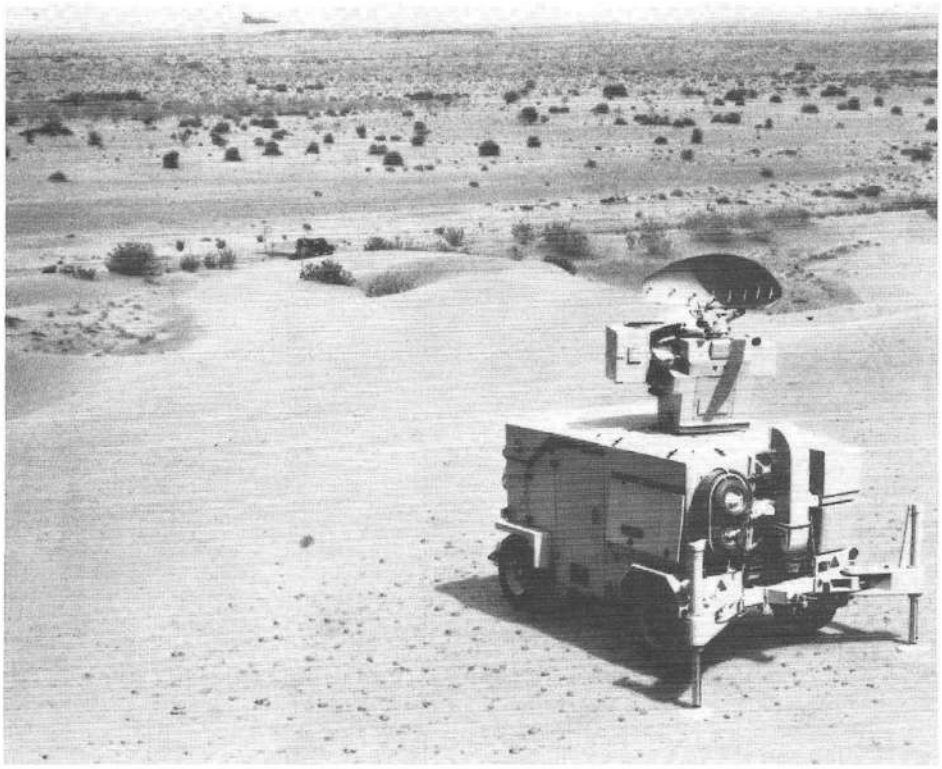
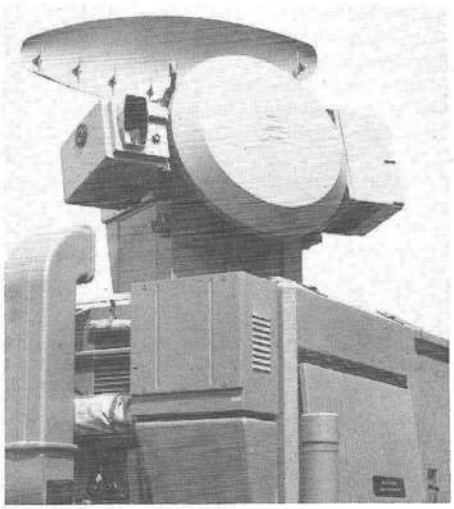
Fieldguard system deployed operationally

2377.181
SKYGUARD ANTI-AIRCRAFT FIRE CONTROL SYSTEM



Skyguard is the fire control system that Contraves have been developing for some time as the successor to the Super Fledermaus (**2376.151**) system that they have marketed so successfully in various versions for many years.

Major differences between Skyguard and its prececessors - apart from a general modernisation of design techniques - are the provision of two radars (one for search and one for track) in place of one and the use of a digital instead of an analogue computer. Another important difference is the use of pulse-doppler type radars in place of pulse radars.



Main system components are a pulse-doppler search radar, a pulse-doppler tracking radar, a TV tracking system, a digital computer, a control console, and a power supply system. The whole is contained in a fire resistant reinforced fibreglass-polyester cabin that can be mounted on a trailer or a wheeled or tracked prime mover, and is air transportable. The power supply system is built into the main equipment but can be removed for external operation and is automatically refuelled directly from cans.

The search radar is a fully coherent pulse-doppler system, the transmitter of which is common to the tracking radar. Working in X-band with a mean power of 200 W it offers fast frequency change and fast PRF change facilities and a choice of 1 and 0.3 microsecond pulses. A cosecant squared antenna with integrated IFF antenna gives a horizontal beamwidth of 1.7° and a 55° beam in elevation. Scanner rotation rate is 60 rpm. The receiver has range-gated doppler filters and offers an MTI improvement factor better than 50 dB. The PPI display has switched ranges from 0.3 to 20 km and can present simultaneously processed MTI video and raw video. Radar search range is 20 km and range resolution 160 m. The system is IFF-compatible and special features include automatic target alarm, automatic lock-on, and computer-controlled symbol markers on the PPI.

The tracking radar is a fully coherent monopulse

Skyguard with X-band search radar and Ka-band tracker with TV camera

Skyguard with Ka-band radar in tracking position

doppler system with a cassegrain paraboloidal antenna having a 2·4° beamwidth. Signal processing circuits provide 80 m acquisition gates around the tracking gate, all gates having doppler filters, and the total acquisition range is 1120 m. The MTI improvement factor is better than 50 dB. The display is an R-trace, displayed on the TV monitor, for tracking supervision and ECM monitoring but target acquisition and tracking is automatic and includes memory tracking and automatic alarm facilities. Special features include fast target exchange and automatic noise jammer tracking.

A closed-circuit TV system provides for optical tracking and automatic TV tracking. An optical sight on a rotating chair is provided for visual target acquisition with provision for target indication by means of a flashing strobe on the PPI.

As part of the program to augment the combat value of the Skyguard, Contraves has designed various technical innovations and developed accessory equipment. These primarily assure optimal acquisition, tracking, and combat of low-flying aircraft under extreme topographical conditions. Besides X-band radar and TV-tracking, Skyguard is now available with fully coherent Ka-band radar. This ensures improved target resolution in terrain where the use of radar is very difficult. At the same time it increases the redundancy of the automatic tracking possibilities. With the additional Ka-band radar Skyguard remains easy to operate. The Ka-data also appears on the Combat Display. The Ka-band radar can be easily and quickly retrofitted to all existing Skyguard fire control units.

The Contraves computer operates in real time to perform threat evaluation functions, calculate ballistic data for guns and command signals for missiles, aid the target tracking operation and monitor, and check-out the entire system.

In addition to the PPI and R-trace displays already mentioned, the control console incorporates a tactical display with numerical read-out, the TV tracking monitor, rolling-ball control for PPI markers, joystick control for manual tracking, and a matrix panel for data input and output.

OPERATION

A search radar data extractor (SRDE) by Contraves AG in Zurich is available and the system can be integrated into Skyguard's fire-control unit. It enhances the degree of automation and the time required for target acquisition and tracking is shortened and threat evaluation automated.

The SRDE system is used for the following main tasks:

(1) Automatic first-target alert coupled with automatic target acquisition.

As soon as the first-target alert is acquired by the search radar, operators are automatically alerted. Thereupon, the target is automatically passed on to the tracking radar which keeps on tracking it. Despite very high clutter suppression of the Skyguard's pulse doppler search radar, alerts will unavoidably be triggered also by false targets in the shape of moving objects (motor cars, ventilating fans, etc). Such false targets are specifically marked and can at any time be wholly or partially erased at operator's discretion.

(2) Automatic threat evaluation regarding targets in the combat area or those already acquired by the search radar.

By the track-while-scan system it is possible to simultaneously track several targets as well as to evaluate automatically the respective degree of threat. Skyguard's digital system computes, among other things, the threat degree for each individual target, based on the angle of the approaching target, velocity, range, etc. Targets are shown simultaneously on the PPI in the order of priority corresponding to threat involved.

As a matter of course, the data supplied by Skyguard's integrated IFF unit are also included in the threat evaluation.

Skyguard is able to control medium calibre guns and/or guided missiles. The Contraves-designed missile launcher uses the proven undercarriage of the Oerlikon 35 mm gun and carries four Sparrow or Aspide missiles in containers, as well as the target tracking and illuminator radar antenna. The launcher is directed either remotely from the Skyguard system or locally by the launcher operator.

For crew training, there are two different simulators available: one is integrated in the system, while the larger one is an additional unit connected to it. (Training Simulator 2)

STATUS

Skyguard was developed by Contraves as a private venture project and, after evaluation, it has been adopted by the armed forces of more than 15 countries. More than 400 units have been ordered, and the system is understood to be under evaluation by certain other countries.

CONTRACTOR

2376.181
SUPER-FLEDERMAUS

A member of the series of anti-aircraft fire control systems produced by Contraves in Switzerland, the Super-Fledermaus Type D IX with MTI is an advanced radar optical tracking and computing system suitable for use with medium calibre anti-aircraft guns. Extreme operational versatility coupled with compact and rugged design make it suitable for use in a wide variety of combat situations and it, and its forerunners, are used by more than 20 nations.

The main equipment is compactly mounted on a four-wheel cross-country trailer and comprises a radar/visual tracker for target acquisition and determining the firing data for up to three separate gun emplacements, and a muzzle velocity indicator for measuring the muzzle velocities of up to three guns. A separate power supply unit, mounted on a two-wheel trailer, generates power for the fire control unit. Auxiliary equipment are a signal box for use by the fire control officer and an optical putter-on for rapid visual acquisition of unexpected targets.

A detailed description of the system was published in the 1970 – 71 edition of *Jane's Weapon Systems*, but systems in use may vary since in recent years Contraves has offered various improvements as modification kits for rectrospective fitting.

CHARACTERISTICS

Type: Combined radar/visual tracker and computer for remote control of medium calibre anti-aircraft guns or missiles

Target detection: Up to a range of 50 km

Target acquisition: All-weather operation with 5 options:

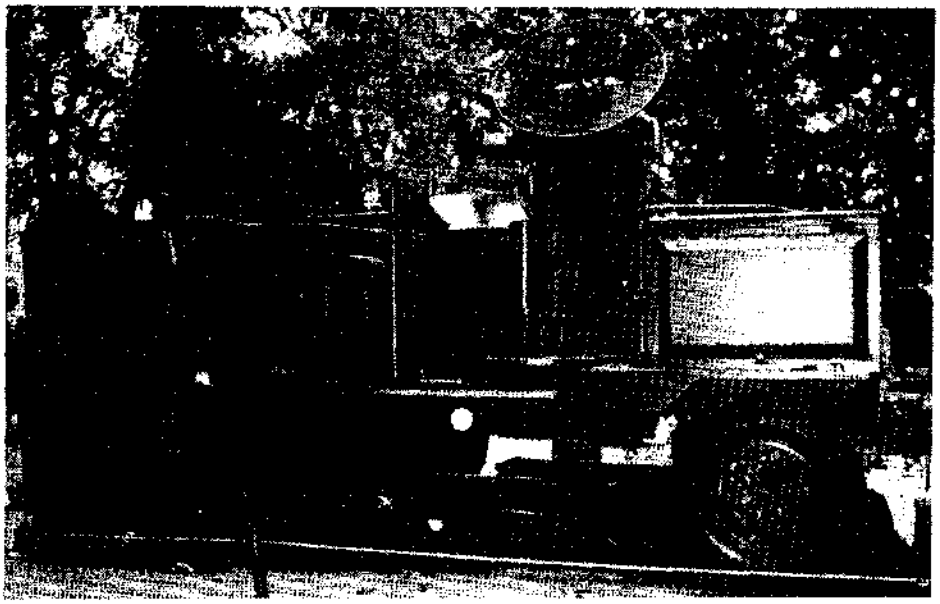
(a) by selectable programmed scanning motion
(b) by optical putter-on
(c) by optical tracker
(d) by tactical radar
(e) by radar/visual combination

Target tracking: Up to a range of 40 km with 5 options:

(a) automatically by radar
(b) automatically by regenerative control
(c) automatically by memory
(d) visually by tracker operation
(e) automatically in range, visually in angle

Firing data computation: Continuous computation individually for 3 gun emplacements

Muzzle velocity and meteorological corrections included



Special modes selectable for diving or curved flights

Muzzle velocity measurement: Separate measurement by built-in equipment for each gun

ECCM: High transmitting power; narrow main beam; high sidelobe attenuation; 2 independent

transmitting channels; jump changes of frequency over wide band; tAGC; STC; FTC
Clutter suppression: MTI data processor
Mobility: Cross-country trailer
Maintenance: Built-in test and calibration equipment. Use of modular plug-in units
CONTRACTORS
Complete system: Contraves AG, Zurich, Switzerland.

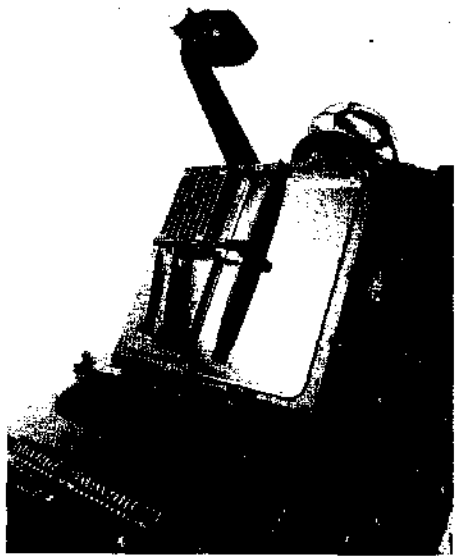
The system is also manufactured by Contraves Italiana SpA, Rome, Italy, and under licence in India and Japan.

Brazilian Army Super-Fledermaus fire control system showing tracker's position to left of radar and the controller position under shelter at extreme left of unit

4586.181
GUN KING SIGHTING SYSTEM

Gun King is an autonomous sighting system for use with automatic anti-aircraft guns, such as the Oerlikon Diana twin 25 mm AA gun GBF-AOB **(4525.131)** or Oerlikon twin 35 mm AA field guns GDF **(4537.131)** although the system is equally well suited for naval applications or operation of other gun types.

Of modular design, Gun King is based on the use of a new Contraves digital computer coupled with an optical system that incorporates a periscopic sight, laser rangefinder, and includes provision for a TV camera for operator training or for use as a tracking module. There is a common optical path in the sight periscope for the laser beam and the aiming sight-line, and these beams are deflected with high accuracy by a gimballed mirror, thus permitting the use of a fixed eyepiece. The periscope has a multispectral optical system and night operation is possible.



The rangefinding function is performed by the laser rangefinder, which uses a multi-divergence neodymium laser. A novel switch-over device enables the laser beamwidth to be reduced for use against ground targets, eliminating ground clutter.

The digital computer calculates all fire control data at high speed with optimum control and accuracy, using filter and ballistic algorithms. In addition it controls the periscope, laser triggering during the tracking phase and the drive electronics. At the instant of optimum hit probability, the operator is given an audio signal to open fire. Target changes can be effected very rapidly because target data is stored in the computer memory. All data relating to weather conditions and weapon parameters is entered into the computer so that the operator is free to concentrate on precise target tracking. Sight and gun are commanded entirely by the operator's control yoke which provides full hands-on control.

Modern DC power electronics and servo-drives are used for gun control, and the battery capacity alone ensures full operational readiness of the entire system from a passive, silent standby status. Up to five combat cycles can be carried out before the engine of the power supply has to be started to provide electrical power.

When employed in a naval role, the Gun King system can be gyro-stabilised and may also be used as a stand-alone fire control facility for several weapons. It can be slaved to other target designation facilities, such as radar or other fire control systems, in both naval and land-based applications.

STATUS
In series production.

Contraves AG, Schaffhauserstrasse 580, CH-8052 Zurich, Switzerland.

Contraves Gun King laser/computer controlled sighting system

UNION OF SOVIET SOCIALIST REPUBLICS

3323.181
SOVIET ARMY FIRE CONTROL

Very little reliable information is available for publication concerning the systems and equipment used by the Soviet Army for such purposes as artillery fire direction, survey, meteorological data acquisition and distribution, tank fire control, tactical data automation, command and control etc. However it is clear from the scale of the USSR's land forces and the level of sophistication displayed by Soviet equipment in general that such aspects of land warfare have not been neglected. Some of the items of hardware known to have entered service are listed briefly below:

(1) reconnaissance theodolite, RT-2: probably used for survey in support of both offensive (eg artillery) and engineering operations
(2) periscope artillery compass, PAB-2: suitable for observer/fire director applications and similar uses
(3) battery commander's telescope, AST
(4) stereoscopic rangefinder, DS-0·9
(5) radar meteorological station, RMS-1: for meteorological data (upper winds and temperatures etc) for use in artillery ballistics computations
(6) topographic survey system: consists of a gyro-compass, transformer, sight, a course plotter incorporating a map display, and radio, mounted in the rear of a GAZ-69TD vehicle
(7) SNAR-2 radar: mounted on AT-L tractor
(8) Arsom: radar for both artillery and mortar locating roles. Dish type equipment.

Laser rangefinders are understood to be added on a retrofitting basis to some earlier types of Soviet tanks, while the latest models include a ballistic computer as well. The T-62s 115 mm gun is reported to be stablised, as is the D-10T2S 100 mm gun which arms the T-54B. The gunner's sight for the latter tank is the TSh 2B-22 or TSh 2-32 and the gun is stablised in both planes.

UNITED KINGDOM

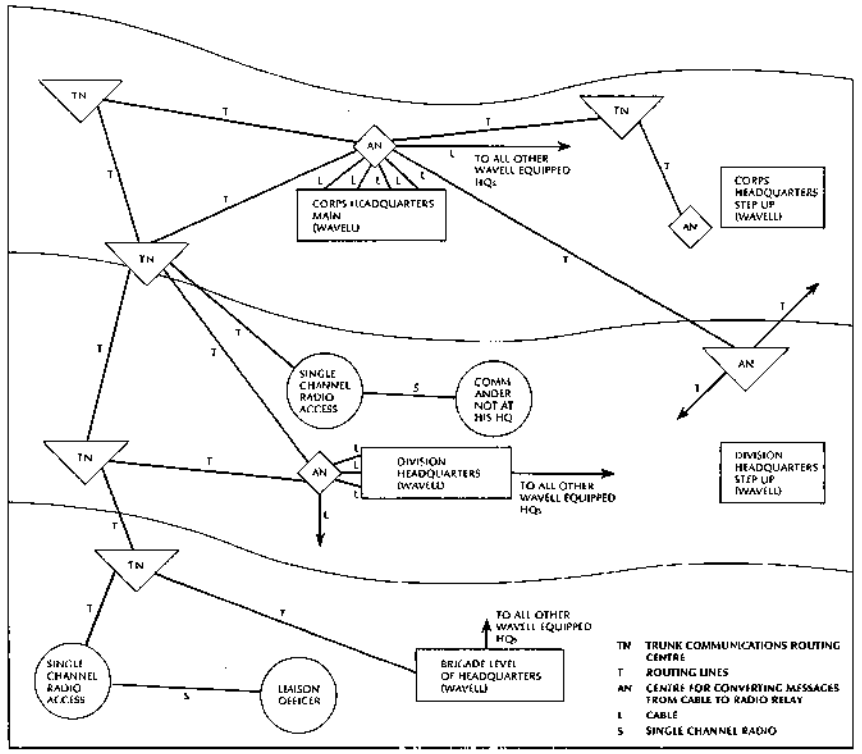
3320.161
WAVELL ADP SYSTEM

Wavell is the British Army's automatic data processing system designed and manufactured to assist commanders and their staffs with the conduct of general operations and intelligence work at Corps, Division and Brigade levels. It is designed to use any suitable communications link and to operate as required with the Battlefield Artillery Target Engagement System (BATES), a semi-automatic data processing and fire control system being developed for the British Army by Marconi Space and Defence Systems. Wavell Stage I uses data links provided on the Army's Bruin trunk communications network. Wavell Stage II enters service during 1985 and will use the new Ptarmigan Tactical Trunk Network.

At each headquarters, conceptually-simple automatic data processing (ADP) facilities will be provided comprising a central processor, bubble memory backing store, and floppy disc drives for loading programs and data. All these will be located in a Wavell vehicle which will connect to the communications system and the remotely-located

visual display units and hard copy printers. Two types of installation are to be provided. At Corps and Divisional headquarters levels the system will be installed in a standard one-tonne container mounted on a Bedford four-ton flatbed prime mover, along with a 20 KW generator. The generator will provide power for the air conditioning and lighting system and, through a power conditioning unit, a 28-volt dc source for the ADP system and back-up batteries. The ADP equipment will be located in a rack based on the Air Transportable Racking (ATR) system. A similar installation is to be provided for use at Brigade HQ but this will be mounted in an FV430 series armoured vehicle with power and environmental control equipment on the roof.

The heart of the system in both types of vehicle will be the ADP equipment rack. The rack will accommodate the central processor unit and associated fast store in two full-ATR units each holding 0·5 Mbytes of semi-conductor memory. Next to the processor will be the interface unit for the communications and terminals, which will be driven at distances of up to 1 km by balanced line drivers accommodated in two half-ATR units each capable of driving 16 channels. Along the top of the rack, the necessary controls and warning lights will be provided as well as two floppy diskette drive units for loading programs and data into the system.



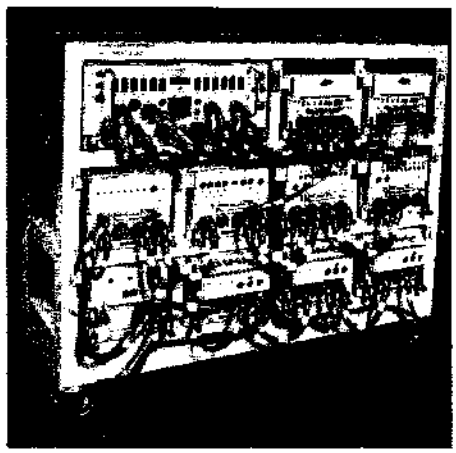
The bottom row of the rack will accommodate up to three units of bubble memory backing store, each having a capacity of 24 Mbytes. The bubble memory offers a number of advantages over the disc. Apart from its low volume and low power dissipation, the bubble is non-volatile if there is power loss and yet can be easily and quickly erased. The data base capacity of each system will be about 72 Mbytes but it is expected that during the life of the system, advances in bubble-memory technology will enable this capacity to be increased by a factor of four.

In operation, raw data will be collated with data entered into the system prior to deployment and with other data generated by the machine itself. It will then be displayed as meaningful subsets of data (or formats) on the staff visual display unit. These formats will be used by the staff to assist with formulating plans and orders and in the preparation of briefs for higher command. General-purpose free-text facilities will also be provided for messages and orders. All formats can be printed out on a hard copy printer for briefing or fall-back and for staff cells not equipped with Wavell.

STATUS

Project Wavell began in the early 1970s as a study of staff functions in the field with the aim of identifying those time-consuming tasks which might be automated. A wealth of detailed information was accumulated, but with senior officers at that time sceptical of the use of computers in matters of command and control, the British Army in general was not clear how to proceed.

In 1976 a decision was made to field a limited system which would use commercial equipment with minimum ruggedisation and from which staff reaction could be obtained. For this trial phase it was decided not to attempt automatic signal message handling in headquarters, to provide ADP only for operations and intelligence functions, and to base the system on existing staff procedures.



Integration of Wavell system with typical communications network

Stage I equipment was fielded in 1978 with the 2nd Armoured Division in the Hanover area. The system was designed to help collect, collate, evaluate and disseminate information to provide commanders with an overall picture of the state of own forces, to make information about own and enemy forces available to supporting arms, to process information from electronic warfare and other intelligence agencies and to build up a picture of enemy deployment and strengths. As the trial proceeded, such was its success that the system was extended beyond this original concept to become widely used by artillery, engineers and logisticians.

In 1979, the Ministry of Defence gave the go-ahead for a Stage II production with the planned introduction of the system in the mid 1980s to the whole of the 1st (British) Corps in the Federal Republic of Germany. A contract valued at £25 million was placed with Plessey Defence Systems for the production of 33 Wavell systems following the £6 million phase-one trial.

Full operation is expected in 1985 giving the British Army a clear lead in the use of ADP on the battlefield. Both the US and the Federal Republic of Germany have similar systems under development but not to the advanced stage of Wavell. When deployed with 1(BR) Corps in 1985, Wavell Stage II will provide the Corps with a unique, highly sophisticated and flexible C^2 system, endorsed by the military user after five years' Stage I experience and well ahead of any operational system available to other armies. The Secure Information Management System (SIMS) at the heart of Stage II will form the core of future applications.

MDP 1000 system of Wavell battlefield C^2 automation system can be accommodated in a wide range of military vehicles (tracked, wheeled, ships or aircraft) or used free standing as shown here

CONTRACTOR

Plessey Defence Systems, Christchurch, Dorset, England.

QUICKFIRE ARTILLERY FCS

The Marconi Quickfire artillery fire control system, introduced at the 1984 British Army Equipment Exhibition, is designed for use at battery and battalion level with all types and calibres of indirect fire weapons. It was a private venture development by Marconi Command and Control Systems, and is a successor to the earlier FACE system (**2415.161**).

While many of the FACE features, such as the tactile colour-coded keyboard and customer-language matrix, have been retained in Quickfire, use of later technology (eg CMOS devices) has permitted significant reductions in weight and volume of the equipment. The result is a unit weighing six per cent that of its predecessor, with three per cent of its volume, at less cost than comparable previous generation equipment.

Quickfire uses full ballistic modelling to provide fire control data and the system can be configured as a Battery (serving up to eight guns) or a single gun system. It is based on a common hardware unit that can be configured for use by a forward observer (FO) as a data module, as battery or battery command post modules, and as individual gun display modules. A plug-in software module stores ballistic data to adapt the unit for operation with specific types of weapon. This basic data is available from a library of FACE programs which currently cover most weapons in general use throughout the world.

Entry of mission data into Quickfire units is by means of a menu-led formats of the matrix whereby visual prompts are given at each stage of the operation. Battery fire control data is computed in less than one third of the time of flight, and the solution is presented in the form of a back-lit LCD which is easily visible in all lighting conditions likely to be encountered. There is storage for up to 100 target locations, ten firing zones, and ten friendly force areas. The system provides for two concurrent fire missions.

Data is conveyed between FOs, command post and gun positions by either radio or cable links, and Quickfire modules have three communications channels which allow for burst transmission of digital data.

As used by a forward observer, the Quickfire module matrix provides preformatted messages to allow the FO to send complete orders for target engagement and to report his own position and friendly locations directly to the command post module. It also receives and displays messages in response.

At individual gun positions, or rocket launchers,

Quickfire module used in the forward observer module role

Quickfire artillery FCS uses common hardware. Same basic module can be used for FO, command post positions as well as ground display module, as here.

Quickfire units are operated as display modules to present all incoming data, while providing answer-back facilities. Individual gun firing data such as, ammunition, charge, fuze, bearing elevation, method of fire and number of rounds are presented.

As a battery or battalion computer module, Quickfire carries out all the necessary survey and ballistic calculations and aids command and control of the guns. Each input from FOs is automatically entered and displayed as required, and command post staff have full authority over the input of data and checking of computations. Under operator control, outgoing messages are automatically transferred and transmitted over the radio network.

CHARACTERISTICS

Dimensions: 316 × 290 × 71 mm
Weight: 7 kg; 6·5 kg FO and gun display module
Power consumption: 6·6 W; 2/7 W FO and gun display module
Met data message: Up to 26 lines (any standard)
Target records: Up to 100
Communication channels: 3
Facilities: Printer interface, real-time clock, touch keyboard, 10 firing zones, 2 concurrent missions, survey, etc

STATUS

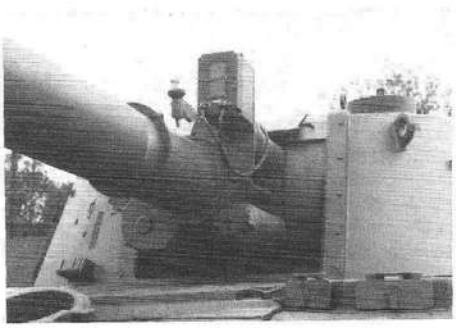
Ready for production.

CONTRACTOR

Marconi Command and Control Systems Ltd, Chobham Road, Frimley, Camberley, Surrey GU16 5PE, England.

4754.181

MARCAL GUN CALIBRATION SYSTEM/MOGUL



The Marconi Marcal gun calibration system is an on-gun system that measures the velocity of every round fired, stores this data and produces a statistical basis for gun calibration, offering a more rapid and accurate way of continuously correcting for variables such as bore wear, met conditions, muzzle velocity etc, that affect the accuracy of fire.

Typically, shell velocity, or a corrected quadrant elevation and fuze setting, where applicable are displayed after each round fired, so that effectively the gun performance is continuously monitored. At the same time the gun data base is automatically updated, enabling calculation of gun laying adjustments on a round by round basis. The equipment is designed for permanent fitting on all categories of field guns of 30 mm or above, and consists of two small units: a doppler radar head, and a control unit containing a microprocessor.

The doppler radar head incorporates a microprocessor and provides accurate velocity measurement with low transmitted power. The control unit includes a data analysis and storage system, an operator display, and an automatic data interface for system expansion. A non-volatile store holds the firing data of the last 50 rounds fired and this information can be retrieved on a simple portable recorder.

CHARACTERISTICS

Radar: 5 mW spread spectrum technique
Transmission duration: 1s (max per round)

Marcal gun calibration system

Beam: 5° (horizontal) × 10° (vertical)
Velocity measurement error: 0·2% (max)
Projectile speed range: 100 - 1000 m/s
Processing speed: 30 rounds/minute
Min projectile calibre: 30 mm

MOGUL

The Marcal muzzle velocity measuring radar is also employed in the Company's Mogul modular gun laying system which incorporates the Marcal system with additional items to suit it for use with SP and towed field guns. In the Mogul system the central unit is the display and processor unit (DPU) which is provided with a fast two-way data bus for on-board operations. A data link compatible with a variety of artillery fire control systems allows for inputs from:

(1) an electronically enhanced indirect and direct fire sighting system
(2) gun safety instrumentation
(3) an inertial gun reference unit
(4) gun control electronics.

Mogul automates the gun laying procedure using the on-board sensors and the microprocessor based control system. A gun attitude reference unit employing a microprocessor and strapdown inertial technology is fixed to the gun mounting to provide direct measurement of gun elevation and azimuth values. A control unit interfaces with the gun laying system and provides rapid autonomous gun laying from the DPU.

Also available is a shell position sensor to confirm that the shell is correctly rammed to avoid fallback, and a gun tube temperature sensor to monitor the approach of cook off conditions.

For towed guns and as a backup system, a direct and indirect optical sight is available which automatically corrects for turret cant and tilt using precision instrumented inclinometers.

STATUS

When the Marcal and Mogul systems were announced in mid-1984 the contractor stated that both were ready for production, although no contract details were available at that time.

CONTRACTOR

Marconi Command and Control Systems Ltd, Chobham Road, Frimley, Camberley, Surrey GU16 5PE, England.

3523.161

MORCOS MORTAR COMPUTING SYSTEM

The Marconi Morcos mortar computing system computes firing data for all types of mortar and is intended to replace the existing manual methods of fire prediction calculation which are slow, prone to inaccuracy and wasteful of ammunition.

Morcos is a single self-contained unit incorporating a computer, keyboard for data entry, display and batteries. The case is built of durable polycarbonate and profiled to fit comfortably in the hand. It is built to full military specifications to withstand adverse climatic, environmental and nuclear effects.

A wide range of drills is available and, as an example, the program for the British Army's L16 81 mm light mortar, includes drills which produce data for HE (high explosive) smoke and illuminating missions, survey problems, target reduction and three concurrent fire missions. It incorporates inputs which take into account variables such as meteorological conditions, charge temperature, difference in altitude between mortar and target, position of own troops, observers' corrections (including laser rangefinders) and individual mortar locations. It has the capacity to accommodate ten mortar positions, fifty targets, ten observer locations and nine positions of own troops (for warning when

own troops are in the danger area).

The computer in Morcos is a microprocessor with access to a semi-conductor backing store. Each ballistic program can predict for one type of mortar and its attendant ammunition. The program can be changed in seconds by removing a plug-in memory unit (called a ballistic module) and by replacing it by another for a different ammunition system. This can be done, in the field, in all weather conditions because the moisture seal in the equipment is not broken.

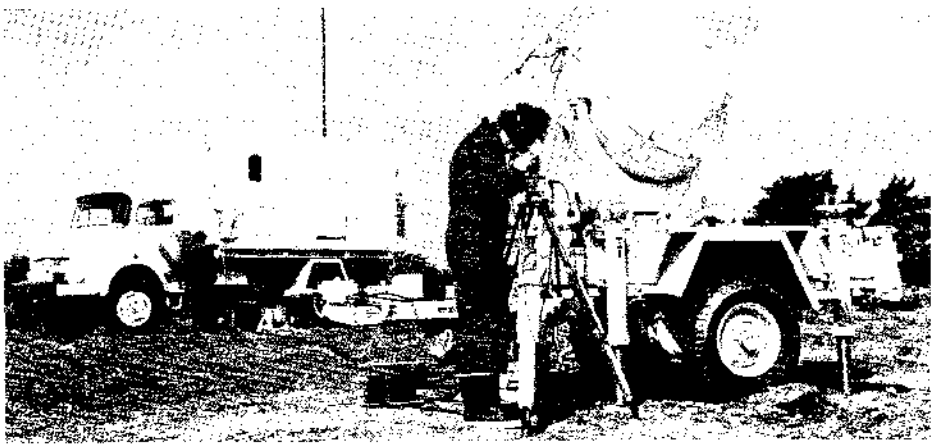
The elastomeric type keyboard is both waterproof and reliable and is illuminated for night operation by a variable brightness electroluminescent panel. The keyboard has twenty-four keys, ten of which are for digits 0 to 9. The display has a capacity for eight alpha-numeric characters and uses high efficiency, extra bright, light emitting diodes, which have a variable lighting control.

Morcos is powered by batteries, which can be either throwaway or rechargeable, or from an external power source. It weighs, including batteries, less than 1·35 kg and measures 23 × 10·1 × 5·4 cm. It is a highly reliable system based on the use of large scale integration and hybrid techniques. Faults can be quickly repaired by easily replaceable sub-assemblies, and no special first line test equipment is needed.

STATUS

Full production and supplied to seven countries.

CONTRACTOR



Marconi Command and Control Systems Ltd, Chobham Road, Frimley, Camberley, Surrey GU16 5PE, England.

2400.161

AMETS - ARTILLERY METEOROLOGICAL SYSTEM

AMETS is the name given to a self-contained, computer-based, mobile meteorological system developed for the British Army by Marconi Space and Defence Systems Ltd and Plessey Radar, for obtaining and processing information on atmospheric conditions automatically. It is capable of processing data from a wind-finding radar and radio sonde complex to an altitude of 20 km every hour, and incorporates a facility to output partial messages within seconds of the radio sonde passing through the relevant height band. A single AMETS will normally provide all meteorological data needed in the area of one army division.

AMETS uses a specially-developed radio sonde with a very accurate temperature sensor. The outputs from radio sonde and radar are fed into a computer which can then calculate the required meteorological information. Measurement of surface pressure, and the average humidity figures which can be provided for the particular zone of operation are stored in the computer memory. The loss of accuracy resulting from this simplification of the radio sonde is negligible for artillery purposes, yet it offers appreciable gains in terms of operational simplicity and reliability in military field conditions.

Plessey WF3M mobile wind-finding radar is primary sensor of upper air winds for AMETS. Well over 50 of these radars had been sold by 1985

CONSTRUCTION

The data processing part of the system is based on an MC1800 computer, produced by Marconi-Elliot Computer Systems, and already in use in a wide variety of military applications including FACE. The Plessey WF3M radar is built to full military standards, and is derived from the Plessey WF3 wind-finding radar used for civil meteorology.

AMETS is mounted in a single instrumentation vehicle with a small trailer carrying the radar. In addition there will normally be a command post vehicle, and reconnaissance and stores vehicles to carry hydrogen and other troop stores. The instrumentation vehicle will carry all the data processing equipment, the radar and radio sonde monitoring and display units and a full range of diagnostic test equipment.

STATUS

In service. A more compact version, called MILIMETS, was introduced in June 1976. This equipment offers sondes as an option and is mounted on Land-Rover vehicles. AMETS is in service with at least three countries (including the UK), and MILIMETS with one.

The Plessey Radar Ltd, Oakcroft Road, Chessington, Surrey KT9 1QZ, England.

2644.161

BATES - BATTLEFIELD ARTILLERY TARGET ENGAGEMENT SYSTEM

BATES is the acronym for battlefield artillery target engagement system which in turn describes a semi-automatic data-processing and fire control system being developed for the British Army. A major feature is the use of distributed data processing, with each command level having computing power appropriate to its function and information on call from other parts of the system using digital communications.

The hardware will incorporate the MCS2010 digital processor, based on Intel 8086 microprocessors, MCS2030 plasma VDUs, MCS2040 data entry unit, MCS2050 gun display units, and an MCS2061 communications trunk interface providing a link to the Ptarmigan tactical network.

The function of the system is to accept inputs from observers and artillery staffs using radar, sound ranging systems, reconnaissance devices, and other sensors, and store, analyse, and display them - including both new and old target information - in such a way as to enable the artillery commander to make decisions. In this aspect the system differs conceptually from that of TACFIRE (**2827.161**): in the latter all possible functions are performed automatically, whereas the British approach is to retain the commander's brain in the control loop.

In-service net and trunk communications systems will link observers and target acquisition equipment with artillery headquarters and fire units; and this, coupled with the automatic data processor, will enable observers to feed target data to the command posts. This will both speed up the engagement of targets and, by reducing the number of human links in the chain, reduce the probability of human error relative to that of earlier systems. At every level of command all relevant data will be presented clearly to the artillery commander - again with the objective of saving time. Included in the system will be equipment to replace FACE - field artillery computer equipment (**2415.161**), the artillery weapon data transmission system (**3215.161**), and the data processing elements of AMETS (**2400.161**).

STATUS

In full scale development. The projected introduction of operational service is in 1987.

CONTRACTOR

Marconi Command and Control Systems Ltd, Chobham Road, Frimley, Camberley, Surrey GU16 5PE, England.

2415.161

FACE - FIELD ARTILLERY COMPUTER EQUIPMENT

FACE is a field gunnery computer system specifically designed to perform quickly and accurately the lengthy calculations which are involved in producing artillery firing data.

FACE undertakes two specific roles. First, as an artillery survey computer it carries out all the calculations necessary in this task. Second, and more importantly, as a gun data computer it processes all the information required to place a shell accurately on the target and displays this information on a console.

FACE has been modernised by replacing the 920B computer by the MC 1800, which uses the latest LSI sliced technology. This has greatly increased the speed of operation and the memory capacity. This improved capability has resulted in a system that can control the fire of up to 32 weapons, deployed as four batteries, each of up to eight weapons. For greater tactical flexibility, FACE can still be deployed at each battery.

OPERATION

While the guns are deploying for action, the console operator in the command-post vehicle begins to receive setting-up data. This is added to the information already in the computer's store which includes a latitude function allowing for earth rotational effects and the muzzle velocity for each gun for each charge. The first input is the geographical reference of the centre of the battery position - the 'battery grid'; next the position of each gun in relation to battery centre, and the temperature of the ammunition charges. Then meteorological information is received by radio and is also entered into the computer. The equipment is now ready to receive data for shooting in the form of target position and height, the type of ammunition to be used, etc. Once all the relevant information has been fed into the computer, it produces answers which are passed to the guns via the AWDATS (**3215.161**).

The forward observer, noting the fall of shot, radios corrections, determined visually or by the use of a laser rangefinder, back to the command post. The console operator feeds these straight into FACE which computes updated gun data for relay to the guns.

Frequently gunners are required to deliver fire in support of a pre-arranged battle plan. In practice, battle conditions often call for changes to this fire plan and because FACE has great speed and flexibility, these changes can be easily accommodated.

Modern weapons tend to be multi-charge in nature and to have both high- and low angle fire capability, employing several types of projectile to give a wide choice of performance. Their versatility could not be fully exploited without the assistance of FACE. A wide variety of gun and rocket programs are available for use with FACE.

STATUS

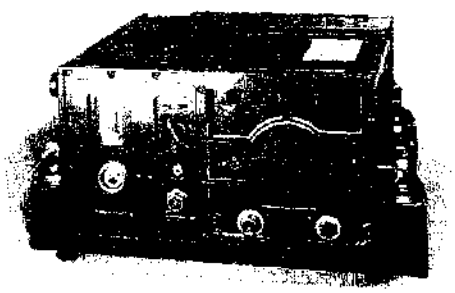
In service with the armed forces of 18 countries.

CONTRACTOR

Marconi Command and Control Systems Ltd, Chobham Road, Frimley, Camberley, Surrey GU16 5PE, England.

4157.181
PADS POSITION AND AZIMUTH DETERMINING SYSTEM

The Ferranti position and azimuth determining system (PADS Mk II) has evolved from PADS Mk I, now in service with the British Army, and FILS the commercial inertial land surveyor system. It is designed to meet an extended military requirement for a compact vehicle- or helicopter-mounted, accurate survey and navigation system, capable of on-board mission processing in near real-time. The equipment displays continuously its position in geographical or UTM grid co-ordinates, together with orientation relative to true or grid north. Alternatively given the co-ordinates of a destination point, the equipment will display continuously the range and bearing to that point, to assist navigation. The system permits the storage of up to 62 waypoints, which may be a combination of established control and new points being fixed, enabling the accuracy of computed values to be improved as new control data is provided during the traverse. Position information is accurate to within three metres and azimuth to within 0·3 mil after mission processing of an open traverse. For traverses of up 15 km between established control points may be fixed to a relative accuracy of better than one metre. The equipment is entirely self-contained and is powered from a vehicle 24 V DC supply.



The main application for PADS is to provide artillery units with position and orientation data for guns, launchers, observation posts and to carry out surveys for target acquisition devices. This greatly improves the effectiveness and flexibility of artillery on the battlefield and provides a saving in survey personnel. PADS Mk II is a single box system in a mounting tray with overall dimensions of 540 × 470 × 500 mm and 51 kg weight, together with a control and display unit which may be mounted in any convenient position in the vehicle. Azimuth is transferred by auto collimation on the systems mirror or by fixing two bearing pickets.

STATUS

PADS Mk I is in service and quantity production for the British Army. PADS Mk II has been developed to meet overseas orders.

CONTRACTOR

Ferranti Defence Systems Ltd, Navigation Systems Department, Silverknowes, Edinburgh EH4 4AD, Scotland.

Main unit of Ferranti PADS Mk II

Control and display unit for PADS Mk II

3125.161
AWDATS - ARTILLERY WEAPON DATA TRANSMISSION SYSTEM

AWDATS is an artillery weapon data transmission system which displays the firing data calculated by the field artillery computer equipment (FACE) (**2415.161**) at the individual guns of a battery. Due to the different geographical location of each gun within the battery and variations in muzzle velocity between guns, there is a small but significant difference between the data for each gun in the battery.

The guns are provided with a data display unit which receives the data from a coding and distribution unit in the command post. The display units can either be installed in the vehicle for self-propelled guns or mounted on a frame for towed guns. Data transmission is by a frequency shift modulation audio frequency signal over existing radio or line channels which are also used for voice communications. Transmissions are audible and take less than three seconds for a complete battery of six guns. AWDATS makes a valuable contribution to the speed of reaction and efficiency of guns within the battery by eliminating the necessity for verbal transmission, checking of gun data and greatly reducing the probability of errors being made.

STATUS

Currently in service with the armed forces of the United Kingdom and a number of other countries.

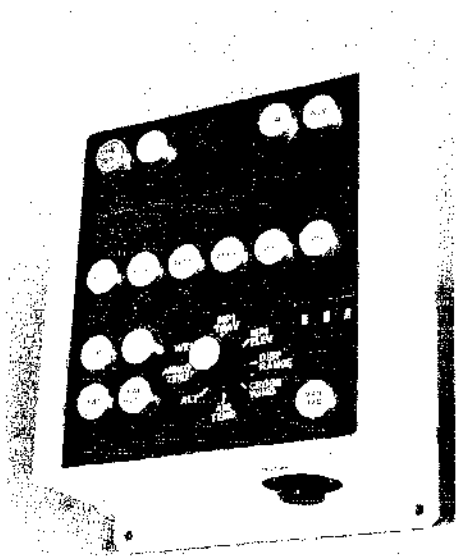
CONTRACTOR

Marconi Command and Control Systems Ltd, Chobham Road, Frimley, Camberley, Surrey GU16 5PE, England.

4583.181
MARCONI AFCS

AFCS (advanced fire control system) has been developed for use on advanced main battle tanks. It is standard fit on the Vicker's Mk 7 and Engesa Osorio and would normally be used in conjunction with sophisticated sighting systems such as stabilised panoramic and thermal imagers, and high performance solid state gun control equipment such as the Marconi GCE 628 (**4582.181**), also fitted in these two vehicles.

The advanced design of AFCS enables it to provide the user with a number of benefits. The system can operate with up to three sights thus providing extremely rapid target switch by allowing the commander to separately acquire targets during a gunner's shoot, and to rapidly and accurately engage those targets when the gunner's target is destroyed. The system also provides an extremely accurate shoot on the move capability achieved by the continual entry of sensor information to the computer upto the moment of firing. With GCE 628 providing the stabilised performance required this ensures that the gun is correctly offset to hit the target at all times.



The system comprises a computer using a 16-bit microprocessor to which information is fed from a tilt sensor and meteorological sensor. Rate signals are taken from the controllers and additional information such as ammunition type, wear and ammunition temperature is taken from the control panel. This contains its own 8-bit microprocessor and a 36-character alpha-numeric display for ease of operation. The computer calculates the required ballistic offsets which are used to inject an aiming mark into the sight, and simultaneously the gun is automatically offset by signals fed to the gun control system.

STATUS

Production.

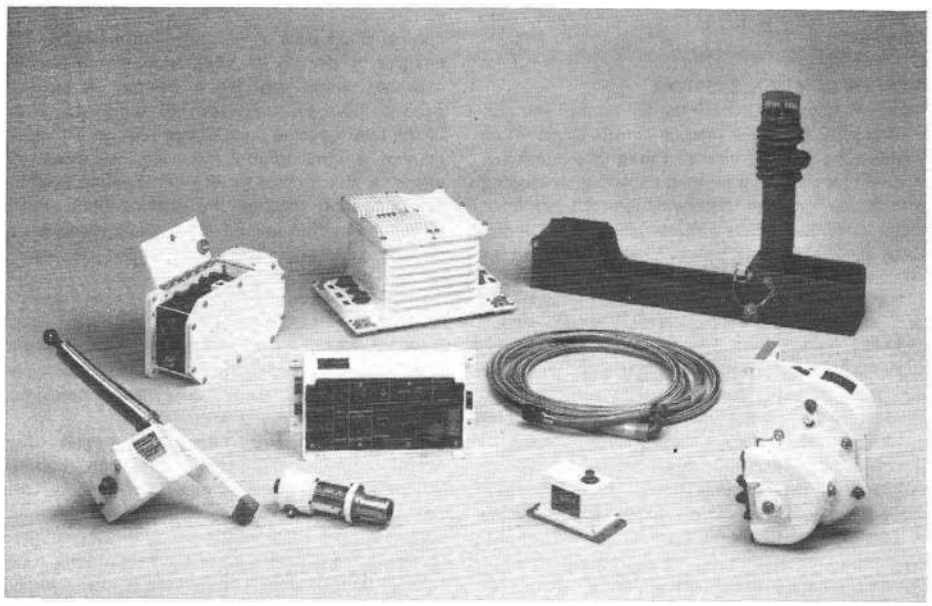
CONTRACTOR

Marconi Command and Control Systems Ltd, Chobham Road, Frimley, Camberley, Surrey GU16 5PE, England.

Marconi AFCS control panel

4582.181
EFCS 600

EFCS 600 has been developed from the SFCS 600 (**3321.181**), a system that has fired over 2000 rounds in trials and is now in service in a number of countries. EFCS has been specifically designed for ease of retrofit into any MBT including M41, M48, Centurion, Chieftain, T55 and Vickers MK1 and MK3, and trials have proved the system to be simple to operate providing greatly improved hit probabilities and considerably decreased engagement times.



An 8-bit microprocessor-based computer cubicle is used to store ballistic information and carry out the calculations required to produce the offsets. A simple to operate commander's control panel incorporates switches to manually input ammunition type, barrel wear and if required, range and meteorological data. An alpha-numeric display provides the user with full function information, and a further switch operates a complete system built-in test routine. Sensors supply azimuth and elevation rates, wind speed/direction and air density, and gun trunnion tilt. A sight mounted laser rangefinder supplies target range.

To engage a moving target, ammunition type is selected then the target tracked with the laser button depressed. On releasing the button, the laser is fired, feeding the range and sensor information to the computer, which calculates the offsets required. The resultant aiming mark can then be laid onto the centre of the target ready for firing. When used with a CRT aiming mark system, an Aiming Mark Drive Unit controls the CRT and provides a dot enclosed by an expanding/contracting circle in the sight's FOV.

The computer is programmed for the particular gun and ammunition natures used, however by simply changing the ROMs the system can be converted for a different gun or ammunition. Enhancements incorporated into EFCS 600 include the ability to interface with thermal sights, a semi-indirect engagement facility, and a new more compact control panel offering simpler operator control. Other compatible items of gun control equipment are listed in the following paragraphs.

Mantis in II configuration

Group photo of EFCS 600 equipment

MANTIS

To provide a full day/night capability for EFCS 600, Marconi have developed Mantis. This utilises a servo driven mirror in the head to allow the use of an accurate electronic link to the gun, thereby providing a degree of accuracy not normally possible with mechanical links. The sight is designed for installation into T54/55 as well as T59 without the need for armour cutting or turret modification. It can be provided in either a Thermal Imager or Image Intensification form through the use of interchangeable elbows such as the OEC II elbow or the MCCS TIVS TI elbow. With the thermal elbow, the glass lens would be changed to germanium. Mantis has been thoroughly tested on firing trials and has proved to provide a flexible, simple to install, simple to use sight with a high degree of accuracy.

STATUS

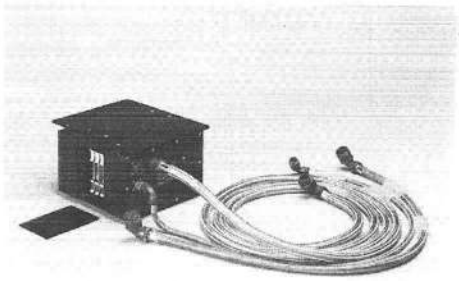
Currently in service with two armies and in quantity production, the EFCS 600 is fitted as standard equipment to the Vickers MK3 main battle tank.

CONTRACTOR

Marconi Command and Control Systems Ltd, Chobham Road, Frimley, Camberley, Surrey GU16 5PE, England.

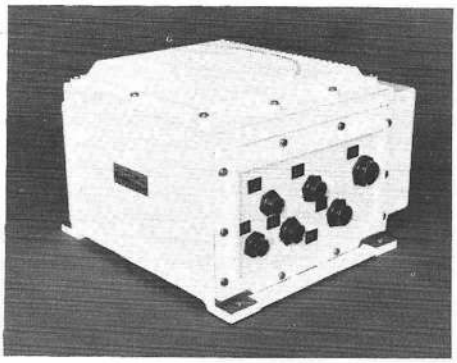
4831.181

MARCONI GUN CONTROL AND STABILISATION EQUIPMENT



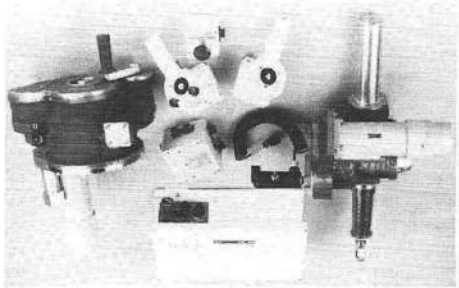
Marconi Command and Control Systems experience in Gun Control dates back to the first electric stabilisation system for Centurion. The considerable expertise built up over this period has provided the background for a range of electric systems designed to meet all sizes of vehicle. All systems supplied by Marconi can be interfaced with fire control systems such as the Marconi EFCS 600.

GCE 628



For modern main battle tanks, GCE 628 provides an extremely high level of performance previously unattainable with electric systems. Installed as standard equipment on both the Vickers Mk 7 and the Engesa Osorio, the system provides: high accuracy in low speed tracking through its modern solid state processing circuitry; rapid target switch ability; excellent shoot-on-the-move capability through high stabilisation performance; full battle readiness in silent watch due to silence of solid state power amplifier and lack of need for running of APU; low thermal signature. The solid state power amplifier utilises state-of-the-art technology to replace rotary metadynes with a high efficiency unit able to use battery power to run the gun control without the need to run an APU. Trials have proved this ability where a full days firing was carried out without charging the batteries. Additional benefits provided by GCE 628 over existing electric systems are compactness and ease of maintenance. These are both achieved through the extensive use of easy-to-replace PCBs and by the built-in ability of the system to interface with a wide variety of test equipment.

GCE 650



The GCE 650 has been developed to provide Gun Control Equipment on T-Tanks such as the T59, T55 and T62, with the advantages of solid state technology. The thermionic amplifier, gyros and vibrating relay are all replaced by solid state electronics combined in a single cubicle that can be mounted under the breech. The elevation control valve and the gunner's duplex controls are both modified. GCE 650 offers 2-axes stabilisation, improved accuracy of lay, excellent reliability, low drift, ease of maintenance and, if the servo motors are modified, can provide considerably improved performance.

GCE 650 cubicle containing processing electronics and 2-axes gyro

Centaur electronic cubicle

PD700 equipment group

Vickers Main Battle Tank

The cubicle used in GCE 650 has also been designed to form the basis of a family of gun control equipment to provide the needs of those tanks between light armoured vehicles and modern main battle tanks. These vehicles such as M41, M48 and new light turrets fitted with 105 mm guns can be provided with a simplified solid-state solution to the requirement for a safe, high performance system when used in conjunction with the solid-state power amplifier.

PD700 POWER DRIVES

To meet the requirement for a power drive for light armoured vehicles, PD700 provides an inherently safe, compact, high performance, electric system that can be fitted to new vehicles or simply retrofitted to existing vehicles. Extensively trialled on vehicles such as Scorpion (with both 76 mm and 90 mm turrets) the Engesa Cascaval and on the Cockerill 90 mm turret, PD700 has demonstrated the ability to comply with the needs of the user. It enables the crew to rapidly and accurately acquire and engage targets and to carry out silent watch surveillance using power traverse. In addition, it complies with the requirements for simplicity of operation, reliability, ease of maintenance and integration to a computer based fire control system such as the Marconi EFCS 600. The equipment provided includes controllers for both gunner and commander, providing both with power control of the gun. In addition, a full range of safety switches and firing handles are available to ensure full compatability with any vehicle. The high efficiency control cubicle is small enough to be unobtrusively installed and allows power traverse and

elevation to be used with battery power alone for long periods.

WEAPON CONTROL SYSTEMS

Marconi's expertise in both the fire control and gun control aspects of tank weapon control systems has enabled the development of Centaur, a combined system that ensures a fighting capability in keeping with the designs and requirements of modern main battle tanks. Essentially a combination of AFCS and GCE 628, Centaur packages the computer electronics of the fire control system with the control cubicle electronics of the gun control cubicle. This ensures a degree of integration not previously available which provides a number of benefits; because the combined unit is a little bigger than either of the two separate units, space savings are made; cabling is considerably reduced; maintenance is eased; a built in test facility can operate over the whole system through the commanders control panel; the system can be more easily expanded to include additional facilities. Centaur provides a weapon control performance that ensures the maximum battlefield capability of a modern main battle tank. When used in conjunction with stabilised panoramic sights and thermal imagers the performance is further enhanced to provide the potential user with a considerable advantage over other systems available.

Marconi Command and Control Systems Ltd, Chobham Road, Frimley, Camberley, Surrey GU16 5PE, England.

4832.181

COMPUTER SIGHTING SYSTEM (CSS)

Designed primarily for use in the Chieftain and Challenger main battle tanks the CSS is a computer based integrated tank fire control system based on the Marconi MC1800 microprocessor which interfaces to the Barr and Stroud TLS-2 tank laser sight. It is a compact system intended for retrofitting in existing vehicles with minimum effort to give maximum improvement in fire power performance. Sensors mounted on the tank provide the computer with variables such as range, wind speed and direction, air pressure, air temperature, trunnion tilt, angle of sight, turret azimuth position and gun elevation position. Together with other variables and ammunition performance the computer calculates the gun super elevation and lead angle.

The system's design provides simple crew operation, rapid engagement time and high hit accuracy to give good battlefield survivability. CSS was developed from the British Army integrated fire control system IFCS which has fired thousands of rounds in the Chieftain and Challenger tanks. A full suite of fault diagnosis equipment is available and with the system self test facilities identification of faults to component level is possible.

STATUS

IFCS and CSS are in quantity production for the Chieftain and Challenger main battle tanks for service in the British Army and elsewhere. A development programme is currently under way to further shorten crew tasks and engagement times and to significantly improve the fire on the move capability.

CONTRACTOR

Marconi Command and Control Systems Ltd, Chobham Road, Frimley, Camberley, Surrey GU16 5PE, England.

2647.181

IFCS – IMPROVED (TANK) FIRE CONTROL SYSTEM

Designed primarily for use in the Chieftain main battle tank (**5006.102**) as a replacement for the FV/GCE No 7 Mk 4 equipment, IFCS is a computer-based integrated digital tank fire control system. Based on the Marconi 12-12P general-purpose digital computer and the Barr and Stroud TLS – 2 tank laser sight (No 1 Mk II), it is a compact system intended for retrofitting in existing vehicles with minimum reduction in the quantity of ammunition carried.

The computer, which can accurately simulate ballistic trajectories out to the longest ranges likely to be used in tank engagements, accepts data for the trajectory calculation from various sensors, which provide continuous information on such parameters as wind speed and direction, air pressure, air temperature, trunnion tilt and angle of sight. Muzzle velocity is derived from ammunition to be fired, charge temperature and barrel wear, which is predicted from a count of equivalent full charges fired. All this information may be readily monitored by the tank commander and can, if required, be overridden by means of a manual input. The equipment is suitable for engaging fixed or moving targets from a stationary or moving vehicle.

OPERATION

When the commander has slewed the turret to the approximate azimuth and elevation of the target, and the gunner has confirmed that it is in his sight, the main armament and ammunition are selected on the firing handle – an operation that automatically charges the laser. The gun is then loaded and simultaneously the gunner lays the sight aiming mark on the target, flashes the laser, and continues to track the target. Range is displayed instantly, both as a digital display in the sights and as an elliptical aiming mark surrounding the target in the sight graticule.

Within about one second (depending on the target and the ammunition to be used) after the laser is flashed, the computer calculates the ballistic trajectory and aim-off for target movement. Then, as soon as the gunner presses the autolay switch, the computer offsets the elliptical aiming mark in the sight to give a new point of aim for target range and speed. Using these corrections, the computer also automatically re-lays the gun, and the gunner fires when the target and aiming mark again coincide.

The controls for all the operator-selected functions are mounted on a single firing handle, which is operated by the gunner's left hand: his right hand is free to lay the gun in azimuth and elevation, using a thumb controller. All system tell-back displays used during an engagement are projected in the sight, so that the operator need never take his eyes off the target nor change his hand positions. Firing handles, thumb controllers, and sights are provided for both the commander and the gunner, but with the difference that the former can override the latter.

Chieftain tank equipped with the IFCS during trials of the system

STATUS

The system is now in quantity production for the UK armed forces. This system is being adapted for fitting to other tanks and fittings have been made in the FV4030/2 (Khalid) MBT for Jordan and the Challenger. The IFCS was also proposed for retrofitting in Italian Leopard Is by Marconi Italiana who have made arrangements with the British manufacturers for licence production of the system as SICAT.

CONTRACTOR

Marconi Command and Control Systems Ltd, Chobham Road, Frimley, Camberley, Surrey GU16 5PE, England.

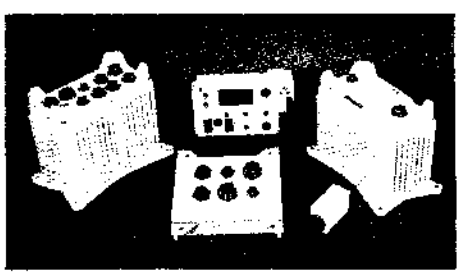
4581.181

MARCONI DFCS

The Marconi digital fire control system (DFCS) was originally designed to cater for both new vehicle and retrofit/modernisation markets where improved fire control facilities are required to meet modern AFV specifications. Use of the DFCS enables light and medium armoured fighting vehicles to be equipped with sophisticated gunnery facilities, giving better hit potential and survivability.

The modular design and compact size of DFCS enables it to be fitted into the small turrets of light armoured vehicles and into the restricted space in tanks such as M41, M48 and T series requiring modernisation. Particular attention in the design of DFCS to manufacturing, quality and testing methods has ensured that production costs are compatible with the weapons fit budget of these vehicles. DFCS offers the full capabilities essential to a modern fire control system including moving target capability, automatic gun laying (Autolay) and a built-in gunnery training simulator. It also has a fire on the move capability for MBT applications.

The DFCS 16-bit digital computer unit calculates a ballistic solution including inputs for meteorological data, relative target motion, barrel wear and trunnion tilt. Its performance is compatible with the accuracy of 76, 90, 105 and 120 mm calibre guns even at extended ranges using low velocity HEAT and HESH rounds. Simple engagement procedures are designed to reduce the dependence on human judgement and skill under stressful battlefield conditions. System ergonomics are such that the gunner maintains visual contact with the target over the entire engagement sequence with all relevant information displayed in the gunner's sight. All necessary controls are mounted on the gunner's handles. A feature of DFCS is that it offers an automatic servo-controlled final lay of the gun in readiness to fire which enables DFCS to achieve faster and more accurate engagements than manual fire control systems. The combination of high first round hit probability, extended range and fast engagement ensures a high probability of battlefield survival.



The main elements of the DFCS are described in the following paragraphs.

COMPUTER

The computer incorporates self-test software and permanently retains data such as barrel wear and 'shooting-in' adjustments. The main programme is held on a plug-in module.

DFCS trials have been carried out in the new Cadillac Gage Commando Stingray

Main DFCS units: power supply (left), CRT controller (back), computer (right), with other elements (front)

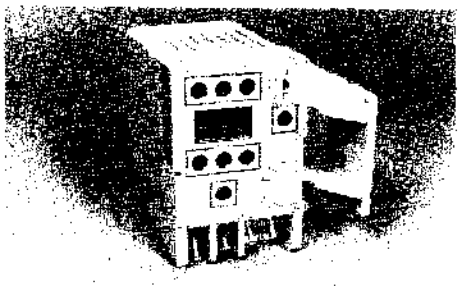
CONTROL PANEL
This provides the following commander's facilities and displays in any language or script:
(1) system and calibration confidence checks
(2) designation and display of ammunition type
(3) entry of ballistic information such as charge temperature, air density, barrel wear and static offset corrections
(4) monitor of sensor inputs
(5) entry of add/drop corrections
(6) manual override of automatic sensors.

CRT CONTROLLER
This produces computer controlled display images in the sight including aiming mark, alpha-numeric range and ammunition type. It also provides simulated target shape and tracer trajectories in the training mode.

BALLISTIC SENSORS
To increase system accuracy further sensors for trunnion tilt (cant) and meteorological conditions are fitted, plus optical encoders for Traverse and Elevation to provide high quality target tracking and to ensure accurate automatic gun laying.

CONTROLS
For a power driven turret servo the firing handle and thumb controller provide the gunner with all the controls necessary to conduct an engagement ie weapon selection, ammunition designation, aiming, autolaying and firing on the firing handle, and target tracking on the thumb controller. Controls are available for both electric and hydraulic driven turret servo systems.

STATUS
Preliminary firing trials took place in 1983 in a Cadillac Gage Commando V-150. In 1984 - 85 DFCS was evaluated in the new Cadillac Gage Commando Stingray light tank with promising results. No contract details have been revealed.



CONTRACTOR
Marconi Command and Control Systems Ltd, Chobham Road, Frimley, Camberley, Surrey GU16 5PE, England.

4143.161
DF1-5 FIRE CONTROL SYSTEMS

This series of fire control systems for tanks and other AFVs includes versions for use with tank laser day sights and for use in conjunction with a thermal scanner. The DF1 model was designed principally for vehicles such as the Scorpion light tank and comprises a laser tank sight and DF1 ballistic range calculator, the latter incorporating a number of microprocessors and circuit cards carrying the ballistic characteristics of different ammunition types. The tank sight's Nd-YAG laser rangefinder provides true target range data, which is used in the DF1 processor with ballistic data to generate gun laying information which is injected into the gunner's eyepieces. The gunner can insert range corrections by the use of 'add' or 'drop' buttons which increase or decrease the ballistic range value by 10 m increments. Such adjustments are meant to combine compensation for such factors as variations from standard ambient conditions within a single correction.

The DF3 is a more comprehensive development of the DF1 intended to equip main battle tanks, and in both cases the preferred tank laser sight is the Barr and Stroud TLS. Addition of a thermal imager, such as the Barr and Stroud IR18 (**3834.093**), to the DF1 or DF3 to provide a night channel results in the DF4 and DF5 fire control systems. The TLS is retained in both cases.

STATUS
The DF1 has been evaluated in Scorpion light tanks, and the DF5 in main battle tanks in the UK and overseas. No production contract details have been disclosed.

Control box of Type DF5 FCS

CONTRACTOR
Barr & Stroud Ltd, Caxton Street, Anniesland, Glasgow G13 1HZ, Scotland.

4148.161
FERRANTI FALCON FCS

The Ferranti Falcon fire control system is a digital system based on the F100-L microprocessor, providing a versatile and cost-effective means of enhancing the combat capability of gun-armed fighting vehicles. Compact dimensions, simplicity of operation and low cost ensure that Falcon application is not restricted to main battle tanks, and other vehicles suitable for fitting include reconnaissance, fire support and infantry combat types. The system is equally suited both to new vehicles and retrofit installations.

Falcon enhances the combat capability by significantly improving main armament accuracy. The system automatically produces an accurate determination of range and a precise compensation for the effects of ballistic and transient variables; it substantially increases the probability of a first round hit. Accuracy is improved against both static and moving targets. The gun-laying sequence is simplified by the injection of a computer-generated aiming mark in the gunner's sight.

The system accepts inputs from a variety of automatic and semi-automatic sensors that enable appropriate fire control parameters such as meteorological conditions, trunnion tilt, laser rangefinder etc to be used in aiming and gun-laying computations. Accurate determination of target range and the automatic compensation made for crosswind velocity, charge temperature, air temperature and pressure, increases the probability of a first round hit at all ranges. Engagement time is significantly reduced by the production of a ballistically and environmentally corrected aiming mark during the gun-laying sequence, and by increasing the speed at which the crew can respond to events. In a Falcon-equipped vehicle the commander can attend to target acquisition and tactical decision making, while the gunner can concentrate on the designated target and on computer-generated data presented to him via his sight.

Ferranti Falcon fire control system equipment

STATUS
In production.

CLASSIC (RGS 2740)

RGS 2740 CLASSIC (Covert Local Area Sensor System for Intrusion Classification) is an extension of the local area sensor system (Project LASS) carried out by the Royal Signals Research Establishment and Racal-S&S Ltd to evolve a system that detects, classifies and remotely displays 'target' information on personnel, wheeled and tracked vehicles by means of a variety of remote ground sensors.

The basic system consists of two main units; the sensor and the monitor. Up to eight sensors can be used with each monitor, and the former are designed to be hand emplaced in suitable tactical locations. Each sensor is coupled to a transducer, either a geophone or an infra-red detector. The unit contains signal processing circuitry which classifies the input and broadcasts a tone-coded message by means of a built-in VHF/FM transmitter. The monitor unit receives this signal, decodes the data and presents the information on an LED display to show sensor identification, type and frequency of intrusion. To extend the range of the sensor transmission, a relay unit is available.

CLASSIC is a modular system with a range of optional accessories, which includes alternative antennas and battery units, transducer/pressure pad switches and a hard copy printer to meet a wide range of ground sensor applications. Standard sensors are the TA 2741 used with the MA 2743 seismic transducer, or the MA 2744 infra-red transducer. The MA 2743 has a switch to select High, Medium or Low Personnel seismic sensitivity, and another switch to select the classification code.

The RTA 2746 monitor comprises a VHF receiver, a tone decoder and an LED display. On receipt of a transmission from a sensor unit, an audible alarm alerts the operator. The sensor's identification and alarm mode setting is displayed on a matrix of three

LEDs for each of the eight possible sensors. The display is inhibited after about eight seconds to avoid excessive battery drain, and a pushbutton is provided to enable viewing on demand if required. A user's map panel provides for drawing of a diagram of a tactical deployment.

STATUS

In April 1984 orders for CLASSIC worth £1·5 million were announced: £1 million from the UK MoD, and £500 000 from more than 10 unnamed overseas countries.

CONTRACTOR

Racal-SES Limited, Duke Street, Windsor, Berkshire SL4 1SB, England.

CLASSIC monitor unit gives audio warning and indicates activated sensor and amount of movement

3943.161
MIFASS

The US Marine Integrated Fire and Air Support System (MIFASS) is designed for the command and control of forces involved in a marine amphibious assault, and is intended for the control/management of all the supporting assets such as naval gun fire, artillery, mortars, close air support, material evacuation support, and forward air defence. It is a combined data gathering and processing system with extensive display provisions and based on a modular philosophy to meet the varying needs of different units within an overall Marine force. When deployed at divisional level, MIFASS includes 18 computer centres. At the heart of each is a plasma display of the combat area which overlays a standard military map with a schematic diagram depicting the positions of all friendly forces and the locations of reported enemy units.

Plasma panels are display devices used on several of Norden's military electronics systems, including the Battery Computer System (BCS). Flat glass panels contain row and column electrodes in a neon-xenon gas mixture. At the intersection of each set of electrodes (750 000 in a MIFASS panel) it is possible to apply voltage and light the panel at that spot.

In a battlefield situation, a map is placed behind the display panel and an operator positions computer-generated alpha-numerics and graphics over it, revealing information about the tactical situation. Two sizes are produced for MIFASS.

Sited at each infantry and artillery command post at the battalion level and above, the centre is part of an organisation that is in contact with dozens of forward observers, and each centre can operate independently. The plasma screen is continuously updated as new data is received. Each commander is part of the integrated control network that brings him commands, delivers requests for fire support, performs computations and transmits orders.

Input data is derived from forward observers, patrols, air reconnaissance, intelligence, and from adjacent MIFASS centres. While still aboard ship, prior to a landing, a MIFASS can receive data from NTDS, and while it remains on board ship after a landing has begun it can exercise control of the landing operations. Air strikes are directed through MIFASS, and for this function the system shows aircraft position and targets; in return the aircraft transmit mission status and fresh intelligence to the system. A regimental level MIFASS goes ashore in one of the landing craft, with its functions taken over during disembarkation by division or shore-based units, so that the overall system remains effective throughout an advance. The battalion level MIFASS receives intelligence and commands from higher levels, calls for fire from forward observers, and target information for input to the system. Remote users, such as forward observers, patrols, and platoon commanders, communicate with MIFASS by means of handheld digital communications terminals (see **3942.161**).

Modular design enables the requirements of these differing operational levels to be met with various combinations of less than 12 basic units, the only difference being the number of these modules required at each centre. At divisional level they occupy a shelter six metres long, while the regimental shelter is half that size. These two types of shelter are air transportable, but at the battalion level the MIFASS elements are not sheltered but are housed in foxholes or other easily relocated centres, and the equipment is designed to be suitable for deployment of this kind.

MIFASS will probably embody a portion of the technology of the US Army BCS produced by Norden (**3510.161**) and is designed to be compatible with all other US Marine Corps systems such as the Marine Air-Ground Intelligence System (MAGIS), and Position Locating and Reporting System (PLRS). In addition, an interface has been designed and certain hardware and software commonality has been identified with Tactical Air Operations Central – 85 (TAOC-85), the air defence and traffic control elements of MTACCS.

STATUS

Field testing of MIFASS with operational units is planned to begin in August 1985.

CONTRACTOR

Norden Systems Inc, Norwalk, Connecticut 06856, USA.

3510.161
BATTERY COMPUTER SYSTEM

The Battery Computer System (BCS), an advanced fire control system developed for the US Army, has been designed to replace the current field artillery digital automatic computer (FADAC) (**1125.161**) and extend the capability of TACFIRE (**2827.161**), the tactical fire direction system. It provides computerised control of artillery fire at the battery level. A real-time command, control and communications system, it is capable of providing simultaneous computations for up to 12 howitzers or guns and handling three concurrent fire missions.

It is a portable, single unit system containing 256 K of memory capacity. By providing direct digital access for forward observers and to battalion TACFIRE, it extends that system's capability to the firing battery level. It also operates in an autonomous mode and can be used for fire planning and the engagement of moving targets.

The BCS is composed of the battery computer unit (BCU) located at the battery fire direction centre and one gun display unit (GDU) for each weapon in the battery. The BCU is the electronic centre for fire control. It maintains a digital communication link with fire direction officers, fire support officers, forward observers, and weapon section chiefs. It performs all required computations for first-round accuracy, with results appearing on a 1728-character plasma display. The BCU contains a data management system which maintains target, fire unit, ammunition, meteorological, map, target, forward observers, and other system information to simplify the FDC tasks. The central processor within the BCU contains 256 K × 24-bit words of memory, with error detection and correction circuitry for fail-safe reliability. The time taken to compute a fire mission with individual data for 12 weapons is two per cent of the time of flight to the target.

The BCU houses a magnetic tape cartridge for software program and data storage, the former permitting central processor programming in under one minute. It interfaces with existing US Army COMSEC equipment and printers. Data are transmitted to the guns in one second. The BCU communicates on the battlefield with WD-1 wire and AM/FM radio.

The communications control device is driven by a microprocessor controller and offers high-speed direct access to the memory module. The BCU contains the main power switches and self-test status panel, so that faults in individual elements can be easily isolated and corrected.

The GDU is the final link in the BCS communications chain. Its place is with each weapon in the firing battery. The GDU consists of three assemblies, a section chief assembly (SCA) and two gun assemblies (GA), plus a signal and power distribution unit. All elements are of solid-state sealed construction.

The SCA is a personal tool for the section chief (weapon commander), the man who commands the weapon crew. Slightly larger than a commercial

hand-held calculator, the SCA is connected by cable to the signal and power distribution unit, giving instant access to all gun-related data and commands. The device contains its own memory bank for sequential or direct access to stored fire mission information. It is equipped with audible alarms and visual cueing to alert the section chief to fire missions and check fires. An eight-digit display shows positive indication of gun commands under all ambient conditions. A single button sequences the display of gun orders.

The two identical GAs on the weapon show the gunner and assistant gunner separate elevation and deflection display. They are connected by wire to the signal and power distribution unit and receive the commands directly.

DEVELOPMENT

Norden Systems of Norwalk, Connecticut, USA, was awarded a multi-million dollar contract for development of the Battery Computer System in September 1976. Marconi Space and Defence Systems Limited of England was Norden's principal sub-contractor, and has incorporated much of the experience gained in the design and development of the British FACE (**2415.161**) field artillery computer equipment.

STATUS

A production contract was awarded to Norden in April 1980. Deliveries began in November 1981. The multi-year contract is valued at about $97 million and in June 1980 Norden awarded MSDS Ltd a $20 million contract for the supply of BCS GDUs. These units are based on the MSDS MC1800 microprocessor which is also employed in the latest version of the FACE field artillery computer equipment (**2415.161**). By April 1985 more than 700 units had been delivered to the US Army. BCS will be deployed with US Marine Corps artillery batteries as well under a separate USMC artillery programme.

Mission assignments for the BCS are received from forward observers who digitally transmit target information to a battalion TACFIRE or directly to the battery computer unit located at the field artillery level

The battery computer unit, one of two elements of the BCS, acting on the information from the forward observer, automatically computes the firing data and displays it on the unit's screen. Also displayed is the status of the battery's howitzers. The soldier will select a gun for the mission and transmit the firing data to the gun display unit located at the howitzer

2643.181

INTEGRATED TANK FIRE CONTROL SYSTEM

Intended primarily for installation in the M60 MBT, in Phase 2 of the product improvement programme, this modern integrated tank fire control system can also be used for the control of different guns in other tanks.

The system is based on the Hughes M21 solid-state ballistic computer. With this are associated a laser rangefinder and sensors to detect and measure trunnion cant, crosswind, ambient temperature, powder temperature, barrel wear and departure error, the automatic sensors being for cant, wind, and rate, while manual inputs include air temperature, air pressure, and barrel wear. The computer can be pre-programmed with the parameters of the different types of ammunition that may be used.

A typical version is intended for the M60A3 tank, and this is composed of two sub-systems, laser/sight and computer.

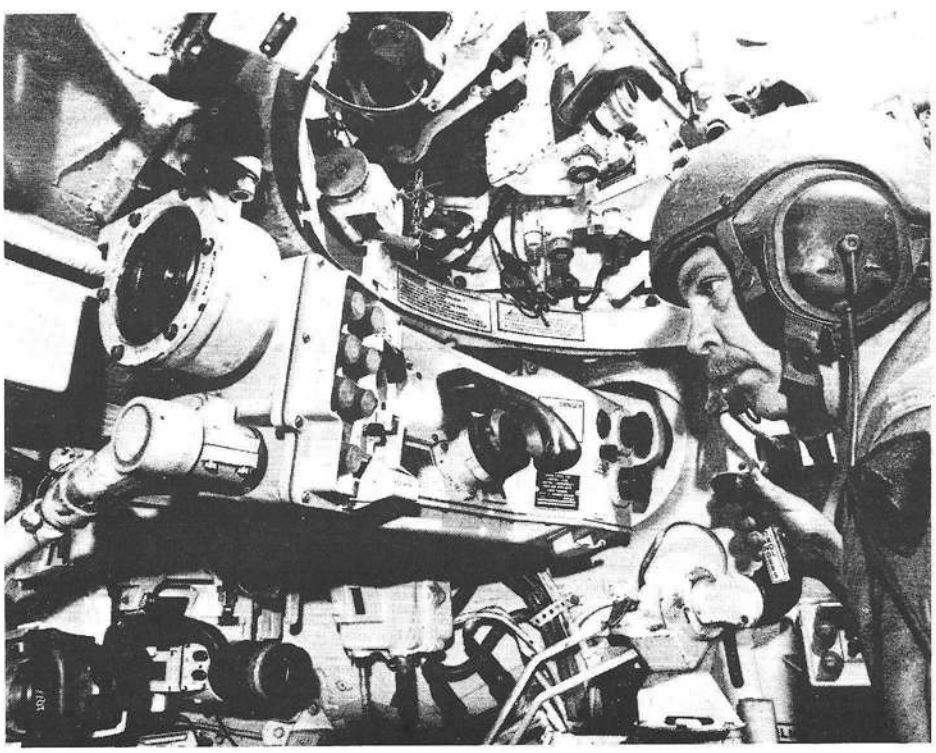
The laser/sight sub-system is composed of two main units:

(1) a commander's integrated laser/sight with control unit and

(2) a laser electronics unit. Range may be fed automatically to the computer or, if more than one return is received, the commander may select the range return based on his assessment of the situation. Since the gunner's sight is boresighted with the laser rangefinder, either the commander or the gunner can fire the laser and/or the gun.

The computer sub-system includes the ammunition selection sensors. The commander or gunner may select one of the four basic types of ammunition to be used. Actually, the computer stores solutions for six ammunitions within the four basic types to accommodate ammunitions stored in different geographical locations. The switch at the bottom of the ammunition selection unit is used to set up either tank moving or stationary conditions.

The computer is a solid-state hybrid. It processes all the input data and commands the sight lines for laying the gun.



The top half of the gunner's control unit panel contains three manual inputs: air temperature, pressure altitude (slowly varying inputs, not required to be very accurate), and manual range in the event of laser failure. All other sensors are automatic. The row of lights at the top of the unit is for self-test. Either a green "System OK" light is lit, or a light comes on indicating which unit is faulty. A red light indicates failure of the system. An orange light indicates that the system will continue to function, but with degraded accuracy. This self-test system removes the trouble-shooting burden from the tank crew, and replacement of system units in the field is easily accomplished. The bottom half of the panel (normally covered) is used for boresighting, zeroing, manual crosswind input (if desired) and a switch to select the ammunition within the four basic types.

Automatic sensors feed data directly into the computer. They are:

(1) the rate unit – used against moving targets from a stationary tank. When the tank is moving, this unit (which is most accurate when the tank is stationary) is switched out and replaced by input from the gun stabilisation system gyros, since inertial tracking rates are required

(2) the crosswind sensor – can be stowed horizontally and is spring mounted to prevent damage when the tank encounters low branches. Since this is the only unit not under armour, a circuit in the computer continuously monitors the crosswind sensor output and can be switched to manual input in the event of failure

(3) the cant unit – senses gun trunnion roll.

M60A3 MBT fire control system in use; crewman is using laser rangefinder

There is also a gunner's reticle projector that mates with his periscope and provides azimuth deflection of the reticle, and the output unit which drives the periscope head mirror, and the commander's sight in elevation and super-elevation.

CHARACTERISTICS

Operational range: 200 – 5000 m
Range resolution: 2 targets can be resolved at a minimum of 20 m apart
Range accuracy: ±10 m
Target angular velocity: 0 – 50 mils/s
Max target speed: 0 – 20 m/s
Cant angle: 0 to ±15°
Crosswind (auto): 0 – 18 m/s
Crosswind (manual): 0 – 23 m/s
Air temperature: –54 to +52°C
Altitude: 200 to 13000 m

STATUS

During 1977 Hughes, and later Kollsman were awarded quantity production contracts for systems for fitting in M60A3 MBTs.

Hughes' European licensees have built and tested laser fire control systems for the Leopard 1 and M47 tanks operated by the Belgian, Italian and Australian Armies. SABCA (Belgium) has begun deliveries to the Belgian and Australian armies. In the latter case Selenia is providing the laser under licence to SABCA. The UK licensee, Barr and Stroud, has been delivering laser rangefinders for a number of years for the Chieftain tank in the UK and overseas.

In April 1983, Spain selected a laser tank fire control system based on the M60A3 to modernise its M48 tanks. About 70 per cent of M60A3 components are used in the Spanish Army system and many will be produced in Spain by ENOSA/EISA of Madrid, under licence.

4156.181

VARO MODULAR TANK FCS

Varo Incorporated produces a range of laser rangefinder computerised tank fire control systems which can be fitted internally to most existing tanks in the world without modification to the vehicle. The systems differ in the level of sophistication provided and they are offered in the Arrowhead I and II series and the Spearhead I and II configurations.

All Varo tank fire control systems incorporate the modular component approach for maximum commonality regardless of tank application. For example, the Varo Model 9897 gunner's laser rangefinder/day sight (**4151.193**) and the Model 9880 passive night sight (**4155.193**) are identical (except for reticles) for each system and for almost all tanks. The original gunner's periscope head assembly is used in most Arrowhead installations by incorporating a bolt-on adaptor kit to which the laser rangefinder and passive night sight are mounted. In the Spearhead series, the stabilised periscope head mirror feature uses a replacement periscope head assembly that directly replaces the existing unit; thus permitting a no-modification bolt-on installation. Similarly, the gunner's and commander's control modules, sensors, computer units and emergency power supplies are essentially the same compact units for all systems; differences being only in the mounting brackets and cable lengths for each type tank. This concept reduces cost and eases logistics and training problems; particularly for those armoured forces which possess a mix of armoured vehicles. Furthermore, it permits a 'building block' upgrade approach as time and budget permit.

All systems are designed and tested to achieve a very high (90 per cent or better) first round hit probability at the usual battle ranges of between 800 to 2000 m. The design concept is based on fast, precise measurements of the three most dynamic battlefield variables: range, trunnion tilt (cant) and azimuth rate (moving target 'aim off' or 'lead').

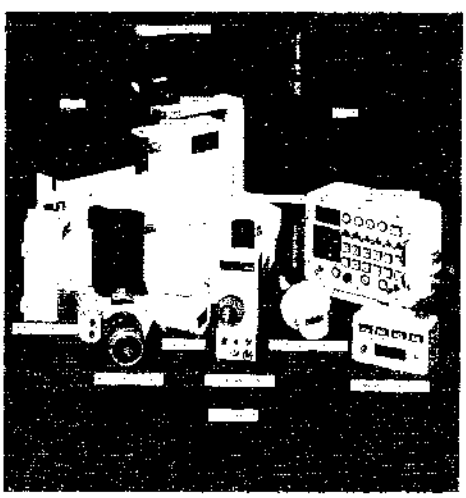
Other less dynamic variables, such as crosswind, barrel wear, air temperature, air density, shell grain temperature etc are corrected in the Arrowhead and Spearhead I series by applying the proper zero for the gun and in the Spearhead II system by continuous sensor measurement and digital computer automatic corrections for any given firing situation. In the Arrowhead series, the gunner applies elevation and deflection values (which appear in his field of view) directly to a simple mil scale reticle, aligns the aim point upon the target and fires. In the Spearhead systems, the gunner's sight picture automatically moves downward the precise number of mils for elevation. The gunner merely aligns this displacement by raising the gun until the centre aim point of the reticle is superimposed upon the target and fires. For moving targets, in the Spearhead I system, the gunner applies a mil readout value to a simple horizontal mil scale reticle. In the Spearhead II configuration a red dot illuminates, is placed upon the centre of mass of the target and the gun is ready to fire.

The Spearhead series incorporates a gyro-stabilised periscope head mirror which affords a steady view regardless of the undulations of the tank and permits accurate laser ranging while the tank is moving.

CHARACTERISTICS

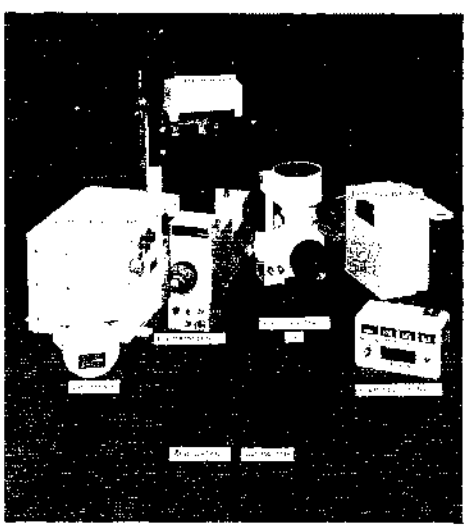
Laser rangefinder
Range: 0 – 9995 m
Accuracy: ±5 m
Resolution: 5 m
Cant angle
Range: 0 to ±15°
Accuracy: ±30 minutes of arc
Crosswind
Range: ±25 m/s
Accuracy: 1 m/s
Azimuth slew rate
Range: 0 to ±50 mils/s
Accuracy: 1 mil/s
Gun elevation
Range: -10 to +20°
Air temperature
Range: -50 to +70°C
Accuracy: ±1°C
Air pressure
Range: 630 – 1080 mb
Accuracy: ±1%

The Model 9895 ballistic computer will accept up to seven input parameters of this sort, and this digital equipment provides automatic lead angle correction for moving targets. Any type of ammunition ballistics can be used in the computation and up to four ballistics can be employed simultaneously. The computer uses an TTL logic and the 16-bit, 4-bit slice architecture is stated to yield faster computation. A 'battle ready' mode provides preset super-elevation for faster start-to-stop engagements.



STATUS

Varo tank fire control systems have been installed in the following tanks: M-41, M-47, M-48, M-60, T-54, T-55, T-59, T-62, AMX-30 and Centurion; as well as prototype development for new vehicles such as the US Army light armoured vehicle (LAV).



Varo fire control systems are tested at the US Army Aberdeen Proving Ground.

CONTRACTOR

Varo Incorporated, Integrated Systems Division, 2201 W Walnut St, PO Box 401267, Garland, Texas 75040, USA.

Spearhead II tank FCS. Spearhead I system uses digital computer instead of ballistic controller unit and has no wind sensor; otherwise same modules are used

Varo Inc Arrowhead II tank FCS units. Arrowhead I version does not have ballistic controller or azimuth rate sensor units

PORTABLE INTELLIGENT FIELD TERMINALS

Litton Data Systems has developed a family of terminals to provide digital communication and computational capabilities to suit various users' needs. Extensive use of MSI, LSI and hybrid circuits permit the microprocessor based units to have a substantial functional capability, low cost and high reliability while maintaining a small size and low weight. The terminal family consists of the fire control calculator being developed for the US Army, the interactive display terminal built for the US Marine Corps and the US Air Force, the digital communications terminal which is in production for the US Marine Corps, and the lightweight digital command terminal which is being developed under a company funded research programme.

All four equipments have been illustrated and described with details of facilities and specifications under the above entry number in the 1983-84 and earlier editions of this book.

STATUS

Production.

CONTRACTOR

Litton Data Systems, 8000 Woodley Avenue, Van Nuys, California 91409, USA.

2827.161
TACFIRE TACTICAL FIRE DIRECTION SYSTEM (AN/GSG-10)

TACFIRE is a computer-based automated command and control information system for planning and directing artillery fire. It consists of central fire direction centres (FDC) at division artillery and at battalions with a remote device at batteries, the battery display unit (BDU), and another remote device, the variable format message entry device (VFMED) with fire support officers (FSO), fire support elements (FSE). Digital communications between FDCs and remote devices are by tactical radio or wire and can be clear or encrypted. There are provisions for voice back-up.

The battalion level TACFIRE is housed in a single S-280 shelter and consists of the following major sub-systems:

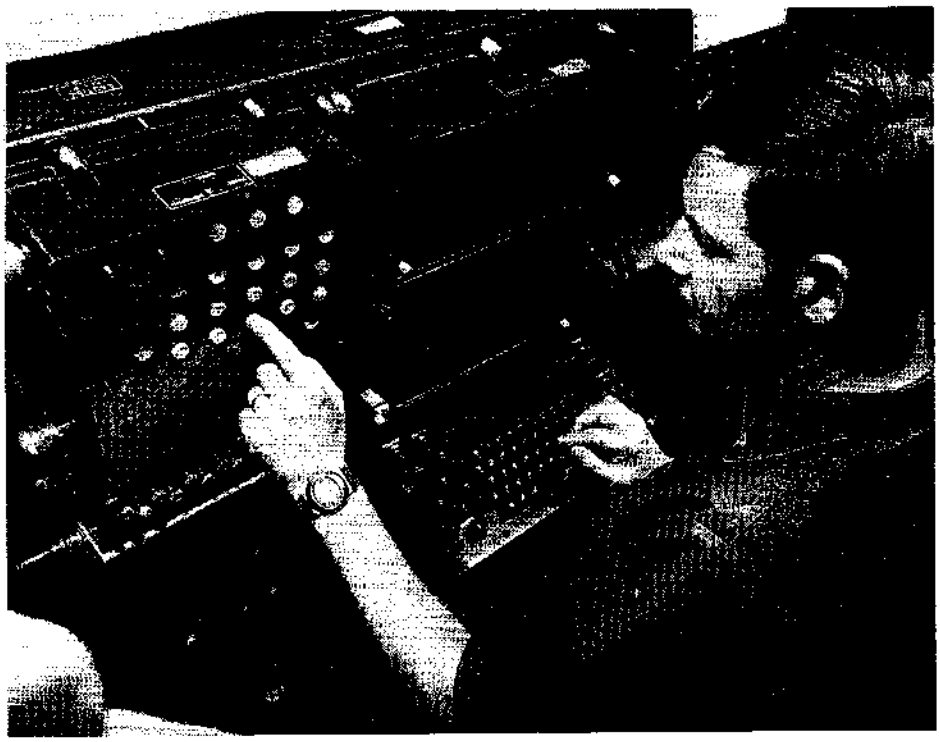
(1) computer (AN/GYK-12) comprising central processor unit (CPU); input output unit (IOU)
(2) mass core memory unit (MCMU)
(3) power convertor group (PCG)
(4) data terminal unit (DTU)
(5) module test set (MTS)
(6) communications control unit (CCU)
(7) removable media memory unit (RMMU)
(8) artillery control console (ACC)
(9) digital plotter map (DPM)
(10) electronic line printer (ELP)
(11) remote control monitor unit (RCMU).

The division artillery level TACFIRE is housed in two S-280 shelters and consists of the same major sub-systems as shown in the battalion plus one additional MCMU, a dual RMMU, an electronic tactical display (ETD), and an auxillary DTU.

The two remote equipments are:

(1) Variable format message entry device (VFMED) consisting of:
Remote data terminal (RDT)
Display editor (DE)
Keyboard
Electronic line printer (ELP).
(2) Battery display unit (BDU) consisting of:
Electronic line printer (ELP)
Remote data terminal (RDT).

The AN/GYK-12 computer, CPU, IOU, memory, is the heart of the TACFIRE system. It is a general-purpose micro-electronic computer specifically programmed to facilitate solution of the real-time command and control system problems required in TACFIRE.



The divisional artillery and battalion computers are identical, except for one additional memory at the former. The other major items of hardware were described in some detail in 1983-84 and earlier editions.

STATUS

In 1981, the US Army procured its fifth option for AN/GSG-10 TACFIRE systems, and production was expected to be complete by 1984.

CONTRACTOR

Litton Data Systems, 8000 Woodley Avenue, Van Nuys, California 91409, USA.

TACFIRE artillery control console. Located at battalion and divisional artillery fire direction centres, the ACC is the primary device to control data into and from the computer manually. This control and display device provides a visual presentation on two CRTs of both incoming messages and computer mission solutions. It also provides for control and initiate action on those data by use of an alpha-numeric keyboard which permits real-time entry and interrogation of the computer in normal user language

---

3316.161
TACTICAL COMPUTER SYSTEM (TCS) AN/UYQ-19(V)

The TCS is a militarised compact general purpose data processing, display and communication system. It is intended for army field use at all echelons in a variety of highly mobile tactical applications. Operationally, TCS is capable of transmitting and receiving addressed data from digital message devices, other TCS or similar tactical computer terminals, or other army standard tactical communication circuits.

Modular design of the TCS allows for setting up in a field environment, and M577 armoured command vehicle, S-250 or S-280 shelters, vans or fixed bases.

The TCS consists of eight major modules:

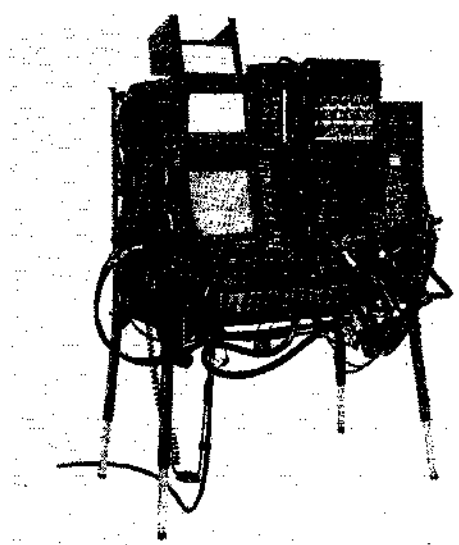
(1) *Processor:* AN/UYK-19, a fully militarised version of the Rolm 1666 Ruggednova computer which possesses an MTBF in excess of 3200 hours and a MTTR of 12 minutes.
(2) *RD-509/G Magnetic Bubble Recorder-Reproducer:* The TCS uses the Intel magnetic bubble memory, a non-volatile, fast-access, high-density memory. It has a storage capacity of 8 megabytes and an access time of 40 ms average, 80 ms maximum. The memory provides instant uploading and downloading and is portable and removable.
(3) *Display/Keyboard:* For operator/machine interface, message reception and control, and tactical display in both message text and graphics mode.

The display is an 8½ inch square plasma panel, which can superimpose the computer-generated information over a paper map or diagram. The keyboard uses elastomeric construction and folds upwards to protect the display face in transit. It features a standard ASCII character set, cursor control and other control switches, and a joystick for graphics interaction.

(4) *Communications Interface:* Provides interface to standard tactical communications circuits from 45·5 to 32 000 BPS. Digital data and voice can be transmitted on any of the 16 channels. Radio wire capability is up to eight nets of 1 to 16 channels each. The communication netting is programmable by the operator.
(5) *Printer/Plotter:* Produces hard copy printout of data and messages, diagnostic data/errors, and accomplishes system logs. The printer is an 80-column, noiseless, non-impact type capable of 1200 lines/minute. It also produces graphical plots of 8400 lines/minute.
(6) *Input/Output:* This module interfaces all others in the basic TCS system and distributes DC power to other TCS modules. Provision for growth allows for the implementation of 64 tactical radio communication channels.
(7) *Memory Loading:* Two memory loading modules plug into the I/O module to store system programs.
(8) *Power Convertor:* Accepts inputs of 50, 60 or 400 Hz power and converts it to 28 V DC. Output capacity is 50 to 2500 watts.

A communications termination unit provides through-shelter or wall connections for field wire, telephone and remote TCS modules, such as additional display/keyboards and printers.

DEVELOPMENT



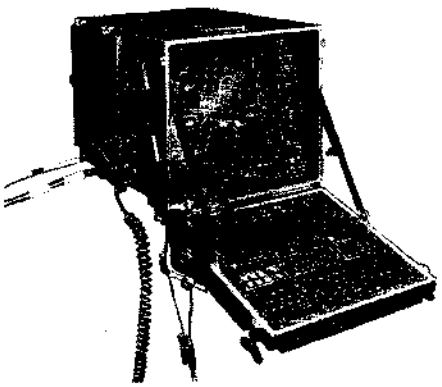
The AN/UYQ-19(V) development was initiated in 1973 by Singer's Librascope Division for the US Army Communications Research and Development Command at Fort Monmouth, New Jersey. Computer programs and a software support centre have also been developed by the contractor.

STATUS

US Army deployment in progress. The manufacturer is under contract for 31 production units.

CONTRACTOR

The Singer Company, Librascope Division, Glendale, California 91201, USA.



The US Army's tactical computer system (TCS), AN/UYQ-19(V)

3317.161
TACTICAL COMPUTER TERMINAL (TCT) AN/UYQ-30

The TCT is a fully militarised tactical computer terminal compatible with existing and planned military communication equipments. The TCT was developed as an intelligent stand-alone terminal capable of communicating digital messages (text and graphics) with other TCTs, tactical computer systems AN/UYQ-19 (TCSs) (**3316.161**), and with forward observer equipments, and will be interfaced with the World-wide Military Communication System (WWMCS).

The tactical computer terminal consists of a plasma display panel microprocessor, a keyboard, communications modems, controllers for external peripheral devices such as a printer, and a bulk memory. Motorola MC 68000 microprocessors provide complete functional flexibility with capabilities determined by the software resident in the TCT. Read only memory (ROM) and random access memory (RAM) totalling 768 K-bytes expandable to one megabyte, with battery back-up, are packaged in the unit. The latest software packages include higher-level languages.

Tactical computer terminal (TCT) is compatible with existing US Army communications equipment

All of these elements, including the required power supplies, are packaged in a single combination case 38 cm high, 43 cm wide and 59 cm deep. The keyboard is an integral part of the case and folds up to form a watertight cover in the transport configuration. In this configuration, the unit is fully immersible to a depth of 1 metre. Cooling is accomplished entirely without the use of fans, either internal or external. The unit operates directly from 24 ±6 V DC vehicular power.

The TCT communicates over two independent full or half duplex ports. It also has provisions for controlling a militarised printer/plotter which is a component of the AN/UYQ-19(V) system. By simple change of the controller circuitry, other hard copy devices can also be accommodated. An additional port is provided through which the TCT may interface with a bulk memory device such as a magnetic tape, large scale semiconductor memory, bubble memory modules or recorder-reproducer flexible disk RD-508/G, a random access memory providing more than five M-bits of auxiliary storage or interchangeable media. An automatic dialling capability is incoporated.

The display consists of a 22 cm square plasma panel which is utilised in both the message text mode and the graphics mode. When used in the graphics mode, tactical information is superimposed over a paper map positioned behind the transparent plasma panel. Larger displays, such as large-screen multi-colour displays at higher command echelons, will interface with the current equipment.

In the graphics mode, the display has the capability of overlaying standard topographic map segments using lines, alpha-numerics and standard or special symbols. It also has the capability of storing these overlays in memory and recalling them at some later time for modification or update. The overlays may be transmitted by wire or radio and hard copies may be obtained by use of an external printer.

The TCT has been packaged to give the maximum mobility possible to operate in the field environment. It meets all appropriate military specifications, including TEMPEST and nuclear survivability requirement.

CHARACTERISTICS

Display medium: Plasma panel
Element resolution: 60 elements per inch 512 × 512 matrix
Character size: 5 elements wide, 7 elements high
Character capacity: 46 lines of 85 characters each
Writing rate: 20 μs per element
Character writing period: 700 μs max
Vector writing rate: 35 μs per element average (computation time included)
Display intensity: 50 ft-lamberts max adjustable to 12·5 ft-lamberts
Refresh: No refresh required

STATUS

During 1976, the TCT was developed from the display/keyboard module of the AN/UYQ-19 tactical computer system, produced for the US Army Communications Research and Development Command. The manufacturer is under contract for the first 104 production units.

CONTRACTOR

The Singer Company, Librascope Division, Glendale, California 91201, USA.

3944.161
PLRS (AN/TSQ-129)

The PLRS AN/TSQ-129 is a portable position location and navigation system which uses frequency and time division multiple access (FTDMA) techniques to provide real-time position tracks on several hundred ground and air user units. The information can be used for such purposes as the direction of artillery fire, naval gun fire, air support, navigation of ground mobile forces and rendezvous, guiding a helicopter through safe corridors when flying 'nap of the earth' missions, etc. Positions can be established with an accuracy of 10 metres or less with slow-moving users, and high-speed airborne users can be located to within 25 metres. The system will provide these facilities for any combination of up to 370 manpack, vehicle or airborne user units within the area of one master station network. A typical area covered by one master station is 90 000 km² from ground level to an altitude of 15 000 metres. For an army corps deployment of four divisions in the forward area and one division in reserve, all five PLRS-equipped divisions can operate on a non-interfering basis and handle some 2000 users over an entire battle area, with the command knowing the position of each user on a continuous basis.

The PLRS network operates in the UHF frequency band, and each user unit automatically transmits a self-identification signal burst on a precise time-ordered schedule, measures time-of-arrival of other user unit transmissions, and automatically relays these measurements when commanded by the master unit to do so. The master unit computes and continuously updates the position of each user unit. The position of every PLRS-equipped unit may be:

(1) remoted and displayed at command and control centres for decision taking
(2) sent to PLRS user units, either automatically or on request
(3) displayed in the master unit for network management and technology control.

Position location information exchanged between the master station and any specified user unit is performed by means of PLRS-formated digital messages, with a limited free text capability. All PLRS transmissions are cryptographically secure, and identical in their spectral signature regardless of their content. This, and the fact that the system utilises composite frequency-hop/direct sequence spread spectrum techniques, give PLRS extremely high electronic security and high jam-resistance.

The master station is housed in a standard US military S-280 shelter, which is air transportable. This contains the network communications facilities, computers, data displays and related equipment required to support a single independent PLRS network, or to co-operate with other master stations in a multi-PLRS network.

The basic user unit consists of a multi-function transmitter/receiver and processor packaged in a 1-ATR short, low case, and equipped with either of two interchangeable input/output devices. In the manpack configuration the hand-held user readout module is employed, together with a battery pack giving 24-hour service. The complete manpack weighs 6·8 kg. The other input/output device is the pilot control display panel for use in fixed- and rotary-wing aircraft, tanks, amphibious assault vehicles, APCs or similar mobile units. This is mounted in a suitable place on the panel and is driven by a remotely mounted user unit elsewhere in the vehicle.

PJH

The US Army has a programme known as the PLRS/JTIDS Hybrid (PJH) that is intended to modify, combine and integrate components of PLRS and JTIDS (Joint Tactical Information Distribution System) to provide a system that will support Army data distribution requirements at divisional level. Three main elements are employed: enhanced PLRS user units (EPUU), JTIDS Class 2 terminals, and net control stations (NCS). The first of these will be issued to almost all Division units concerned with data communications, identification and position/location, and between 750 and 1000 EPUUs will be allocated to each Division. About 50 to 70 JTIDS terminals will be assigned to major users within the Division.

PJH had reached the advanced development phase by early 1984 and deployment was planned for 1988.

STATUS

The PLRS has been developed for the US Army and US Marine Corps. A $260 million multi-year contract for 11½ systems including 23 master stations and 3500 user units was awarded to Hughes in July 1983. Deployment planned for 1986.

CONTRACTOR

Hughes Aircraft Company, Ground Systems Group, Fullerton, California 92634, USA.

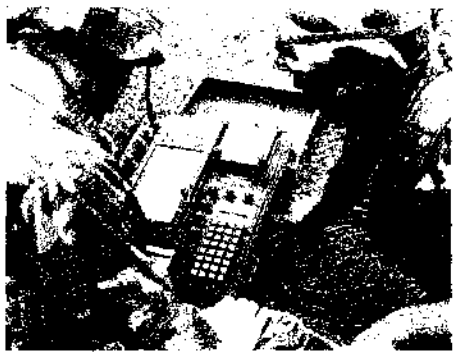
3936.151
REMBASS

The Remotely Monitored Battlefield Sensor System (REMBASS) is an unattended ground sensor system evolved from Remote Sensors (REMS), which is already in service with the US forces. REMBASS will detect and classify both men and vehicles and it is intended to provide forward units and formations with detailed information on the happenings in the zone immediately to their front. It can also be useful in rear areas for the detection of intruders.

The system works by using remotely monitored sensors placed along likely approaches. These sensors respond to a wide variety of influences, infra-red, acoustic, seismic, mechanical energy, magnetic field changes and others. Each sensor produces a signal giving a detection and sends this signal by FM radio incorporated in the body of the sensor. The sensor remains passive when it is not transmitting a detection signal, so it is virtually impossible to locate. The signal may pass direct to the monitor unit, or it may be repeated by emplaced repeaters. With the use of relays/repeaters for ground application, REMBASS is designed to provide targeting data at up to 100 km range. Once at the monitor the signal is demodulated, decoded, displayed and recorded. The system provides up-to-date information over a wide area and, due to the variety of sensors, it is largely self-checking, ie the information from one type of sensor is checked against that from another, virtually eliminating false alarms.

The sensors can be emplaced by hand, artillery shell or dropped from aircraft. Once in position they remain passive until some activity alerts their detection system. They then detect and identify the target and transmit that information before relapsing into passivity, waiting for the next movement near them. The range over which the information radios work is limited and the repeaters are themselves

emplaced by the same means. All sensors and repeaters contain their own batteries and have an operational life of weeks rather than days. They are not re-charged when the batteries run down; another sensor is dropped into place.



The monitors display information as it comes in, but they also store it and can produce it as a hard copy for analysis.

STATUS

The development phase ended in 1983 and full scale production is due to start in 1985. Initial operational capability (IOC) is planned for the second quarter of fiscal year 1987. During 1985 work is expected to start on an improved REBASS incorporating the latest technology to reduce weight and size.

CONTRACTOR

RCA Automated Systems Division, PO Box 588, Burlington, Massachusetts 01803, USA.

REMBASS sensor monitoring set in use. It incorporates a built-in printer to record data as well as serving as a field operations centre

3940.161

US TACTICAL DATA HANDLING PROJECTS

The US Army and Air Force and the Defense Advanced Research Projects Agency (DARPA) are responsible for a number of projects and programmes, all of which are intended to support one or other aspect of ground forces data collection, processing, dissemination and presentation facilities. The following paragraphs of this entry summarise the main examples of this series of projects.

ACS

Development of the Artillery Computer System (ACS) for the US Marine Corps is continuing. This will be a lightweight, battery-operated computer that will provide rapid, accurate gun-pointing data for individual batteries.

ADDS

The US Army Data Distribution System (ADDS), also called the PLRS/JTIDS Hybrid (PJH), will modify, combine, and integrate components of PLRS and JTIDS in an evolutionary five-phase programme to take advantage of the state of development of these two projects. The PJH programme will support Army near real-time data distribution requirements at divisional level. It contains three primary elements: enhanced PLRS user units (EPUU); JTIDS Class 2 terminals; and net control stations (NCS). The first of these are assigned to almost all units in a division area that participate in data communications, identification and position location/navigation. JTIDS terminal will be allocated to those users whose volume of data cannot be handled by the EPUU and who are heavily involved in interservice communications, for example air defence formations which need to exchange information with both ground units and air forces. The NCS provides overall system network management. The PJH system will support data communications requirements in the five functional areas of fire support, air defence, intelligence/EW, manoeuvre control and combat service support.

ADDS will enter its final phase of development in 1985, with deployment planned for 1988.

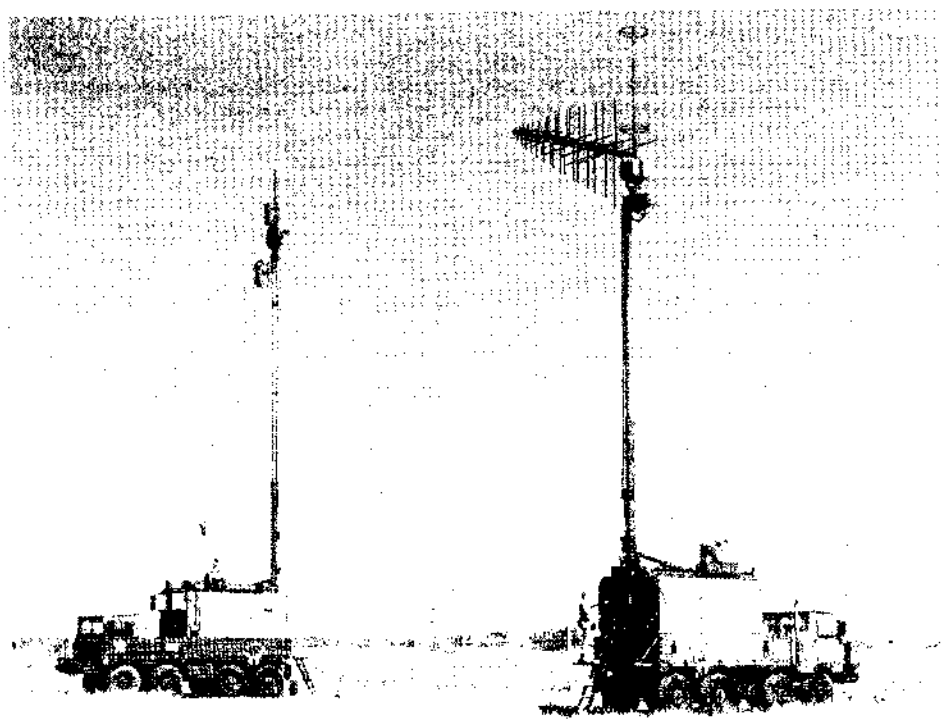
PLSS

The precision location/strike system (PLSS) will provide a 24-hour all-weather capability for USAF aircraft to attack a variety of ground targets. In particular it is intended for tactical use against air defence systems that depend on very accurate guidance and detection radars to control anti-aircraft artillery and surface-to-air missiles. The system has been described in detail (**3228.351**) in previous editions of *Jane's Weapon Systems* (1978 and earlier), but in brief, it relies on the use of specialised distance measuring equipment and other equipment on highly instrumented aircraft to detect electronic emissions from enemy radars and relay that information to a ground-based central processor facility. The Lockheed TR-1 aircraft is the airborne platform for the tactical reconnaissance system (TRS) and PLSS. In the former configuration the TR-1 carries the ASARS II (Advanced Synthetic Aperture Radar System) imaging radar and several other sensors. Information collected by these sensors is transmitted on a digital data link to a TR-1 ground station that processes and sends out reports in less than 15 minutes to users from Army group or Air Force level down to division and air operations centre levels. The concept is similar for TR-1 PLSS operations. Three TR-1 aircraft carrying PLSS sensors form a triad that transmits threat radar information to a ground station. The PLS ground station, if necessary, can direct a PLSS-equipped strike aircraft or guided weapon to attack the radar, or any other precisely known target. The TR-1 aircraft relays strike guidance to the attacking aircraft or weapon.

Fiscal year 1986 is the last year of the 27 aircraft TR-1 procurement programme in support of PLSS and reconnaissance missions. One hardened European ground station and one deployable ground station will support PLSS operations. Two hardened ground stations in Europe will support reconnaissance missions. Funding requested in fiscal year 1986 included: $262·6 million to continue TR-1 and sensor procurement (including five more aircraft); $94·2 million for a hardened TR-1 ground station; $112·8 million for PLSS procurement; and $63·1 million for PLSS research, development and engineering.

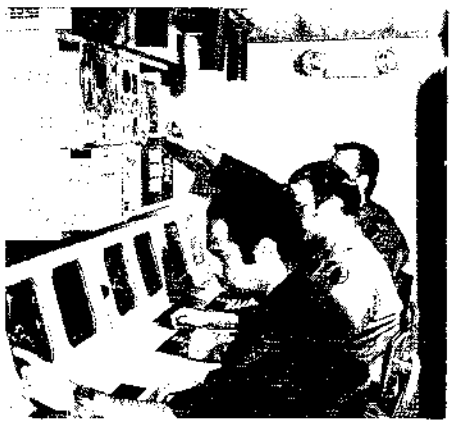
Joint STARS

Joint Surveillance and Target Attack Radar System (Joint STARS) is a combined US Army/USAF development programme formed by the merging of USAF's Pave Mover project with the Army's Battlefield Data System (BDS), which, in turn, supplanted SOTAS. (See this entry number in 1983-84 and earlier editions of *Jane's Weapon Systems*). The Joint STARS radar system will locate and track moving targets at extended ranges in the land battle areas of the 2000s. It will give target position information for indirect artillery fire and use of other weapons such as the projected Joint Tactical Missile System (JTACMS). It also provides the ground commander with real-time moving target data from both Army and USAF platforms via a common secure data link.



Airborne tests of the General Electric multimode surveillance radar (MSR) proposed by the Boeing/GE team competing in the JSTARS programme have demonstrated detection and location of ground targets in real-time. The ability to perform MTI and synthetic aperture radar (SAR) from an airborne platform has provided essential data on typical tank column manoeuvres. An unprocessed airborne MTI image showed a column of tanks beyond visual range, and viewed against a map overlay this showed the tanks in relation to the road. A time integration display shows ground processed MTI and map underlay with the dots denoting moving targets. Each sweep of the radar cumulatively adds new detections to the displays and in this way high traffic areas can be detected and additional intelligence data derived from it.

Target ranges contemplated extend to more than 100 km into hostile territory, and initially the Army plans to employ the OV-1D Mohawk aircraft as the carrier platform. The eventual aircraft will be a military version of the Boeing 707, designated the C-18. In 1985 the programme was at the full scale engineering development stage, but a radar contractor had not been named.



BETA-LOCE

By 1983 BETA had been deployed with US Forces in NATO in Europe, as the Joint Tactical Fusion – Limited Operational Capability Europe (JTF-LOCE), using a computer system developed by TRW under DoD direction. Two more testbed installations for demonstration and evaluation of ASAS (see below) data correlation were also deployed at USAF and Army sites in the USA. In Europe, the LOCE deployment consists of a central automated data processing centre, interface units at sensor ground stations, and local/remote user display terminals. Sensor inputs to the system include: Sigint, imagery intelligence, and human intelligence (Humint).

The European configuration (BETA-LOCE) employs computer software architecture designed to detect, identify and locate target and significant battlefield threat activities by the simultaneous processing of numerous sensor reports through self-

GTE's Western Division has developed and produced a number of remote tactical data relay sub-stations, similar to this one, and a centralised processing centre for the US Army

Battlefield data will be handled automatically by the US Army in centres similar to this RCA mockup of an ASAS/SEWS signals intelligence control and analysis centre

correlation, cross-correlation, and aggregation. The last of these is the computer aided process of identification of parent units based on 'sensed' or known data concerning subordinate entities. This process is operator initiated.

In exercises carried out in Europe during 1983 using BETA-LOCE, which was installed in late 1982, it is reported that analysts were able to predict battlefield events significantly earlier than was previously possible. NATO interest is said to be encouraging and the system capabilities are being demonstrated to major US and allied commanders.

Experience gained from use in the field of the LOCE system will be applied in the development of more sophisticated systems such as ASAS/ENSCE, below.

TJF

The Joint Tactical Fusion (JTF) system programme is part of a broad US programme of development in the area of new technologies for defeating large scale armoured attacks by means of deep interdiction tactics. JTF is intended to provide automated facilities to process, analyse, and distribute intelligence reports obtained from a wide range of sources. This information will assist battlefield commanders in assessing the status of opposing forces and their dispositions. In the longer term, the authorities are considering a more advanced version that will permit access to direct real-time intelligence.

MCS

The Manoeuvre Control System (MCS) is a command and control system being developed by the US Army to provide an automated information network to assist battle staffs in operational control of the mobile units under their command. Development began in September 1980 with the introduction in the European theatre of a prototype system using microprocessors and minicomputers. From an initial introduction of three systems, the prototype has grown to some 20 systems which are being used in the field. The eventual system will consist of a network of small computers that will enable tactical commanders to have access to information on the status and disposition of their forces and those of their opponent. The European prototype version is being used for additional development.

The first MCS production contract was awarded in 1983 and deployment of this equipment is planned to start in 1985 with an IOC in the latter half of 1986. Contractors involved include Singer Librascope, General Dynamics, Datametrics, Ford Aerospace & Communications, and Rolm Corp.

ASAS/ENSCE

The all source analysis system (ASAS) will be the control system for the Intelligence/EW subsystem of the Army Command and Control System, and is being developed together with the US Air Force Enemy Situation Correlation Element, within the Joint Tactical Fusion Programme. Numerous sophisticated sensor systems have been deployed, but the ability to process and distribute their information to battlefield commanders is still restricted in scope and speed by the manual and partially automated processing facilities now available. ASAS will provide modern minicomputer systems to speed up the process and enhance its accuracy and effectiveness. The acquisition plan will provide initial components of baseline systems in the mid-1980s, and systems will evolve via pre-programmed product improvements and software refinement based on the experience gained in the field by users. The ASA/ENSCE system architecture is modular. Division ASAS, corps ASAS, and ENSCE systems can be configured differently as force structure and mission requirements dictate. Design began in 1984 and field deployments are planned to follow later this decade.

ARS FIELD ARTILLERY COMPUTER SYSTEM

The ARS field artillery computer system is a digital computer-based system designed to provide user-oriented fire control facilities for the direction of artillery fire at the artillery battalion level. Facilities include automated computation, transmission and display of firing data and commands within the battalion.

The basic configuration of the system comprises:

(1) the main equipment within a computer control sub-system (CCS), and consisting of the artillery computer unit, tape reader, three VHF transmitter/receivers, one radio receiver, a telephone switchboard and power supplies
(2) three battery display sub-systems (BDS). Each BDS is a compact two-man portable equipment designed for use at firing battery command posts. The main items of equipment are carried in a rugged frame and comprise a firing data display, VHF transmitter/receiver, telephone set and battery pack.

The CCS is generally housed in a military shelter carried on a 4 × 4 cross-country vehicle such as the TAM 110 T7 BV.

The main operational features of the ARS system include:

(1) integrated fire control of an artillery division consisting of up to three firing batteries equipped with guns, howitzers or rocket launchers
(2) engagement of stationary or moving targets
(3) 200 target locations, 30 of which can be correction points and 10 forward observer positions
(4) fire control of one, two or all three batteries
(5) three separate fire missions at any given time
(6) firing data and commands for each battery separately
(7) division fire, where simultaneous hits on a single target from all three batteries are required
(8) voice communications between CCS, BDS and other sub-systems such as meteorological stations, forward observers, higher command etc
(9) data transmission from CCS to BDS and facilities for data reception from forward observers via cable or radio link
(10) simultaneous data transmission and voice communication over the same channel.

The ARS computer itself is a single unit that incorporates a dual Čajavec-52 micro-processor, power supply and an operator's console that carries controls and displays for the operation of the system. Input data includes battery information such as: grid co-ordinates; base direction, deflection and site; muzzle velocity changes or measured value by MV radar; projectile weight variations; powder temperature (for each battery). Ammunition data inserted into the computer includes: shell type, fuze type, low/high trajectory, charge number (manual or automatic selection). Three different types of standard met messages up to 30 lines can be accepted, and target data consists of grid co-ordinates, polar co-ordinates relative to the forward observer, and grid-shift from known point. Additionally, for moving target engagement there is provision for insertion of time intervals between firings, target speed and direction, or polar co-ordinates relative to FO (artillery radar measurements), or selected impact point co-ordinates. All input data parameter values are automatically checked against acceptable standard limits as a validity test and checked data can be accepted, rejected or left to the operator's decision.

The following principal computational functions are performed:

(1) initial calculations of technical data based on topographical information, met data, weapon data for a particular battery and chosen combination of shell, fuze and charge
(2) firing data such as deflection, angle of elevation, site, fuze setting, range, time of firing, charge, shell and fuze type
(3) adjustment of fire, based on information from FOs
(4) calculation of fire correction points
(5) fire transfer calculations from correction point to designated new target
(6) use of data from one battery to provide firing data computations for adjustments of other batteries in the battalion
(7) calculation of firing data and commands for moving target engagement

ARS formats firing data output messages and transmits them to the selected battery, and this includes all fire control data computations, the selected shell/charge/fuze combination, as well as the fire command. An input/output display presents input data as well as computer messages. There is software supported guidance for the operator in entering data and to ensure the correct operating sequence. Other software facilities include a target file manager, test module, input/output data conversion module, ballistic calculation module, fire transfer/correction module, and a dual processor executive system.

System enhancements available as options are: FO direct data entry facilities; on-line laser rangefinder operation; on-line sound ranging equipment; land navigation sub-system; and an advanced command display unit.

CHARACTERISTICS

Accuracy: 0·001 of range (in metres) in bearing and elevation
Fuze setting: 0·1 s
Firing data computation time: 0·5 to 5 s
Data link speed: 1200 bit/s
Correction code: BCH
False alarm probability: Less than 10^{-6}
Modem: DPSK
Firing data display unit: 300 × 200 × 150 mm
Weight: 12 kg
Power supply: 21 - 29 V DC, 15 W
Computer unit: 680 × 420 × 550 mm
Weight: 60 kg
Power supply: 21 - 29 V DC, 1200 W

STATUS

In production and believed operational with Yugoslav Forces.

CONTRACTOR

SPDR, Federal Directorate of Supply and Procurement, 9 Nemanjina Street, 1101 Belgrade, Yugoslavia.

4585.161

SUVOA FIRE CONTROL SYSTEM

Suvoa is a Yugoslav coastal artillery fire control system for the direction and control of coast defence gun batteries. Target data is principally obtained from an M70 optical director, supplemented by radar in certain conditions.

Target information from the M70 optical director is fed to a battery distribution unit from where firing data is passed to individual gun batteries. The data is automatically read off and transmitted in a synchronised way. The necessary corrections are set on the rangefinder which calculates them and passes them on to the guns. Transmission is by means of cable data links. Gun crews have only to bring gun traverse and elevation settings into coincidence with the values sent from the director.

In poor visibility or darkness radar range and bearing data may be substituted for the optical target data, but for safety reasons it is recommended that the radar should be separated from the gun battery by a distance of about 1000 metres. The range and bearing information derived from radar must be corrected for parallax before being sent to weapons from the rangefinder.

CHARACTERISTICS

Traverse: 360° unlimited
Range: 1000 – 50 000 m
Vertical base variation: 5 – 600 m
Total reading error: 50 m to 10 km range; 200 m to 20 km range; approx 3% to 50 km range
Measuring telescope
Magnification: ×18
Field of view: 4°
Inlet pupil diameter: 54 mm
Exit pupil diameter: 3 mm
Exit pupil distance: 14·8 mm
Adjustment: ±5 dioptres
Reticle: 0 – 35 mils L/R
Periscope: 356 mm
Observation telescope
Magnification: Variable ×3 – ×10
Field of view: Variable 20°, 6°
Inlet pupil diameter: 15 mm – 50 mm
Exit pupil diameter: 5 mm
Exit pupil distance: 15·8 mm
Adjustment: ±5 dioptres
Reticle: 0 – 35 mils L/R
Periscope: 256 mm

DEVELOPMENT

The system has been developed in both stationary and mobile versions. Equipment at each gun comprises a section commander's control box, range data receiver, siting device and bearing indicator. Electrical power for all units (including radar and M70 optical director) is derived from two mobile engine-driven generators, each of which is connected to the system via a transformer unit. The radar is housed in a transportable shelter with the necessary parallax computer.

STATUS

In production and believed operational with Yugoslav Forces.

CONTRACTOR

SPDR, Federal Directorate of Supply and Procurement, PO Box 308, Knez Mihailova 6, Belgrade, Yugoslavia.

NAVAL FIRE CONTROL AND ACTION DATA AUTOMATION SYSTEMS

CANADA

4046.261
ADLIPS

ADLIPS (Automatic Data Link Plotting System) is a modular low-cost, command, control and tactical data communication system designed to replace electro-mechanical plotting tables and associated radar displays in non-TDS (tactical data system) equipped ships. The system provides transmission, reception, filtering and display of target track data from Link 11 and Link 14 data communication networks. ADLIPS also collects and processes own-ship sensor data to compile rapidly a composite tactical display and interchanges target track, weapon assignment and status data with own ship's weapon systems. When operating in a TDS environment, ships fitted with ADLIPS can share tactical data with each other as well as aircraft and other ships that are data link equipped.

The main presentation is on the situation information display (SID) console, which has a 20-inch (51 cm) diameter CRT for displaying synthetic and radar tactical data presentation. Three operator stations, each with quick action controls, a tracker ball and an alpha-numeric keyboard enable the SID to serve as an efficient man/machine interface. The plasma displays are suitable for use in high ambient light conditions and the display area measures 22 × 22 cm. They each have an operator station which has the same functional layout as the display console operator stations.

An HF Link 11 radio transmitter/receiver provides for communications over this data link, and a Link 11 modem (AN/USQ-76) allows operation in either picket or net controlled modes. This unit generates and recognises Link 11 control codes, preambles and data formats and provides error detection and correction. For Link 14 a CV-2757/SGC interface converts the low-level signals from the computer to the high-level signals required by the cryptographic equipment and the inverse conversion.

The complete ADLIPS has a capacity of up to 140 air, surface and sub-surface tracks, and has a full NTDS repertoire.

STATUS

Litton has contracts for and is building 16 ADLIPS sets for the Royal Canadian Navy, and the first was installed in HMCS *Skeena* in October 1981.

CONTRACTOR

Litton Systems Canada Limited, 25 Cityview Drive, Rexdale, Ontario M9W 5A7, Canada.

2046.261
CCS-280 COMMAND AND CONTROL SYSTEMS (DDH-280) CLASS

This equipment is a shipborne automatic data handling and display system based on the Litton L-304 single processor version digital computer. Designated AN/USQ-501(V) data processing set, it comprises one digital computer, eight multi-function displays, and other peripherals.

The computer is fitted with a 40K 32-bit word memory capable of expansion to 80K words by addition of plug-in modules to the existing processor mainframe. Increased I/O capability can be achieved by adding units to the existing data bus using available minor channels in the I/O modules. The system includes radar signal simulation, which provides superimposed or separate radar targets that are variable in size and brightness for training. Displays are multi-purpose and identical. Quick action buttons provide mode selection and independent selection of up to seven separate radar videos with independent offset and range scales of 1 to 152 miles (1·6 to 244·6 km) in binary increments. Category selection of symbology is programmable on-line, independently, at each display.

Basic operating software has been provided by the manufacturer. In the case of the CCS-280 the Canadian armed forces chose to write all the operational software in a program generation facility provided by the contractor. The overall system provides real-time co-ordination of sensors and weapons by the command at the unit and force level to:

(1) collect, process, and display tactical information from all sensors
(2) control aircraft and other remote surface units
(3) direct own ship's and force weapons
(4) control own ship manoeuvres
(5) exchange information and orders within own ship and force.

STATUS

The system is currently operational at sea in HMC ships *Iroquois*, *Athabaskan*, *Huron*, and *Algonquin*. A shore installation for training and program maintenance and generation is fitted in the Combined Support Divisions, Halifax.

CONTRACTORS

Litton Systems (Canada) Limited.

Collins Radio (Automatic Link Equipment).

2047.261
UNDERWATER COMBAT SYSTEM (UCS) 257/280

The UCS 257 and/or UCS 280 comprises two AN/SQS-505 sonar sets (**1792.453**), an anti-submarine warfare data system (ASWDS), and ancillary equipment for both hull-mounted (HMS) and variable depth sets (VDS). Both AN/SQS-505 sonars are electronically identical and comprise a transmitter group, a receiver group, a control indicator group, and a transducer. The ancillary equipment for the hull-mounted set consists of a retractable hull outfit with dome. The ancillary equipment for the variable depth set consists of the AN/SQA-502 hoist group (including tow cable) and a variable depth body (including gyro compass).

The ASWDS is an action data system designed to accept primary target information from hull-mounted and/or variable depth sonars and secondary target information from radars. This information is processed by a high speed general purpose computer to provide action information to the command, computation of fire control solutions, and a weapon control.

A prototype of the system has been installed and evaluated in HMCS *Terra Nova*. Production models are fitted in HMC ships *Terra Nova*, *Gatineau*, *Kootenay*, and *Restigouche*, all of which are anti-submarine DDE 'Restigouche' class destroyers commissioned to take ASROC. The AN/SQS-505 sonar system is installed in the four DDH 280 class anti-submarine destroyers which have two helicopters, and Mk 32 torpedo tubes are fitted instead of ASROC.

STATUS

No longer in production.

4049.261
RADOP SERIES NAVAL FIRE CONTROL SYSTEMS

The Defense Division of CSEE offers a range of naval fire control systems suitable for the smallest patrol craft to vessels of more than 200 t, for directing guns against air and surface targets. In addition, these systems provide for surface and low altitude radar surveillance, optical surveillance, and target identification. The range of systems consists of differing combinations of CSEE optical or electro-optical directors, and one or other of the Racal/Decca marine radars.

Four basic systems have been developed in this way:

(1) RADOP 10 series with the CSEE Lynx (**3426.293**) director
(2) RADOP 20 series with the CSEE Panda Mk 2 (**3425.293**) director
(3) RADOP 30 series with the CSEE Naja (**3561.293**) director
(4) RADOP 40 series with the CSEE Najir (**4255.293**) director.

Essentially, all four have the same optical surveillance capability, but they differ in their weapon control performance. For each RADOP series, all the Racal/Decca marine radars of group 12 (1226, 1229, 1230 and 2459) are suitable, so that it is possible to select between 3 or 10 cm wavelength radar, 12- or 16-inch (30 or 40 cm) diameter CRT display, and relative motion, true motion or anti-collision presentation.

Each RADOP version can be optionally complemented by an automatic plotter, radio navigation aids, and an air surveillance radar.

Additional details of the CSEE E-O directors are given in the appropriate pages of the Equipment Section of this volume, under the reference numbers listed above, and in the following paragraphs the characteristics of individual systems of the RADOP series are summarised. (The Racal/Decca 1229 radar has been employed as an example in all cases, and obviously use of a different model would modify weights and/or dimensions.)

RADOP 10

This comprises a Racal/Decca radar, CSEE Lynx optical sight, and a control panel. It provides for radar and optical surveillance, optical target tracking and control of a small calibre gun. It is crewed by two men: the radar operator who is in charge of radar surveillance and target designation, and the Lynx operator who is responsible for optical surveillance and weapon control. RADOP 10 is suitable for patrol boats weighing up to 100 t. System weight is approximately 400 kg.

RADOP 20

This system consists of Racal/Decca radar, a CSEE Panda Mk 2 optical director, and a control panel. Services provided include radar and optical surveillance, optical target tracking, and control of one or two guns. The division of responsibilities between the two-man crew is the same as for RADOP 10. This version is suitable for patrol craft of more than 100 t and weight is about 560 kg.

RADOP 30

The equipment is as for the previous two systems, but with a CSEE Naja director in place of the Lynx or Panda Mk 2 director. This adds the possibility of remote control facilities from the Naja console to those provided by the RADOP 10 or 20 systems. The system weighs approximately 700 kg.

RADOP 40

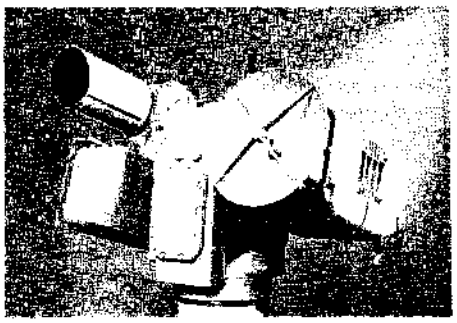
This system incorporates a Racal/Decca radar and a CSEE Najir director. It is manned by two operators: the radar operator in charge of radar surveillance and target designation, and the Najir operator responsible for optical surveillance and weapon control. System weight is approximately 850 kg.

STATUS

In production for various navies including those of Cameroon, Saudi Arabia, Senegal and Uruguay.

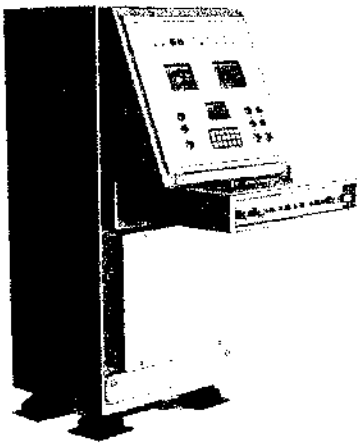
CONTRACTOR

CSEE (Compagnie de Signaux et d'Entreprises Electriques) Division Défense, 17 place Etienne-Pernet, 75738 Paris Cedex 15, France.



3102.281
CANOPUS NAVAL WEAPON CONTROL SYSTEM

Canopus is a lightweight naval tracking system capable of directing and controlling anti-air and anti-surface weapons and also providing optical target designation facilities. The system is designed for all-weather operation and is therefore able to deal with a wider range of operational requirements than an entirely optical or electro-optical tracking unit. Included in the system is an operational fire control console with its associated gun fire computer.



The Canopus system performs the following functions:

(1) autonomous optical surveillance over the full horizon
(2) automatic or semi-automatic target acquisition on radar target designations
(3) tracking of air targets including sea-skimming missiles and surface targets with the Ka-band radar, the TV tracker in bearing, elevation and radar range, and, optionally, the infra-red tracker
(4) target designation to or from other fire control systems.

Target data is sent to the artillery computer which performs ballistic computations for gun fire control.

Thomson-CSF lightweight E-O director (TRS 906) for Canopus naval FCS

Typical Canopus console

Association of the Canopus tracker unit with an artillery computer constitutes the Vega Canopus fire control system.

STATUS

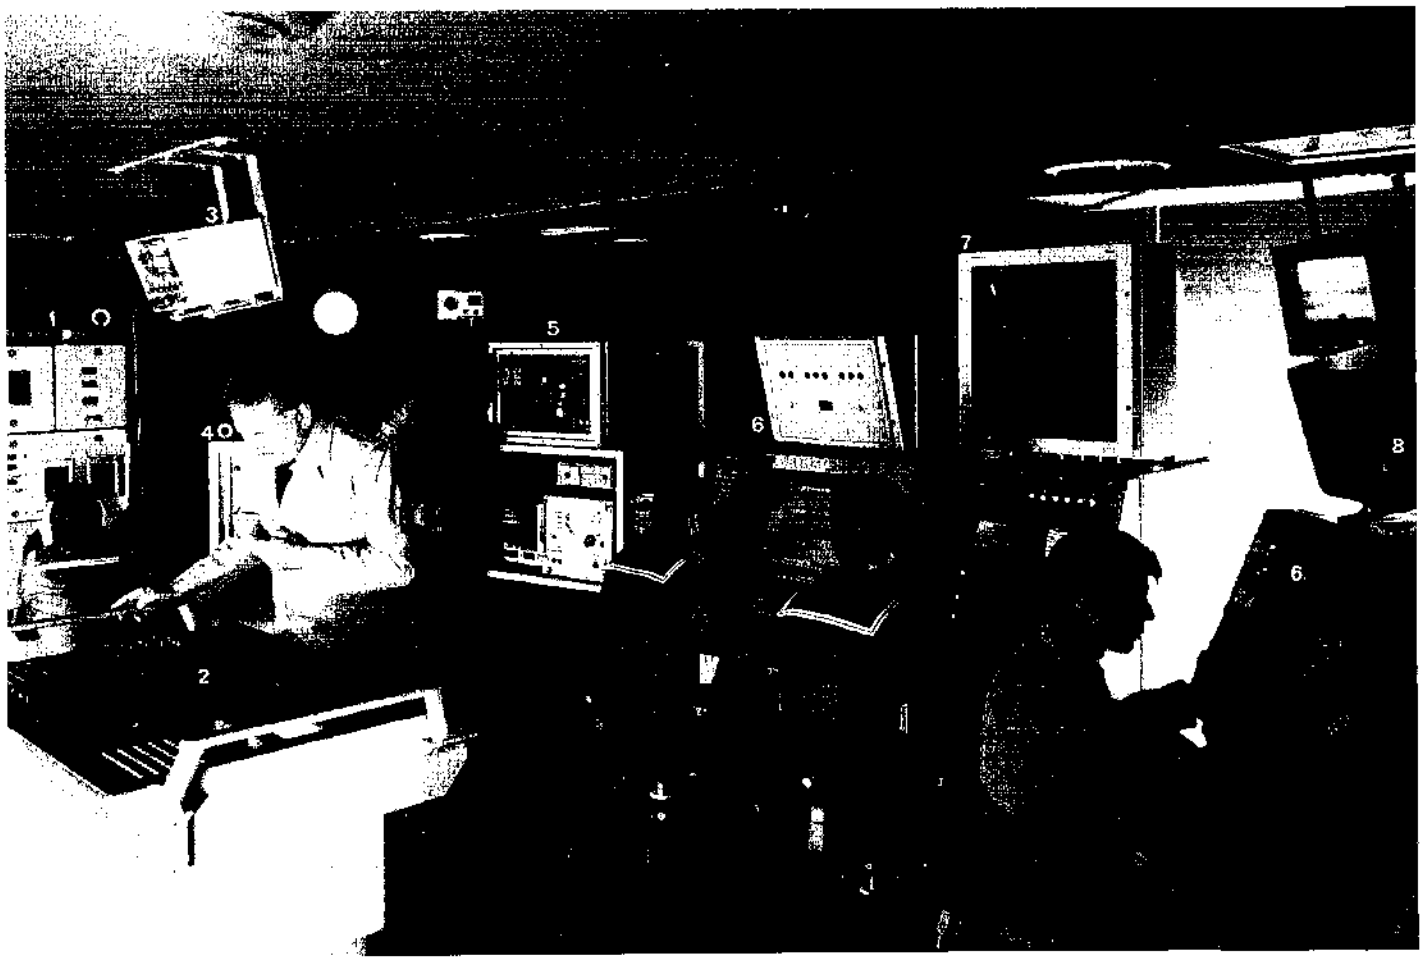
In production and delivered to several foreign navies.

CONTRACTOR

Thomson-CSF, Division Systèmes Défense et Contrôle, 40 rue Grange Dame Rose, BP 34, 92360 Meudon-La-Forêt, France.

4572.281
THOMSEA NAVAL COMBAT SYSTEMS

Thomson-CSF now produces the former VEGA series in their latest versions as the Thomsea naval combat systems, a range of modular integrated naval systems. The basic components of a Thomsea NCS are as follows:



(1) a combined (air and surface) surveillance and target designation radar (Triton G, Triton II MTI, Triton S or Sea Tiger)
(2) one or more fire control radars, Castor II fitted with television tracking
(3) one or more E-O directors fitted with television tracking, infra-red tracking, laser rangefinder or K-band radar
(4) a computer, or several co-operating computers
(5) tactical information unit: console and tactical table
(6) a track-while-scan (TWS) system, incorporated with the tactical table or the console; it allows simultaneous tracking of 16 to 64 air or surface targets detected by the surveillance radar.

Various other equipments may be associated with the system to augment the ship's capabilities in performing the following functions: designation and tracking (optical sights and directors), radar identification and analyses (IFF, ESM), electronic countermeasures (jammers, chaff-launcher), submarine detection (sonar), navigation (radar, log, heading and vertical reference system). The following weapons are controlled or are fed target co-ordinates:

(1) guns of any calibre
(2) surface-to-surface missiles
(3) surface-to-air missiles
(4) surface torpedoes, conventional or wire-guided
(5) ASW weapons (torpedoes or rockets).

The number and type of fire control systems as well as computer capacity are essentially dependent on the ship's armament. The choice of surveillance and ASW equipments is more dependent on ship's tonnage and missions.

Tactical information units are designed to take into account diverse operational criteria defined by users. The basic unit is constituted of the operational consoles for surveillance and fire control radars, to which is added the tactical table. On the surveillance console and tactical table PPIs, analogue video is complemented with synthetic marks, alpha-numeric labels relating to followed tracks, vectors, symbols and track plotting. The data fed by associated equipments – fire control and navigation radars, radar analyser (ESM), optical devices, sonar – are displayed on the PPIs. Complementary devices added to the display unit allow for: fire correction for surface

Typical light frigate CIC

Key: 1 *sonar*, **2** *tactical display desk*, **3** *informal telecoms terminal*, **4** *ASW fire control*, **5** *ESM/EW*, **6** *tactical and search radars and displays*, **7** *fire control console*, **8** *Crotale fire control*

targets, from splash plotting; data display; inter-ship exchange of track data, from stations equipped with a data link (received tracks are displayed on the PPIs); and recording of simulation or tracks for exploitation or operator training.

Tactical problems are solved by calculations inside the system providing: true-motion presentation on PPI; display of relative bearing and range between two tracks, one of which may be the radar carrier (RBL); display of the collision course and of the time required to intercept a track (CTS); the closest point of approach (CPA); extrapolation of tracks for a given time (time to go); generation of fixed points and measurement of the time elapsed since their initiation (datum).

The operator communicates with the system easily and rapidly through a keyboard. This easy reading of decision-making elements by the operator and technical problem solving reduces to a minimum the reaction time between detection and fire command.

The fire control radar console, which includes the computer, provides the operator with:

(1) acquisition of the designated air or surface target
(2) choice of the operating mode
(3) monitoring of the quality of tracking, using radar or television screens
(4) gun control and fire correction.

Interfacing with associated equipments, whether analogue or digital is achieved with specific couplers. In the tactical table and in the console, digital data flow over a bus-type line. A microprocessor controls display and operational functions. The following concepts are embodied in all Thomsea systems:

(1) modularity, which allows a great variety of configurations as well as adaptation to the most diverse needs
(2) physical separation of the surveillance and fire control platforms and antennas
(3) choice of several different frequency bands. This makes it possible to optimise each function to reduce the system's vulnerability to ensure basic protection against jamming
(4) operational redundancies such as using the fire-control radar for surveillance and the surveillance radar for the guidance of some weapons.

Another significant advantage gained by separating the antennas is greater detection range at the surface of the sea or at low altitudes, obtained by installing at the greatest possible height the surveillance antenna which is not required to meet the same platform rigidity constraints as the fire-control directors.

STATUS

Development of these naval combat systems started in 1967. The first system manufactured, a Vega type I-43, controls two guns, Exocet missiles and AEG SSI4 torpedoes. It has been operational since the end of 1971. From the early systems, mostly adapted to small tonnage ships, to the systems currently available, the evolution has been towards an enlargement in the choice of basic equipment to meet the requirements of a broad range of tonnage and missions, with a particular emphasis on the self defence capability against sea-skimmer missiles.

Thomson-CSF, Division Systèmes Défense et Contrôle, 40 rue Grange Dame Rose, BP 34, 92360 Meudon-La-Forêt, France.

4053.261

TAVITAC TACTICAL DATA HANDLING SYSTEMS

The former Vega 3C tactical data handling systems, now designated TAVITAC (Traitement Automatique et Visualisation Tactique) are of modular design for both hardware and software. This makes them highly flexible, fit for any type of ship, and capable of meeting any particular operational need. The display consoles are vertical and horizontal. They can be fitted with different types of screen: monochrome or colour, circular or rectangular. Consoles can receive raw video from several radars, superimposed on synthetic video. Display capacity can be adapted to needs by means of a video compression device associated with optimised processing for picture generation. The consoles can be associated with various data processing computers which can be integral with the consoles or set in separate cabinets.

Software can be adapted to associated sensors and operational requirements, and can be produced on civilian computers which are compatible with the Thomson-CSF computers employed in TAVITAC systems. Standard functions are:

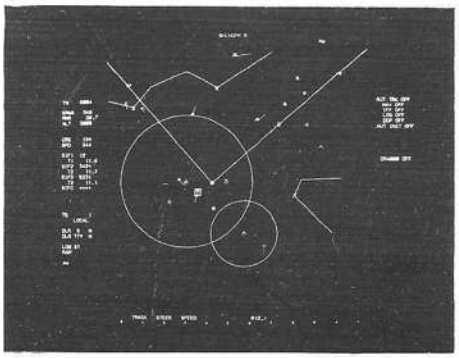
(1) automatic tracking of air and surface tracks, associated with an extractor (TWS), with manual or automatic initialisation, allowing anti-surface gunfire
(2) rate-aided manual tracking
(3) manual entry of tracks and special points
(4) track identification
(5) threat evaluation
(6) display of local and external tracks received via data link, with associated symbols, speed vectors and alpha-numeric data
(7) display of optical and ESM bearings, of positions of targets tracked by fire-control directors, of circles, vectors, launching figures
(8) transmission of local tracks via data link
(9) dispatch of target designations to weapons
(10) aids to tactical navigation.

Extended capabilities are:

(11) fully automatic process of engagement of air targets, including track initialisation, threat evaluation, timely target designation, weapons coupling, fire orders, optimised management of directors and weapons in case of simultaneous attacks
(12) tactical situation recording and replay in real- or accelerated-time
(13) training facilities in association with a video simulator
(14) coastline storage and display on PPIs on request
(15) tracking of submarine positions, processing of ASW weapon parameters, guidance of attacks by ASW helicopters or other aircraft.

The display system configurations can be adapted to suit particular ships and their weapon systems. Typical systems might include one console only for the smaller systems, with automatic tracking of 16 air or surface tracks, two to four consoles for larger systems, suitable for modern medium-tonnage ships, with automatic tracking for 16 to 32 air or surface tracks, or up to ten consoles, or more, for larger systems designed for heavy tonnage ships, allowing automatic tracking of up to 200 tracks, with vectors, circles, circle sectors, coastlines, etc.

For all proposed structures, the number of computers devoted to processing of tactical information is defined according to the needs and to the degree of redundancy required.



Different types of console are available: vertical consoles for incorporation with a fire control console, modular vertical consoles, tactical tables with one or two operator positions, and large horizontal consoles with two or three operator positions.

A console is made up of the following modules: a combined radar-synthetic image generator module including a renewal memory of the associated computer, a PPI display module, input devices (order keyboard(s), video control panel, rolling-ball control unit(s)), and alpha-numeric display on a TV or a plasma screen (alpha-numeric information can also be displayed on the PPI edges). Display capabilities are adjustable to customer requirements up to 200 tracks and 100 different symbols.

In the French Navy such systems are known under the name SENIT (Systeme d'Exploitation Navale des Informations Tactiques). Four F2000 T class frigates that France is to supply to Saudi Arabia will be fitted with SENIT naval tactical display systems produced by Thomson-CSF.

Tactical weapon control console

3743.481

DLA ANTI-SUBMARINE FIRE CONTROL SYSTEM

The DLA anti-submarine fire control system is designed on a modular basis to provide the necessary flexibility to permit its use aboard various classes of surface ships, to accommodate various types of weapons, and to enable it to be completely integrated within a ship's combat system. This is achieved by assembling the DLA system from two basic modules: a 'target' module and a 'weapon' module.

The former is built around a large CRT for the

display of tactical information, and a microprocessor. The microprocessor is of similar or identical technology to that employed in the weapon module and its function is to accept target data from sonar systems (eg bearing, range, and doppler), and from these to compute the target parameters required by the weapon module (course and speed).

Weapon modules are specific to the weapon(s) fitted in the ship (eg torpedo, A/S missile, rockets, or depth-charges), and current 'standard' weapon modules are available for all French torpedoes as well as the Mk 44, Mk 46 and A 244 types, and for the Creusot Loire/Bofors 375 A/S rocket launcher. Other types of weapon can be accommodated by the designers on request. The weapon module computer accepts data on target bearing, range, course and speed, and processes this information to produce the necessary parameters for the sequencing, setting, and launching or firing of the A/S weapon.

The DLA is supplied either as a completely self-contained system, with both types of module, or as a weapon module (appropriate to the ship's weapon fit) with a suitable interface for integration into a vessel's combat system performing target designation and computation.

STATUS

In series production for the French Navy and one foreign navy.

Thomson Sintra, Activités Sous-Marines, 23 rue de Courcelles, BP 096-8, 75362 Paris Cedex, France.

1522.261

SENIT NAVAL TACTICAL DATA HANDLING SYSTEMS

The French Navy's naval tactical information systems for surface vessels are identified under the acronymic designation SENIT (Systéme d'Exploitation Navale des Informations Tactiques), and five systems of this kind have been identified. All five have the broad functions of gathering, co-ordinating, and distributing sensor data and other information, presentation of information on appropriate displays, and certain weapon system control functions. A digital computer, or computers, provides the central processing facilities. The five systems differ in accordance with the nature and operational role of the vessel fitted and the sensors and armament installed. Details of the five versions identified to date appeared in the 1979-80 edition of *Jane's Weapon Systems*, and in preceding editions. No information has been received concerning any successor systems that may be employed aboard new generation French warships.

STATUS

In addition to the SENIT systems produced for French Navy vessels, a certain number of systems have been supplied to foreign ships according to the manufacturers, but no details have been obtained. Four frigates for Saudi Arabia are to be equipped, as noted in **4053.261**.

CONTRACTOR

Thomson-CSF, Division Systèmes Défense et Contrôle, 40 rue Grange Dame Rose, BP 34, 92360 Meudon-La-Forêt, France.

1739.461

DLT-D3 SUBMARINE TORPEDO FIRE CONTROL SYSTEM

The DLT-D3 torpedo fire control system is used in French Navy submarines. All types of torpedo employed by the French Navy can be launched, including wire-guided. The system may also be expanded for anti-surface missile applications.

Target data is fed to the system from on-board sensors, which comprise fore and aft sonars, acoustic rangefinder and attack and surveillance periscopes.

The system employs a general purpose digital computer, associated with a CRT display terminal. The following functions are performed by the system:

(1) updating of the tactical situation from the data delivered by the various sensor systems fitted and the navigation equipment
(2) assistance in calculating target components by the use of special recorded programs
(3) weapon control, ie computation of the firing path, remote setting of torpedoes, and firing sequence control. The system is designed for launching any type of torpedo
(4) maintaining a chronological record
(5) maintenance assistance by means of test programs.

DLT-D3 submarine torpedo fire control system

The DLT-D3 operating programs have been compiled to permit tracking of eight targets, simultaneous guidance of two wire-guided torpedoes and preparation of a third for launching. Each of the three displays of the terminal is dedicated to the presentation of the following data, in accordance with the program implemented: tactical situation, firing path, and alpha-numeric display of parameters (tote) and decoding of the designations and functions of the two common keyboards. Conversation between the operator(s) and the computer are by means of these keyboards. Emergency launch of torpedoes is possible from either bow or stern station.

The system is designed to be served by one or two operators at the operations centre, and one operator at the bow station with possibly another at the stern station. The equipment arrangement, typically, is one CIMSA 15M125 digital computer (QTD), a monitoring and control console (VIC), an azimuth relay (RZ), a true-bearing diagram (GZ) in the operations centre, a tube selection panel (PAT), and tube servicing station (PST) in the bow and/or aft torpedo tube compartments.

STATUS

This system is in service in 'Daphné', 'Agosta' and 'SNA' class submarines of the French Navy, and is in production for all French and foreign 1200-ton class submarines.

CONTRACTOR

Thomson Sintra, Activités Sous-Marines, 23 rue de Courcelles, BP 096-8, 75362, Paris Cedex, France.

4501.481

UX 37 SUBMARINE INTEGRATED COMBAT SYSTEM

Based on some 30 years of experience in R & D, and the supply of passive sonars, directional and other sonars, and fire control systems, Thomson Sintra has enlarged the performance of its equipment to develop the integrated combat system UX 37.

The main functions of this system are:

(1) harmonisation of the detection function, tactical situation elaboration, weapon control and guidance
(2) to increase the range and the accuracy of the sonars in accordance with the range of modern weapons such as wire-guided torpedoes and anti-submarine missiles
(3) to reduce the submarine crew requirements by means of a major expansion of automation.

Organisation of the combat system around a modular architecture provides for rapid and simple evolution of system elements at different levels in the future, simple maintenance and increased reliability.

The hardware comprises: port and starboard arrays of three antennas; two forward antennas; one HF sonar interception array; one sonar transmission array; four or five equipment cabinets, three colour display consoles. The functioning of the UX 37 system is described in the paragraphs that follow under its three main operational purposes: Detection; Tactical situation; Preparation, launch and guidance of weapons.

Detection

(1) Acoustic: the long range passive sonar gives accurate bearing measurement on radiated noise and sonar pulses. Capacity for handling 20 tracks

Three-colour large-screen display console of UX 37 submarine weapon control system

gives bearing automatically or manually, and there is a high performance passive rangefinder for use on sonar pulses or other radiated target noise. The range is measured on the first five targets of the 20 automatically tracked in bearing. The intercept sonar provides bearing, frequency and range measurements on targets. A CW/FM active sonar set provides facilities for obtaining Doppler information, bearing and range data measurements, torpedo warning, own noise warning, underwater telephone facilities, audio watch, and as an additional function a sound ray tracer can be incorporated

(2) Optical: the information derived from the periscope and any electro-optical sensors are integrated

(3) Electromagnetic: provisions are included for the display of data obtained by the submarine's radar and ESM installations, and for the presentation of ESM warning signals.

Tactical Situation

(1) Central display: on this unit is presented the elaboration of the tactical situation relating to up to 100 targets in relative bearing terms

(2) R/H display: this is used to display up-dating information on four targets in true bearings based on the last 20 minutes of tracking data.

Weapon Handling and Launch

The UX 37 system provides the following: weapon status display; engagement of up to four targets simultaneously; weapon management and guidance with simultaneous launch of two wire-guided torpedoes, and firing of an anti-submarine missile.

STATUS

Development.

GERMANY (FEDERAL REPUBLIC)

1824.281

AGIS COMBAT INFORMATION SYSTEM

AGIS (Automatisiertes Gefechts- und Informations-system für Schnellboote) is a fully integrated command and fire control system which has been developed for the West German Bundesmarine's Type 143 fast patrol boats.

AGIS includes the areas of command and fire control system WM 27 (HSA) (**1259.281**), the optical auxiliary fire control system OG.TR 7/3 (Officine Galileo), weapons, data transmission system LINK 11 (Collins), log system SAL 59 (Jungner), gyro compass system PL-41 (LITEF), IFF system (Siemens) and ESM system. The weapons associated with the system are two 76/62 OTO C guns (OTO Melara) both against air and surface targets (**5533.203**), two wire-guided torpedoes Seal (AEG-Telefunken) (**2178.441**) and four surface target missiles MM 38 Exocet on two double launchers (**1156.221**).

In addition to AGIS, the RF, VHF and UHF transceiver units and their associated communications operator stations serve for external communication in the radio-telephone, radio teletyping and radio keying modes – unencrypted and encrypted. Internally, communication is ensured via the simplex/duplex system (Philips). Furthermore, navigation and direction finding aids include an echo sounder, magnetic compass, Decca navigator and navigation radar.

The AGIS mission centre is the combat information centre with the two control units for torpedo direction, the artillery control system for guns and missiles, the horizontal tactical display and the vertical plot. From here, the S143 can operate as lead boat for other units (eg S142 or S148). The system is controlled by two freely programmable digital computers processing the sensor data for displaying on the different displays or for weapon control. One of the computers is for generation and utilisation of the tactical situation and for target assignment to the command units, and the other one operates as fire control computer for target tracking, determination of firing parameters as well as for control of weapons and weapon consoles.

In addition to own ship information acquisition, the automatic data transmission system, LINK 11, permits the display of data on targets outside own ship detection range and to transmit tactical information to other units.

The AGIS is also employed on the new class 143A fast patrol boats. A successor to the class 143 combat system, it mainly differs in having the ASMD (RAM) system in place of the stern gun and the torpedo system is replaced by a mine launcher. The class 143A is equipped with an FL1800 ESM/ECM system.

STATUS

Fitted in Type 143/143A fast attack craft.

1825.281

SATIR ACTION INFORMATION SYSTEM

SATIR (System zur Auswertung Taktischer Informationen auf Raketenzerstören) is the tactical data automation and display system fitted in the three 'Lütjens' class guided missile destroyers of the West German Bundesmarine. These ships are a modified version of the American 'Charles F Adams' type and are fitted with US radars such as the SPS-52 three-dimensional search and target designator, SPS-10 surface warning set, SPS-40 air surveillance, and SPG-51 fire control radars for the Tartar surface-to-air missiles. Weight and space considerations decided the Bundesmarine against the installation of the US NTDS (Naval Tactical Data System) and SATIR was developed in its stead to meet the German requirement and in general compliance with the B-2 Concept, a NATO standardised system for destroyers and above. Beyond the participation of Univac, no other reliable details have been obtained.

A version of the SATIR system is fitted in the six vessels of the Type 122 'Bremen' class; this is described in detail in 1982-83 and earlier editions (**3504.281**).

3504.281

CLASS 122 FRIGATE COMBAT SYSTEM

The combat system of the new Class 122 frigates for the German Federal Navy permits the repulsion, engagement, deception and destruction of air, surface and underwater targets as well as communication with other units at sea, in the air and ashore. For the performance of these tasks the combat system consists of a central computer system for processing and correlation of the incoming information which is acquired by means of sensors and data transmission, as well as of display consoles with the synthetic scenario for dialogue during decision-making, and for any resultant missions.

All major functions can be monitored from the combat information centre with the aid of an optimised number of personnel in a reliable, co-ordinated and effective manner and can be controlled directly or indirectly. The high processing speed and the large storage capacity of the computers as well as the very fast peripheral equipment and a considerable redundancy permit measures for equipment maintenance and repair in parallel with the major tasks outlined above. A suitable computer set-up, special system instructions as well as a modular software structure permit effective real-time processing. As far as software programs are concerned, a distinction is made between the mission software, maintenance software, support software and general software for administrative and other purposes.

This system, which is now being progressively deployed with the West German fleet, is described in detail in 1982-83 and earlier editions of *Jane's Weapon Systems*, together with a list of sensor equipment and weapons fitted in these ships.

SER 100 NAVAL FIRE CONTROL SYSTEM

The SER 100 naval fire control system (FCS) is formed by the integration of the Racal Decca 2459 F/I dual-band search navigation radar (**1941.253**) and the Selenia-Elsag NA 18 electro-optical (E-O) FCS (**4058.281**), with its multi-function console (MFC), to produce a small, but very cost-effective combat system for use in naval vessels of corvette size or below. Facilities provided include: air and surface search, precise navigational information, target plotting and target indication/designation, and weapon control functions.

By means of the MFC all the combat system-related functions can be implemented and when the operator is not engaged in fire control he can readily attend to other tasks. In the basic configuration the MFC can provide the command with tracking information (CPA, TPCA etc) for navigation, anti-collision or shadowing purposes in addition to the facilities available on the bridge display. Where more than the basic configuration is required, an additional command tactical console (CTC) can be integrated for target evaluation, target indication and navigation facilities, with back-up provided by the MFC. In every case, the final E-O designation is completed in the MFC using a 'B' type presentation, and after designation the target is acquired by the E-O system by use of a special 'frozen frame' technique, after which it is tracked and then engaged.

The main items of equipment are described in the following paragraphs:

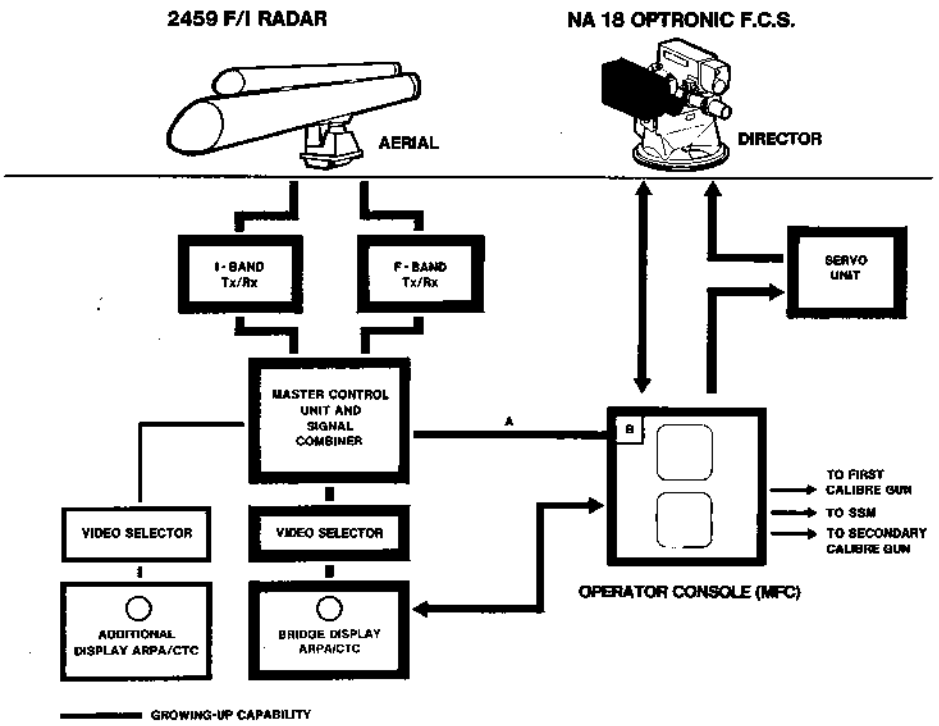
The 2459 radar is an F/I-band system with separate, co-located antennas for each band, and mounted on common turning gear for minimum top weight and to reduce the demands on mast space. Remote video selection of raw or processed, combined or single F- or I-band signals is available. Sophisticated signal processing developed from the Racal Decca 'Clearscan' system is employed, as are ECCM and anti-clutter measures against rain/sea interference. A master control unit and signal combiner allows selection of up to ten modes of processed or raw radar video. For combined air and surface surveillance the I-band beam is directed horizontally, while the F-band beam is centred at an elevation angle of 15 degrees. The standard I-band transmitter has a peak power output of 75 kW, but an alternative 25 kW version is also available. F-band peak power is 30 kW. The combined antenna is rotated at 22 rpm.

The NA 18 E-O FCS is described in **4058.281**, in the Italian pages of this section, but is amplified here in the context of the SER 100 application. It can be fitted with a TV camera and a laser rangefinder, respectively performing angular and range tracking. An IR thermal imaging camera, also performing passive surveillance, may be added without any major change

to the basic system configuration. The NA 18 can also be used for surveillance, detection, tactical evaluation and navigational functions, due to the transfer of radar video to its console. Ballistic, tracking and weapon aiming calculations are performed by an ESA multiprocessor capable of providing gun output orders for two different calibre guns and target indication data to a surface-to-surface missile system.

Operation fo the NA 18 is via a MFC. Target designation may be autonomous (by tracker ball) using a PPI/B-scope presentation, or from external sources such as an optical sight, ESM/EW, etc. Tracking is automatic by TV or IR and laser rangefinder, with the ability to override this by a joystick control on the console. Temperature, pressure and muzzle velocity corrections are applied automatically to the ballistic computations.

The relationship between the elements of the SER 100 system are shown diagrammatically in an adjacent illustration.



STATUS

The SER 100 system is stated to be in series production although no details have been released of fittings or contracts.

SEAGUARD NAVAL WEAPON CONTROL SYSTEM

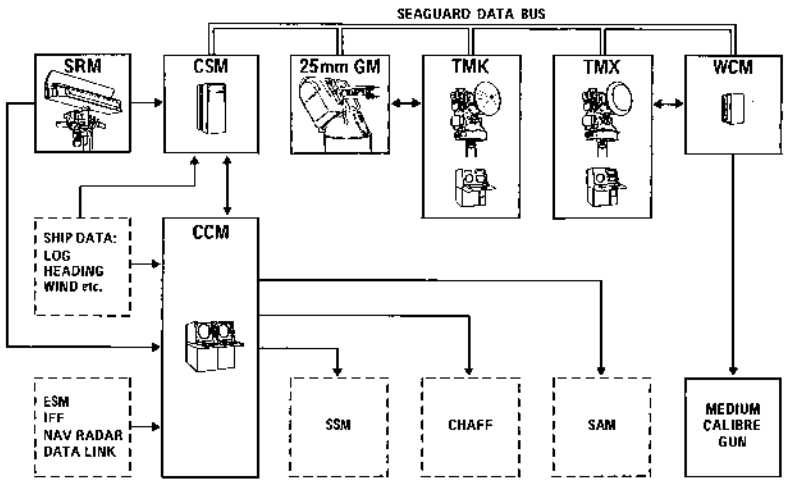
Seaguard is a modular system that can be configured in a variety of ways. This entry is concerned with the equipment configured as a general fire control and combat system. The Seaguard CIWS configuration is described in the Naval Surface-to-Air Weapons section of the book (**4016.231**).

The Seaguard equipment modules comprise the following:

(1) Plessey Dolphin search radar (**4004.253** in 1982-83 and earlier editions), module (SRM)
(2) Ku-band tracking radar module (TMK)
(3) X-band tracking radar module (TMX)
(4) 25 mm gun (**4017.203**) module (25 mm GM)
(5) command and control module (CCM)
(6) common support module (CSM)
(7) weapon control module (WCM).

The SRM is a dedicated high data rate, dual beam, C-band equipment that provides target detection and indication in severe environmental and ECM conditions for sea skimming and high diving missiles, as well as general air and surface surveillance.

The TMK is a high dynamic three-axis multi-sensor (Ku-band radar, FLIR and laser) all-weather tracking system, said to be impervious to the multi-path effect, enabling tracking of high-speed manoeuvring missiles throughout the hemisphere including sea skimming and zenith diving missiles in a dense ECM environment. Detailed monitoring and mode selection of Seaguard automatic engagement sequence are performed by a single operator at the tracker/weapon console.



The TMX consists of a high dynamic three-axis multi-sensor (X-band radar, FLIR and laser) tracking system enabling long range accurate tracking throughout the hemisphere. Its tracker/weapon console provides the detailed monitoring and mode selection of Seaguard automatic engagement sequences. As an option, target data can be provided for overall control of SAMs, with the tracking module providing, for example, CW illumination through its X-band radar when required.

The 25 mm GM has a high dynamic canted two-axis gun mount carrying four independent KBB 25 mm cannons having a combined rate of fire of 3400 rounds/minute, permitting engagement of high speed manoeuvring missiles throughout the hemisphere including sea skimming and zenith diving missiles in all conditions of ship motion. The below-decks ammunition feed system, protected from environmental and NBC conditions, has a ready-use capacity of 1660 rounds (18 engagements) and permits topping up during firing. The high energy 25 mm KBB APDS ammunition has proven 1 hit - 1 kill capability against all types of anti-ship missiles, and is also claimed to be effective against aircraft.

The CCM is a console providing the command facility to control and monitor surveillance sensors and to supervise tactical engagements.

The CSM houses a data processor and interface module that provides data processing facilities for the search radar module and interfacing with non-Seaguard systems.

The WCM is a data processor providing optimum gun control, ballistic computation and gun aim point prediction for any type of medium calibre gun in AA/SU modes.

Seaguard configured as a ship's combat system

Each module of the Seaguard modular range of equipment has its own dedicated data processing facilty, and they are interconnected by a common data bus that also serves to link into the overall ship's weapon system. Configured as a fire control system, Seaguard provides integrated flexible weapon control and a layered air defence.

STATUS

In series production following a contract from a West German shipyard for Seaguard systems to be fitted in four frigates under construction for the Turkish Navy. Other contracts were under negotiation in May 1985.

4489.281

SEA TIGER

Sea Tiger is a derivative of the naval electro-optical fire director system originally developed for the US Navy as the Seafire project (**3727.281**) by two of the participants in that programme, Texas Instruments and Ferranti. The Sea Tiger system is designed to provide passive surveillance using high resolution daylight television and high resolution forward looking infra-red (FLIR) for night surveillance, and typical applications include navigation, search and rescue, aircraft and missile detection, and detection of surface craft (ships etc) at the horizon. For fire control purposes three-dimensional tracking is provided by an automatic video tracker used with a laser rangefinder. The system processor carries out calculation of gun or missile orders using three-dimensional track information, ship's sensor inputs and stored ballistic data. Other facilities include handing-off of targets and line-of-sight designation from other ship systems and there is spare computer capacity for distributed processing. Laser target illumination facilities are provided for guidance of laser seeking ordnance such as the US Navy's 5-inch

laser guided shell and air-launched weapons such as LGBs. Laser target designation is frequency codeable to facilitate multiple attacks/targets, and to aid protection from countermeasures.

The Sea Tiger equipment comprises an E-O director mounted above deck and incorporating a daylight TV camera, thermal imaging IR sensor, and a Ferranti Type 905 multi-role laser for designation and laser rangefinding. The E-O director is connected by a data link and video link with a below-deck console that contains the computer for the automatic video tracker and fire control calculations. Provisions are included for interfacing the Sea Tiger system with other ship's sensors and data processing facilities.

Operational applications of the system include passive surveillance by day and night, target detection and designation for defensive and attack purposes, close-in point defence capability, and laser target marking for laser guided weapons such as naval ordnance or air-launched bombs.

STATUS

Joint marketing programme by Texas Instruments and Ferranti world-wide, excluding the USA where it is understood that a US Navy contract for the Seafire system (which contains a number of system elements common to the Sea Tiger system) was awarded to Texas Instruments in November 1983.

ELBIT ISRAELI NTCCS

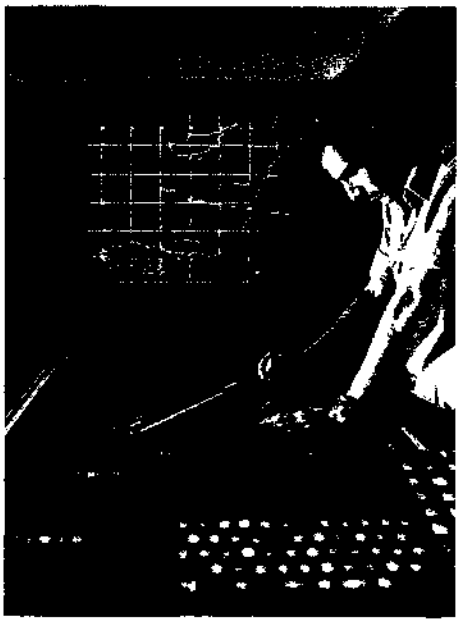
The Elbit Israeli Naval Tactical Command and Control System (NTCCS) is a computer-based system to provide the commanders of ships with real-time tactical information on their area of activity. Using data from own ship sensors and other task force participants, the system processes the data and presents a tactical situation picture. In addition, the NTCCS provides navigational computations, message exchange services between task force units and shore-based headquarters, and recording of tactical data for future debriefing and off-line analysis.

Input data are provided by sensors such as search and fire control radars, EW and ESM systems, sonar, automatic navigation system, ship's log and gyro-compass, and manual inputs including optical sight information and the various communications channels. Additionally, information from other units can be inserted via data link or underwater communications links.

Items of equipment incorporated in a typical NTCCS include: digital computer(s); input/output controllers and interfaces for ship's sensors; radar plot extractors; tactical alpha-numeric tote displays; alpha-numeric terminals for the command team and sensor operators; numeric display generators for plotting tables; display generators for tactical display consoles (PPIs); and tape recorders. The tactical situation will be displayed on a high resolution coloured raster display.

Depending upon the particular ship and its sensor and weapons fit, specific functions performed by the NTCCS include the following:

(1) compilation and presentation of tactical situation pictures
(2) management of the exchange of tactical data between task force units (including submarines and aircraft)
(3) detection, tracking and processing of target data
(4) correlation of EW/ESM and radar data
(5) computation of navigation and manoeuvre data
(6) computation of intercept locations
(7) computation of EW countermeasures area
(8) presentation of correlation charts from the computer
(9) data recording.



The system was especially designed for the tough environment of small patrol craft (missiles/guns) but is also suitable for larger ships with additional displays as desired.

STATUS

Operational with the Israeli armed forces.

4579.281

RESHET NAVAL COMMAND AND CONTROL SYSTEM

Reshet is a shipborne tactical command and control system for vessels of all sizes. It provides the command with an updated and comprehensive picture of the overall tactical situation, based on data from own ship's sensors and information derived from consorts and/or shore-based facilities, via data links.

Several versions have been designed (**3800.261** in 1983-84 and earlier editions), but all are composed of one or more tactical display consoles (TDCs), a central data processing unit, and in certain cases a data management terminal, as well as the essential interface equipment needed to connect the system with sensors and weapon systems.

Operational requirements met by a typical Reshet system include: real-time assembly, assessment, display and application of all available data; co-ordination of task force actions; over-the-horizon targeting; prevention of 'data saturation'; and modernisation of existing CIC facilities.

To fulfil these functions the following facilities are required:

(1) automatic tracking of multiple targets from search and fire control radars' video data
(2) exchange of tactical information and messages within data link network stations
(3) threat evaluation by classification, correlation, execution of triangulations and selective data display according to operator-defined categories
(4) navigational calculations and other computations for operational purposes
(5) tactical display in colour, with maps, grid, targets and bearing lines, datum points, danger zones, future positions, track histories and other tactical data
(6) comprehensive display, editing and data manipulation facilities such as zoom, off-centring, true/relative motion display, declutter, etc
(7) anti-submarine warfare calculations and display
(8) alpha-numeric presentation of target data, cursor position, system, messages and other information
(9) designation of tracked target to weapon systems and other units
(10) hard copying of tactical scenario for analysis.

All these facilities are provided by a typical Reshet multi-functional system, which might consist of a central processor unit, a number of consoles used as the target acquisition and designation (TAD) position, tactical editor console, commander's tactical console, and data link equipment. The Reshet system's modularity allows two alternative simplified versions to be configured for smaller ships. These differ from the complete system mainly in the display capabilities. The single console configuration replaces the tactical editor console with a data management terminal that provides the tactical editor with data in tabular form, and supplies the commander with a full picture on the tactical console. The minimal system configuration, Reshet TADS/Data Link includes the target acquisition and designation system console and data management terminal, with the central processor unit. This configuration is sufficient to provide: display of data from ship's own radar(s), automatic tracking, synthetic symbols, data link management and display, and target designation capability.

The tactical display console (TDC) component of the Reshet system can be used as an independent fully computerised multi-function unit. In such a role it can provide: local data processing, display of maps grids and zones, navigational solutions and display, automatic updating of own position, local processing of operator requests, definition of targets and bearing lines, computation and presentation of targets and their track histories, etc.

STATUS

In production and operational with Israeli and other naval forces.

CONTRACTOR

DG NAVAL FIRE CONTROL SYSTEM

The DG (Dvora/Gabriel) weapon control system is based on the FCS developed for the Gabriel anti-ship missile system (**6019.221**) as fitted in the 'Dvora' fast missile boat. It is especially adapted for smaller naval craft like 'Dvora' class vessels, enabling boats equipped with this system to enjoy a fire power normally available only on larger ships.

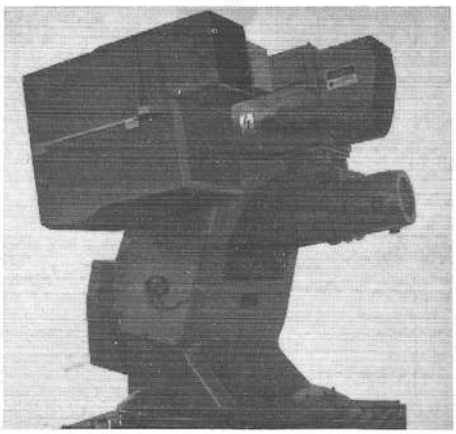
A variant of the basic Gabriel integrated fire control system, the DG system has been designed for missile control and guidance only. The system handles search, acquisition and tracking of surface targets, target designation from one unit to another and Gabriel missile trajectory precision guidance.

The main sub-units of the DG system are: fire control tracking radar (FCR) components, comprised of antenna (FCRA), transmitter (FCRT), and receiver (FCRR); a standard search and navigation radar (adapted by the Electronics Division of MBT Weapon Systems to designate targets to the weapon system); a stabilised periscopic optical sight (OS); a display control and processing unit (DCPU); a vertical reference unit (VRU); and Gabriel missile fixed single launchers.

Only two operators are required to operate the system. One, the optical sight operator, handles search and tracking by means of the periscopic OS from the closed bridge, while the other, the DCPU operator, handles FCR operation and missile control and guidance.

STATUS

No information released.



CONTRACTOR

MBT, Israel Aircraft Industries Ltd, Yehud Industrial Zone 56000, Israel.

ITALY

4058.281
NA 18 FIRE CONTROL SYSTEM

The NA 18 is an electro-optical (E-O) fire control system (FCS) belonging to the latest Elsag series of naval fire control systems. It was developed to serve as either a lightweight autonomous system for use aboard small and medium tonnage vessels, or as an alternative to a radar FCS in ships which lack the space to fit a radar system. In larger ships, the NA 18 can be operated as a back-up to the existing radar fire control lines-of-sight, especially in the presence of heavy ECM or when a low-flying target is to be engaged and tracked.

NA 18 E-O director equipped with TV camera, laser and infra-red thermal camera

This system forms a major element of larger naval combat systems, such as the NA 30 (**3861.281**) and SEN series (**4824.281**) described below, or advanced FCS such as the SER-100 (**4825.281**) described in the International pages of this section of *Jane's Weapon Systems*. Readers are referred to the latter entry for additional information on the NA 18 FCS to that given here.

The E-O director consists of an Elsag servoed pedestal which carries a television camera and a laser rangefinder. As an option an infra-red sensor capable of passive surveillance duties can be readily integrated with the system. A wide range of sensors can be embodied at the customer's choice to provide a variety of operational facilities.

The operational console contains TV display monitors, all operating controls and a digital multi-processor based on the Elsag-designed ESA 24 microprocessor. This last component provides high speed, high resolution tracking, ballistic data and gun calculations for aiming up to two different calibre guns.

Apart from the laser (which provides target range data) the NA 18 is a completely passive system that provides for:

(1) acquisition of targets, designated by external sensors or self-designated when the surveillance mode is adopted, by automatic scanning patterns
(2) inter-director designation from/to other weapon control systems
(3) automatic tracking of missile, aircraft, ship and shore targets.

As the operator's console is capable of presenting search or navigation radar video on the same TV display monitor, this console can perform the command and control function on small ships.

NA 18 operator's console with radar and TV image presentation

STATUS

In series production and in service with several navies.

CONTRACTOR

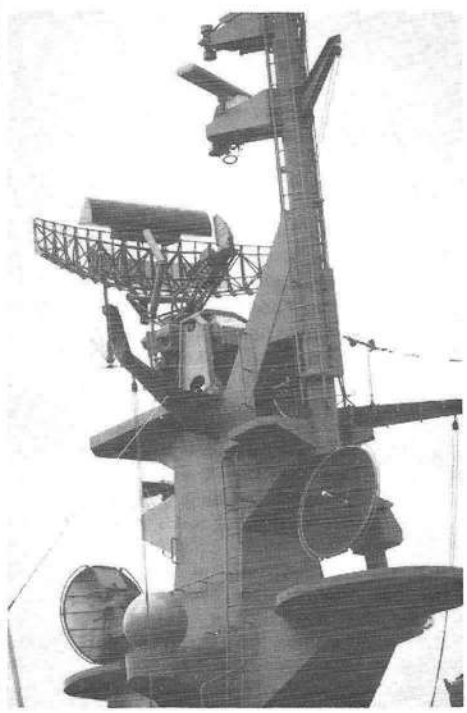
Consorzio Sistemi Navali Selenia-Elsag, Via Panama 52, 00198 Rome, Italy.

4059.281
NA 21 FIRE CONTROL SYSTEM

The NA 21 Mod 0 is a digital system embodying Elsag ESA 24 microprocessors and is the natural development of the NA 10 series of fire control systems (**1550.281** in 1982-83 and earlier editions). The system employs the Orion 10X tracker radar, in a frequency-agile version and with associated television camera, for the direction of guns of two calibres, surface-to-surface and surface-to-air missiles against air and surface targets. A TV tracking system is associated with the radar line-of-sight. For SAM control, the NA 21 is linked with the Albatros missile launcher system and the system is connected to the ship's main CIC network also. There is a single operator console below deck.

The system can carry out:

(1) programmed search, at low elevation if necessary, with the system's own radar
(2) surveillance using the ship's search radar
(3) automatic target acquisition by external or self-designation
(4) inter-director designation to other weapon systems
(5) tracking of missile, aircraft or surface targets by fire control radar and TV
(6) optical back-up by television to radar tracking
(7) weapon control with automatic fire capability.



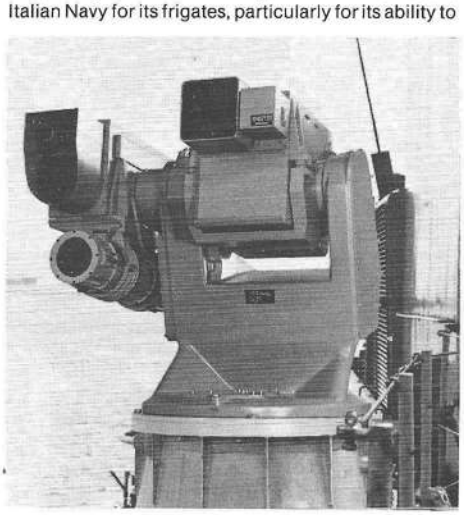
STATUS

In series production and in service with several navies.

CONTRACTORS

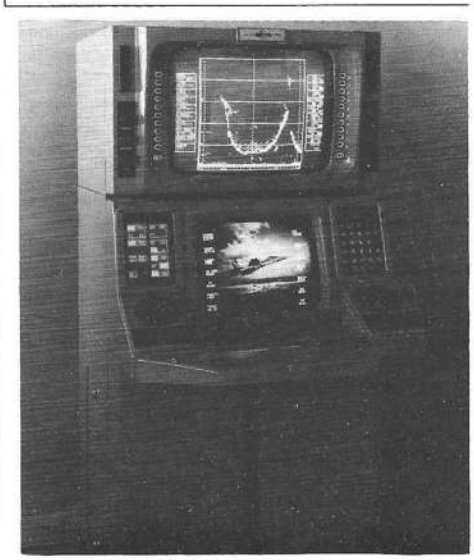
Elettronica San Giorgio (Elsag), Via Hermada 6, 16154 Genoa, Italy.

Consorzio Sistemi Navali Selenia-Elsag, Via Panama 52, 00198 Rome, Italy.



NA 21 FC radars as installed aboard a corvette. Search radar is the RAN-10S

3861.281
NA 30 SERIES FIRE CONTROL SYSTEM



The NA 30, as adopted by the Italian Navy for installation in new corvettes entering service from 1985, combines the facilties and performance of the NA 30 family of fire control systems already installed in ASW frigates of the 'Maestrale' class, the helicopter carrier '*Garibaldi*' of the Italian Navy (see this entry number in previous editions), and the Dardo CIWS (**1920.281**). The Dardo/NA 30 combination has been adopted by a number of foreign navies as well as the Italian Navy for its frigates, particularly for its ability to

Orion RTN-30X radar/TV director for NA 30 aboard a 'Maestrale' frigate

Electro-optical director for NA 30

NA 30 multi-function supervision console

provide a rapid automatic reaction to high speed air threats.

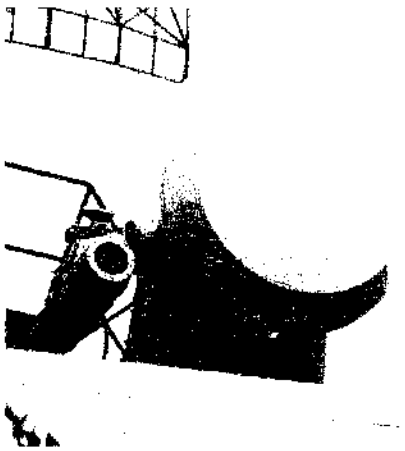
The NA 30 is provided with a single director for target tracking. The Orion 30X radar (**1936.253**) has high output power, MTI, ECCM and anti clutter features to give an extensive search range and high tracking accuracy. An infra red pointer is used to complement the angular radar automatic tracking, while a TV camera is employed for monitoring and visual control.

The system is able to control, in a co-ordinated fire control mode, a surface-to-air missile system such as the Albatros (**2228.231**), and medium/short range guns for up to three gun outputs. Ballistic computations are performed for up to two different calibres. According to the contractor, the combination of the missile component with the guns allows the engagement of supersonic targets in rapid succession. The procedure employed to initiate a firing reaction and the selection of the most appropriate weapon(s) is performed in a fully automatic mode against aircraft and missile targets.

When integrated with the RAN-30X search radar, ESM and CIC equipment, the NA 30 constitutes the SEN-300 combat system (**4824.281**) intended to equip low and medium tonnage ships to provide high performance facilities.

STATUS

In series production.



CONTRACTOR

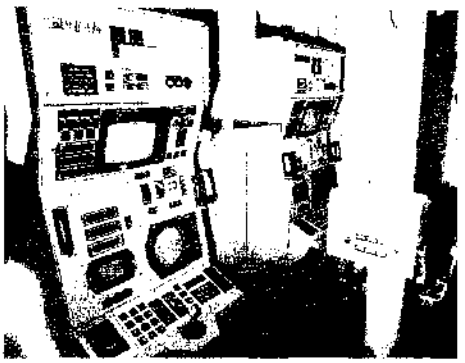
Consorzio Sistemi Navali Selenia-Elsag, Via Panama 52, 00198 Rome, Italy.

1920.281

DARDO FIRE CONTROL SYSTEM

The Dardo close-in weapon system was designed and developed for the Italian Navy's 'Lupo' and 'Maestrale' class frigates and the helicopter carrier, *Garibaldi*, for their defence against sea-skimming and diving missiles. The system is described in an earlier entry (**4497.231**) in this volume. Several other navies have adopted the system also.

Orion 20X tracking radar with TV camera used in Dardo system



Fire control for the Breda compact twin 40 mm L/70 naval gun used in Dardo is provided by a system based on an Elsag data processing and interfacing unit working in conjunction with a Selenia servo-controlled fire control director carrying radar and electro-optical sensors, and an operator's console. In addition to target data provided by Dardo's own sensors, other operational information is derived from other ship's systems such as search radar(s), ESM/ECM, and manual optical target indication sights. Specific operational functions of Dardo include:

(1) defence against sea skimming anti-ship missiles
(2) defence against diving missiles
(3) defence against manned aircraft
(4) effective ranges 300 to 3500 m.

In Dardo a radar of advanced design and optimised for tracking low-flying targets is employed. The system is designed for fully automatic operation by means of:

(1) direct use of search radar information, with automatic data evaluation and target selection
(2) automatic target acquisition
(3) target tracking, automatically and with high performance in the presence of noise/ECM
(4) automatic gun fire control.

Sensors include the RAN 10S search radar (**1699.253**), Orion 20X tracking radar (**1935.253**), optical sights, ship's log, compass, attitude references, wing velocity etc.

Dardo supervision consoles

STATUS

In series production for the Italian and other navies.

CONTRACTOR

Consorzio Sistemi Navali Selenia-Elsag, Via Panama 52, 00198 Rome, Italy.

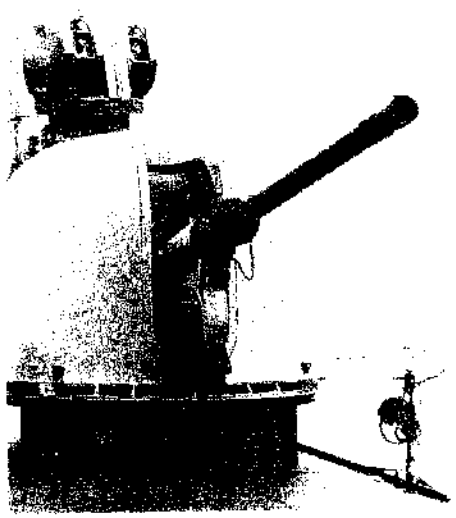
4047.281

LINCE FCS

The LINCE system has been designed by OTO Melara as a self-contained naval fire control director, principally for light and medium calibre guns. The system is designed for tracking and firing against low altitude attacking aircraft, fast patrol boats, and S/S sea skimmer missiles. It is especially effective in tracking and combatting targets moving at low elevation angles (when sea clutter might obscure the target and nodding might strongly affect automatic aiming) in the face of ECM or under radar silence.

The LINCE system, operating as an autonomous firing director, is able to perform the following functions:

(1) surveillance for surface and low air targets
(2) target designation acceptance from an external designation source
(3) target acquisition and tracking by CCTV camera system (or IR camera)
(4) automatic tracking (angular and range) of the target by means of TV tracker system and laser rangefinder
(5) manual rate-aided tracking (angular and range) of the target by means of a joystick or a tracking ball
(6) gun prediction calculation for air or surface target
(7) introduction of range and lateral spotting corrections
(8) kill and damage assessment.



All these operations need only one operator at the LINCE system console.

The director is in the form of a pedestal in which both a TV camera or IR camera and a laser rangefinder can move in elevation; the pedestal has 360 degrees continuous training. The firing computer gives the elevation and bearing lead angles in the form of synchro signals for directing the gun.

The LINCE system is capable of operating in two main modes: completely automatic and semi-automatic or manual. In the fully automatic mode, the target is tracked by the tracker system which, processing the video signal, keeps the line of sight continuously on the target; the range data are automatically provided by the laser rangefinder. Kinematic lead angles and ballistic functions are provided by the firing computer; the introduction of the meteo data is entrusted to the operator, who is provided with suitable hand controls.

In the semi-automatic or manual mode (back-up mode), manual tracking is performed by means of a joystick or a tracking ball; the manual introduction of the range with the relevant spotting corrections is possible through suitable hand controls, while the introduction of the lead angles and of the ballistic corrections is performed through pedals. In both modes of operation, firing is carried out by operating the firing pedal.

Acquisition and angular tracking (manual or automatic) are by the contrast technique applied to the image of the target against its background, as viewed by a high resolution camera (TV or IR). Range information is gathered by means of a high repetition frequency laser rangefinder.

LINCE electro-optical director head

Both the image camera and the laser rangefinder are mounted on the director head, provided with high precision servos, stabilisation unit (including a triad of integrating gyros) and a suitable protective dome with transparent elevating windows. Calculation of automatic kinematic lead angles and ballistic functions is achieved through the use of a hybrid computer, employing microcomputing techniques, operating on the target geometrical and kinematic data, and on the projectile and meteorological data.

Range and lateral spotting correction introduction (only when firing against surface or shore targets) is by operator intervention. The computer, the video and the laser processing unit, servos, supply and logics electronics, monitoring, displaying, and ancillary units are included in an operator console.

The Lince system has been developed in three versions, each with an appropriate set of sensors in the director head. The basic mode (DL, daylight) uses a high resolution daylight TV camera able to provide acquisition and tracking up to 15 km in clear weather daytime conditions, with a field of view of about two degrees, and a Neodymium YAG laser rangefinder. The DL/LLL (daylight/low light level) version has the same sensors as the basic model, but with the addition of a LLL TV camera which permits acquisition and tracking up to six km in low light conditions, with a field of view of about four degrees. By the substitution of an IR camera for the LLL TV camera the DL/TV/IR model is obtained which can provide enhanced facilities in daylight, dusk and impaired visual conditions.

CHARACTERISTICS

Traverse: Unlimited
Elevation: -25 to +72°
Angular velocity: >60°/s
Acceleration: >100°/s²
Range: >15 km (ship target); >8 km (aircraft target)
Weight
Optronic head: 220 kg (approx)
Operator console: 300 kg (approx)

4624.281

SEN SERIES COMBAT SYSTEMS

With the aim of meeting the weapons control requirements of medium-low tonnage ships where there may be space and resource limitations, but where sophisticated facilities may be necessary to meet operational needs, the Selenia-Elsag Naval Systems Consortium has designed and developed a family of combat systems known as the SEN Series.

SEN-100

The SEN-100 is a modular, fully integrated system configured for small and very small vessels, such as OPVs, hydrofoils and small fast patrol boats. The system takes into account not only the self-defence capability required against attacks from the air and surface ships, but also covers the performance of a wide range of peacetime tasks such as; surveillance and control of coastal waters, protection of trade lanes, EEZ protection, intruder prevention.

The basic equipment consists of; a search or navigation radar, a multi-function console and an electro-optical (E-O) fire control system (FCS). A single operator is required for the management of the system, and the following operational tasks are performed:

(1) radar surveillance
(2) E-O surveillance
(3) radar tracking of surface target (track while scan (TWS) mode)
(4) E-O tracking
(5) gun control
(6) surface-to-surface missile management.

The search radar used is the RAN 10X operating in the X-band and capable of providing reliable data in hostile environments involving the presence of both clutter and ECM. The antenna platform is both roll and pitch stabilised. It is provided with a range of ECCM, and the TWS performance permits effective use of SSMs.

The multi-function console contains two monitors, one for presentation of radar video and the other to display the TV (or IR) image from the E-O director. Manual rate-aided tracking as well as auto-tracking of surface targets are available, and the console concentrates all facilities for auto-designation, target tracking, gun control and SSM management.

The E-O director employed is that of the NA 18 (**4058.281**) FCS equipped with low-light level TV, laser and IR sensors. The number and types of sensor are selected according to the operational requirements of the ship to be fitted.

SEN-300

The SEN-300 system represents the optimal solution when surface warfare and air attack/defence imply heavy threats, and is designed for fitting in vessels of between 400 and 600 tons, such as FPBs and corvettes.

Particular attention has been given to missile threats and a special-to-purpose anti-missile capability is one of the claimed features of the system.

The basic SEN-300 consists of; a search radar, tactical console, one or more multi-function consoles, and radar FCS. Expansion facilities included permit the integration of passive and active EW systems (eg. the INS-3 or RQN-3B) as well as additional E-O lines-of-sight to maximise effective use of fitted weapons. A minimum of two operators is required for complete management of the basic SEN-300 and the main operational tasks that can be undertaken are:

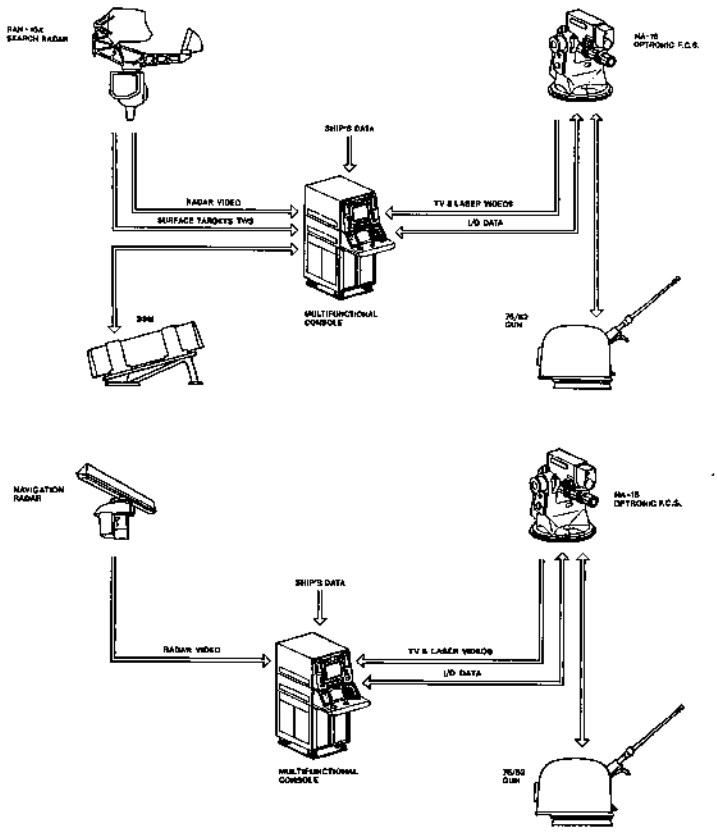
(1) extended radar and IR surveillance
(2) tactical evaluation command and control
(3) surface target tracking (search radar in TWS mode)
(4) target tracking by own tracking radar or E-O
(5) gun control
(6) SSM management
(7) ESM surveillance
(8) ECM control.

The tactical console has three seated operator positions. Information from the various ship's sensors, communications and ESM are collected, filtered and presented on a 22 inch CRT. Supplementary information is available via three seven inch monitors. The multi-function console(s) enhance the surveillance capability, thanks to the autonomous search carried out by the fire control radar. Presentation of the main search radar video is also possible. Only one operator is required at the console for surveillance or for controlling the guns for SSM management.

The FCS employed is the NA 30 (**3861.281**) and its main operating features are:

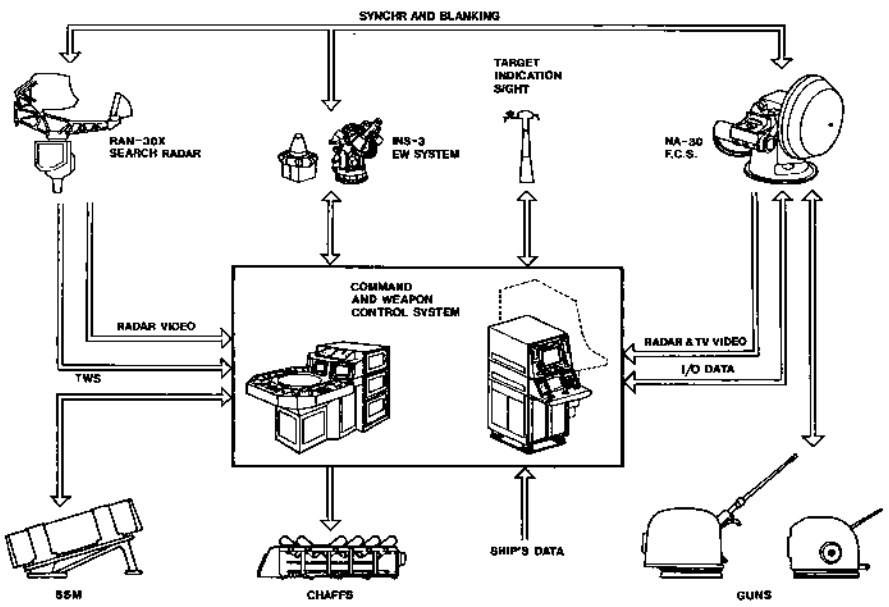
A dual operating mode (A) fully automatic (no human intervention from detection to firing) in anti-missile role; and (B) automatic after designation when operated by a conventional FCS.

Ability to control guns of two different calibres and supplying data and CW illumination (when required) to SAMs.



Features of the monopulse Orion 30X tracking radar of the NA 30 include; true coherent MTI, pulse coded modulation, high power, and anti-nodding facilities. The NA 30 can provide a special-to-purpose anti-missile capability, and when operating as a CIWS no human intervention is needed, the action is automatic from the first detection by main search radar to firing.

STATUS



In series production, but no fitting or contract details released.

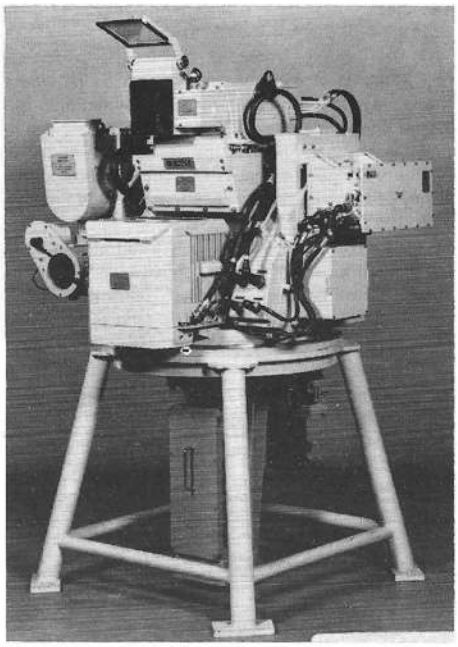
OG 30A NAVAL MULTI-SENSOR DIRECTOR

The OG 30A is a naval multi-sensor director which is composed of the Officine Galileo thermal imaging camera, the FIAR P0700 laser rangfinder and the P4651 TV camera, mounted on a servo-controlled two-axis stabilised pedestal. This multi-sensor with its related video converter, TV tracker and displays is integrated to provide the electro-optical (E-O) line-of-sight in the NA 30 FCS (**3861.281**), but is equally suitable for use with other FCS or alone as an autonomous FCS sensor system.

It performs the following functions: panoramic surveillance; observation and identification; acquisition and automatic tracking, of surface and aerial targets.



CHARACTERISTICS

Daylight TV camera: P4651
Field of view: 1·8 × 2·4°
Image format: 3:4
Scanning standard: TV CCIR

Sensor: Vidicon tube (S18 Phosphor)
Minimum sensor resolution: 700 TV lines per picture height
Galileo thermal camera
Field of view: 3 × 6°
Image format: 1:2
Instantaneous field of view: 0·25 mrad
Frame rate: 25 Hz
Lines per frame: 200
IR detector type: CMT linear array
Wavelength: 8 - 14 microns
Operating temperature: 77° K
Laser rangefinder P0700
Wavelength: 1·06 microns
Output: 20 - 25 MW
PRF: 15 Hz
Range: 400 m - 15 km
TV tracker P4700
Pedestal
Elevation: -25 to +85°
Azimuth: 360° continuous
Velocity: 2·2 rad/sec (elevation); 1·5 rad/sec (azimuth)

STATUS
In service with the Italian Navy.

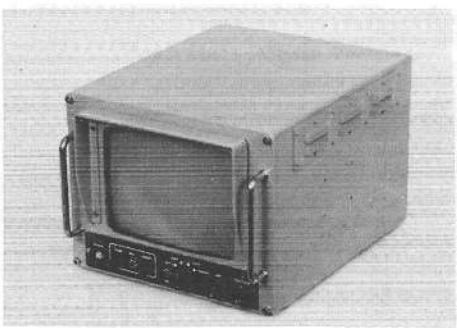
4498.461
SACTIS COMBAT INFORMATION SYSTEM

SACTIS is the abbreviated title given to the submarine action information system being developed for Italian Navy submarines of the Sauro class by SMA in collaboration with Datamat and other contractors. The former concern was selected as prime contractor for this project in 1981 when it was decided to equip this class of submarine with a new AIO system. Two versions are to be produced known as SACTIS 1 and 2, or by the Italian Navy designations MM/BSN-716(V)1 and MM/BSN-716(V)2, respectively. The two versions are intended for fitting in the second and projected third batches of Sauro class boats. In both cases the principal functions include:

(1) automatic data acquisition from all sensors (eg hydrophone, sonar, passive ranging system, search and attack periscopes, radar ESM, navigation system, depth sounder etc)
(2) manual data input
(3) real-time computation of ship's position and target position (from bearing data only)
(4) data display (raw and processed) with four different presentations: unfiltered situation; tactical situation; time/bearing display; tactical operation tabular evaluation
(5) calculation and display of data for typical manoeuvres such as screen or barrage penetration, evasion, target interception or collision course, approach and divergence routes, CPA
(6) data and event recording
(7) playback for training and analysis.



The hardware comprises two display groups which have vertical CRT displays and keyboards for data input and system management, with separate alpha-numeric 'tote' displays above the situation display CRTs; a central processor unit based on a Rolm MSE 14 digital computer; disk memories; a printer; a specially designed interface unit for input/output between SACTIS and the various sensors. The two displays are arranged side-by-side to form a two-man operating console and up to 30 separate targets can be displayed, from which individual track histories can be selected for examination and ten of them presented as filtered targets. Main sensors connected to the system include the BPS-704 radar, IPD-70 sonar system, and the Thetis electronic warfare system.

The later SACTIS 2 version includes provision for connection with the submarine's A184 torpedo fire control system (**3252.481**), and inclusion of the ELT/810 sonar prediction system. There is also extended computer capacity and a third operator position at the SACTIS console.

STATUS

4827.481
SUBMARINE INTEGRATED COMBAT SYSTEM (SICS)

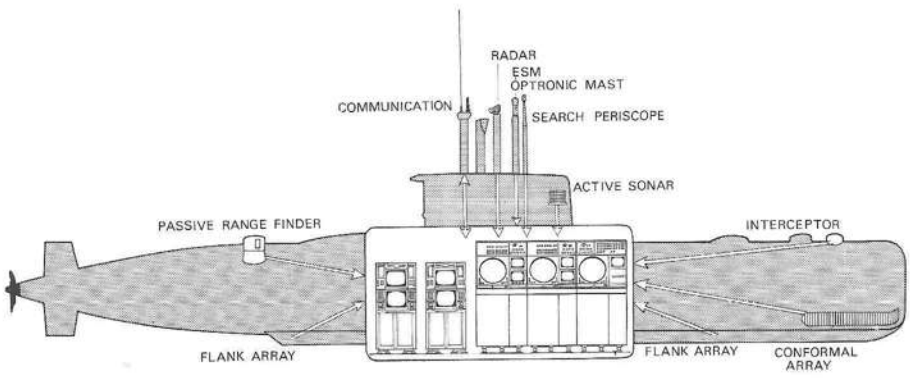
The Italian submarine integrated combat system (SICS) has the following functions:

(1) sensor and tactical data handling
(2) fire control
(3) command
(4) common services

The system hardware is designed in a compact, modular fashion to permit adaptation or expansion as required. Other features include data and video distribution network, advanced computer technology and sensor data processing for optimum weapons utilisation. Growth potential was considered essential to permit changes in sensor and weapons outfit and modifications to operational procedures are unavoidable during the life of a modern submarine.

The system uses general purpose consoles which are completely interchangeable for operational functions. This allows consoles to be reconfigured simply to accommodate changing role requirements, and also permits consoles to change their roles while the boat is 'on patrol' according to varying operational circumstances to permit a reduction in manning requirements whenever possible.

The system's sensor and tactical data handling controls the processing of inputs from sonar, periscope, ESM, radar, log and compass, and other navigational equipment. This part of the system also provides database storage and related compilation, prediction and tracking facilities.



The FCS function provides for weapon status monitoring, computation of optimum target engagement and the computation of weapon pre-settings before launch. Guidance signals during weapon run are also performed, if appropriate.

The co-ordination, evaluation, designation and other command functions are carried out by the system together with comprehensive monitoring and display facilities, using data directly from sensors to produce a filtered situation picture.

It is possible that different versions of SIC will appear to comply with the different weapons fits of various classes of submarine. Such differences are likely to become apparent as alternative digital processor/computer configurations and/or operator/display console arrangements are made. No confirmed details of hardware have been received, but contractor data reaching *Jane's Weapon Systems* indicates individual weapon control sub-system configurations from different manufacturers.

STATUS
Development.

CONTRACTORS
SICS is manufactured by Elsag in collaboration with two companies of the FIAT Group, Whitehead-Motofides, and SEPA, with the participation of USEA in the sonar sensor element. This group of Italian underwater warfare interests have since formalised the relationship with the establishment in November 1984 of the WELSE consortium, in which Elsag has a 50 per cent holding, with Whitehead and SEPA having 25 per cent interest each. The WELSE consortium is based at the Elsag headquarters in Genoa, and future SICS activities will probably be directed from this establishment.

Outline of typical SICS arrangement

3252.481
A184 SUBMARINE TORPEDO FCS

The A184 system is the fire control system for submarines equipped with Whitehead A184 wire-guided homing torpedoes. The system comprises a computation, display and control station (CCRG), which uses a SEPA ULP12/M mini-computer, the local control and switching box for the torpedoes, and the torpedo electronics. Sensor inputs to the system include radar, navigation and attitude information, periscope, and acoustic data from the integrated active/passive IPD70 sonar system (**3233.453**).

Target and ship's own data from these sources are used to calculate and display target positions and target vectors, impact point predictions, tactical situation, a launch and guidance display, and wire guidance signals. These functions are grouped in the CCRG. The local control and switching box connects the signals from the CCRG to the selected torpedo, provides launching tube control, and feeds electric power to torpedoes in the tubes. Within the torpedo, the electronic control unit carries out wire signal interfacing, torpedo steering in accordance with CCRG commands, computation of target data from the torpedo acoustic head, and torpedo homing.

4828.281
SEPA NAVAL FIRE CONTROL SYSTEM

The Società di Elettronica per l'Automazione (SEPA) member of the FIAT Group, in addition to participating in the WELSE underwater warfare consortium and contributing to the SICS programme (**4827.481**), offers naval fire control systems (FCSs) for various other applications independently. Such digital systems are mostly based on the use of SEPA militarised mini and microprocessors of the company's ULP Series.

For example a developed version of the torpedo and weapons control sub-system for SICS is available separately as the FCS Mk 3, for submarine command and control, and another version has been developed for 'Maestrale' class surface ships as the FCS Mk 2.

FCS Mk 2

The surface ship FCS Mk 2 includes provision for full integration with the ship's combat system (SCS). It incorporates SEPA AM073 digital processor, and the main functions of the FCS Mk 2 are:

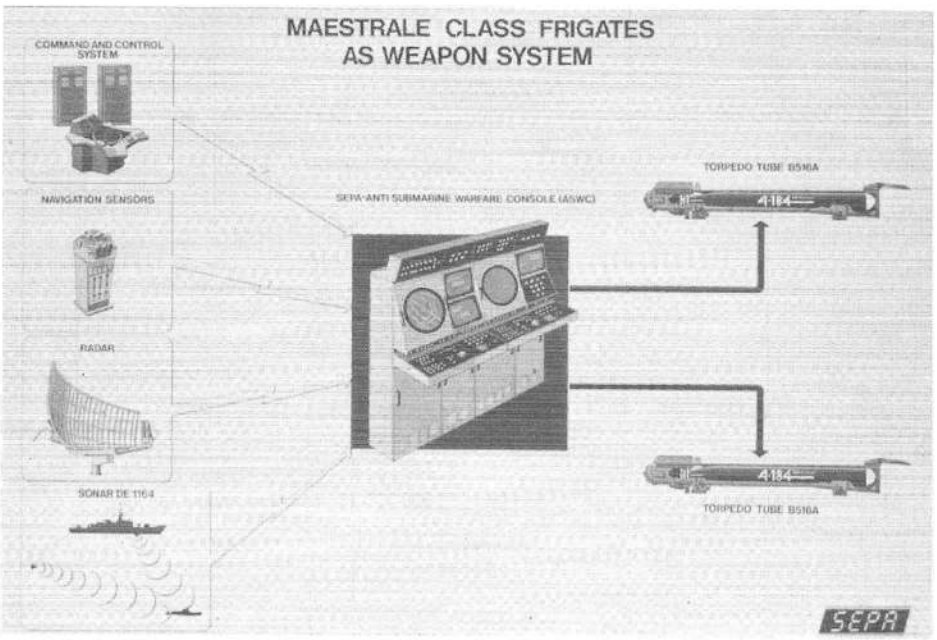
(1) evaluation and display of the tactical situation
(2) weapons control
(3) acoustic sensor prediction
(4) tracking, classification and evaluation of surface and underwater targets
(5) threat evaluation
(6) countermeasures control.

The main sensor inputs will include navigational data, search radar information, and DE 1164 sonar signals, and the FCS Mk 2 interfaces with the ship's command and control system. The principal weapons controlled are the port and starboard B516A torpedo tubes.

FCS Mk 3

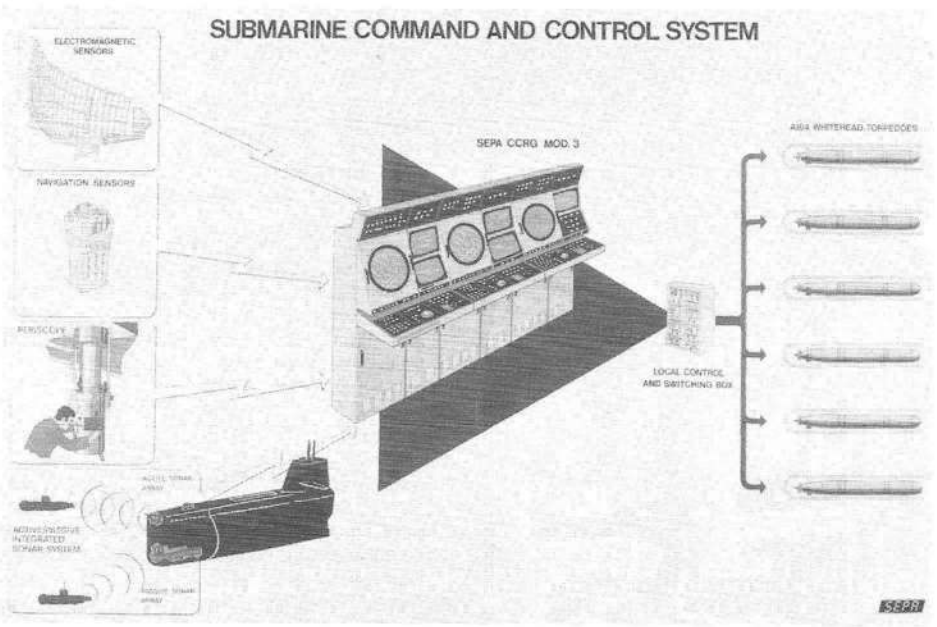
This is a fully integrated submarine command and control system having as its main functions:

(1) acoustic sensor performance prediction
(2) prediction of counter-detection range
(3) target motion analysis
(4) threat evaluation
(5) target designation for attack
(6) weapons control (torpedoes and missiles)
(7) countermeasures control.



Inputs to the system include: active and passive sonar data, navigational information, radar and ESM/EW sensors, periscope. Weapons include A184 torpedo tubes, which are connected via a local control and switching box.

STATUS



Production, but no fitting details released.

IMICS (INTEGRATED MINE-HUNTING COMBAT SYSTEM)

The integrated mine-hunting combat system (IMICS) is a combination of the Datamat/SMA MM/SSN-714 mine-hunting action information sub-system (MACTIS, **4499.261**), the FIAR AN/SQQ-14A sonar (**3234.453**), SMA MM/SPN-703 navigation radar (**3482.253**), an Elmer telecoms sub-system, and the Datamat MM/SSN-715 navigation sub-system.

Its functions are:

(1) to plan mine-hunting operations
(2) search, detection and classification of submerged targets
(3) analysis of target characteristics
(4) generation, display and storage of action information for the co-ordination and control of mine-hunting operations
(5) navigation
(6) external telecommunications and data link for the automatic exchange of data among fleet units
(7) guidance of surface or submersible vehicles for mine neutralisation
(8) recording of operational data and events.

The MACTIS element is located between the sensor sub-systems, the neutralisation sub-system and the platform, to carry out its various functions to optimise the performance of the tactical tasks. The following units comprise MACTIS: an operator station with one 16 inch graphic video screen, a functional keyboard and a tracker ball, two display units (bridge and CIC/ops room) for data display and navigation, processing signal distribution and power supply units.

The AN/SQQ-14A is a solid-state mine detection and classification sonar, with a two frequency variable depth beam, which enables two operators to simultaneously detect, memorise and classify mines. Separate search, classification and memory display consoles are provided. Comprehensive navigation equipment, in addition to the MM/SPN-703 navigation radar, is provided to ensure precise positioning of the ships and accurate plotting of underwater objects encountered.

4499.261
MM/SSN-714 MINESWEEPER DATA PROCESSING SYSTEM

Under the designation MM/SSN-714, SMA and Datamat have developed a digital navigation and plotting system for the Italian Navy's new Lerici class of mine countermeasures ships. The main functions of the SSN-714 MACTIS (mine-hunting action information sub-system) are:

(1) automatic computation and presentation of the ship's current position
(2) display of the tactical situation
(3) analysis and presentation of target characteristics
(4) location of surface targets
(5) event recording
(6) operations planning
(7) guidance of surface and underwater craft

The system is based on a computer of the same or similar type to that employed in the SACTIS submarine AIO system (**4498.461**), namely a Rolm MSE 14 machine. In the SSN-714 system this is interfaced with recording units, display units, controls, printer and ship's sensors. The principal items in the last of these categories are radar, sonar, compass, log and various navigation aids. The operator's display has a vertical screen CRT and a keyboard for communications with the system, and there are supplementary data readout display units and associated input controls on the bridge and in the operations room.

MACTIS is the central sub-system of the Integrated Mine-hunting Combat System (IMICS, **4826.481**).

Digital plotter unit of MM/SSN-714 system

4500.261
MM/SSN-715 NAVIGATION AND TRACKING SYSTEM

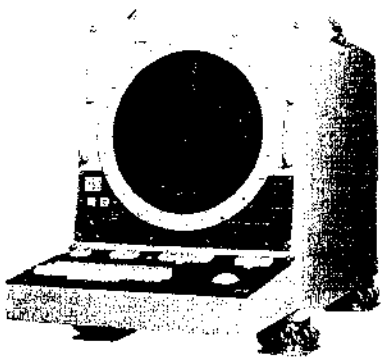
This system was developed for the Italian Navy's Sparviero class of military hydrofoils and it performs the following functions:

(1) mission planning
(2) navigation and tactical plotting
(3) navigational calculations for own ship and various categories of other targets
(4) vector computation and presentation.

The system is based on the use of a Rolm microcomputer which is interfaced with a hand-held input/output terminal device, a video extractor unit, and an X/Y plotter display unit. Inputs to the system include ship's radar, gyro and log.

The SSN-715 is used as an auxiliary system for navigation purposes to provide tracking of own ship's position as well as that of a target tracked by the navigation radar, presented on a chart by means of the X/Y plotter. Use of the latter means of presentation ensures rapid interpretation of the data and removes possible ambiguities, and the provision of a portable hand-held input/output control for operation of the system materially assists the tasks of the ship's command team personnel.

It is also employed as an important sub-system of the IMICS installation (**4826.481**).



STATUS

Production.

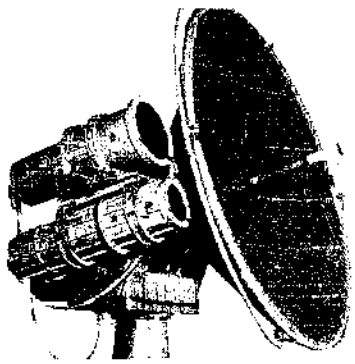
1551.261
ALBATROS WEAPON SYSTEM

Albatros is a naval all-weather missile and gun weapon system. The missile used is the Aspide (**1656.331**), a new multi-role weapon developed by Selenia under an Italian MoD contract. Missile control is provided by the Albatros Missile Section (**2228.231**), which is integrated with the gun fire control system to achieve a total weapon system. The naval guns can be of any type, provided the required performance matching with the relevant gun fire control system is ensured.



The original development, referred to as Albatros Mk1 Mod 1, was a system for integration with an Elsag gun fire control system and it evolved in various production configurations with the common designation of Albatros Mk2. These configurations comprise:

(1) Albatros Mk2 Mod 3, associated with Elsag type NA10 gun fire control sytems (**1550.281** in 1982-83 and earlier editions)
(2) Albatros Mk2 Mod 5, with Elsag type NA21 gun fire control system
(3) Albatros Mk2 Mod 7, with Elsag type NA30 gun fire control systems
(4) Albatros Mk2 Mod 8, with Ferrant WSA-4 gun fire control systems (**1524.261**)
(5) Albatros Mk2 Mod 9, with Hollandse Signaal-apparaten WM 25 fire control systems
(6) Albatros Mk 2 Mod 11, with PEAB 9LV 200 fire control systems
(7) Albatros Mk 2 Mod 12, with Thomson-CSF Vega/castor fire control systems.

For each configuration the system is available in single or double headed version (type 1/1 or 2/1), the latter having the ability to engage two targets simultaneously. Missile guidance is provided by radar illumination of the tracked target through the director antenna. Pre-flight information and launching orders are produced by the Albatros Missile Section and the relevant consoles are contained in a panel fitted in the weapon control console so as to enable full fire control by a single operator, both for missile and guns. The two weapons can be employed simultaneously; however missile engagements are normally performed at long ranges (out to 15 km), permitting target shifting or reiteration of firing, while anti-air gunfire actions are initiated at shorter ranges or the guns are used in the surface fire or shore bombardment roles. Engagement of surface targets can also be accomplished by means of the Aspide missile.

Albatros Mod 3 operator's control console

Albatros dual-channel tracking and illumination radar

STATUS

At the end of 1983 the orders received for naval installations included the following: Cantieri Navali Riuniti (CNR) Lupo class frigates (10); Blohm & Voss frigates (7); Bazan frigates (5); CNR frigate refitting (1); CNR light aircraft carrier (1); Tacoma corvettes (2).

Consorzio Sistemi Navali Selenia-Elsag, Via Panama 52, 00198 Rome, Italy.

3184.261
IPN-10/20 TACTICAL DATA DISPLAY SYSTEM

The IPN-10 is a display system tailored for small and medium tonnage ships, such as corvettes, frigates, and destroyers, where a simple system for control of the tactical situation and weapon co-ordination is generally requested. The system is suitable for both installation on new vessels and for retrofitting of older vessels; in the second case it is possible (with this minor change) drastically to improve the tactical capabilities of the ship, starting with its reaction times.

The main tasks of the system are presentation of the tactical situation, by display in a clear, self explanatory mode, and automation of some of the functions normally performed manually by the operators (such as tracking, vectoring, etc). The IPN-10 is composed of a number of display consoles, variable, in the standard configuration, from one to six. All the consoles are of common type and are interchangeable; their operational role (such as surveillance and tracking, weapon control, ASW control, tactical evaluation, etc) can also be changed during the operation of the system, so that the CIC can comply with the changeable requirements of the tactical situation. A central unit interfaces the sensors (radars, sonars, interceptors, etc), the weapon systems (fire control systems, surface-to-surface missile systems, anti-submarine torpedoes), medium or low speed data links, and the display consoles.

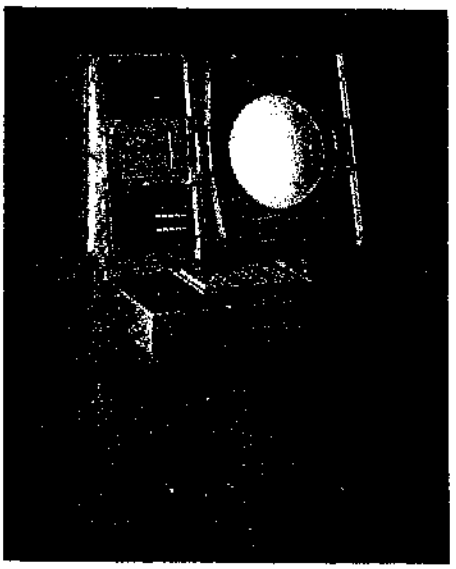
From a technical point of view, the IPN-10 is a fully digital system using all solid-state components (except the CRTs). The consoles (SVC-16) use a 16-inch (406 mm) CRT and can be used as independent radar repeaters. A 22-inch (559 mm) version (MHC-22) is also available for the conference

or evaluation role. The processing capability is distributed throughout the system and resides in a number of NDC 160/E mini-computers, housed in each display console and in most of the system attachment units (which include all interface circuits, D/A and A/D converters, video extractors, power supplies, etc).

(1) single console system for fast patrol boats
(2) with two consoles for corvette-size vessels
(3) with five consoles for use aboard frigates
(4) a six-console system with enlarged data processing capabilities based on two CP-7010 computers (Selenia type CDG 3032). With the denomination SADOC-2, this configuration has been adopted for Italian Navy 'Lupo' and 'Maestrale' classes of frigates

Most system configurations are provided with multiple serial data bus connection which allows complete interoperation with co-operating processors enabling a 10 Moit/s data rate on each bus with data flow control distributed and transparent to the application software.

From the early 1980s IPN series systems usually incorporated a number of standard NDC-160/E mini-computers employed as embedded processors in the display consoles as well as being distributed in many basic units of the system. The NDC-160/E is a general-purpose, micro-programmed 16-bit machine which normally has 64 K words core store and/or solid-state memory.



Multiple operator horizontal console for IPN-10 system

STATUS

PN-10 systems are in production and are installed on CNR 2400 t and 3200 t fast frigates and on CNR 600 t corvettes. In 1982 a new order from the Spanish Navy was reported.

IPN-20 systems are in production and are being installed on the Italian Navy 'Lupo' class frigates.

Single operator vertical console of IPN-10 command and control system

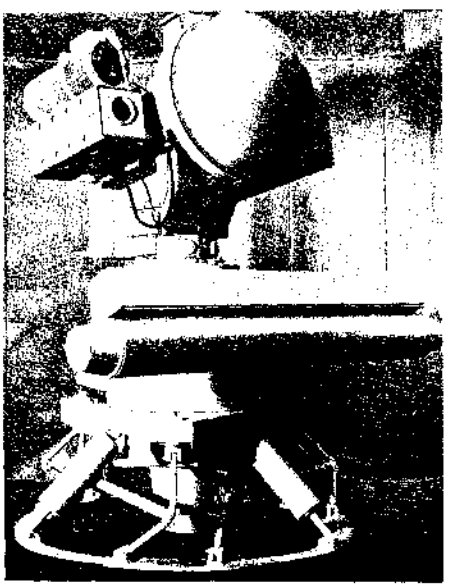
4271.281

GEMINI NAVAL FIRE CONTROL SYSTEM

The Gemini weapon control system has been designed for use aboard smaller naval vessels to provide one-man fire control facilities for guns and/or missile armament for low-level self-defence purposes. It is engineered on a modular basis so that extended versions can be configured to meet differing operational requirements and to enable its use on various classes of ship from corvette to frigate size.

The system consists of a two-axis stabilised I-band search antenna mounted coaxially with a K-band tracking antenna. The most important benefits of the two antennas in one assembly are: all round unobscured coverage for both search and track; both antennas can be located in the most favourable position, ie on the masthead (important for small craft); extremely accurate target designation as errors due to search-track antenna misalignment caused by ship deformation are eliminated.

The use of I-band for search ensures reliable target detection. The K-band tracker permits accurate, pinpoint tracking down to sea-skimmer levels and avoids the problems of surface reflections and multiple imaging. The narrow K-band pencil beam is also very difficult to jam.



Gemini is designed for one-man operation from below deck but two-man operation is possible during operationally tight situations. A labelled position display presents the search radar video and pertinent synthetic data for surveillance and target indication. A monitor and control display shows the tracking information (A-scope) and alpha-numerics and also displays the lightpen operated controls. Lightpen operation with associated microprocessing minimises the number of hardware controls. Functional changes can easily be carried out since, in most cases, only software is affected.

While the basic configuration will serve the needs of numerous vessels, a number of options are available to expand the system and adapt it to special requirements. These include:

(1) radar: more powerful transmitters, travelling wave tube, larger search antenna, combined I- and K-band tracking; transmitters/receivers (and display) for navigation, circular polarisation, In/log/MTI/DF
(2) vertical reference platform
(3) optronics: TV camera/IR camera (combined with autotrack), laser rangefinder
(4) target tracking facilities: track-while-scan; video extractor
(5) IFF
(6) shock absorbing mounting for director
(7) radar data handling.

STATUS

In production.

LIROD 8 NAVAL DIRECTOR

LIROD 8 is a lightweight combined eight-millimetre wavelength pulse doppler radar/electro-optical director designed primarily for use as an autonomous target tracking and observation system aboard naval vessels of all sizes. It is particularly suited to all-weather applications where high accuracy combined with low-level capability and high resistance to jamming are required. Its light weight makes the system appropriate for gun direction on small ships, while it may also be used as an additional tracking and monitoring channel within a WM20 Series weapon control system (**1259.281**).

The LIROD 8 system comprises the following main elements:

(1) a director sensor head very similar to that employed in the LIOD lightweight optical director (**3143.293**), but which carries a complete K-band monopulse doppler tracking radar and a television camera instead of the original sensors employed in LIOD. Alternative EW trackers can be fitted (eg laser-tracker)
(2) a control unit containing electronics for performing the target acquisition and data processing functions
(3) a control console which permits one-man operation below decks and incorporates a display with light-pen controls and computer facilities for tracking and gun control

Signaal's LIROD lightweight TV and radar tracker. A further development carries a package containing a K-band radar, a TV camera, an IR camera and a laser rangefinder

(4) one or more target designation sights for indication of visually-detected targets, whether intended for subsequent radar or electro-optical tracking, or not. These are also used for track monitoring and correction
(5) an interface cabinet to match the ship's weapon fit.

Operational functions that the system can perform autonomously include: optical and radar surveillance for air and surface targets; target designation for anti-air and anti-surface engagements; air or surface fire control; automatic radar/E-O tracking or rate-aided tracking of one air or surface target; air or surface target gun prediction calculation; simultaneous control of two dual-purpose guns of the same or different calibre; engagement monitoring, kill assessment and gunfire correction; and system status monitoring.

STATUS

Both standard and extended versions in production in 1983, 20 systems delivered.

CONTRACTOR

Hollandse Signaalapparaten BV, PO Box 42, Hengelo, Netherlands.

1259.281

M20 SERIES FIRE CONTROL SYSTEMS

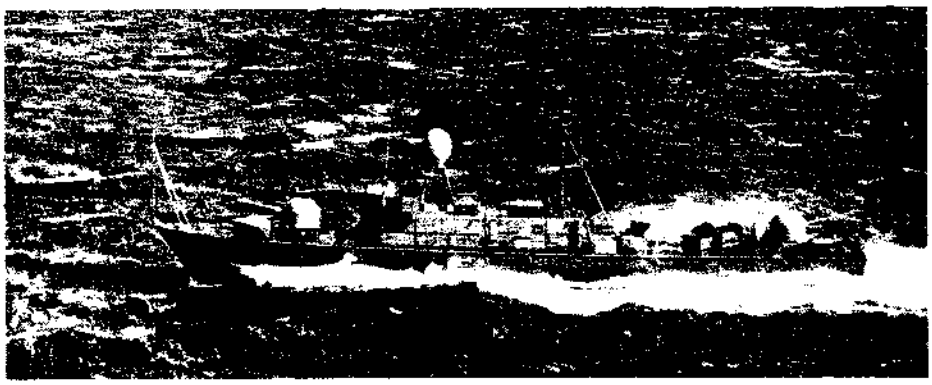
The M20 Series comprises a range of integrated ships' fire control systems for use with guns, missiles and torpedoes, and designed for fitting in vessels ranging in size from fast patrol boats to destroyers. Principal applications are medium/close-range air defence and close-range surface defence. Simultaneous engagement of several targets is possible. A further use is for shore bombardment.

Computation and control is based upon a central digital computer, and the range of available sensors includes separate search and tracking radars, and optical trackers. The use of TV trackers is a further option.

The search and target tracking radar sub-system comprises separate search and track antennas, mounted on a common stabilised platform, the whole being enclosed in a weather-proof radome. Both antennas are fed from a common I-band transmitter. During search 100 per cent of the output power of the transmitter is supplied to the search antenna. After target detection and designation to the track radar, the output power is divided, by means of the waveguide switching, so that a certain percentage is supplied to the track antenna for target tracking. A dual arrangement is available with separate search and tracking radars.

In one version of the system (the M26), only the search antenna is fitted. In this case it is mounted on top of the stabilised platform, and enclosed in a hemispherical radome. In all other versions the track antenna is fitted above and the search antenna below.

The M20 series of systems, with the advance of electronic technology, have evolved to embody the latest available hardware, especially in the area of data processing, and the current range is the WM series of systems listed in the following paragraphs. The computers employed can be summarised: M20 computers are hard-wired program types; WM20 computers are re-programmable, while in order of miniaturisation these general-purpose machines are as follows: SMR, SMR-S, and SMR-MU, denoted by the suffixes /31, /41 and /61, respectively. Successive SMR generations of computer are upwards software-compatible.



Individual 'M' and 'WM' series versions of this system have been described in greater detail in previous editions (**1259.281** 1983-84 and earlier).

STATUS

The total number of delivered or contracted M20 Series systems of all versions exceeds 300. Many versions of the system are fitted in numerous classes of vessel.

CONTRACTOR

Hollandse Signaalapparaten BV, PO Box 42, Hengelo, Netherlands.

West German Type 143 class of fast patrol boats are fitted with WM20 Series FCS

1663.261

CIDIS - COMBAT INFORMATION DISPLAY SYSTEM

CIDIS is a modular display system designed for use in ships' combat information centres, where data from a number of external sources such as search radars, IFF and data link have to be processed by digital computer and organised and presented for use by the command team. The normal computer is a Signaal SMR family machine, but other types may be employed. The combination of CIDIS and digital computer constitutes DAISY, a digital action information system (**4496.261**).

The equipment comprising a CIDIS installation consists of a display central unit and a number of display consoles appropriate to the operational functions of the system. The former unit can contain a sensor data distribution unit which acts as the interface between the various sensors and the displays, a video extractor which converts the sensor signals into digital form used in the computer for target detection and tracking, and a computer data distribution unit which interfaces the displays to the computer.

There are two types of display console, vertical and horizontal or 'conference' type. The former is produced in two versions, one for the presentation of radar video and one for sonar video; in each case the console has two indicators, a 40 cm labelled position display (LPD) and a 7-inch (178 mm) TV-type alpha-numeric display (tote). The horizontal console, with a 40 cm LPD for radar presentation, has two operator positions and a third supervisory position. One or two 7- or 15-inch (178 or 381 mm) TV-type totes can be associated with each horizontal display for the presentation of either supplementary alpha-numeric information or TV video.

Instead of the 40 cm LPD unit, a 40/50 cm PVD unit can be provided for bright synthetic presentation.

Functions of the CIDIS include:

Display of raw video from ship's sensors on the LPD.

Display of synthetic data from the computer in two forms: (1) as synthetic data consisting of symbols superimposed on raw radar video on the LPD, with or without track labels, at the operator's discretion or (2) as alpha-numeric information on the tote display.

Communication with the computer by means of manual input keyboards. Quick-entry keyboards, handwheels and a rolling ball, and as special options a light-pen and touch-input device, can be connected.

STATUS

CIDIS and DAISY systems have been delivered for the navies of: Argentina, Belgium, India, Malaysia, Netherlands, Nigeria and Thailand.

CONTRACTOR

Hollandse Signaalapparaten BV, PO Box 42, Hengelo, Netherlands.

4496.261

DAISY AND FORESEE (C^4) SYSTEMS

DAISY is a modular digital action information system designed to be used in combat information centres on board ships, where data received from several sources, such as search radars, secondary radars, sonar, data links etc must be processed and presented to the command and control team. DAISY forms the heart of a sensor, weapon control and command (SEWACO) system (**1664.281**).

A DAISY system consists of a data handling cabinet and a number of display consoles appropriate to the operational functions of the system. The data handling cabinet contains the data handling computer, a sensor data distribution unit and one or more video extractors. The data handling computer normally used is a Signaal SMR family machine, but other types may be employed. The sensor data distribution unit performs the interface between the various sensors and the displays, while a video extractor converts the video from either a primary or secondary radar into a digital form used in the computer for target detection and tracking. The combination of DAISY hardware and system software constitutes the Foresee C^4 action information system for comand, control, communication and co-ordination.

For the display sub-system of either the DAISY or Foresee system two multi-purpose types of display console are available: a vertical display console (VDC) and a horizontal display console (HDC). The VDC is a single operator display console, while the HDC is a conference-type display console provided with two operator positions and a supervisory position. Both VDC and HDC are provided with a 40 cm labelled position display (LPD) as the main display unit. For the presentation of either alpha-numeric data in a tabular format or TV video the VDC is equipped with one 7-inch (178 mm) alpha-numeric display and the HDC with one or two 7- or 15-inch (178 or 381 mm) alpha-numeric displays. Instead of the 40 cm LPD unit each type of display console can be provided with a 40/50 cm display unit of the plan view display (PVD) family. This display family is formed by three different PVD units: the PVD, the plan view display mixed (PVDM) and the colour plan view display (CPVD).

The PVD unit is a random-scan graphic display used for a bright presentation of a large amount of computer generated synthetic data. The PVDM is used for a time-shared presentation of time-compressed raw video and computer generated synthetic data. The CPVD is a penetron type display used for a four-colour presentation of computer generated synthetic data. VDCs and HDCs provided with a display unit of the PVD family are also provided with a display processor which performs display-related processing functions.

The DAISY/Foresee tasks include:

(1) presentation of raw sensor information from primary and secondary radars
(2) compilation and presentation of tactical air, surface and sub-surface pictures
(3) data link operation
(4) designation of targets to weapon systems
(5) assistance in operations, including ASW helicopter direction and tactical navigation.

Communication with the data handling computer is performed by means of manual input keyboards, programmable quick-entry keyboards, a rolling ball and handwheels. Other special input and designation devices such as a light-pen and touch input device can be integrated optionally.

STATUS

DAISY and Foresee systems have been delivered for the navies of: Argentina, Belgium, Canada, Greece, India, Indonesia, Malaysia, Netherlands, Nigeria and Thailand.

DAISY is a designation of the Royal Netherlands Navy.

CONTRACTOR

Hollandse Signaalapparaten BV, PO Box 42, Hengelo, Netherlands.

1664.281

SEWACO - SENSOR, WEAPON CONTROL AND COMMAND SYSTEM

Under the SEWACO designation Hollandse Signaalapparaten produces integrated sensor, weapon and command systems of varying configurations intended for corvettes, frigates and higher-level combat ships. The same designation is now used also for integrated submarine systems. Full advantage is taken of the integration of the various sub-systems. System functions can be carried out using centralised or decentralised data processing, depending on the operational status of the combat system components.

A SEWACO system in general comprises primary radar sensors for long, medium and short range air and surface warning, and the search part of the combined search and tracking radar of the WM20 Series weapon control system, secondary radar sensors such as IFF and helicopter transponders, sonar, ESM, and IR sensors. Furthermore, the system includes an action information system of the DAISY or Foresee type, a weapon control system of the WM20 Series optionally extended with one or more separate tracking and illumination radars (STIR), radar/optronic (LIROD) systems, electro-optical (LIOD) system and optical target designation sights. Communication equipment including automatic data links, one or more primary and secondary video extractors and/or plot history generators for automatic initiation and tracking of air and surface targets, an ECM system and a newly developed sophisticated very short range air defence system against sea-skimmers completes the system. As the system components are of modular concept, the SEWACO system's configuration can be matched to specific requirements.

In some configurations not all the above system components will be of Signaal manufacture. In these cases, however, Signaal takes the responsibility for system integration.

The first integrated SEWACO system was developed for the Royal Netherlands Navy frigates of the 'Tromp' class. This system has been followed by new generations of SEWACO systems in which new technologies have ben incorporated, eg for the sensors, computers and displays.

In defining the DAISY or Foresee action information system (**4496.261**), the nerve centre of the ship's combat system, a configuration is created guaranteeing at any time a rapid and efficient counter-attack with the ship's complete potential against air, surface and sub-surface threats, even with reduced manpower 'on watch'. This is achieved by rapid and where possible, automatic collection of all the necessary data from sensors and automatic data links, the processing and display of these data, computer-assisted threat evaluation and recommended weapon assignment and target designations to appropriate weapon systems. The displays of DAISY are generally mixed displays, ie they present radar and/or synthetic information. Depending on the requirements, various types of display are available. Normally the displays will be of the labelled position display (LPD) type. In cases where no radar data loss is permissible, displays are available based on time compression video. Other types are displays based on the digital scan conversion principle and synthetic-only random access bright (graphic) displays. If required the mixed displays can be provided with multi-persistence penetron-type CRTs, while synthetic-only displays can be equipped for multi-colour presentation.

The displays which are used for picture compilation and command and control functions are available as one-operator vertical display consoles and as horizontal tactical display consoles for two operators and a supervisor. Each display is provided with one or two alpha-numeric display units (totes).

Although each display is intended for a specific function, the displays have multi-function capabilities. By means of operator controls including touch-input devices, light-pen and rolling ball, the operator communicates with the display processor or directly with the central DAISY computer. The processors and computers used in DAISY, as well as in all other Signaal-made computerised system components, are of the SMR family, the fourth generation of which is now in production.

Note: SEWACO sequence numbers are used only for the Royal Netherlands Navy. All other SEWACO systems are assigned a specific customer-related number. Software for most SEWACO systems and sub-systems is also produced by Signaal.

Vertical display consoles for Signaal SEWACO system

SEWACO I

The principal sensors of the SEWACO I system in the new Royal Netherlands Navy guided missile frigates are the Signaal 3D multi-target tracking search and target designation radar (**1589.253**) and the combined search and tracking radars of the WM25 fire control system (**1359.281**) which is integrated into SEWACO I and the Signaal ESM system. The 3D radar incorporates a slotted wave-guide antenna for IFF/SIF facilities also. Navigation and helicopter control functions will be provided by a dual Decca Transar radar system, with port and starboard scanners to ensure gapless 360° coverage. There is also a secondary radar system as a further aid to helicopter operations. Long-range sonar is fitted. In addition the two SPG-51 fire control radar groups for the ship's Tartar surface-to-air missiles will also be linked with the system. Among the weapons associated with SEWACO I will be Tartar, Standard SM2 MR, the Harpoon SSM, the NATO Sea Sparrow point defence system, and a twin 4·7 inch (109 mm) gun turret.

SEWACO II

This system is for ten Royal Netherlands Navy standard frigates and for two Hellenic Navy S frigates. Sensors include the Signaal LW.08, and ZW.06 radars, the combined search and tracking radar of the WM25 weapon control system and ESM system, two optical target designation sights and an automatic data link. Non-Signaal sensors include IFF, a helicopter transponder system and the AN/SQS-505 sonar set. The SEWACO system consists of Signaal's DAISY digital action information system, WM25 weapon control system, including a separate tracking and illumination radar (STIR) on which a TV-camera is mounted, while the weapons fit comprises the OTO Melara 76/62 dual-purpose gun, Harpoon SSM, Nato Sea Sparrow, ASW torpedoes and a Lynx ASW helicopter. A very short range air defence system specifically for defence against sea-skimmers is to be installed on these ships in the future. For typical action information purposes, DAISY includes five vertical one-operator consoles, two conference-type command displays for two independent operators and a supervisor, and one sonar display console. For weapon control purposes a WM25 weapon control console and a STIR control console are supplied. An ESM console completes the summary but the last four ships are fitted with a Signaal ECM system.

SEWACO III

Discontinued programme.

SEWACO IV

This is the designation of the SEWACO system supplied for the new 'Westhinder' class of escorts for the Belgian Navy. No official details have been revealed but the following data derived from published sources correspond with what is known of these new vessels and their weapons and equipment fits. Functions of the SEWACO system include:

- Air, surface, and sub-surface warning;
- Compilation and display of tactical air, surface and sub-surface situations;
- Threat evaluation and automatic air target selection for engagement by the appropriate weapon system;
- Weapon assignment and fire control by the WM 25 FCS against air, surface, sub-surface, and shore targets;
- Anti-submarine warfare;
- Electronic warfare;
- Data link operation;
- Assistance in tactical operations, including ASW-helicopter direction and navigation;
- Target simulation for training purposes.

Sensors comprise a DA.05 air and surface warning and target indication radar, WM25 combined search and tracking radars, a commercial Raytheon surface search/navigation/helicopter control radar, IFF/SIF, helicopter transponder, a French-made ESM system, data link, optical director, and sonar. Weapons controlled by the SEWACO system include NATO Sea Sparrow surface-to-air missiles, Exocet surface-to-surface missiles, dual-purpose gun, anti-submarine rocket launcher, ASW torpedoes, and ECM systems. The weapon control and combat information equipment consists of the WM25 FCS for missiles, gun, and A/S rockets, three horizontal displays for combat information functions and each

with its own separate alpha-numeric 'tote' display, a sonar display console, radar plotting table with true-motion computer, and one video extractor for automatic air and surface tracking.

SEWACO V

This designation is given to the SEWACO system for the mid-life conversion of the six 'Van Speyk' class frigates. Sensors include an LW.02 air warning radar, a DA.05 air and surface warning and target indication radar, a Decca navigation radar with two displays, IFF and helicopter transponder system, two optical target designation sights, two sonar sets, an ESM system and an automatic data link. The action information system is of the DAISY type and includes four horizontal tactical display consoles with alpha-numeric displays and a plotting table. The weapons fit comprises an OTO Melara 76/62 dual-purpose gun, controlled by an M45 weapon control system, Seacat launchers controlled by an M44 system, a Harpoon SSM system, ASW torpedoes and ECM equipment. The ship will be equipped with an ASW helicopter.

SEWACO VI

Now under construction are two Royal Netherlands Navy L frigates (air defence frigates). The SEWACO system for these vessels comprises: Signaal LW.08 extended range and elevation cover version, a stabilised DA.05, ZW06 and Goalkeeper search radar sensors; a Sphinx ESM system; Ramses ECM system; two optical target designation sights; and weapon control system consisting of three STIRs (one 1·8 m and two 2·4 m scanners) with high power coherent transmitter chains. CW illumination for Standard SM1 MR and for Sea Sparrow missiles is provided by each STIR. The system provides a high level of autonomy by means of automatic threat evaluation and STIR and weapon selection for example. The Goalkeeper close-in weapon system will be installed. The DAISY system includes six vertical consoles, two horizontal consoles and a sonar display console, primary and secondary video extractors. In addition to the normal DAISY functions it has extensive air defence software facilities. IFF, VESTA and data link are also integrated in the SEWACO system.

The weapons are the SM1 MR to be launched by Mk 13/4 launcher, Sea Sparrow from eight-cell launcher, Harpoon surface-to-surface missiles, RBOC countermeasures, Mk 46 torpedoes and the EX 83 30 mm gun portion of the Goalkeeper CWIS.

SEWACO VII

This version has been nominated for the Royal Netherlands Navy's M frigate SEWACO system which as well as including all normal sensors and weapon systems will incorporate an integrated communications system.

STATUS

Ships fitted or to be fitted with SEWACO systems include: two guided missile frigates, ten Standard frigates and six 'Van Speyk' class frigates of the Royal Netherlands Navy; four Belgian escorts; two Royal Netherlands Navy Air Defence frigates; four Indonesian corvettes; South Korean and Nigerian frigates; the Greek 'S' frigates; Spanish escorts; Argentinian frigates and corvettes; Malaysian corvettes; Thai corvettes and Turkish frigates. Currently more than 70 systems have been delivered or are under contract.

CONTRACTOR

Hollandse Signaalapparaten BV, PO Box 42, Hengelo, Netherlands.

3516.261

GOALKEEPER NAVAL FCS

The Goalkeeper system is based on an integration of the American General Electric Company GAU-8/A 30 mm multi-barrel Gatling gun (**4042.203**) and new Signaal fire control equipment to form an autonomous, rapid-reaction close-in weapon system (CIWS) for ship defence (**3616.231**). The design is especially directed toward the anti-ship missile threat as well as low-flying aircraft targets.

Rapid target detection is achieved by the I-band search radar with its horizontally stabilised antenna rotating at high speed. Threat evaluation is accomplished through an integrated video processor and threat evaluation program. Target designation and acquisition are rapidly effected because of the close integration of all the system elements on a single mount. A combined I-band and K-band tracking radar enables the system to track accurately all types of target, including sea-skimmers, under all sea states. Anti-clutter and ECCM features are included to maintain this capability in adverse conditions.

Prediction calculations are performed by a digital computer, and firing accuracy is achieved through the use of a low-dispersion gun coupled with appropriate ammunition and a rigid, stable mount. Residual bias errors in the system can be eliminated by a closed-loop spotting procedure in the tracking-to-firing cycle.

The chosen kill mechanism is warhead detonation (assured kill); although a few 'control kills' may be expected these are considered unpredictable, and therefore to be regarded as a bonus if they occur. Intercept range is approximately 500 m.

The main operational tasks of the Goalkeeper system are to counter the following threats:

(1) priority 1 threats such as anti-ship missiles like Exocet (**1156.221**) characterised by a more or less constant low-level trajectory and speeds of about Mach 1

(2) priority 2 threats from sea-skimming anti-ship missiles which include in the final attack phase a pull up manoeuvre followed by a dive onto the target at supersonic speeds of up to Mach 2.

Additionally, Goalkeeper can engage manned aircraft, or small patrol craft.

STATUS

Goalkeeper systems have been ordered for the Royal Netherlands Navy, and for the Royal Navy.

CONTRACTOR

Hollandse Signaalapparaten BV, PO Box 42, Hengelo, Netherlands.

1261.281

M40 SERIES FIRE CONTROL SYSTEMS

The M40 Series of fire control systems comprises a range of combined radar and optical directors for the control of short-range missiles and gunfire against air and surface targets. Target designation is performed by one of the ship's search radars. The M44 is used with the Seacat missile and the M45 is for the control of medium and light calibre guns.

The M44 is a fire control system for ships of frigate or destroyer size. The radar/visual director allows radar-automatic target tracking and visual detection and tracking in bearing and elevation. The stabilisation equipment is embodied in the director, so that no axis conversion is needed and the system is lightweight. It supplies accurate fire control data to the short-range Seacat.

The computer is programmed for: tracking of an air target, tracking of a surface target, firing bracket computation, launcher control.

After the Seacat has been launched, it is gathered by the director operator by means of a flight controller. This is fitted on the aiming bar, which is used for visual target acquisition and tracking. The guidance process is also visual, but provision is made for blind guidance by means of a second range gate and an F-scope on the computer display panel.

For target indication the system can be connected to a TI unit, thus providing target bearing and range to the M44 director and the radar. The lock-on and tracking procedure is fully automatic.

The radar is a conventional I/J-band fire control radar and includes various ECCM devices and special provisions so that it can operate under adverse weather conditions. For training purposes the computer can be provided with a special program to control an electronic marker in the field of view of the binoculars, thus simulating a Seacat flight.

STATUS

M40 Series FCS have been fitted or specified for: Netherlands 'Van Speyk' class frigates; Indian 'Leander' class frigates; the Malaysian frigate *Hang Jebat*; the Thai frigate *Makut Rajakumara*; Australian 'River' class anti-submarine frigates. Licence production in India for 'Leander' class frigates.

CONTRACTOR

Hollandse Signaalapparaten BV, PO Box 42, Hengelo, Netherlands.

3766.481

GIPSY SUBMARINE DATA HANDLING AND WEAPON CONTROL SYSTEM

Gipsy is an automated data handling and weapon control system designed for the Walrus II class submarines of the Royal Netherlands Navy. The system forms the link between the submarine's sensors and its weapons. The system consists of seven identical display and computer consoles (DaCCs). The built-in computer is of the SMR-MU type; the 16-inch (406 mm) plan view display (PVD) provies a high-load-synthetic picture together with compressed radar video or sonar video and the control panel is a multi-purpose unit. The use of identical DaCCs offers maximum flexibility.

A central control unit (CCU) is used to regulate the mutual data transfer between the DaCCs and the sensors and weapons. For this function two SMR-MU computers are provided, one active and the other a hot standby machine. The large amount of data from the sonars is handled by two extra SMR-MUs, also housed in the CCU. Three types of sonar are fitted (towed array, flank array and circular array), and other sensors and data sources include a noise analyser, ESM facilities, radar, periscopes, and position finding equipment.

The weapon control system can control a mixed load of weapons for sub-surface and surface engagements, and the ship's launching system consists of two mutually independent sections, each of which is controlled from a launching system control panel (LSCP). The interface with the weapons (modern sub-surface missile) is formed by two identical distribution cabinets. All hardware necessary for the integration of these weapons is included in the distribution cabinet, avoiding the necessity for additional equipment.

The main functions of Gipsy are:

(1) sonar display and control. This makes it possible to omit the original sonar displays and controls

(2) contact evaluation. This entails displaying information obtained from all sensors in a time/bearing format

(3) classification. Where ESM, ASM and noise information is compared with cassette tape stored libraries to provide a rapid classification of the target

(4) contact motion analysis. Modern tracking filters are used for the automatic determination of target movements

(5) tactical plot and general plot functions giving an up-to-date survey of the tactical and/or navigational situation or an historical situation survey

(6) weapon control. Whereby the weapon systems are provided with the requisite aiming data

(7) simulation and test to verify the system's operability and to aid in operator training for the functions (1) to (6).

Additional functions can be inserted easily due to the fact that the system is highly software-oriented.

STATUS

Two systems have been delivered for fitting in the first two boats of the 'Walrus II' class for the Royal Netherlands Navy, together with a reduced system for shore-based training.

CONTRACTOR

Hollandse Signaalapparaten BV, PO Box 42, Hengelo, Netherlands.

1662.481

SINBADS - SUBMARINE INTEGRATED BATTLE AND DATA SYSTEM

SINBADS is a compact data handling and weapon control system suitable for use in submarines of the small coastal type and up to the larger, ocean-going type. It succeeds the Signaal M8 Series of torpedo FCS (**1375.481**) for submarines. The computer used is the Signaal fourth-generation general purpose machine SMR-MU, and the complete system combines the weapon control and data handling functions.

The data handling function covers sensor display and sensor selection for track initiation. The raw sensor data of all sensors can be displayed. Each individual sensor is indicated with a unique label. The development of SINBADS is based on the application of modern passive sonars, capable of automatic tracking of targets. The tracking algorithm is based on modern filtering techniques and the tracking system basically includes as its main mode of operation a 'bearing-only' analysis which, however, also accepts other inputs of target information. The complete tracking system functions as an interactive system in which the command can intervene in the tracking process. For this purpose there are four display formats available.

SINBADS can handle five targets and three torpedoes simultaneously. These can be guided, unguided or a mixture thereof. The system also includes data recording from on- and off-line use, weapon simulation for training, on-line failure monitoring, and an emergency mode for which hand controls are provided to enable torpedoes to be set, fired and controlled in case of a computer or display failure.

SINBADS DUO

Under this title a successor to SINBADS has been designed which broadly fulfils the same functions but the design is based on the same philosophy as the Gipsy system (**3766.481**) offering very high availability and more flexibility in control.

STATUS

SINBADS deliveries began in late 1977 and in early 1980 at least 18 systems were in hand. Known contracts include: Argentina, six; Greece, four; Indonesia, seven; Peru, four; Turkey, four.

Following the basic Gipsy philosophy, SINBADS-M systems are in production as fully integrated sensor/weapon/command systems, incorporating sonar (SIASS, **5636.453**), ZW07 radar (**4051.253**) and communications.

CONTRACTOR

Hollandse Signaalapparaten BV, PO Box 42, Hengelo, Netherlands.

1375.481

M8 SUBMARINE TORPEDO FIRE CONTROL SYSTEM

The M8 is a digital computer-based fire control system for use in submarines for the direction of torpedoes against either surface shipping or submerged targets. It was produced in several versions with designations ranging from the M8/0 of the mid-1950s prototype to the latest. M8 is now out of production and succeeded by SINBADS (**1662.481**), Gipsy (**3766.481**) and Submarine SEWACO (**4587.481**). The basic system comprises a torpedo display control and computer console, a sound path display unit, amplifier and supply unit, distribution box, local control panel(s), and gyro angle setting units. Complete system weight is about 900 kg. The system may be operated by one man, or two men if the submarine is operating with consorts.

The system will accept target data inputs from a range of sensors which includes radar, sonar, passive sound detection systems, periscope observation and consort reports. Ship's own navigational data is also fed into the M8 computer. The display, which has range scale settings for 20, 10, and 5 km, presents the positions of all contacts from all sensors, simultaneously. One or more sensors may be connected to the computer for torpedo engagement, and up to three targets may be attacked simultaneously. The computer is programmed to provide firing data for wire-guided, programmed, conventional, and other types of torpedo, and performs automatic calculation of target position, course, and speed. The CRT display can give true motion, relative motion, or off-centred presentation of the tactical situation.

DEVELOPMENT

The M8 Series originated in a Royal Netherlands Navy contract awarded in 1965 for the development of a torpedo FCS for the 'Dolfijn' class submarines. West German interest in the system gave additional impetus to subsequent development and led to the successful development of systems for use in both submarines and surface ships. Two types of torpedo were involved, the AEG Seal and Seeschlange, for use against surface vessels and submarines respectively. This successful collaboration with the West German industry continued and M8 Series systems are standard fitting on all submarines produced by Howaldswerke Deutsche Werft in Kiel. The ultimate development is the SINBADS system described in **1662.481**, but other related developments are the M9 systems in the West German 'Köln' and 'Thetis' class vessels, and the M11 systems for two new Argentinian fast patrol boats.

STATUS

The following list is believed to record accurately the known installations.

Argentina	Type 209 (2)
Colombia	Type 209 (2)
Equador	Type 209 (2)
Germany (Federal)	Type 205 (5)
	Type 206 (18)
Greece	Type 209 (4)
Netherlands	'Dolfijn' class (2)
	'Potvis' class (2)
	'Zwaardvis' class (2)
Norway	Modified Type 205 (15)
Peru	Type 209 (2)
Turkey	Type 209 (2)
Venezuela	Type 209 (2)

4587.481

SPECTRUM SUBMARINE SEWACO SYSTEM

Submarine SEWACO (Sensor Weapon Command and Control) is a fully integrated combat system designed to carry out all tactical functions from contact search to target engagement. It is suited for small displacement and larger patrol submarines.

In its full configuration Submarine SEWACO (SPECTRUM) includes a multiple array broad and narrow-band sonar suite (SIASS), a command system including interchangeable multi-purpose display and control consoles and a weapon control system compatible with modern wire-guided torpedoes and air-flight weapons. Radar (ZW07) also forms part of the complete system configuration. SEWACO subsystems are fully integrated and incorporate a software-based, multiprocessor modular design. Internal and external communications systems are also available in SPECTRUM.

SPECTRUM main elements and sensor systems

Data collected by SPECTRUM's sonar suite and other external sensors (eg ISM and radar) is processed to localise and identify contacts. The search results from the multiple sonar fit are correlated and displayed on the interchangeable consoles to generate a concise tactical picture. From this information decisions are made about target designation and prioritisation, threat assessment, weapon assignment and tactical manoeuvring of own ship. Weapon employment from warm-up, presets through launch and post-launch guidance are accomplished by the weapon control function. SPECTRUM also incorporates functions for navigation, data logging and crew and operator training and is capable of integration with electro-optical sensors (periscopes) and electronic navaids.

The full sonar suite consists of passive bow-mounted, flank and wavefront curvature ranging sonars which can detect, track and analyse multiple narrow and broadband contacts. An acoustic intercept sonar provides torpedo and acoustic threat warning. Contacts in automatic track are automatically subjected to passive bearings-only contact motion analysis (CMA). A new generation CMA algorithm is employed which has demonstrated speed and accuracy in at-sea trials. An electronic classification library is included with a capacity of up to 300 specific platforms.

SPECTRUM's weapon control function is compatible with various submarine launching systems and submarine-launched weapons. To ensure maximum reliability for weapon launch and control three firing modes are provided. The system is capable of simultaneous launch and control of four modern acoustic wire-guided torpedoes and four submarine-launched missiles.

SPECTRUM employs a distributed data processing

system incorporating multiple general purpose SMR-MU computers and microprocessors. The system includes multi-function operator consoles with interchangeable functions, two functionally redundant passive sonar systems, a duplicate set of common and two fully independent and separate weapon electronic units. Any point of failure that would render the system incapable of launching and controlling weapons is avoided. Moreover, the federated software in which each processor is self-supporting and capable of operating autonomously in combination with any multipurpose operator console is fault-tolerant and provides for graceful degradation of system functions in the event of a malfunction.

STATUS
SPECTRUM is in production for installation on board new generation diesel-electric patrol submarines.
CONTRACTOR
Hollandse Signaalapparaten BV, PO Box 42, Hengelo, Netherlands.

NORWAY

3744.281
NAVKIS

NAVKIS is the navigation, command, control and information system designed and developed for 2800-ton coast guard vessels in service with the Royal Norwegian Navy. When the development and production contract was awarded in 1978, three main priorities for the NAVKIS system were established: navigation, command and control, and air surveillance and gun control. To satisfy these priorities, while meeting a requirement for the use of equipment of differing levels of sophistication, it was decided to base the design on a number of autonomous sub-systems. Data transfer between the sub-systems and most of the sensors is provided by an autonomous multiplex data transmission system known as BUDOS.

Sensors providing navigation or target information to the system include a Plessey AWS-4 air and surface surveillance radar (**3171.253**), two Decca I-band navigation radars (**3127.281**), a PEAB 9LV 200 Mk 2 autonomous fire control system (which incorporates tracking radar and low light-level television), two optical target designation sights, and navigational inputs such as Decca Navigator, Loran C, navigation satellite receiver, echo-sounder, compasses, gyros, ship's log etc.

A navigation computer, KS-500 with a 64K store, continuously monitors the radio navigation receivers and ship's reference sensors to calculate 'own' position and velocity through Kalman filters. All relevant material is recorded on a cassette. In addition, the computer calculates factors such as sea currents, log errors, gyro drifts etc. Display/operator consoles for the navigation facilities are provided in the operations room and on the bridge.

The command, control and information system (CCIS) is the main operational unit within the overall NAVKIS system, and its main functions are those of surveillance and tracking of all targets. It is also employed for control of the ship's helicopter. This part of the system has much in common with the Kongsberg MSI-80S naval AIO system (**1975.281**) and the main operating console is situated in the operations room, together with the AS/GC (air surveillance and gun control) console.

Functions of the CCIS in addition to target tracking and surveillance include: presentation of radar data from any of the ship's radars on the main tactical situation display; identification and continuous automatic tracking of 16 targets; identification and automatic plotting of up to 64 other targets; display of targets from the air surveillance console; video map display of geographical features and/or reference grids etc.

The radar sub-system provides distribution of radar data and integrates information from the two Decca navigation radars and the Plessey AWS-4 (which has digital MTI), as well as providing an interface with the 9LV 200 Mk 2 tracker radar.

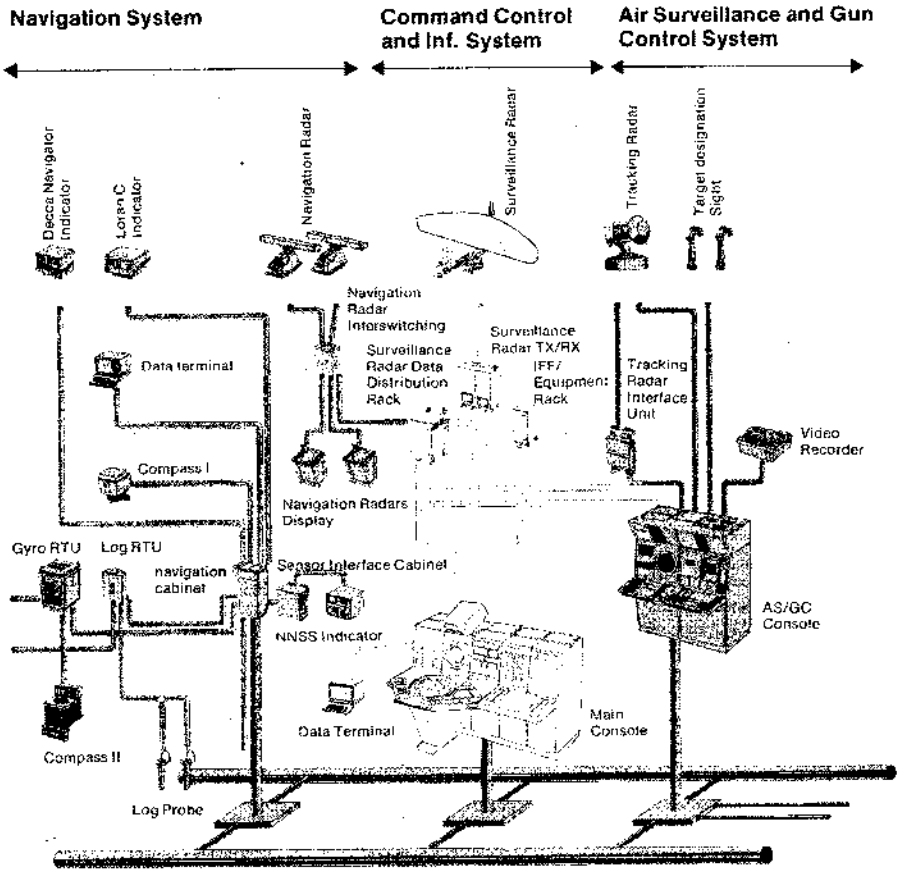

Diagram of Kongsberg NAVKIS system for Norwegian Coast Guard ships

1975.281
MSI-80S FIRE CONTROL SYSTEM

The MSI-80S is a weapon control system for small ships and was initially specified and developed for the Royal Norwegian Navy's new 'Hawk' class fast patrol boats. The system is equally suitable for tactical data handling and fire control functions in larger ships such as corvettes or frigates. The system provides a multi-target capability using low-cost conventional navigational radars, stabilised electro-optical sensors for night/passive operations, and target filtering/tracking techniques. Homing surface-to-surface missiles, wire-guided torpedoes, and an AA gun can be controlled individually or simultaneously.

Typically, the armament consists of six Penguin SSMs, four torpedoes, and a 40 mm gun. Inputs to the MSI-80S include the twin Decca TM1226 radars, an electro-optical tracker system which incorporates a TV tracker and laser rangefinder, infra-red scanner, optical sights, and electronic warfare sensors. The low-light television camera channels and displays supplied by Marconi-Elliott Avionic Systems Ltd comprise a Marconi low-light camera, incorporating an automatic light control system enabling both daylight and low-light operation. Line-of-sight stability is assured by mounting the camera on a stabilised sensor platform. This platform, manufactured by A/S Kongsberg Vapenfabrikk, also carries the other sensors, both active and passive, which are collimated with the television camera. To preserve the advantages of concealment and surprise attack, the basic philosophy is to employ the various passive sensors. The efficacy of this method rests largely upon the tracking and other software of the fire control computer. In the MSI-80S reliance is placed upon programs which have already been proved in the MSI-70U submarine system, described above. The tracking and guidance problems are solved either automatically or semi-manually by man/machine integration and in the latter case the computer serves as a data bank. Data from all available sensors can be used at any time and in any order.

A three-man operating console is provided, this being crewed by:

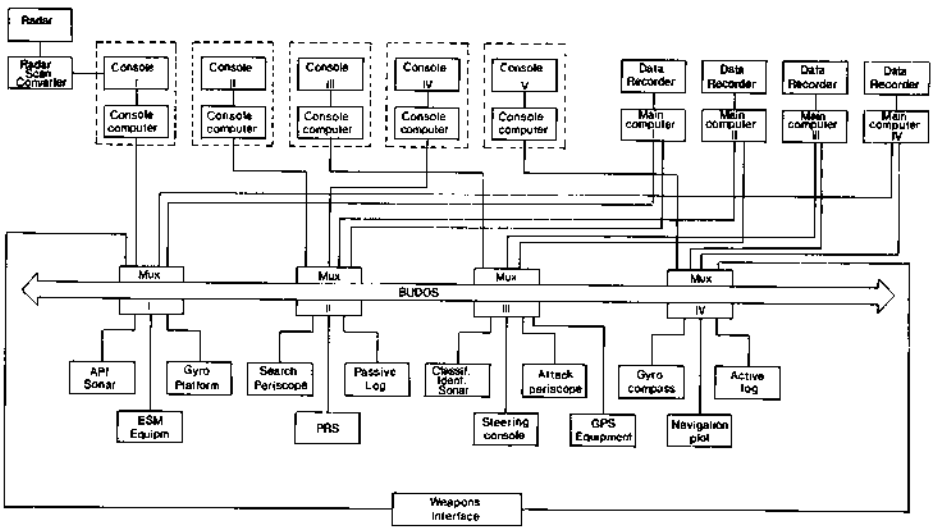
(1) tactical operator, who initiates and controls target data calculations and the overall tactical situation plot
(2) weapon control operator, who selects, controls, and designates the guidance mode(s) of the relevant weapons
(3) passive sensor operator, who operates the passive sensors and feeds relevant data to the target tracking system.

A fourth position is provided at the console for the commanding officer.

A horizontal 23-inch (584 mm) CRT is used for the presentation of raw radar and computer-generated data, and a 12-inch (305 mm) CRT is provided for the display of alpha-numeric data. The latter can also serve as a back-up for the main tactical display (23-inch).

STATUS
Development and technical evaluation were completed by early 1978 and series production for the 'Hawk' class ships is now completed. Variants of the system are also in production for foreign navies.
CONTRACTOR
A/S Kongsberg Vapenfabrikk, Postbox 25, 3601 Kongsberg, Norway.

4573.481
MSI-90U SUBMARINE AND WEAPON CONTROL SYSTEM



In 1982 A/S Kongsberg Vapenfabrikk conducted a Basic Command and Weapons Control Study in response to the concept and definition phase of a programme connected with the new West German (211-class) and Norwegian (P-6071 or ULA-Class) submarine projects. The system, MSI-90U, is a modern software-based system which uses distributed processing, high-capacity serial data transmission, and multi-function common consoles. It forms a common core of identical hardware and software for both projects (Norway and Germany), covering the following areas:

(1) data transmission system
(2) central computing complex
(3) display and operating controls related to situation processing and weapons control
(4) the torpedo/ship interface.

Consequently the two national integrated combat systems will consist of the MSI-90U basic command and weapons control system, the actual sensor systems selected by the respective navies and the weapons fitted.

The MSI-90U is modular with a minimum number of different building blocks (consistent with the operational requirement) and the system consists of the following main hardware components:

(1) a micro-processor based computer system, KS-900F, developed by Kongsberg for these projects
(2) standardised multi-purpose operator consoles, KMC 9000 developed by Kongsberg
(3) the BUDOS data bus, a standard Kongsberg product designed primarily for interfacing digital shipboard systems and meeting NATO Stanag 4156
(4) a torpedo board interface developed by AEG-Telefunken under contract to Kongsberg.

Block diagram of a typical MSI-90U configuration

Main tasks accommodated by the software tools provided with the multi-processor computer complex are: sensor integration functions such as target motion analysis (TMA), classification and identification, threat evaluation and weapon assignment/operation. There are also a number of supplementary facilities such as tactical evaluation and navigation, threat evaluation, engageability analysis, pre-programming of movements, sound trajectory calculations and display, input and presentation of geographical fixed points and areas, data recording, simulation and training.

Operator/system communication is by means of the multi-purpose consoles which are flexibly configured for the main operational tasks required. Each console is equipped with a console computer for operator input handling, picture/data presentation, local computations and data exchange communications. Picture and data are presented on two equivalent colour raster scan displays on each console. Data is exchanged within the system and between the system and other ship's systems by the BUDOS data bus system which is a set of bus-connected multiplexers. This is the core of the MSI-90U system.

STATUS

Development of the main system components and special software modules began around 1980, and a full-scale development contract was awarded and signed in 1982. Prototype multi-purpose operator consoles were demonstrated in mid-1983. A complete prototype will be ready for testing in a factory-based test stand in early 1986. The MSI-90U is expected to succeed the MSI-70U (**1929.481** in 1983-84 and earlier editions) in the Royal Norwegian Navy.

3512.281
DATASAAB COMMAND AND CONTROL INFORMATION SYSTEM (CCIS)

The Datasaab CCIS is a multi-display, computer-controlled system for the collection, storage, evaluation and transmission of naval tactical data, commands and messages. Although specially adapted to the handling of action data on modern frigates and corvettes, the basic principle of the system also applies to smaller or larger vessels.

Typical configuration of the modular equipment includes four horizontal and two vertical displays. Horizontal displays include a local air plot to present the tactical air space situation within the ship's operating area, a surface plot depicting all surface movements within a given area, a sub-surface plot for ASW purposes, and a weapon co-ordination and control station. Operational and tactical area situation is displayed vertically on two large screens.

Datasaab CCIS horizontal display with PPI designed for three operators with alpha-numeric keyboard and rolling ball for target designation

A horizontal control position consists of a console for three operators with a 16-inch (406 mm) PPI and, for each operator, identical input devices (rolling ball and alpha-numeric keyboard). The PPI presents true-motion raw radar picture, track information, target designation and tell-back symbols, vector lines and intercept solutions. Using the input devices on the console, the operators have control of radar selection, tracking, data link communication, weapon co-ordination display selection and recording.

Significant operational features of the system include the following:

(1) presentation of data from ship's sensors – radar, ESM, sonar etc
(2) automatic and rate-aided tracking
(3) presentation of geographical reference information
(4) weapon co-ordination and control
(5) data link communication
(6) on-line recording of tactical information
(7) tactical navigation
(8) intercept calculation
(9) ship data library
(10) simulation and training.

COMMAND DISPLAY

Vertical situation displays with 24-inch (610 mm) screens enable the command team to perform evaluation and control functions. Additional information is provided on alpha-numeric displays underneath the large screens. Any information which is relevant to the tactical situation can be extracted by and displayed for, the command team. The screens display: charts, reference grids, operator-generated charts, track information with history marks, target designation and tell-back symbols, alignment and pointer symbols and vector lines. Data tables, system reference information and operator tell-back and warning are presented on the alpha-numeric display.

Tracking, by PPI operators, is initiated by the selection of a target from the raw radar picture using keyboard and rolling ball. A number of symbols and track numbers are available for track labelling. Track location, heading and speed updating is by any one of three methods: automatic tracking using extracted radar data; rate-aided tracking controlled by rolling ball; external updating based on received track data via data link.

The entire equipment complex is assembled from components of the Datasaab Censor 900 display and data processing hardware range, which was developed and produced specifically for defence and ATC systems and for naval applications. For the naval part of the system's range of possible applications, a number of modifications taking into account the specific requirements of a naval environment were necessary.

The central computer complex consists of two Datasaab Censor 900 processor systems operating in parallel. Each contains a full operational program and is capable of taking over all system functions if the other unit fails. In case of failure, immediate switchover is assured with no loss of information. Information input to, and output from, the ship's sensors is interfaced with a set of fast microprocessor units. A number of peripherals such as console teletypewriters and cassette tape recorders are available for specific customer needs.

STATUS

A version of this system has been delivered to the Danish Navy for installation in frigates and corvettes. The first system entered service in 1977.

CONTRACTOR

Datasaab AB, 17586 Järfälla, Sweden.

3186.261
EPLO TACTICAL DATA SYSTEM

EPLO (Electronic Plotting System) is designed to overcome the inherent shortcomings of manual techniques for handling tactical information on board small ships such as fast patrol boats and corvettes. It is an automated system in which the level of sophistication has been governed by cost-effectiveness and space restrictions. The system compiles a tactical picture of an area of operations, and allows data exchange with other ships and with naval radar control centres equipped with a compatible system.

Operational features include the following:

(1) target selection and semi-automatic tracking by means of track symbols on a true motion stabilised raw radar picture
(2) exchange of tactical data via a data link with other ships and shore radar stations
(3) target assignment to on-board fire control system by special assignment symbols
(4) synthetic presentation of the plotted tactical situation, including reference information such as maps, geographical grids, and fixed points
(5) calculation and numerical presentation of range and bearing to target as well as speed and course of target
(6) continuous recording on magnetic tape of the tactical situation.

Targets are selected from the raw radar information displayed on a 16-inch (406 mm) PPI by positioning a free target symbol over the echo. There is a repertoire of 13 different symbols and 24 selectable numbers are available for the labelling of tracks. The symbol co-ordinates are stored and the symbol is presented on the radar PPI and the 24-inch (610 mm) plot indicator. Updating of target position is achieved in cyclic fashion, with either a slow cycle time of two minutes for updating 24 tracks or a faster 30-second cycle time for updating six tracks. Selection of a particular mode is made from the keyboard and depends upon the number of tracks involved.

To correct deviations when tracking in the semi-automatic mode, the target may be moved to the new echo position by means of a rolling ball tracker control. The PPI displays only the new position together with the track history consisting of up to 15 symbols in reduced size. All selected targets in either cycle-time mode are described by their course and speed as well as range and bearing.

The EPLO operating console is arranged as follows. A vertical display is used for the presentation of synthetic data which include video maps, target tracks, alignment symbols, pointer symbols, and vectors. A horizontal display presents the true motion stabilised raw radar picture on which are superimposed target symbols, markers, vectors, and pointers etc. Tabular displays are provided for readouts of target data and other information and keyboards allow for data insertion, control of symbols, and exchange of information.

STATUS

The system has been supplied to the Royal Swedish Navy and to the Danish Navy. No other fitting details have been released.

CONTRACTOR

Datasaab AB, 17586 Järfälla, Sweden.

1541.281
TORCI TORPEDO FIRE CONTROL SYSTEM

The TORCI torpedo fire control system is produced in several versions by Philips Elektronikindustrier AB (PEAB) for the operation of guided torpedoes against surface targets from fast patrol boats. It is normally supplied with a PEAB I-band frequency-agile surface search radar, but can be used with other radars. The principal tactical functions of the systems are:

(1) presentation of search radar information
(2) presentation of the combat situation for the direction of surface engagements
(3) rapid designation of surface targets
(4) automatic or manual target tracking
(5) guidance of two simultaneous torpedo salvoes

The equipment comprises three units: the main display console, target tracker console, and an electronics/power supply unit. The last of these can be located remote from the two manned consoles.

The main display console is provided with a PPI for the presentation of search radar data, synthetic symbols for tactical data, and relative or true motion presentation can be selected by the operator. The console also carries controls for operation of the system and for target designation and houses the torpedo computer and the program selector.

Either manual or automatic target tracking is possible, and the torpedoes can be fired in salvo with chosen dispersion as well as one by one.

STATUS

Swedish vessels equipped with TORCI systems include the 'Spica I' class of fast torpedo boats, in which TORCI is used with an HSA M22 radar/fire control system (**1259.281**), and the new 'Spica II' class. In the latter class, TORCI is used in conjunction with another PEAB fire control system, RAKEL (the Swedish Navy's version of 9 LV 200), which provides gun fire control against surface and air targets. A number of foreign navies also use TORCI. Similar equipment, the TCI family, is in use on board submarines in the Swedish and other navies.

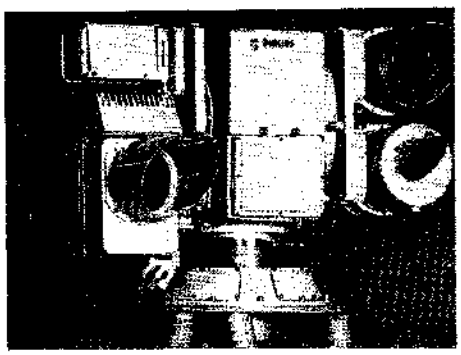
CONTRACTOR

Philips Elektronikindustrier AB, 17588 Järfälla, Sweden.

3248.281
9 LV 100 FIRE CONTROL SYSTEM

The 9 LV 100 is a lightweight, inexpensive ship-board system derived from the 9 AA 100 (**2648.181** in 1977 and earlier editions) land-based system. It is intended to control one, or possibly two, 30 to 76 mm guns against air and surface targets, and surface-to-surface missiles. Because of its light weight, it can be used on very small boats, from 50 tons up, but it is also well suited for larger ships, eg 300 to 400 tons, with a limited armament. It is also seen as a secondary, independent director-computer sub-system to supplement more comprehensive weapon control systems on board heavily armed ships, when employed with a 9 LV 200 Mk 2, for example. This combination is designated 9 LV 300 (**4026.281**).

The main units of a 9 LV 100 are:



(1) a lightweight radar, operating in the E/F band
(2) an optronic director with TV and laser, with provision for the addition of an IR-tracker
(3) a 41 cm PPI display
(4) a control and display console, with TV-monitor and gun and director controls
(5) computer and associated units.

The 9 LV 100 systems allow for:

(1) search for surface and air targets
(2) tracking of one air or surface target with the director in fair weather and daylight; and with IR at night
(3) tracking of one surface target with radar track-while-scan (TWS) under all weather conditions
(4) gun, or missile, fire control using director or TWS data.

CONTRACTOR

Philips Elektronikindustrier AB, 17588 Järfälla, Sweden.

9 LV 100 optronic director equipped with IR camera, TV camera, and laser

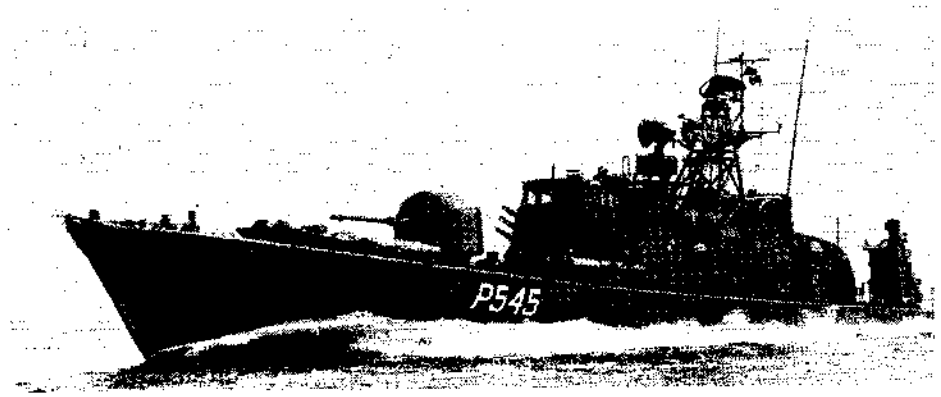
---

1542.281
9 LV 200 FIRE CONTROL SYSTEM

The 9 LV 200 has been developed as a fire control system for use on small ships from 80 tonnes and upward, for the direction of dual-purpose guns (40 to 120 mm) and other weapons such as anti-ship missiles (Exocet, Penguin, Otomat, etc) or wire-guided torpedoes. In its basic form the system has the capability for directing one or several guns against one or more targets simultaneously.

Target data are obtained from an I-band search radar and a J-band tracking radar, and there is provision for D-band air warning radar with IFF to be incorporated also. The I-band equipment in the 9 LV 200 is used for both search and tracking of surface targets and for air search. If the D-band pulse-doppler radar is included, a combined antenna system for I-band, D-band, and IFF Mk 10 is used. The J-band tracking radar can also be modified with a pulse-doppler function to improve performance in adverse clutter conditions against small low-flying targets.

The search radar is of the frequency-agile type, incorporates comprehensive ECCM facilities, and is provided with a stabilised mounting. A helical scan pattern is used. The director radar is a monopulse equipment, with frequency agility, and the pedestal also carries a TV camera.



A full description of operational functions appeared in the 1976 edition of *Jane's Weapon Systems*.

STATUS

The 9 LV 200 has been operational with the Swedish Navy since 1973 and has been delivered to foreign navies as well. The original 9 LV 200 is now being followed by the 9 LV 200 Mk 2, see below (**3127.281**).

CONTRACTOR

Philips Elektronikindustrier AB, 17588 Järfälla, Sweden.

Danish Navy 'Wilemoes' class fast patrol boat fitted with 9 LV 200 weapon control system which incorporates television tracker based on JAI 771 low light-level TV camera by JAI

3127.281
9 LV 200 Mk 2 WEAPON CONTROL SYSTEM

The 9LV 200 Mk 2 combat information and weapon control system is suitable for use in all types of naval and offshore patrol vessels of 100 tons and upwards. It is optimised for data gathering, compilation and tactical evaluation for the control of one dual-purpose gun (57, 76 mm or larger), one anti-air threat gun (single or twin-mounted 20-40 mm), and surface-to-surface missiles. There are also options for torpedo control. Simultaneous engagement of separate targets is possible, one of which can be an air target. Modular design enables the system to operate independently or as part of a Philips C³I system aboard larger ships.

A typical 9LV 200 Mk 2 installation consists of:

(1) an X-band search and surveillance radar with frequency agility or MTI, with or without on-mounted IFF
(2) a combined Ku-band electro-optical director for gun fire control (with or without TV tracker)
(3) tactical and missile control console for overall viewing, threat evaluation and analysis, data link control and target designation to guns, missiles, or torpedoes
(4) a gun control console, mainly for air surveillance and target designation to the director and fall of shot observation; this console can also be used for fire control against surface targets
(5) a surface gun console primarily for gun fire control against surface targets tracked by the surveillance radar; this may also be used as an air surveillance back-up console
(6) two 'bridge pointer' target designators for use by look outs for direct optical target designation, typically against surface-to-surface missiles
(7) wind sensor.

OPERATION

Surface targets: a three position console with 16-inch tactical display provides for presentation of search and surveillance data from the I/J-band frequency agile search radar to the Plotter, Combat Information Officer and Missile Officer. Automatic TWS plotting of up to 16 multiple targets is possible, with presentation as numbered symbols and with full interchange of designated target data with weapon systems. Target data can also be exchanged with other ships via a VHF/UHF voice channel and short burst transmission.

Air targets: search radar video is presented on a 12-inch PPI on the AA gun control console. Pulse doppler processing for MTI is available. Target designation to the director for automatic acquisition of air or surface targets is provided and TWS facilities for air targets can be provided. The Ku-band monopulse tracking radar is mounted on the director and has automatic acquisition with CFAR control. Facilities include switchable frequency agility. Electro-optical sensors can include TV, infra-red camera and laser with automatic tracking capability. CW illumination for operation of semi-active radar guided missiles is also available.

Computation: this is by means of a digital processor, rather than the analogue techniques used in the earlier version, and simultaneous engagements of air or surface targets are possible. An additional console is provided if the torpedo fire control is exercised.

STATUS

In production.

CONTRACTOR

Philips Elektronikindustrier AB, 17588 Järfälla, Sweden.

KD Handalan *of the Royal Malaysian Navy, armed with Bofors 57 mm and 40 mm guns and Exocet MM 38, all controlled by a version of 9 LV 200 Mk 2*

3747.281
EOS-400 FIRE DIRECTOR SYSTEM

The Saab EOS-400 is a TV tracker and laser rangefinder fire director system. Accurate target position is obtained using the well-known Saab television tracker for automatic tracking in conjunction with a laser rangefinder, both these units being mounted on a common training and elevating stabilised platform. This unit is the only above-deck item of equipment, apart from the weapon being controlled (usually a gun or guns). Below deck, the control/display unit is usually located in the operations room. The only other major item, the electronics cabinet, can be sited in any convenient position in the ship.

The control/display unit contains a TV monitor and a joystick for sensor platform operation, a mode selector, and target data displays. The electronics cabinet houses the video tracking electronics and other control electronics. The video output is connected to the platform and the video output to the control/display unit.

The system is capable of tracking one target among several in close formation, tracking when radar tracking is not possible, and either surface or air targets may be tracked. Inputs from other systems include those from a ship's surveillance radar, and reference data from ship's compass. The system calculates ballistics for several guns and gives gun-laying data.

CHARACTERISTICS

Tracking parameters
Training: Unlimited
Elevation: -30° to +85°
Platform
Angular speed: ±175°/s in azimuth and elevation
Angular transducers: Multi-speed synchros
Stabilisation: Rate gyros in 2 axes
Tracking: Digital correlation
Contrast selection: Automatic black/white
Lock-on area: Whole field
Daylight camera
Scanning standard: 625 lines
Camera tube: Si-vidicon
Night camera: IR camera optional
Laser rangefinder
Wavelength: 1·06 μm
Repetition rate: 10 Hz
Beamwidth: 1·5 mrad

STATUS

Introduced in September 1979. A new version entered the market in 1983, and this has been ordered for fitting in Finnish Navy corvettes.

CONTRACTOR

Saab Missiles AB, 58188 Linköping, Sweden.

4025.281
9 LV 400 SERIES C³I SYSTEM

The 9 LV 400 Command, Control, Communication and Intelligence (C³I) system is designed for tactical command from flotilla leaders of frigate size and upwards. It has greater surveillance capabilities than the 9LV 300 providing a separate air search radar and integrated ESM/ECM which permits automatic tracking and threat evaluation of a large number of air and surface targets.

The command and control functions are also an improvement on the 9LV 300. The 23-inch tactical electronic plot is included as standard. Separate consoles are used for air and surface surveillance.

The command capability is further augmented by a high capacity data link using the time division multiple access principle. This data link allows for exchange of target data and commands between ships and also between ships and command centres ashore. All transmissions are encryoted to a very high degree of security.

In its standard configuration the 9LV 400 WCS provides simultaneous control of four separate guns of different calibres, SSM and various kinds of ECM. Optional control of a SAM system is also available.

STATUS

In service.

CONTRACTOR

Philips Elektronikindustrier AB, 17588 Järfälla, Sweden.

4026.281
9 LV 300 NAVAL C³ SYSTEM

The 9 LV 300 is an extended C² and WCS suited for larger FPBs or squadron leaders up to corvette size.

The system contains extensive command, control and communication functions including tactical navigation, scenario predictions and weapon simulations. The command sub-system consists of a horizontal PPI for display of radar video and synthetics and an optional vertical 23-inch multi-colour electronic plot for situation display.

The 9LV 300 contains two autonomous AA channels, normally a 9LV 200 radar and a 9LV 100 optronic sub-system. All the capabilities of these two systems are inherent in the 9LV 300 enabling simultaneous engagement of two air targets, surface target engagement using TWS and firing of SSMs.

STATUS

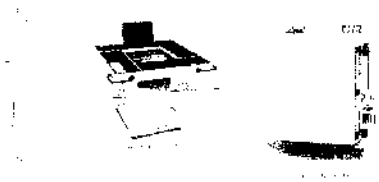
In service.

CONTRACTOR

Philips Elektronikindustrier AB, 17588 Järfälla, Sweden.

Swedish mine warfare vessel Carlskrona *is fitted with a version of the 9 LV 300 command and control system for operational as well as training purposes*

4568.281
9LV+50 ASW SYSTEM



For surface anti-submarine vessels the 9LV+50 ASW sub-system may be added to the 9LV fire control systems raising the designation to 9LV 350 and 9LV 450 respectively. The ASW sub-system contains its own computer hardware and software. The ASW plot contains one PPI, an alpha-numeric display, officers' and operators' panels. The same computer and display techniques are employed as in the 9LV systems (**4025/6.281**).

The main tactical functions of the system are:

(1) search and target tracking in association with the ship's sonar system
(2) presentation of sound path propagation on a sound path indicator presentation, integrated with the ASW plot (i.e on the same CRT display as the PPI)
(3) continuous presentation of the combat situation
(4) evaluation of target data and prediction of future target position
(5) calculation of control signals for A/S rocket launcher
(6) calculation of own ship's course and time to fire charges for depth charge attack. The last facility is optional. The basic system is designed for control of the Bofors 375 mm twin A/S rocket system with all available types of A/S rockets including Erika and Nelli. Any type of A/S homing torpedo can be accommodated if this option is specified. Sonar is the principal sensor and various models of different manufacture may be employed. Other inputs to the system are the ship's gyro reference system, and the ship's log
(7) Calculation of control data for A/S homing torpedoes.

STATUS

Production believed to be in progress.

Main elements of typical 9LV+50 ASW FCS

CONTRACTOR

Philips Elektronikindustrier AB, 17588 Järfälla, Sweden.

4027.281
9CSI 500 STINA

The 9CSI 500 STINA (coastal/offshore surveillance and information system) is primarily designed to support a number of peacetime duties, including, but not limited to: maritime traffic control; monitoring of ships with dangerous cargoes; supervision of warships; surveillance of territorial limits for illegal immigration, smuggling etc; surveillance of economic zones, eg for the prevention of illegal fishing; and command of sea rescue operations.

A complete system, eg for nation-wide coverage, normally comprises more than one centre. The concept is modular. A complete system furthermore comprises sensors of various kinds, mainly coastal radars, and communication equipment for data and voice.

Although primarily a peacetime system, the 9CSI 500 can also be used as a naval headquarters in wartime. For mainly wartime use, however, the more comprehensive 9CSI 600 is available (see **4028.281**, below).

A 9CSI 500 centre normally comprises:

(1) computers for data processing, file handling, and generation of graphic pictures
(2) up to three operators' consoles, each consisting of a 41 cm vectorial graphic display, PPI, monochrome or multi-colour, with a control panel, an alpha-numeric display terminal with a keyboard, and a communications panel
(3) one or more colour graphic displays of the raster scan type, mainly for remote presentation
(4) a printer for logging of events and actions
(5) data transmission equipment.

Radars of different types and radio communication equipment constitute complete systems to fulfil the operational requirement.

A 9CSI 500 centre receives inputs from a variety of sources including: coastal and shipboard radars, observers and look-outs, pilots, harbour authorities, and radio traffic monitoring by 9CSI 500 operators.

Various degrees of input automation are possible. Radar inputs can be fully automatic, from extractor equipped radars, semi-automatic, or manual. Radar inputs are displayed continuously on a PPI. Data and standardised telex messages are entered directly. Other inputs are entered by the operators using the keyboard of the alpha-numeric terminal.

The input data is processed to form target tracks. When more data about a target becomes available, eg identity, type of cargo etc, the operator enters it using the text terminal while associating the data to the target number. In this way, the operators compile a comprehensive picture of the situation in the supervised area.

The situation is displayed against a background of coastlines and other references on the PPIs and the graphic displays. The latter show different categories of targets in different colours. If the situation is very complex, selected categories of targets can be shown one at a time, eg all unidentified vessels. Track data are stored in the computer memory for at least 24 hours, and can be recorded at selected intervals on paper by means of a printer. If a situation requires a close study, the operator can order play-back of a target 'history'. Such a play-back is 30 or 300 times faster than real time.

Commands are given either as data messages or by voice. A number of data links of variable complexity are available. These range from a standard telex to high speed automatic links. Data exchange will normally follow standardised formats, but the data link also accepts free text. Messages exchanged by voice can be recorded on a tape cassette recorder, which is an integral part of each communications panel.

Operational functions provide the following:

(1) automatic input from up to six radars
(2) automatic tracking of up to 200 targets, using radar data
(3) automatic plotting of the targets on graphic display
(4) inputs via data links, radio/telephone or telex networks
(5) display of maps and other reference data, at different scales. Continuous positioning of the centre of the displayed area. Total geographical area covered is 2048 km²
(6) logging of selected events and actions.

STATUS

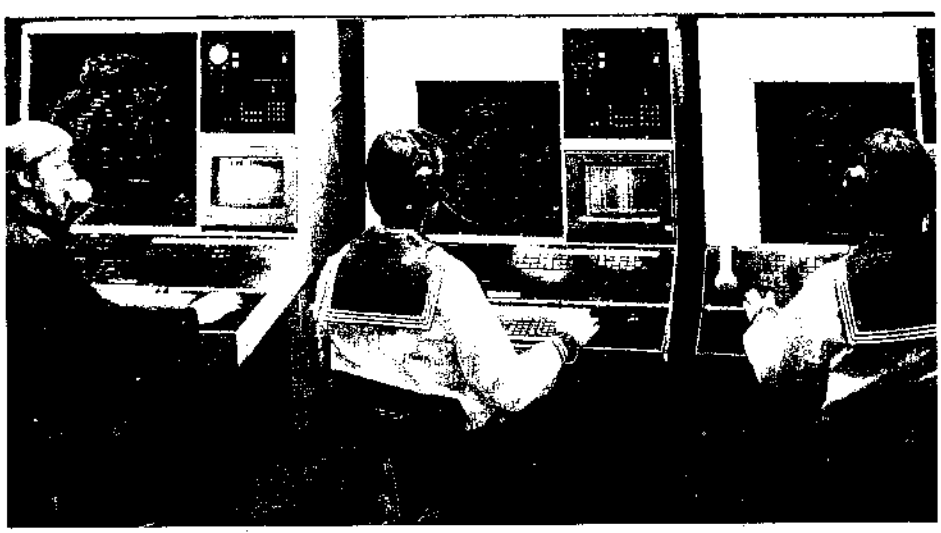
In service with the Swedish Navy.

CONTRACTOR

Philips Elektronikindustrier AB, 17588 Järfälla, Sweden.

4028.281
9CSI 600 STINA

The 9CSI 600 STINA (naval command, control, communication and intelligence system) is designed to automate many of the functions involved in information gathering, filtering and compilation of data, presentation, and transmission of orders and commands with high speed and accuracy. These systems are designed as general purpose equipment but in particular as supplements to the extensive 9 LV family (above) of shipboard combat information and weapon control systems. Like 9 LV systems, 9CSI systems are highly modular using standardised building blocks.



A 9CSI 600 STINA system comprises not only one or more command centres, but also sensors, mainly radars, for gathering input data, and data link communication equipment for exchange of data ship-to-shore and vice versa and for exchange of orders and commands. The 9CSI 600 is primarily designed as a military system for use during a general alert and in wartime. However, many of the functions implemented are equally useful in peacetime for maritime traffic control, coast guard prevention of smuggling and illegal immigration, co-ordination of sea rescue operations etc. For mainly peacetime use, the 9CSI 500 STINA is available (**4027.281**).

Designed as a modern military system, the 9CSI 600 incorporates fast, secure communication with anti-jamming capability and ECCM features in the radars; all in order to enhance survivability of the functions. Speed of communication is achieved in the 9CSI 600 by using a mesh of point-to-point links and the time division multiple access (TDMA) principle over radio links to exchange data and command messages. Security is obtained by encryption of all messages. Anti-jamming and low probability of intercept are inherent in the TDMA principle and can be further enhanced by using spread-spectrum or frequency-hopping techniques.

Other features of 9CSI 600 communications are a high degree of automation and routeing of messages adapted to a changing network with priorities and error correction. The speed of transmission is adapted to the medium used for different routes.

Provisions have been made in the 9CSI 600 centres for storage of intelligence in a data base, which can also contain information about own forces, their status etc. In order to assure proper secrecy for such information, a part of the data base is intended to be 'user programmed'.

A major sensor in 9CSI 600 systems is the 9KR 400 coastal surveillance radar (**1549.153**). This is available for fixed or mobile installations and normally provided with an automatic plot and/or target extractor to permit unattended operation and data transfer over narrow band channels to the centres.

A typical 9CSI 600 STINA operator's console

The plot and target extractors can work not only with the 9KR 400 but also with other radars to allow upgrading and automatic inputs. The centres will also accept semi-automatic and manual inputs.

9CSI 600 design is highly modular, which permits the building of command centres of various sizes for different tasks, eg central and regional headquarters. The number of operators' consoles and commanders' consoles is variable, as are computer capacity and the exact display configuration. A standard building block is the operator's console shown in the photograph. It consists of a 41 or 51 cm monochrome or colour display (PPI), an alpha-numeric display terminal with a keyboard, and a communications panel. The latter permits fast access to radio channels and telephone lines. Also shown is a raster-scan colour display.

The computers for storage and processing of data receive inputs in different ways. Inputs from extractor equipped radars are entered automatically, as are data link reports. Other inputs can also be entered automatically if received in standardised formats. Non-standardised messages, eg verbal reports over radio or telephone, are entered by the operators using the keyboard of the alpha-numeric terminal. The operators compile a picture of a situation which is continuously updated. The commander and his assistants can now be assisted by the computer to assess the situation and plan the tactics by using prediction and simulation of alternatives. After decisions, commands are transmitted over the data link using a library of standard orders. A situation picture compiled in one centre can be transferred in full or in selected parts to other centres and to ships. In this way, commanders at all levels have continuous access to up-to-date, accurate information, including relevant parts of the intelligence data base.

DATASAAB SUBMARINE ACTION INFORMATION AND FIRE CONTROL SYSTEM

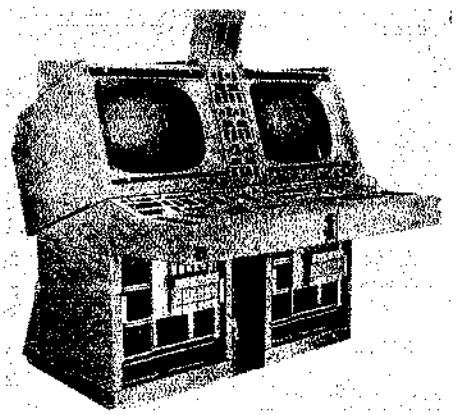
This system, or a specific version of it, is also known by the initials NEDPS, from Näcken Electronic Data Processing System, because of its use in the 'Näcken' class of submarines of the Swedish Navy.

The Datasaab AB action information and fire control system is a fully integrated system to acquire, process and display information for tactical evaluation and to form a basis for decisions regarding selected targets and torpedo guidance. The system includes complete hardware and software for controlling wire-guided homing torpedoes. Also included is computer control and monitoring of ship's function, such as propulsion, steering, depth keeping, trim, storage battery condition, etc.

The system has a dual computer configuration, the information being gathered through an extensive data collecting system from the different surveillance and weapon systems as well as from the navigation system. The information is presented to two operators on two separate displays, each of which is equipped with input facilities in the form of special keyboards and rolling balls. After target acquisition the tracking is carried out automatically and relevant fire control data are calculated continuously. Upon firing, the torpedoes are normally controlled fully automatically with graphic and alpha-numeric presentation of all relevant information. The operators at the tactical and fire control displays can at any time take over or adjust the procedure.

Block diagram of Datasaab submarine action information and fire control system

ACTION INFORMATION SYSTEM



One of the display consoles is intended for the tactical display operator. Target data and additional information are displayed for him on the tactical display console. Information is collected from the various sensors in the submarine such as sonars, periscopes, radar, ESM, gyro, log. Most data from the sensors are supplied automatically to the computer by suitable transmitters and interface units. Target data, ie bearing, range, course and speed, are calculated from the data supplied. It is possible to obtain the relevant target data from passive bearing information only.

The tactical display shows target data, own ship's course and speed, torpedo status, etc, thus providing the tactical display operator with a clear picture of the tactical situation. Target data are displayed alpha-numerically on the screen, eg target designation, type, range bearing, course, speed, etc, as well as an input data table for computing new data. The latter is intended as a 'tell-back' indicator in connection with data input.

FIRE CONTROL SYSTEM

The fire control operator uses the second display console in the system. The display presents target data and torpedo data to form a basis for decisions regarding selected targets and torpedo guidance. The equipment enables the fire control operator to carry out an attack on several targets and with several salvoes simultaneously. Tube preparations which have to be made immediately prior to launching, ie pressure equalising and opening of bow caps and hull fairing doors, are actuated from the keyboard associated with the fire control display console.

The torpedo fire control system hardware consists of a display console with keyboard and rolling ball which is connected to the computer. The torpedo fire control display shows the torpedo firing situation as well as data regarding selected targets and torpedo attacks in plan and tabulated forms. The tabular part of the display covers target data for selected targets, supplied from the action information system, and torpedo data for a torpedo attack. Torpedo data consists of input data, instructions and computed data.

Datasaab submarine action information and fire control system operators' consoles

The computer system utilises standard modules from the Datasaab AB computer Censor 932. It comprises two central processors each equipped with primary memory and bus system. The total capacity of the primary memory is 64 K words, expansible to 128 K words. Each central processor is capable of taking the full system load, thus giving complete redundancy. Normally, however, when both are active, they are used for separate tasks.

The display system utilises standard modules from the Datasaab AB Display System 800. It comprises two complete display units with display generators. Each operator has a special keyboard and a rolling ball for communication with the computer system. Each display generator can drive both display units, and the operator can choose which one to use by means of a switch on his display panel. The display generator equipment is housed in a cabinet under the respective display console.

The interface equipment is modular, the modules containing standardised channels for digital and analogue input and output signals.

STATUS

Datasaab has delivered four sets of the NEDPS version to the Swedish Navy, one for each boat of the 'Näcken' class of submarines and one for a training simulator at the Bergas Naval College.

CONTRACTOR

Datasaab AB, 17586 Järfälla, Sweden.

UNITED KINGDOM

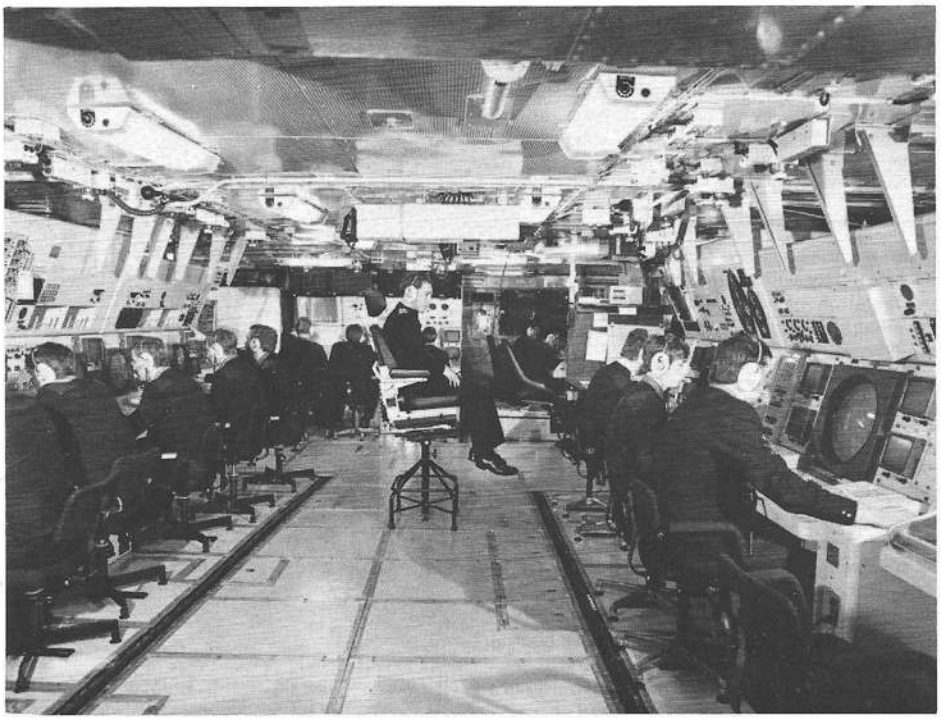
4045.261

CACS 1

Ferranti Computer Systems Limited (FCSL), Bracknell Division, has received a multi-million pound contract from the Ministry of Defence for nine new operational systems for the Royal Navy. Known as CACS 1 (Computer Assisted Command System 1), the systems have been designed for fitting in new construction Type 22 frigates. CACS 1 will incorporate two FM1600E computers, 12 Argus M700 miniprocessors and several F100-L microprocessors.

CACS 1 is the first of a family of new command systems for the Royal Navy, incorporating modern computers and a new operator interface. It will provide a substantial increase in system capability which can be directly employed to enhance the command functions necessary in a modern warship. Both the hardware and software will be constructed in modular fashion so that further system development and expansion can be implemented after installation on board and experience at sea, enabling the system performance to keep pace with changing and increasing requirements.

The CACS system architecture is based on a powerful computing facility consisting of two FM1600E computers, the latest and most powerful in the very successful Ferranti FM1600 series. These are connected by a distributed highway to several display positions, each of which contains its own Argus M700/20 microprocessor system to optimise operator effectiveness.



The consoles are based on the new Plessey Series 9 display system which, with greatly increased quality and capacity, supersedes the Mk 8 display technology used in ADAWS. There is extensive use of video re-timing and scan compression techniques. The principal input device is the light pen, which replaces most of the rolling ball and keyboard functions.

CACS employs an all-vertical display concept which, besides offering the operator a more comfortable and efficient working position, overcomes severe shipfitting constraints and the problems associated with conventional horizontal dual-operator displays.

The most significant advance from the user's viewpoint will be the implementation of the 'prompt' interface for operator communication with the system. For CACS 1 the interface has been further developed to include the use of light pens and two TV monitors, one for tote data and one for handling operator inputs. With this interface the tote displays information relevant to the current task in hand and indicates 'prompts' or choices, which when used in conjunction with the light pen and/or keyboard allows the operator to input data and control the system in a logical sequence. The need to remember complicated manual injection sequences has been eliminated with a consequential reduction of operator training requirements.

DEVELOPMENT

The origin of CACS 1 can be traced back to 1977 when Ferranti was responsible for a study on behalf of the Director, Surface Weapons Projects (Naval) of proposed improvements to the AIO system of the Type 21 frigates at half-life refit. It had been appreciated by the Naval staff that the operational environment and the projected weapon and sensor fits of those ships had outgrown the capabilities of their present system as established in the late 1960s.

General view of HMS Boxer *operations room*

Towards the end of this study MoD(N) extended the scope of the work to encompass the Type 22 frigates, as it had become clear that these new construction ships would need an enhanced AIO capability also. A number of design concepts were presented to DSWP(N) who decided that, despite the extra development and production costs involved, the design that involved the greatest changes to system hardware architecture was the one that would best meet their requirements. The resulting development contract was placed on Ferranti in 1979 and detailed work on the design of CACS 1 was initiated, with Ferranti nominated as design authority for the first time for equipment of this type. The development work has been carried out in close co-operation with the MoD at ARE, Portsdown.

STATUS

A Royal Navy contract has been placed for the CACS system for installation in the Type 22 frigates. CACS 1 is now at sea in HMS *Boxer* and *Beaver*, with a limited software operational assembly. The system will be fully operational later in 1986. Ferranti supply the FM1600E, Argus M700, and F100-L computers as well as acting as prime contractor and design authority. Plessey Displays is the main display contractor. Further feasibility studies have been carried out for the Royal Navy, in which the application of the CACS family to other ships has been assessed. A version designated CACS 4 has been nominated for the new Type 23 frigates, and another version. CACS 5, has been nominated for the third batch of the Type 22 class.

1524.281

WSA-400 SERIES NAVAL WEAPON CONTROL SYSTEMS

Derivatives of the RN Type 21 frigate Weapon System Automation 4, (WSA-4) (**1496.281**) intended for other classes of vessel carry designations in the WSA-400 Series. There is considerable commonality of both hardware and software between WSA-4 and the WSA-400 Series versions, the principal differences being those necessary to accommodate varying combinations of sensor equipment and the weapon systems fitted for specific operational roles.

Three versions of the WSA-400 Series were fitted in the Vosper Thornycroft Mk 10 frigates for the Brazilian Navy. These ships form the 'Niteroi' class and comprise two types; one specialised anti-submarine type, whose armament includes Ikara missiles, and a general-purpose type fitted with Exocet surface-to-surface missiles. In addition, both types carry Seacat surface-to-air missiles, 4·5-inch (114 mm) Mk 8 guns, anti-submarine weapons, and a torpedo armed helicopter.

Each type of vessel is equipped with three digital systems based on Ferranti FM 1600B computers, and comprising one tactical and display system, and two fire control systems.

The first of these is a development of the Computer Assisted Action Information System (CAAIS) (**1046.261** in 1980-81 and earlier editions), also being fitted to a large number of RN ships, and in the case of the Brazilian vessels, designated CAAIS-400. This system provides target indication to the fire control systems and Exocet missile system and assists in controlling the torpedo-carrying helicopter. Sonar data, which may be derived from the hull-mounted sonars or the variable depth sonar are transferred in parallel to CAAIS and the two fire control systems in each ship.

STATUS

In service. Successor systems belong to the WSA-420/CAAIS 450 series (**3505.281**), in which the former are principally for weapon control and management while the latter systems are for action information organisation generally.

CONTRACTOR

Ferranti Computer Systems Ltd, Western Road, Bracknell, Berkshire RG12 1RA, England.

3505.281

WSA-420 AND CAAIS 450 SERIES FIRE CONTROL AND ACTION INFORMATION SYSTEMS

These systems are based on and incorporate many of the proven features of WSA-4 (**1496.281**), WSA-400 Series (**1524.281**) and CAAIS (**1046.261** in 1980-81 and earlier editions) now in service with the Royal Navy and other navies.

The first main differences between these new systems and their proven predecessors is the computer and associated hardware architecture, where the latest generation of computer and display technology is used. This enables a more compact system to be provided at a cost-effective price without the need for separate computer cabinets. The equipment is housed mainly in the operator's console. Secondly, operation has been optimised to meet the requirements of small ships where reduced manning levels are desirable. It utilises conversational techniques in conjunction with a keyboard and tabular display tote on a TV monitor. This provides a simple means of system control whereby the operator is guided through the process of injecting relevant information to the computer, thus reducing both operator errors and training time.

Bearing in mind the operational requirements, Ferranti has designed a range of new systems which embody a combination of the latest technology and proven techniques, to operate with modern sensors and weapons. These include:

(1) WSA-421 – fire control system with tracker radar (receiving target indication from an external source)
(2) WSA-422 – fire control system with tracker radar and limited AIO facilities
(3) WSA-423 – integrated fire control and AIO system
(4) CAAIS 450 Series – AIO systems.

All systems can include on-board training aids, such as radar echo generators, simulated weapon tellbacks etc.

WSA-421 Fire Control System with Tracker Radar

This is designed primarily for frigates and corvettes fitted with an independent, but linked, AIO/CIC system such as CAAIS 450. For such vessels the main armament would be a 76 mm-calibre gun or a heavier weapon such as a 4·5- or 5-inch (114 or 127 mm) gun. The secondary armament could be a similar or smaller calibre weapon, or a surface-to-air missile. Two tracking heads provide the WSA-421 with two independent channels of fire. The fire control prediction is performed by a Ferranti FM1600E computer. The system accepts target indication from the ship's AIO system.

WSA-422 Fire Control System with Tracker Radar with Limited AIO

Designed primarily for vessels of patrol craft size to provide weapon control and surveillance tracking for deployment of 35 mm to 127 mm-calibre guns and/or surface-to-air missiles and optionally, surface-to-surface missiles, the system uses the FM1600E computer.

The main sensor is the ship's surveillance and/or navigation radar. A tracker radar and OFD which can mount a laser rangefinder in addition to the E-O or CCTV is also fitted, thus providing two independent channels of fire and enabling two gun mountings to be controlled. Although the tracker radar will normally be paired with the main gun, the flexibility of the system enables any sensor-target pairing to be achieved. The composite weapon system console is manned normally by a single operator with provision for up to three operators in active conditions, and houses all displays, indicators and controls for surveillance tracking, target designation, control of weapon sensors and of the armament. Manual rate-aided tracking, with computer-generated symbology, is available on up to 60 targets. The power of the FM1600E computer is such that additional facilities may be provided if required, such as a remote-controlled, stabilised video tracker, comprising CCTV and laser rangefinder, to assist tracking in poor ECM environments.

Ferranti combat system WSA-422 system console

WSA-423 Integrated Fire Control and AIO System

This system is designed for vessels of patrol craft and corvette size to provide weapon control and AIO/CIC facilities for the deployment of guns (35 mm to 130 mm), surface-to-air and surface-to-surface missiles.

WSA-423 is an extension of the WSA-422 system with added AIO facilities to provide an integrated system. These facilities will enable a tactical picture to be compiled on a labelled radar display from one or two surveillance radars for the purpose of command appreciation, using a sub-set of CAAIS programs, including the solution of simple command and navigation problems. In this system, a separate command console is provided, which houses a 16-inch (406 mm) LRD and the necessary hardware to provide auto-tracking of targets on one surveillance radar and an inter-ship digital data link, if fitted. The power of the FM1600E computer is such that additional AIO functions and equipment can be incorporated, if required.

CAAIS 450 Series AIO Systems

This series is designed to provide AIO facilities for a range of vessels of FPB size or larger. Provision is made for passing target indication data to associated fire control systems, which could be a sub-set of WSA-422.

CAAIS 450 can accept tactical data from two surveillance radars, from sonar and ESM equipments. Auto-tracking of targets is provided on both radars. Although the FM1600E computer's capability includes driving up to eight 12- or 16-inch (305 or 406 mm) LRDs, the exact display fit will depend upon the particular application. A basic configuration would have three displays: two for picture compilation and one for command appreciation. Additional display requirements can be envisaged for such functions as ASW, helicopter control, ESM/ECM management or data link management. The software provided is generally derived from the CAAIS programs. However, due to the versatility of this configuration, which results from the use of a powerful computer, specific applications may require that some special software is needed so that the full capability of associated weapons and sensors can be realised.

STATUS

Production began in 1980. Implementation of the first fittings of systems of this series are now in progress. WSA-421 has been selected by the Royal Navy for firing systems. WSA-420 and CAAIS 450 series systems are in production for a number of overseas navies (including Brazil).

CONTRACTOR

Ferranti Computer Systems Ltd, Western Road, Bracknell, Berkshire RG12 1RA, England.

3746.481

SUBMARINE TDHS (DCC)

The submarine Tactical Data Handling System (TDHS) is the action information organisation (AIO) and fire control system designed for the new class of SSK submarine, known as the Royal Navy Type 2400. It has been given the type designation DCC and is derived from DCA/DCB systems in use in British nuclear submarines.

The weapons fit for Type 2400 includes dual-purpose wire-guided torpedoes (anti-submarine/anti-ship), anti-ship air-flight missiles, and submarine mines. The fire control for weapons is integrated in the tactical system, which comprises the following: long-range passive sonar, a medium-range passive/active sonar with a cylindrical array located in the bow, sonar intercept, analysis and classification facilities, passive ranging using three aligned arrays on each side of the vessel, underwater communications, bathythermograph, and a sound speed-measuring system.

Other sensors include search and attack periscopes, and both are provided with facilities for fitting a variety of electronic and electro-optical devices. A Type 1006 surface surveillance and navigation radar, and omni-directional and directional warning antennas for the boat's ESM system are carried on a separate mast or incorporated in the search periscope.

Digital data transmission and processing is employed and the sensors and DCC are closely integrated; target bearing and range and velocity data are processed to provide accurate target motion analysis. The tactical system consists of a three-position console with electronics in the lower compartments and six 12-inch (305 mm) circular cursive displays, light-pen units, fire control order and status units in the upper positions. DCC receives tactical and environmental data from the submarine's sensors via a digital data bus. The data is collated, processed, evaluated and presented on the circular displays for final assessment and decision.

The system also provides all necessary weapon control functions. The system computer is the Ferranti FM 1600E; a second fully redundant computer is provided to allow for 'fall-back' modes and future software expansion. Light pens provide the main man/machine interface, and all selection and switching facilities are provided at the operator console positions.

STATUS

First production orders placed.

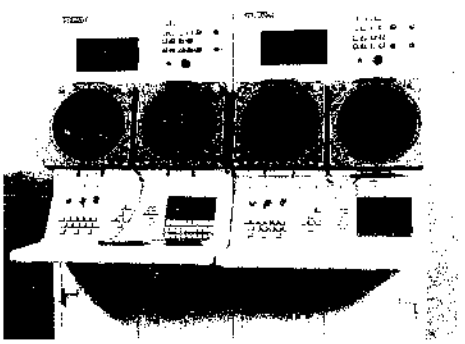
Ferranti Computer Systems Ltd, Western Road, Bracknell, Berkshire RG12 1RA, England. (Prime)



4272.481

KAFS SUBMARINE AIO AND FCS

KAFS is suitable for conventional submarines of all sizes. The system uses the advanced computer technology, latest processing techniques and software algorithms incorporated in similar systems in RN nuclear submarines and the new 2400 tonne class 'SSK'; these provide operational facilities such as picture compilation, target motion analysis and fire control so that the commanding officer may carry out the wide variety of tasks on which such a submarine can be employed. These include area surveillance, attacks on surface and underwater targets, operations in inshore waters (such as minelaying or periscope reconnaissance), intelligence gathering and participation in ASW exercises.

The system hardware and software has been specifically designed in a compact, modular manner to provide a wide range of operator facilities which can be adapted or expanded as necessary to meet individual system requirements.

A high level of automation minimises the requirement for operator intervention so that one operator can control the total system and carry out an urgent attack. However provision is made for two operators who may be necessary in a multi-target situation. Automatic multi-contact association is carried out on all data received from on-board sensors together with simultaneous and automatic target motion analysis (TMA) on 35 or more tracks. The tactical picture is then presented to the command in labelled plan or time/bearing format, as required, on software displays. Two different types of weapon may be prepared for discharge and all weapon discharge functions can be by remote control if required. Two or more wire-guided weapons may be guided automatically at two or more separate targets,

Double KAFS console

or a combination of guided and salvo weapons may be fired. Integration with the navigation system provides the accurate conduct and data recording of such activities as minelaying and periscope reconnaissance.

The main elements of the KAFS system configuration are shown in the photograph. The operator console is located in the control room and is linked by a MIL-STD-1553 data bus to the weapon control equipment in the torpedo room. The base of the operator console houses the FM1600E central processor, the input/output control unit, 256 K semiconductor store, display drive unit, magnetic cartridge unit and PCU, interface units and power supply units. The processor is the latest in the series of 24-bit F1600 computers designed by Ferranti and supplied for RN surface ship and submarine systems and a wide variety of overseas systems.

The top half of the console has two identical operator positions each having two display areas, a light pen, control panel and a command data panel. Either operator position can control the whole system thereby allowing one position to be shut down in patrol states. The display areas provide the operator with a labelled plan or time/bearing display according to his selection, and a tote providing pages of data and instructions to enable the operator to interact with system control, picture compilation, navigation modes, target motion analysis and weapon fire control.

Training can be carried out on AIO, fire control and weapon control procedures while the system is in the operational mode. Facilities are provided for emergency control of weapon discharge and guidance independent of the central processor. Tube status, weapon status and system status are displayed on a local control panel which also provides weapon discharge and control facilities in fallback mode; maintenance and fault-finding facilities; and training facilities. Microprocessor-based port and starboard weapon interface and tube switching units are provided on a modular basis according to the number of tubes and weapon types. Facilities are provided for weapon pre-heating in stowage and battery/gas monitoring to detect hazardous conditions.

DEVELOPMENT

Studies of an AIO and FCS for RN nuclear submarines carried out by Ferranti in the 1960s led to the Tactical Data Handling System (**3746.481**) which was built under MoD contract for the 'Swiftsure' class of SSNs. A production order has been placed for the first two RN 2400 tonne SSK systems and an unspecified foreign navy has ordered three systems.

Ferranti Computer Systems Ltd, Western Road, Bracknell, Berkshire RG12 1RA, England.

3508.281

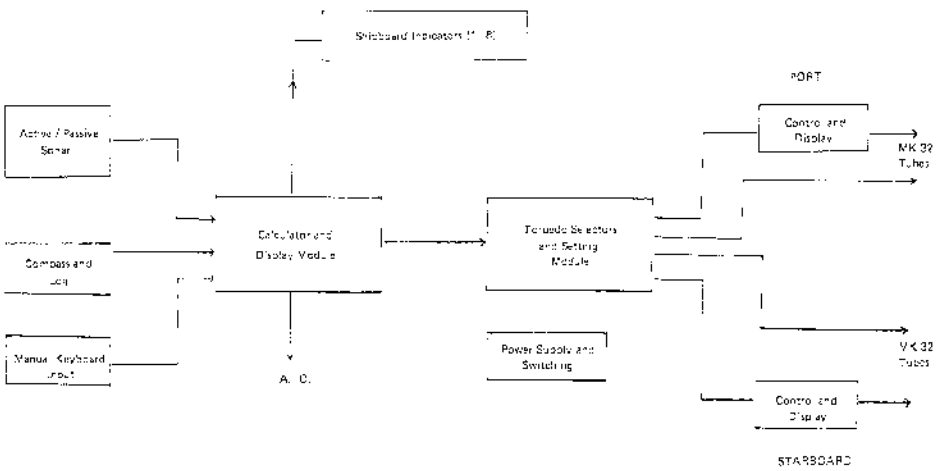
CONTROL FOR SURFACE-LAUNCHED TORPEDOES (CSLT)

CSLT is an independent miniaturised torpedo fire control developed by Vickers for operation on any ship having Mk 32 torpedo tubes armed with either MK 44, Mk 46 or other tube-compatible torpedoes. The main features of the system are: small size (control room equipment about 0·1 m³); microprocessor computation; sensor smoothing and target prediction software derived from proven in-service systems; modular construction; flexible interfaces. The equipment is of rugged construction designed for operation in severe naval environments and comprises:

(1) calculator and display module
(2) torpedo selection and setting module
(3) shipboard indicators
(4) local control and display modules (port and starboard)
(5) power supply and switching unit.

The calculator and display module is supplied either as a bulkhead-mounted unit or as a VCS module for incorporation into a user console. Its

interfaces accept data from the ship's sensors and a manual keyboard input, and send processed information on relative target motion to the torpedo selection setting module, shipboard indicators and the AIO.



The torpedo selection and setting module performs these functions in either a semi-automatic or a manual override mode. For certain torpedoes, an ancillary setting module is required. The shipboard indicators display course-to-steer and up to six in number may be sited as appropriate. Two local control and display modules are situated above decks, one each in the vicinity of the port and starboard mountings, to provide monitoring, local control and override facilities.

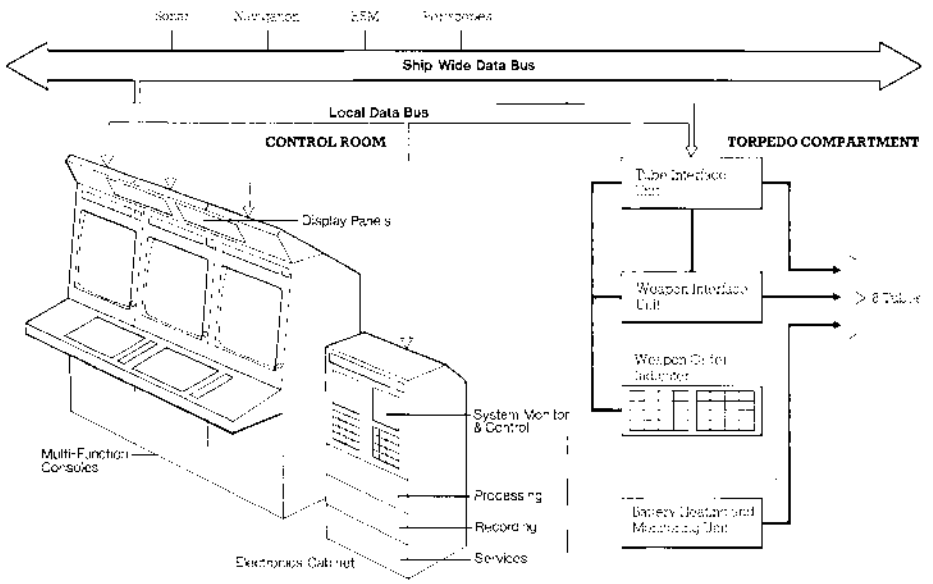
SUBMARINE TACTICAL COMMAND AND WEAPON CONTROL SYSTEM



This is the latest in a series of submarine tactical information organisation and weapon control systems from Vickers Shipbuilding and Engineering Ltd (VSEL), Weapons Department. It is designed for close integration with ship sensors, using the latest technology to reduce size and minimise maintenance and logistic costs. Functions are partitioned and adaptable to any tube configuration or weapon type. The software concepts from previous systems have been improved and repackaged into smaller units using techniques based on distributed microprocessors.

Well-developed and proven algorithms provide the command with accurate target motion analysis allowing early decisions and initiatives to be taken against potential targets. Raster scan colour displays provide AIO and fire control operating positions and a command surveillance display. Light-pen control and a user-friendly man/machine interface optimise operator performance within the system.

Processing is carried out by a number of microprocessors and processing electronics and displays are linked via a digital data bus. The design anticipates that data will be distributed within the weapon system by a ship-wide data bus which gives the flexibility to cope with the requirements of each sensor and weapons fit.

STATUS

No contract details have been released.

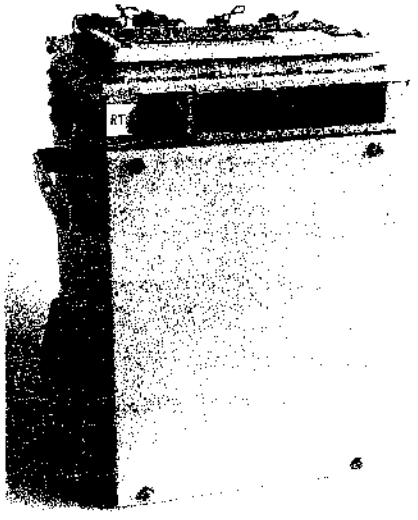
4577.481

VSEL COMBAT SYSTEM DATA BUS



The VSEL combat system data bus (CSDB) is for use in warships and provides a flexible self-contained communications medium to which various user equipments can be connected via any type of digital interface. It will be fitted in RN submarines and is applicable to new or existing systems.

The CSDB converts all interfaces to a common format and controls data exchange on a single highway, allowing the advantages of bussed data to be exploited in new or existing systems. Remote terminals are used for interface conversion and data is exchanged on dual redundant serial, single 'twisted pair' highways under the control of one or more bus controllers (BC). The electrical and protocol characteristics of the bus connecting RTs and BCs is based on the communications standard defined in Mil Std 1553 B (Def Stan 00-18 Part 2).

For a particular application the CSDB can be configured by selection of interface equipment to match the weapon system requirements. RTs can be

Block diagram of VSEL combat system data bus (CSDB)

Remote terminal of VSEL CSDB

embedded in the user equipment or free standing. The preferred method of connection is determined by overall system design, balancing data rate, total number of bus links and availability demands. Embedded terminals generally comprise an interface unit between the data bus and the internal computer highway of the user equipment and may contain any level of redundancy up to the complete duplication of the interface.

Free-standing RTs are autonomous units containing a fully duplicated bus interface and are otherwise designed to communicate with any number of users over a wide variety of serial or parallel links. The bus controllers are independent of RTs and users and provide the basis for control of the combat system. The number of bus controllers is determined by the system requirements for availability of data communication. Their main functions are to control the transfer of messages between RTs, monitor the system, diagnose faults and provide guidance instructions to the maintainer. They can also be used to monitor individual messages and extract data as determined by the system designer.

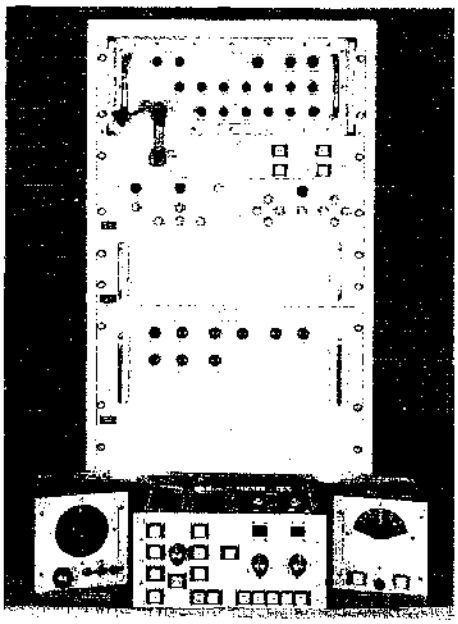
THORN EMI TORPEDO FIRE CONTROL EQUIPMENT

The Thorn EMI Torpedo Fire Control Equipment is a lightweight system for deck launched torpedoes and is currently compatible with Mk 44 and Mk 46 lightweight torpedoes.

The equipment may be used as an independent system with full manual setting and firing capability which could be appropriate to smaller vessels. Alternatively it can be interfaced with conventional A/S and weapon system computers found in a wide range of warships for automatic or semi-automatic monitoring and fire control with full manual 'fall-back', or 'stand-by' facilities.

The equipment will set and monitor the torpedo operating parameters, state of readiness and torpedo tube states and operation for up to two triple barrel launchers. Local displays indicate ships head, optimum launch bearing, sonar contact and allow optimum launch conditions to be established. It includes test facilities for system checking and which allow simulated firings to be practised.



The equipment is supplied in modular form to ease installation and is VDS compatible.

STATUS

A number of these systems have been supplied and have been in service for several years.

STWS-1 SHIPBORNE TORPEDO WEAPON SYSTEM MK 1

The STWS-1 is a lightweight torpedo system developed for the RN and designed as a self-contained system to help position a ship for weapon launch and control. The equipment is suitable for fitting in all classes of vessel. Main features of the system include:

(1) launchers for lightweight 12·75-inch (324 mm) diameter homing torpedoes
(2) optimised for ASW roles
(3) minimum manning requirement
(4) port and starboard triple torpedo tube mountings
(5) integration with ship's AIO/CIC system
(6) automatic arming and battery priming of torpedo during the launch phase
(7) jettison facilities for safe emergency disposal of torpedoes
(8) tube muzzle doors for torpedo protection
(9) simulator facilities for outboard training.

The total system consists of two sub-systems, the information sub-system, and the action sub-system, linked by the anti-submarine warfare director (ASWD), who is in control of the complete system.

The information sub-system provides the ASWD with sufficient continuously updated information from the ship's sensors and other sources to enable him to advise the command on the tactical requirements for torpedo engagements. Target information, together with ship's heading and speed is applied to the SWTS-1. The processed target information is passed through the ship's AIO/CIC system and displayed for the ASWD.

The action sub-system contains a series of interlocks which requires a correct sequence of operations to release the torpedo. Faulty operation automatically inhibits release.

STATUS

Fitted to RN frigates and destroyers, and to various ships of other navies. When a contract for five ship-sets of STWS-1 systems was ordered for the RN in January 1979, this raised the total number ordered to over 25.

CONTRACTOR

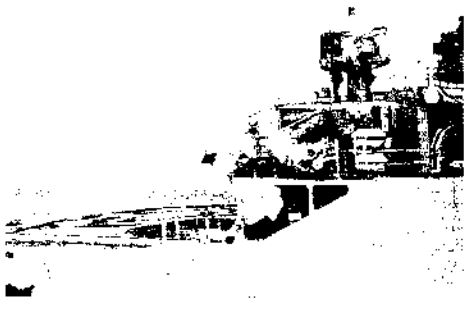
Plessey Marine, Templecombe, Somerset BA8 0DH, England.

3742.481

STWS-2 SHIPBORNE TORPEDO WEAPON SYSTEM MK 2

STWS-2 is a second-generation system developed from STWS-1 (**3103.481**) and is suitable for use against any sub-surface target held by the AIO/CIC of the ship. It is a quick-reaction anti-submarine weapon system, capable of pre-setting and firing the new Stingray and Mk 46 torpedoes.

The system consists basically of triple torpedo tubes fitted to port and starboard of the ship and a microprocessor based tracker and predictor working in near-real time. The system accepts target track data on its information channel simultaneously from either:



(1) the AIO/CIC either automatically or manually as the primary mode of operation
(2) the ship's sonars – as the secondary mode
(3) manual injection as the back up mode.

Target track data is passed to the tracker, which computes the target's current position and the fire control problem is then displayed. This information is also passed to the predictor, which computes the target's future course, and the fire control solution is generated and displayed. The fire control solution chosen optimises the probability of acquisition of the weapon in use. The action channel enables the A/S warfare director to select and pre-set the most appropriate weapon.

The system has an in-built diagnostic routine which also uses the microprocessor to continually monitor the system functions.

STATUS

STWS 2 is fitted in certain Leander frigates and all the Type 22 class ships, some Type 42 destroyers, and a follow on production order is in progress at the Newport, South Wales factory for other RN vessels.

STWS 2 launcher discharging a Stingray torpedo

CONTRACTOR

ADAWS 2 ACTION DATA AUTOMATION WEAPONS SYSTEM

This was the first of a new series of action data automation systems developed for the RN and based upon Ferranti FM1600 series digital computers, and using Plessey display equipment, to provide improved performance and facilities over those of the ADAWS 1 which used Poseidon computers. The important operational difference is that ADAWS 2 and later systems provide, in addition to the action data automation functions, fire control facilities for the various weapons carried by the vessel.

The ADAWS 2 was designed for the Type 82 guided missile destroyer HMS *Bristol*, and accepts inputs from multiple sensors including radars, sonar, passive devices, and data link. The FM1600 micro-circuit computer suite performs the co-ordination, processing, distribution, and display of tactical information derived from these sources. Fire control calculations and co-ordination are also performed by the computers for the armament of Sea Dart surface-to-air missiles, the Ikara ASW weapon, 4·5-inch (114 mm) gun and other weapons fitted.

Inputs to the system comprise the search radars Types 965, 992 and 1006, two fire control/director radars Type 909 for the Sea Dart missile systems, data links, sonars Types 170 and 184, unspecified EW and passive direction finding equipment, and various manual input facilities.

Among the conventional weapons linked to the ADAWS 2 are included facilities for the direction of various categories of co-operating aircraft such as fighters and ASW helicopters.

Auto tracking of targets is available (using the Ferranti LFX limited area full extraction and LAX limited area auto extraction) with or without auto initiation of tracks. More details of these facilities will be found in the entry for CAAIS (**1046.261**) which appeared in earlier editions.

Two Ferranti FM1600 computers are employed with a total of 2 × 192 K words of core store. In this system, in the event of one computer failing, various reduced modes of operation are available using the surviving machine. Programs are included for threat evaluation for the Sea Dart missile system, as in ADAWS 4 fitted in Type 42 GMDs (**1234.261**).

In comparison with the earlier ADA systems, still more comprehensive processing is performed on sensor data, and the Plessey Mk 8 digital autonomous displays provide improved facilities for the presentation of operational data in the form of a combined radar and synthetic picture.

The ADAWS 2 display system comprises a number of labelled plan displays (LPD) and electronic data displays (totes) both of which use 305 mm CRTs, and two three-man tactical displays (using a 560 mm CRT). The LPDs are used for picture compilation and weapon control, the tactical displays which replace the traditional projection type plotting tables are used by the command for tactical appreciation and the totes provide alpha-numeric readouts of information in response to the operators' inputs to the computer system through their individual keyboards.

STATUS

The ADAWS 2 equipment for HMS *Bristol* was installed in 1970; further ships of this class were cancelled for economy reasons and Type 82 remains a 'class of one ship'.

CONTRACTORS

Ferranti Computer Systems Ltd, Western Road, Bracknell, Berkshire RG12 1RA, England – main contractors, digital equipment, and software.

Plessey Displays Ltd, Station Road, Addlestone, Weybridge, Surrey KT15 2PW, England – displays, interface, and drive equipment.

1234.261

ADAWS 4 ACTION DATA AUTOMATION WEAPON SYSTEM

This system is essentially a smaller version of the ADAWS 2 (**1044.261**), using the same hardware, but with variations to accommodate the requirements of the Type 42 guided missile destroyer class of vessels and the differences in armament compared with the Type 82 GMD with which the current ADAWS series originated. ADAWS 3 was designed for the CVA 01 carrier which was subsequently cancelled.

The ADAWS 4 is produced in two slightly different versions for the RN Type 42 GMDs and the Type 42s supplied to the Argentinian Navy. The systems fitted in the Batch II and Batch III Type 42 GMDs again have minor differences to reflect the changes to weapon and sensor fits and are thus designated ADAWS 7 and 8, respectively.

The ADAWS family of systems also includes ADAWS 5 (**1235.261**) and ADAWS 6 (**1830.281**). Specific benefits of the modular nature of these systems are reductions in the development effort required and in the time necessary for system proving.

The central data processing complex includes two Ferranti FM1600 micro-circuit digital computers, with a Plessey Mk 8 digital display system for the presentation of tactical and other information. The computers provide up to a total of 2 × 192 K words of core store, and they will gather data from all the ship's sensors, assemble and correlate this information and that from other vessels obtained via data link, and present it to the command teams on appropriate display consoles.

All information from own ship and consorts in data link contact will be accessible at any console, and on a selective basis, eg either air situation or underwater situation. The computers also include programs to assist in the evaluation of the relative threat posed by different targets, thus assisting the command in the selection of targets and assigning weapons, particularly the twin-headed Sea Dart missile system. When action is joined, the computers also provide control of ship's weapons. In addition to providing all the aiming and fire control computations for the Type 42's Sea Dart missiles, the ADAWS 4 also includes fire control for the 4·5-inch (114 mm) automatic gun mounting, and the calculation of intercept instructions to be passed by radio to fighter aircraft or anti-submarine helicopters.

DEVELOPMENT

Development of the ADAWS 4 was a continuation of the ADAWS 2 work, and began in 1967. Ferranti and Plessey Radar worked as major sub-contractors to the UK MoD (Navy) in respect of the RN Type 42 destroyers. In the case of the Argentinian Navy, Ferranti worked as main contractor with Plessey Radar as a major sub-contractor.

STATUS

A total of 12 ships of this class was planned originally (two for the Argentinian Navy and ten for the RN). Subsequent changes in the RN fleet, due to the loss of HMS *Sheffield* and *Coventry* in the Falkland Islands campaign of 1982, and the addition of Batch III comprising four ships launched between 1980 and 1982, led to a British complement of 12 ships. Because of the elapse of some ten years between laying down the first of class and launch of the latest, and because of design changes affecting both size, armament and sensor fit, individual ADAWS fitted in Type 42 ships can be expected to differ appreciably in detail.

Ferranti is responsible for implementation of modifications to the system which arise because of changes in operational requirements and to weapons/sensor fits.

CONTRACTORS

Ferranti Computer Systems Ltd, Western Road, Bracknell, Berkshire RG12 1RA, England.

Plessey Displays Ltd, Station Road, Addlestone, Weybridge, Surrey KT15 2PW, England.

1235.261

ADAWS 5 ACTION DATA AUTOMATION WEAPON SYSTEM

This system is essentially a further version of the ADAWS 2 system that is fitted to the Type 82 guided missile destroyer, HMS *Bristol*, and uses the same basic hardware and a large proportion of the software of that system, but configured to meet the requirements of vessels of the 'Leander' class of frigates equipped with the Ikara ASW weapon system. A major difference is that only a single computer is employed. The requisite software for all the ADAWS family of systems is generated and maintained by a Ferranti program team working in collaboration with the ARE, Portsdown. The sensor, computer programming, and display arrangements for the ADAWS 5 are optimised for the principal role of this class of vessel (ASW) and the Ikara anti-submarine weapon which is the main armament.

The system receives inputs from the search radars Types 994 and 1006, and provides auto-tracking of targets by LAX (limited area auto-extraction), including the special processing of transponder returns from helicopters engaged in anti-submarine warfare operation and Vectas. The IFF associated with the Type 994 radar is also controlled by the computer in association with its integral auto-decoder. On the sonar side, the system receives inputs from Type 184 (main search sonar), Type 199 (variable depth sonar) and Type 170 (attack sonar) which also controls the A/S Mortar Mk 10. Target data are processed, correlated and formed into tracks by the computer, which also controls the firing of the Ikara weapon and provides assistance to the helicopter controller during Vectas. The AS 1077 sonar trainer is also fitted to provide on-board training, both for the sonar operators and the AIO team. Other facilities include data banks and Seacat missiles.

The system hardware is similar to that used in other ADAWS but on a reduced scale, namely, one FM1600 computer, one display central equipment, two tactical displays and six LPDs/totes.

DEVELOPMENT

Development has been carried out in conjunction with the other ADAWS programmes by the same companies and government agencies, and originated in 1967.

STATUS

Eight systems have been manufactured by Ferranti for HMS *Leander* and other ships of the first batch of 'Leander' class frigates.

Software and hardware modifications, including increasing the core store to 128 K words, have been carried out in order to keep the system up-to-date with the latest operational requirements.

CONTRACTORS

Ferranti Computer Systems Ltd, Western Road, Bracknell, Berkshire RG12 1RA, England.

Part of the digital display system supplied by Plessey for ADAWS 5 on HMS Leander

Plessey Displays Ltd, Station Road, Addlestone, Weybridge, Surrey KT15 2PW, England.

1830.281

ADAWS 6 ACTION DATA AUTOMATION WEAPON SYSTEM

ADAWS 6 is the designation of the new system for the RN anti-submarine cruisers HMS *Invincible* and HMS *Illustrious*. A slightly different version, designated ADAWS 10 will be fitted in HMS *Ark Royal*. Ferranti and Plessey, who in partnership have produced ADAWS for preceding RN ships, were contractors for the computer complex and display systems for this class of ships.

HMS *Invincible*, the largest ship to be built for the RN since the Second World War, is claimed to have a more comprehensive automated AIO than any previous vessel, and its functions include deployment and control of the ship's own weapons and aircraft as well as command and control of co-operating forces.

Invincible's armament includes the Sea Dart missile (twin launcher), Sea King helicopters, and Harrier V/STOL strike aircraft. Sensors include a Type 1022 long-range surveillance radar, IFF/SIF, Type 992Q search and target indication radar, two Type 909 radars for the Sea Dart system, Type 1006 navigation radar, data links, EW and sonar.

There is a significant area of commonality in both armament and sensors with other RN ships (Type 42 and Type 82) that have Ferranti/Plessey ADAWS, and

as would be expected the new ADAWS for HMS *Invincible* embodies parts of the systems developed for these classes. In ADAWS 6 the two computers are employed in a very similar fashion to those in the ADAWS 2, including the ability to operate in a range of reduced modes in the event of malfunctions. Additional software to meet the special requirements of the *Invincible*'s new operational role were generated by a Ferranti team in collaboration with the ARE, Portsdown.

STATUS

The first ADAWS 6 system was delivered to *Invincible* in 1977 and the system for *Illustrious*, the second ship of the class, in 1980. ADAWS 10 for *Ark Royal* was delivered in 1983.

4578.281

NAUTIS COMMAND AND CONTROL SYSTEMS

The naval autonomous information systems (NAUTIS) series of modular naval command and control systems developed by Plessey Displays is based on the company's range of autonomous intelligent consoles. This is itself based on the well-proven Series 9 display hardware, and now known as the Nautic Intelligent Display system.

Use of Nautic consoles permits systems to be configured for a wide range of applications calling for from one console workstation to a full combat display system which would comprise several consoles in a configuration linked by a local area network or a data highway. The Nautis system uses distributed processing rather than a single central computer or computer complex, offering flexibility and a high degree of survivability. The embedded processors interface with an international standard data bus and a dual-redundant system data highway complying with Mil Std 1553 B. Configurations using other ship data highways are also available.

Typical of a larger Nautis complex is the Nautis-D system

The full range of available information within the Nautis system is presented on a single screen and the large Nautic display is partitioned into a number of areas: labelled radar picture with computer graphics superimposed and totes giving summaries of sensor, weapon and system status, threat tables and general information. Control procedures are simplified by an interactive menu with prompts on the same screen.

System configurations have been defined for fitting in a variety of ship types. The Nautis system for each application is denoted by an alphabetical suffix:

Nautis-A: assault ships and auxiliaries
-C: cruisers
-D: destroyers
-F: frigates
-K: helicopter support ships
-L: assault and logistic landing ships
-M: minehunters and minesweepers
-N: minelayers
-P: corvettes, patrol craft and light forces
-R: aircraft carriers

Typical configurations range upward from the single Nautic console of a Nautis-P which provides command, control and navigation facilities for a patrol craft or small vessel. In this configuration a labelled radar display permits tactical information to be presented graphically on the radar picture and automatic tracking of up to 20 surface and air targets.

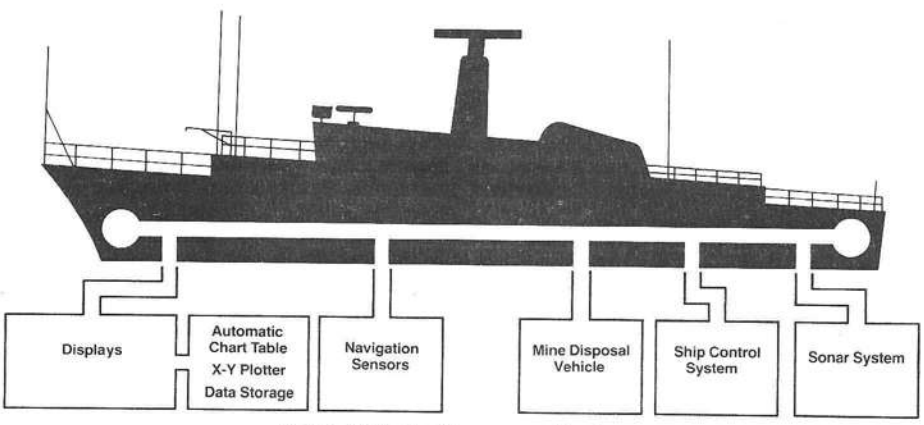
Nautis-F is a multi-console system where individual workstations have the facilities provided by the Nautis-P consoles, but improved by the more powerful multi-processor architecture permitted by the distributed database of the Mil Std 1553 B system highway. Such a configuration has increased system capacity for the wider range of sensor interfaces, and more complex applications software. Nautis-D is configured for larger warships requiring comprehensive command and control facilities, and eight or more Nautic consoles may be employed. A system of this sort can be expanded to operate with a centralised database.

Nautis-M, the version for minehunters and minesweepers, provides all command and control and navigation facilities for naval mine countermeasures operations and typically is a three-console configuration. Plessey Displays, in association with CAP Scientific, was awarded a contract in 1984 to supply Nautis-M systems for a new class of Royal Navy single role minehunters.

Plessey Nautic autonomous intelligent console

This system comprises three Nautic consoles linked by a high-speed digital data highway, and, using data from radar, sonar, communications and navigation sensors it provides integrated operational control; a continuous, accurate record of own ship's position; updated underwater and surface pictures; navigation and safety facilities; and planning and control of ship's track. The consoles will be used to co-ordinate the detection, classification and disposal of mines. Autonomous intelligent consoles eliminate the need for a separate data processing cabinet. A high-speed digital highway provides for future expansion and diversification in equipment and applications, such as the inclusion of surface weapon control and ESM information.

A task-oriented keyboard gives operators ready access to the database that provides aids in manoeuvring the ship at all times. A Nautic console on the bridge for use by the Officer of the Watch is capable of presenting the MCM picture if required. The operational console can be supplied with colour raster viewing units capable of dealing with radar and synthetic presentation. Console operation is by means of an interactive prompt facility controlled by a keyboard and rolling ball.



STATUS

In production. In March 1984 a £2·5 million UK MoD contract award to Plessey Displays for Nautis-M to be fitted in a new class of RN Single Role Minehunters was announced, with Plessey as the prime contractor and CAP Scientific as sub-contractor. CAP is primarily concerned with software.

CONTRACTORS

Nautis-M minehunting command system

3104.481

MCS10M MORTAR Mk 10 CONTROL SYSTEM

The MCS10M is a modernised version of the well-known MCS10 anti-submarine-attack fire control system which combines a Type 170 sonar, a computer with displays, and mortar interface equipment with the ASW Mortar Mk 10 system (**6008.241**).

The modifications undertaken by Plessey Marine on behalf of the UK MoD (Navy) applied to both the Type 170M sonar and the mortar interface equipment.

In the former equipment one new MC70 cabinet replaces the three originally required, and entirely new electronics are employed which incorporate built-in monitoring. In the sonar control room, existing vacuum-tube equipment in the centre display unit, computer, and SCU tester have been modified to solid-state and the CDU has a new CRT. Additional control facilities have been provided and there are minor modifications to recorders and power supplies.

The stabiliser and plane converter units of the interface with the mortar and transducer have similarly been converted to solid-state circuitry and other modifications have been made to electrical and servo elements of board control, tilt train unit, and remote repeaters.

STATUS

In service with Royal Navy.

4306.261
CANE

The Racal Command and Navigation Equipment (CANE) series is a family of low-cost integrated systems providing comprehensive command, control and navigation facilities for smaller warships and marine policing vessels. It is designed to integrate information from a variety of shipboard radar, sonar and navigation sensors and present a constantly updated display to the command. Computer-generated plots and records are produced. The system is modular and supplied in various forms to meet differing operational requirements: computer-based navigation, comprehensive tactical display, command and control facilities, and target indication to fire control systems may be included.

The original RN CANE 1 system has been improved to produce CANE 2 for the latest RN requirements. It includes high-resolution radar auto-tracking, video mapping on radar displays and inputs from Satnav, Omega, Decca Navigator and Hi-Fix 6 radio positioning systems and can also be integrated with the ship's weapon system.

The CANE 100 and 200 series have since been developed to meet the need for integrated command, control and navigation in smaller vessels based on experience gained with CANE 2 to provide relatively low-cost integrated systems.

CANE 100 is aimed primarily at fast attack craft, patrol boats and submarines. The basic element is a table-mounted control and display unit with a large capacity alpha-numeric display, control panel and integral KS 590 computer. By itself it forms a comprehensive integrated navigation system operating with various combinations of log, compass, and radio navaids, such as Satnav, Omega, Decca, and Loran C. It also provides an effective command and control capability and can be extended to add an automatic chart table, an operations display unit giving high-performance automatic radar tracking, target indication to multiple fire control systems and the capability to position own ship automatically by radar. An automatic plotter will produce geographically true hard copies of the tactical situation including own ship's track and the positions and movements of radar targets, and a data printer may also be added.

The CANE 200 is designed for the more complex needs of larger ships such as corvettes and is also based on CANE 2. It provides all the facilities of CANE 100 with additional display consoles to meet increased requirements for surveillance, target tracking, and command and control of air, surface, and sub-surface operations.

STATUS

CANE has been in service with the RN since 1977. CANE 100 and 200 were announced in September 1981 and are in producton to meet the requirements for smaller warships, including missile and gun armed fast attack craft and fast patrol boats, up to and including corvette size.

CONTRACTOR

Racal-SMS Ltd, Cox Lane, Chessington, Surrey KT9 1SB, England.

1831.281
MINE COUNTERMEASURE CAAIS

Development of this special version of computer-assisted action information system (CAAIS) (see **1046.261** in 1980-81 and earlier editions) was entrusted to Ferranti. The new class of MCMVs have reinforced plastic hulls and one of the engineering tasks undertaken by Ferranti was to reduce the magnetic signature of the computer equipment. At the heart of the system is an FM1600B computer driving two Deccascan displays equipped with Ferranti manual input assemblies which enable operators to communicate with the computer by means of alpha-numeric keyboards and tracker balls.

The CAAIS system for MCMVs fulfils a triple role: it compiles and displays information with the speed and precision required for successful MCM operations; it makes the detailed calculations necessary for the accurate navigation and control of the ship; and, as in all CAAIS systems, it provides a comprehensive display of the tactical situation, such as would be required when the ship is on patrol duties.

The ability of CAAIS to accept automatically and process sensor information presents the command with the ability to reduce errors and action-time operator fatigue, and generally to increase the MCMV's ability to meet its designated task. Peripheral interfaces include the high definition surface surveillance radar, radio fixing aids, the minehunting sonar and the ship's auto-pilot.

The principal advantage that CAAIS for the MCMV offers over other systems is a hardware and software package that provides an automatic and accurate navigation and ship-handling system with good repeatability (the ability to relocate previously detected objects on the sea bed), that places the control of the sonar with the command and enables comprehensive records to be taken and to be transferred to relieving ships.

STATUS

Fitted in 'Hunt' class MCMVs. Ferranti has developed a mine countermeasures control system to meet the requirements of smaller MCM vessels; this is described in entry **3506.281**.

In 1982 the RN commissioned an MCMV shore-based training complex (AS1076 Arcturus) which embodies an MCM CAAIS and sonar simulator system supplied by Ferranti Computer Systems Ltd.

CONTRACTORS

Ferranti Computer Systems Ltd, Western Road, Bracknell, Berkshire RG12 1RA, England.

Decca Radar Ltd, Decca House, 9 Albert Embankment, London SE1 7SW, England.

3506.281
MINE COUNTERMEASURES CONTROL SYSTEM

Development of mine countermeasures CAAIS (**1831.281**) for the UK MoD (Navy) enabled Ferranti to design a mine countermeasures control system (MCCS) which meets the requirements of MCM vessels of 35 to 50 m overall length, while incorporating much of the software programs already written for the RN. In these vessels, it is anticipated that the primary role will be minehunting but that a capability of minesweeping, at least with wire sweeps, will be included. Many of the functions will be common to both systems, but the severe constraints on availability of space in the smaller vessels have led to the design of a compact two-man console for MCCS which contains the majority of the electronics directly associated with this system. MCCS is one of the WSA 420/CAAIS 450 family of modular combat systems (**3505.281**).

The main functions of the system are accurate navigation of the ship, including assistance in maintaining the ship on the desired track, a comprehensive and flexible presentation of the operational picture, computer control of the mine-hunting sonar and extensive data recording facilities. Of these functions, accurate navigation is the most important, and here the emphasis is on processing the inputs from navigational aids rather than use of radar fixing, where greater errors can be expected. The Ferranti system can interface with a number of different navaids with performance parameters which are likely to suit most operational scenarios.

At the heart of the system is an FM1600E computer which is more powerful and of more modern architecture than the FM1600B used in the RN's MCM vessels. This computer and the majority of the associated peripheral control units are housed in the base of a console, which includes a labelled plan display and keyboard and tracker ball. An improvement to the operator interface has been provided by the inclusion of the 'prompt' system first introduced in CAAIS 450 (**3505.281**), whereby the computer leads the operator through his manual injection sequences by showing him the available options on the lower half of his television tote display. The minehunting control officer (MHCO) is presented with a tactical plot comprising computer-generated symbols and, by utilising the wide choice of display range scales available, he can have access to the entire operational picture without moving from his chair. The two-man console also enables the commanding officer to have full access to the operational picture. In the same way as for navaids, the MCCS can accommodate a wide range of mine-hunting sonars. By means of a two-way interface with these sonars, the system brings the control of searches to the MHCO, thus leaving the operators to concentrate all their effort on detection of mine-like objects, while detections are cut in to the computer which then organises their display to the MHCO without any loss of accuracy. Furthermore, assistance is given in relocating objects already held in the computer store by directing the sonar to the appropriate bearing and range.

A large amount of current operational data is stored and is immediately available to the MHCO. This data includes sea bottom type sonar information, seabed obstructions and environmental data; as well as results of previous minehunting/sweeping activity in the area of interest. A summary of the tasks carried out and the results achieved is recorded on magnetic tape, which can then be passed to a relieving vessel and fed into its computer, enabling it to continue the work without unnecessary delay and wasted effort. For longer-term records, the same data is output to a line printer as a permanent hard copy and an X/Y plotter can also be incorporated.

Another important feature of the design of MCCS is the use throughout of materials which have a reduced magnetic signature. Utilisation of proven hardware modules that are already in naval service and built into the operator's console make installation on board much easier and reduces the setting-to-work time considerably.

CONTRACTOR

Ferranti Computer Systems Ltd, Western Road, Bracknell, Berkshire RG12 1RA, England.

1496.281
WSA-4 FIRE CONTROL SYSTEM

Weapon System Automation Mk 4 (WSA-4) is the digital weapon control system designed for Type 21 ('Amazon' class) RN frigates. In these ships WSA-4 interfaces with the computer-assisted action information system (CAAIS **1046.261** in 1980-81 and earlier editions) and, like that system, is based on the Ferranti FM1600B digital computer. The system has been designed to provide accurate fire control in anti-aircraft, surface, and naval support gunfire modes, to react rapidly to a threat, and be operated by a minimal crew. Weapon direction and target designation is usually performed at a CAAIS display position. Target data are passed to WSA-4 and the relevant tracker radars and visual sights are automatically controlled to acquire the target. The WSA-4 may operate independently from CAAIS however, using the tracker radars in surveillance mode, or accepting target indication from the visual sights. A key operational feature is the use of electronic data displays (EDDs) and light-pens in a 'conversational' mode. The EDDs provide the operator with information and sets of valid choices from which he selects to control the system. This simplifies control and reduces the training requirement.

Weapons controlled are the Seacat missile and a 4·5-inch (114 mm) gun. Sensors controlled are two RTN-10X tracker radars (**1368.253**), which are equipped with closed circuit TV, and two visual sights – a lookout and aiming sight and a pedestal sight. System capability is for two simultaneous air engagements, or one air and two surface engagements, and there is provision for emergency control of weapons.

STATUS

In service.

Ferranti Computer Systems Ltd, Western Road, Bracknell, Berkshire RG12 1RA, England.

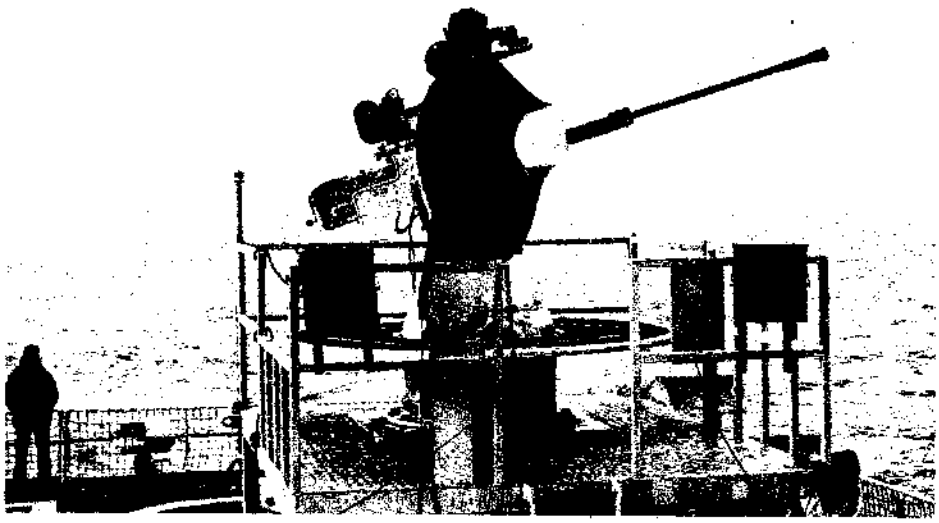
4273.281
F100-L FIRE CONTROL PREDICTOR

For naval optical fire directors (OFD) and on-mount directed gun systems, Ferranti Computer Systems are offering a gun predictor based on the F100-L microprocessor. The predictor calculates the required aim-off angles that are applied to correct the gun aimer or the operator's sight line, enabling the gun to be accurately repointed.

The principal sensors are binocular or IR sights and laser rangefinder, and the system can accept additional inputs for target indication. Alternatively, manual range input is available for surface mode, and fixed fly-through range for an air engagement.

In action the operator tracks the target while the computer monitors tracking rates and calculates the necessary aim-off angles.

STATUS



An order for the predictor from the Marinha do Brasil has been received for the supply and fitting of the Laurence, Scott (Defence Systems) (LSDS) Ltd Mk 5 OFD, in new construction Brazilian corvettes for emergency fire control of Vickers Mk 8 4·5-inch and Bofors 40 L70 40 mm guns. These predictors underwent joint integration trials prior to delivery in July 1985.

Land and sea trials of the LSDS Ltd LS30R (Rarden) mounting, incorporating a prototype predictor, were carried out by the Royal Navy in 1981, following which an initial order for the LS30(B) mounting using an Oerlikon KCB cannon was placed with LSDS Ltd.

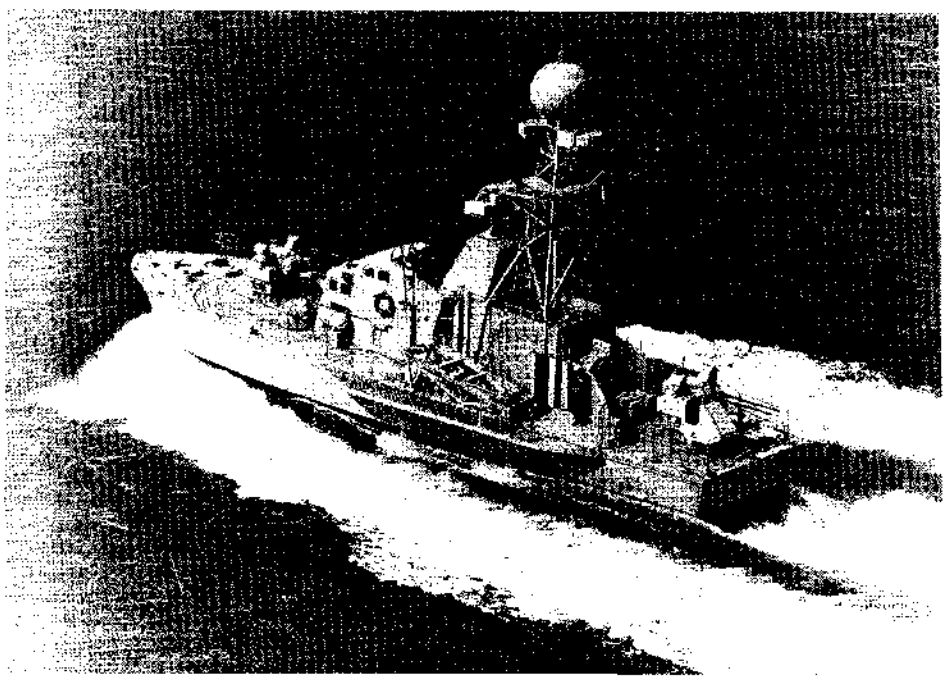
1828.261
MARCONI/BAe LIGHTWEIGHT GUN FIRE CONTROL SYSTEM (SAPPHIRE)

The Bracknell Division of British Aerospace Dynamics Group (formerly Sperry Gyroscope) and Marconi Radar Systems have collaborated to create a cost effective lightweight gun fire control system. Designed for any size of warship from fast patrol boats upwards, the system is capable of maintaining rapid and accurate control over small and medium calibre guns against air, surface, and shore targets. The system is fully automatic, thus keeping manning requirements to a minimum: only one man, in an essentially supervisory role, is required to operate the system.

The main components of the system are:

(1) the Marconi 800 series autonomous tracking radar, ST802 (**1508.253**)
(2) the BAe Digital Weapon Controller (DWC 100) consisting of the 1412 computer (**1443.063** in 1973-74 and earlier editions), associated interfaces and power unit
(3) the control console, incorporating the display and control units for one man to supervise the radar, predictor, and gun.

The total package is designed to be compact and lightweight, thus being suitable for installation in FPBs, corvettes, frigates etc. The predictor uses a dedicated computer leading to operational simplicity and autonomous operation. The radar uses monopulse processing giving a significant advantage in that it is free from fade noise when compared with a conical scan radar. The system will control servo-operated guns with calibres from 20 mm upwards.



In order to make full use of the possible roles of naval guns the system offers three main modes of operation:

(1) anti-aircraft (AA) for defence against high- and low-level air targets:
  (i) AA direct is the normal mode against fast moving air targets. The predictor automatically points the gun and indicates when target is within firing range
  (ii) AA free generation (coasting) mode is entered automatically if the target fades, and the predictor provides extrapolated target flight path data from last known target position and velocity data
(2) surface (SU) for use against surface vessels moving at speeds up to 60 knots:
  (i) SU direct is the normal mode. Splash spotting corrections may be applied for range and bearing using radar data. The predictor provides extrapolated target position data if the target is obscured. Where appropriate, 'throw off' facilities are provided for practice against surface targets
  (ii) SU blind. In this mode target bearing and range are input from the ship's AIO or radar display
(3) naval gunfire support (NGS) including:
  (i) direct bombardment. This mode of operation is used for bombardment of a shore target visible from the ship
  (ii) indirect bombardment. In this mode of operation the gun is trained on to a shore target using spotting corrections from a shore observer
  (iii) blind bombardment. This is used to bombard a point defined by present range, bearing and height from map co-ordinates
  (iv) 'radar assisted' bombardment. This is used when a discrete radar echo ashore can be tracked. Offsets are then added using map co-ordinates to take account of the separation between the radar echo and the required target.

In SU and NGS modes, fuze computation is provided for use with star-shell and window. The system can also be used to give surveillance information by means of horizon search or sector scan.

OPERATION

The system is intended to be integrated with a ship's surveillance and action information organisation and it is this that normally provides initial detection of an aircraft. The Sapphire search facility, however, gives the FCS autonomous operation against the low-level threat. In this, the pencil beam is programmed to search and detect low-flying aircraft, anti-ship missiles and surface craft. Because of the narrow concentrated beam shape and the digital MTI processing, detection is enhanced.

An 'October' class FPB of the Egyptian Navy on trials in the Solent after major modernisation and re-equipment by Vosper Thornycroft. The work apparently entailed fitting of a Marconi/Sperry Sapphire FCS and Marconi ST802 tracker and S810 search radars can be seen

True horizon search mode gives detection of an anti-ship missile with a target area of 0·1 m² at 12 to 15 km. Automatic or manual target acquisition may be selected to provide detection of 4 m² strike aircraft at 25 km. Detection of surface targets is horizon limited.

Sapphire has the fast reaction time necessary to deal with the low-level threat, whether aircraft or sea-skimming missiles, typically seven seconds, including time to slew to the target bearing.

The television control mode may be used to switch to a second attacker in a stream attack. In this case during the closing stages of an engagement the pointing of the director is manually moved to the second target, after which control is switched back from TV to radar. An electro-optical fire detector can provide an alternative fire channel or can be used in conditions of radar silence, and a laser rangefinder may also be incorporated.

Threat assessment is carried out either on central AIO or on the radar display when in autonomous mode. Digital MTI largely eliminates sea and land clutter and enables low-level targets to be seen through the clutter. Auto acquisition circuitry enables the FCS to slew, search in elevation and acquire the target without manual intervention. Target designation is from either a target vector given to the FCS by ship's surveillance radar AIO, or from the radar display in autonomous mode. Target tracking is carried out normally by radar, either actively or in the case of a jammer, in passive mode. Switching between the two is automatic. In conditions of radar silence the operator may use the television to track the target which again is accomplished automatically after manual acquisition. If an optical sight forms part of the system, tracking may be carried out from this also.

Against very low-level targets, for example less than 1°, the tracker automatically enters the low angle television mode to overcome the effects of multi-path signals. If the aircraft rises above a line of sight of 1·5°, the low angle mode is automatically terminated and full radar tracking is resumed.

A very wide range of ECCM facilities are built into the radar tracker to counter enemy use of jamming techniques. The equipment uses monopulse angle sensing, has continuously variable frequency control and has MTI which enables the radar to see through chaff. Automatic passive/active switching, automatic TV tracking and many other facilities deal with virtually every jamming situation.

CHARACTERISTICS

Radar

Radar beamwidth: 2·4°

Frequency: Band 8·6 – 9·5 GHz

Peak power: 200 kW (typical)

Mean power: 160 W (typical) Non-MTI

Pulse length: 0·3 μs

PRF: Non-MTI 3000 Hz; MTI 4400 Hz

Receiver noise figure: 10 dB

MTI: Coherent on receive improvement factor: better than 25 dB

Computer

Type: 1412A

Capacity: 16 K words

Storage: Semi-conductor, fixed program store

Gun order calculation: 64 times/s

Output refresh rate: 512 times/s

STATUS

First orders were taken in 1976, among them fittings in a number of Egyptian fast patrol boats.

SPERRY SEA ARCHER FCS

The Sperry Sea Archer series of naval fire control systems now embraces several versions, ranging from the purely optical Sea Archer 1 to models with multiple sensor capability and correspondingly greater operational facilities. The various versions which have been identified so far are described in the following paragraphs.

Sea Archer 1

The Sea Archer 1 optical fire control system (OFCS) has been designed to provide the advantages of computer-controlled gunnery within a simple system. The predictor itself is similar to that used in the Marconi/Sperry Sapphire system (**1828.261**), a full blind fire radar system. Sea Archer controls servo-operated guns with calibres from 30 mm upwards against aircraft, missiles and surface vessels. While designed as the prime gun controller for FPBs, the system is equally suitable as a secondary weapon controller for larger ships.

The system is comprised of two basic modules, an optical fire director (OFD) incorporating tracking sensors including a range-only-radar or laser rangefinder, and a gun control console containing a digital weapon controller, operator control panels and system communications. In the simplest configuration, an aimer uses binoculars fitted to a line-of-sight, stabilised director to acquire and track the target. To assist in target acquisition the system can accept information derived from the vessel's surveillance radar to slew the OFD on to the target bearing. Optronic sensors such as a television tracking camera may be fitted to give below-decks operation. A TV auto-tracking unit is available if required.

Sea Archer 1 weapon control console

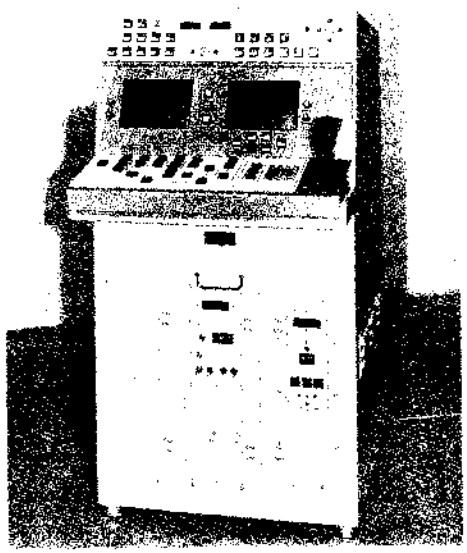
Information regarding the target range, training and elevation is automatically transmitted back to the weapon control console. The computer, utilising ballistic and meteorological data already entered into the system, then calculates gun aiming orders. The gun is controlled from the control console. To reduce reaction time to a minimum, gun slew occurs as soon as the target is acquired and offset adjustments are then made when a valid prediction solution is computed. Typically this process takes two seconds. The gun is fired by means of the console foot push when a valid prediction is achieved and the future range display indicates that the target is within effective gun range.

The system uses a Laurence, Scott line-of-sight, stabilised director operated by an aimer in a standing position. The director provides target training and elevation information in a synchro format to the control console. Provisions are made for voice and signal communication from the director to the control console. The system can accept target bearing from action information systems and the director will slew into line with this data, thus assisting the aimer to acquire the target. To provide accurate range data, the customer is offered the choice of two types of rangefinder. These are a laser rangefinder or a range-only-radar. The laser interrogation unit or the radar transmitter/receiver are mounted on the OFD. They may be energised by the director aimer at the OFD or by the console operator seated at the weapon control console. Range data from the rangefinder is accepted and processed by a Sperry digital weapon controller.

The weapon control console contains the operator's control panel and the digital weapon controller. Its two main roles are to provide a manual interface to the digital weapon controller, and to calculate and control system functions. The control panel provides the manual interface to the system and enables the operator to select the desired engagement mode and to enter ballistic and environmental data. The panel has a numeric display to enable the operator to examine required parameters and push-buttons to provide the necessary operational control signals. The digital weapon controller incorporates the necessary electronic interfaces and the latest Sperry 1412 series mini-computer. The computation techniques and electronic interfaces have been successfully proven with 30 mm, 40 mm, 76 mm and Vickers 4·5-inch (114 mm) Mk 8 guns.

The system is capable of three modes of gun fire control as follows:

(1) AA



In this mode the system is designed to achieve minimum reaction time against fast moving air targets. The director aimer acquires the target and activates the rangefinder. Target data are fed to the control console where the digital weapon controller calculates gun aiming signals. The gun slews onto line with the computed data and when the target is within gun range the digital weapon controller indicates that the system is ready to engage the target. Firing can be achieved from the director or the control console.

(2) Surface

In the surface mode the optical director is aimed at the target and the rangefinder is activated to establish the target range. Gun aiming orders are then computed from the target data transmitted by the director. Splash spotting corrections, observed by the director aimer, are applied via the control console.

(3) Naval Gunfire Support

In this mode the gun is used to bombard shore targets. The target co-ordinates are inserted manually at the control console and gun orders calculated and corrected for ship movement by dead reckoning. Spotting corrections, observed by a shore or ship based observer, are applied at the control console.

Sea Archer 2 weapon control console

Sea Archer 1A (GSA7)

This version is an enhancement of Sea Archer 1 which provides complete integration of a TV sub-system with below-decks control by joystick giving an improved surveillance capability and the option of manned or unmanned director on deck. It also has provision for controlling two different types of gun-mounting (alternately). The ballistics for both gun types can be carried in the 1412A computer. Infra-red sensors may also be integrated in the Sea Archer 1A system.

Sea Archer 2

The blind-fire version of the system is designated Sea Archer 2. In this model the manned optical director mounted on deck is replaced by an unmanned weapon control director, thereby enabling the control of weapons to be performed entirely from below deck. The weapon control director is a mounting on which a

variety of sensors may be fitted: laser rangefinder, TV tracker, infra-red tracker, and M-band precision radar tracker. The director may be automatically positioned using target designation data from other ship sources.

The narrow-beam M-band (millimetric wavelength) monopulse radar tracker provides good angle and range resolution for precision low-angle tracking because specular multi-path reflections and sea clutter returns are minimised. Also M-band operation reduces the effects of fog, haze and smoke. An air-cooled transceiver houses a 1·06 micron high repetition-rate laser for rangefinding. The TV tracker employs charge-coupled device sensors, and this equipment is entirely solid-state. It processes angle data based on centroid, edge, or correlation tracking. The IR tracker is thermo-electrically cooled, and is an infra-red imaging and tracking sensor operating in the 3·4 to 4·2 micron spectral region. It processes angle data based on centroid edge, or correlation tracking. All four of these sensors can be mounted on the weapon control director tracking head, which can be trained through 360° and has an elevation angle coverage of -20 to +85°. Installation weight is about 300 kg.

A one-man weapon control console is provided below deck for operation of the ship's weapon system, and computer assistance to the operator is provided at all times for search, acquisition, and tracking phases. A full range of engagement modes is available, as outlined for the Sapphire FCS (above). Sea Archer 2 is also marketed in the USA by the American Sperry Corporation (**4270.281**).

Sea Archer 30 (GSA8)

In early 1985 a new design, designated Sea Archer 30 (GSA8/GPEOD), was announced as part of a £20 million contract for systems to be fitted in new RN Type 22 and 23 frigates. The Gun System Automation 8/General Purpose Electro-Optical Director has a mast-mounted E-O sight that includes a TV camera, thermal imager and laser rangefinder, and the complete system provides a digital autonomous fire control capability for a single operator to manage and direct the ship's 4·5-inch gun.

STATUS

The first contract to be announced for the Sperry Sea Archer 1 naval fire control system was for eight systems to be installed in vessels of the Sultan of Oman's Navy. Three types of ship are involved, all of Brook Marine construction. Three of the vessels are equipped with Exocet anti-ship missiles (**1156.221**), probably the 37·5 m class *Al Bushra*, *Al Mansur* and *Al Nejah*, and the Sea Archer systems will control these weapons, and either OTO Melara OTO 76 Compact or Breda Meccanica 40 mm gun mountings. In the case of the Exocet fitted ships, Sperry provides target designation systems consisting of a surveillance radar feeding data to a display used for target detection, threat assessment and target designation to the Exocet system and to the Sea Archer. One of these Sea Archer installations is for a logistic command and landing craft built by Brook Marine.

Other contracts have been placed by countries in the Far East and Sea Archer 1A (GSA7) has been ordered by the RN for their new Hong Kong patrol vessels.

Sperry Gyroscope is now the Bracknell Division of British Aerospace Dynamics Group.

In 1985 a Royal Navy contract for a number of Sea Archer (GSA8/GPEOD) systems for fitting in Type 22 and 23 frigates was announced. This system will be supplied for export as the Sea Archer 30 by BAeDG.

1928.281

TARGET ACQUISITION SYSTEM (TAS)

The Improved Point Defense Surface Missile System (IPDSMS) is a surface-to-air system that will provide self-defence for a variety of ships against the anti-ship missile threat through the 1990s. It can react automatically in seconds to threats in any type of weather. It is a highly reliable system that can be maintained through the use of on-line monitoring, built-in tests and equipment, daily system operability tests, and computer-aided fault isolation. It also has been designed to withstand the adverse effects of physical environment and electro-magnetic interference.

IPDSMS is formed by the integration of a target acquisition system (TAS) and a fire control and launcher system, the NATO Sea Sparrow Missile System (NSSMS). These two systems are under two separate projects, with TAS under contract from the USN with Hughes Aircraft Company in Fullerton, California. Installation of TAS in DD-963 'Spruance' class destroyers and in high-value auxiliary ships began in early 1980.

Although developed as a sub-system to IPDSMS, TAS is designed to designate targets to other weapon systems, such as guns. It is an automatic system composed of a radar, an identification friend or foe (IFF) system, an AN/UYA-4 console, and an AN/UYK-20 digital computer. The system is designed so that the functions of threat detection, track, IFF, evaluation, and designation can be carried out automatically with the operator only monitoring system operation.

As originally conceived, TAS comprised a family of five versions, of varying complexity, and these were designated from Mk 20 to Mk 24 inclusive. The differences between the various TAS configurations were described under this entry number (**1928.281**) in earlier editions of *Jane's Weapon Systems*. The model currently being produced is that known as Mk 23, this being the Radar Automatic version, and as such represents the most sophisticated model except that the infra-red search system has been deleted.

The lightweight TAS Mk 23 antenna sits on a roll-stabilised pedestal and rotates at a rapid two-second scan rate. It searches in two regions: in excess of 20 nautical miles for point defence target designation; and more than 90 miles for surveillance and air control. A third, mixed, mode is a combination of normal and long-range modes.

TAS provides optimum radar performance against close-in and distant targets in detecting moving targets in clutter, and discriminating targets in jamming environments.

NSSMS automatically accepts target designation from TAS and assigns a tracking illuminator radar to the target. The illuminator slews to the location designated by TAS, acquires the target, and locks on. The computer assesses engageability, assigns the launcher, and transmits the firing order to one or more of the missiles. When more than one target is designated, a second tracking illuminator is assigned to the second target and the procedure repeated. Additional targets may be sequentially engaged as each tracking illuminator becomes available.

The firing officer's console contains the controls and indicators for assignment of the launcher system, missile frequency assignment, missile run-up, firing orders, and status monitoring. The controls and indicators provide him with the means to override the automatic operation throughout the engagement sequence.

The main IPDSMS configuration, as on the DD-963s, will consist of a TAS and an NSSMS fire control radar set. However, IPDSMS may be installed in larger or high-value ships with several NSSMSs interfaced with one TAS.

STATUS

The Mk 23 has completed all operational tests and is now in its sixth year of production. In early 1985 the USS *Ranger* became the first aircraft carrier outfitted with the TAS.

CONTRACTOR

Hughes Aircraft Company, Fullerton, California 92634, USA.

USS John Young *(DD-973) is one of the 'Spruance' class destroyers fitted with TAS. The antenna group is located just behind the aft mast*

3748.281

R-76 FIRE CONTROL SYSTEM

The R-76 fire control system is a naval director system which operates on both surveillance and tracking modes. It is based on a very low weight multi-mode radar which can be mounted high on a ship's mast, thereby assisting overall performance, particularly early target detection. Gyro-stabilisation is provided, and dual monopulse tracking permits simultaneous missile and target tracking, displayed on the dual A-scope. There is also provision for instantaneous action data entry for weapon system control.

In addition to the radar, there is an alternative director configuration having a TV contrast tracker unit mounted on the radar sensor platform for low-level target tracking and operation in the face of countermeasures.

Operational functions performed by the R-76 include search for air and surface targets, automatic detection, precision tracking, and direction of weapons which may include guns and missiles. The radar is capable of operating in several modes, among them 'track on jam'; simultaneous target tracking, illumination and intercept of air targets; surface target tracking and illumination; detection of enemy missile launch; continuous surface search. In addition to control of fire against surface and air targets, the system provides direct and indirect naval gun fire support and illumination fire. All data processing is accomplished by distributed dedicated micro-computers.

The below-deck operator console has two A-scope displays for simultaneous tracking of two targets, with independent control handles for each and instantaneous action entry for weapon system control. Using this system it is possible to track one

target on one display and control a missile on the other. There is also a tactical console with a normal PPI display and operator controls for management of the overall system.

STATUS

The HR-76 made its first appearance as a major element of the H-930 combat control system marketed by Honeywell (**3749.281** in 1982-83 and earlier editions), and among the foreign sales of this equipment, South Korea is thought to have fitted the H-930 under the designation Mk 93 fire control system. In September 1979, the manufacturers of the HR-76 announced that this system is to be available on its own with the designation R-76, for fitting aboard all classes of vessel from patrol boat size craft upward, and also for shore coastal defence applications. In late 1982 it was disclosed that the R-76 system was to be installed in a Royal New Zealand Navy 'Leander' class frigate. The R-76C5 version of the system has been selected to modernise this class of RNZN ships.

CONTRACTOR

RCA, Government Systems Division, Missile and Surface Radar, Moorestown, New Jersey 08057, USA.

2633.281

GUN FIRE CONTROL SYSTEM Mk 56

Gun fire control system (GFCS) Mk 56 is a shipboard, intermediate range anti-aircraft gunfire control system designed for use against subsonic aircraft and surface targets.

Its primary functions are first to track aircraft targets and secondly to compute train, elevation, parallax, and fuze orders for shipboard guns. The system can also be used to control gunfire against surface targets.

To accomplish its purpose, the system uses a radar sub-system for automatic tracking of either visible or obscured targets, an optical sub-system for tracking visible targets, an electromechanical computer sub-system for computing gun orders, and servo-mechanisms for operating the director power drives.

GFCS Mk 56 may be used against different types of target under different operational modes. The computing sub-system is designed for optimum performance against the types of target most dangerous to own ship, which are incoming high-speed torpedo planes, dive bombers, and medium altitude bombers. Slightly less effectively, the system can also be used against all types of surface vessels.

SYSTEM FUNCTION

The Mk 35 I/J-band radar is of conventional auto-follow design, the elevation and traverse error signals derived from the radar receiver when the target moves away from the radar line-of-sight being used to servo the radar antenna back on target. Inserted in the servo loop are the tracking control circuits which accept the error signal inputs and process them to produce, on the one hand, tracking signals for the line-of-sight gyroscope and, on the other hand, elevation and traverse rate outputs to the fire control computer.

The tracking signals are passed to a gyro unit which is processed to point at the target. The antenna power drive, in driving the antenna to line up with the gyro, automatically compensates for ship's motion due to roll and pitch. The gyro and power drive units form part of the gun director, and from this sub-system are taken two sets of outputs to the computer, one set defining the target line of sight relative to the ship and the other set defining it relative to the gyro platform.

Other inputs to the computer are own ship's speed and course taken from the log and gyro compass and target range from the radar. In addition values are set in for gun dead time and initial velocity, true wind speed and direction. From this information and the fixed displacements between the guns and the radar antenna the computer generates train elevation and fuze orders for the guns.

DEVELOPMENT

Development of the system was initiated by the USN at Massachusetts Institute of Technology in 1942 with industrial support furnished by the General Electric Company and the system went into service in the USA in 1947. More than 700 systems were delivered, and although production ceased in 1955 the system is still widely deployed, particularly in US forces but also in 11 other countries.

STATUS

This classic GFCS is still maintained as operational equipment aboard many USN vessels. Other navies known to have Mk 56 are those of Argentina, Brazil, Chile, Colombia, Germany (Federal Republic), Greece, Japan, Peru, Spain, Taiwan, and Turkey.

Mk 56 fire control director on USS Edward McDonnell (Stefan Terzibaschitsch)

2632.281

GUN AND GUIDED MISSILE DIRECTOR Mk 73

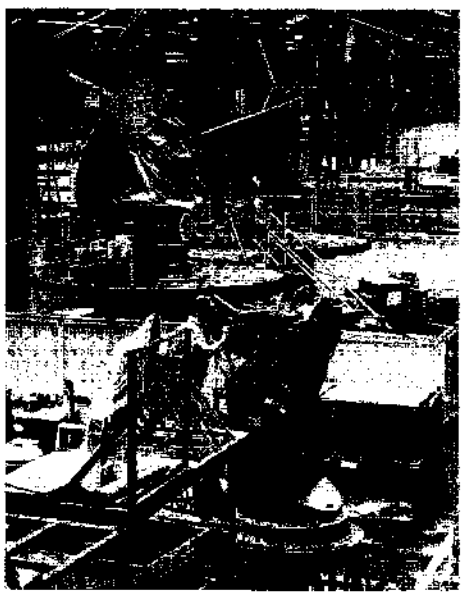
This equipment is a major component of the gun and guided missile fire control system Mk 74, one application of which is to the Tartar surface-to-air guided weapon system, and in later models, the Standard naval air defence missile.

Gun and guided missile director Mk 73 is an unmanned, direct-drive motor-driven two-axis unit. It serves as a mount for the antenna of another major component of the system - radar set AN/SPG-51. Three gyroscopes with on-mount electronics provide rate stabilisation. It also provides a platform for the low light-level TV camera Mk 15. The radar line of sight can be rotated continuously in train and can be elevated from -30 to +83° relative to the deck plane. The Mk 73 director mount motors are controlled by the Mk 26 controller developed by General Electric as a more modern, solid-state power drive system, of lighter weight and more compact dimensions than earlier amplidyne systems. The Mk 26 controller contains the controls, servo electronics, and power conversion amplifiers to power the direct-drive motors in the Mk 73 director's elevation and train axes.

DEVELOPMENT

In common with other Tartar sub-systems, development of the director began in 1956. The first prototype was completed in 1958 and the equipment went into service in 1960. Currently in production, 150 systems have been delivered to date for use in USN and foreign ships. While the basic Mk 73 configuration has remained virtually unchanged, the design has been in a continual state of 'Mod' refinement so that the latest servo-mechanical techniques could be incorporated. The Mod 2 version has been produced since 1969. The Mod 1, an earlier producton version, incorporated amplidyne motor-generators and non-solid-state electronics. The even older Mod 0 is still in use after more than 20 years, and a Mod 3 version never progressed beyond the design stage. The Mod 4 became the basis for the Mk 80 director (**1921.281** in 1980-81 and earlier editions) for the Aegis system. The first Mod 5 (now designated Mod 6), a complete factory conversion of Mod 1 units that have been operational for some years, has been accepted by the USN. User nations include: Australia, France, Germany (Federal Republic), Italy, Japan, Netherlands, Spain, and USA.

New Mk 73 Mod 6 director prior to delivery for USN DDG-15 modernisation programme



STATUS
Three USN ships of the DDG-15 ('Berkeley') class were the subject of a modernisation programme which entailed refurbishment and modernisation of the Mk 73 gun and guided missile directors. General Electric was awarded a major contract for this work in late 1979 and the first hardware for shore tests was delivered in September 1979, followed by a second refurbished Mk 73 in December of the same year. The modernised equipment is designated Mk 73 Mod 6. General Electric is also under contract to produce two Mk 73 directors and associated hardware for a Japanese guided missile destroyer and to supply Mk 73 kits and parts for the Federal Republic of Germany. Under 1984 funding, three Australian ships are being modernised with two Mod 6 directors each.

Since the late 1950s General Electric has supplied more than 150 Mk 73 directors.
CONTRACTOR
General Electric Company, Ordnance Systems Division, 100 Plastics Avenue, Pittsfield, Massachusetts 01201, USA.

4014.281
Mk 82 (AEGIS) GUN & MISSILE DIRECTOR
The director Mk 82 and the associated director control Mk 200 are components of the Director Group Mk 81 used aboard new Aegis-fitted ships of the USN. The Mk 82 evolved from the Mk 73 family of directors (**2632.281**) employed for Tartar (**6006.231**) and Standard (**1122.231**) naval surface-to-air missile guidance and control. It incorporates the best features of the earlier system but with enhanced search and slew capabilities and a considerable reduction in weight. Other improvements are a new DC torquer gyro and the elimination of hydraulic brakes. These and other improvements are stated to bring a reduction of about 50 per cent in peak power requirement, a calculated MTBF of 2000 hours, and a reduction in weight from approximately 3450 kg to 1217 kg. Improved search and slew capabilities were required to match the SM-2 version of Standard employed in the Aegis weapon system, the quoted characteristics being a horizon search rate of 72°/s, with a rate accuracy of 0·5 mrad/s and an acceleration of 2·5 rad/s².

The Mk 82 director carries the AS-3156/SPG antenna assembly for the Raytheon Mk 99 Mod 1 FCS missile guidance radar (**1247.253**) on an elevation-over-train pedestal and provides stabilisation for the radar line-of-sight. The director provides search pattern and tracking by responding to rate commands from the fire control system. There are no limitations in train or elevation and the system provides train and elevation data and radar line-of-sight rates in traverse, elevation, and cross-traverse for the fire control system computer.

Compared with the Mk 73 director, the Mk 82 has a much lower profile, in addition to being much lighter.
DEVELOPMENT
The Mk 82 director was designed and developed by General Electric Company, Ordnance Systems Division for the USN Aegis fleet air defence system (**2507.231**). It is developed from the Mk 73 director, also produced by General Electric, and some of the Mk 82 modifications and improvements have been incorporated in the Mod 2 and Mod 5 versions of the earlier system.
STATUS
In production for the USN Aegis air defence system, under contract to Raytheon Equipment Division, who produce the Mk 99 Mod 1 FCS guidance radar for Aegis under contract to RCA. General Electric is building Aegis directors for the USS *Ticonderoga* (CG-47) class of ships. Ten ships (40 directors) are included under present funding. Twelve more directors are included in the 1984 budget (for three ships, CG 57/58/59, with four directors each). At least 24 ships of this class are planned for construction in the next five years.
CONTRACTOR
General Electric Company, Ordnance Systems Division, 100 Plastics Avenue, Pittsfield, Massachusetts 01201, USA.

Aegis Mk 82 directors in final assembly and testing. Mk 200 control is partially visible (right centre) in system test area

1241.281
GUN FIRE CONTROL SYSTEM Mk 86
The Mk 86 GFCS was designed as the major fire control system for the gun batteries being installed in the five most recent classes of USN ships: the new CG-47 guided missile cruiser class (with Aegis combat suite); the nuclear powered cruisers (CGN-36 and -38), which have both the new Mk 45 5-inch (127 mm)/54-calibre lightweight automatic gun mount and Standard missiles; the DD-963 'Spruance' class destroyers (also with the Mk 45 and Sea Sparrow missiles); the DDG-993 'Kidd' class guided missile destroyer; and the amphibious assault ships (LHA). In addition, the Mk 86 is being used in the DDG-19 upgrading programme. The Mk 86 also provides the third Standard missile tracking/illumination channel on the CGN-38, DDG-993 and DDG-19 (upgrade) classes. The main elements of the system are a high data-rate I-band surface search radar (AN/SPQ-9), an I-band air target tracking and horizon search radar (AN/SPG-60), an optical sensor system, a computing system based on the Mk 152 and AN/UYK-7 machine, and the operator display consoles. Surface, shore, and air targets can be engaged, and the computer is stated to be capable of programming to track automatically up to 120 targets using a track-while-scan routine.

The Mod 8 system selected for the DDG-19 class is essentially the same as that used aboard CGN-38 cruisers except for a redesigned operator's console. This incorporates improved ergonomics and provisions for advanced electro-optical sensor systems.

Expanded operational capability is provided by the integration of the USN's new 5-inch (127 mm) guided projectile and the Seafire (infra-red, laser, TV) electro-optical system (**3727.281**).
OPERATION
The Mk 86 system handles multiple radar sensor inputs, with each radar operating independently and linked via the computer. The SPQ-9 provides surface search as well as low-level air coverage for defence against low-flying threats and for helicopter tracking. The SPG-60 is an automatic scan-to-acquire and tracking radar that also operates in a horizon search mode. The optical sensor system can range from a simple CCTV camera chain to a comprehensive electro-optical sensor system such as Seafire. The complete Mk 86 can be interfaced with other ship's systems (NTDS etc) and can receive data from other sensors or from any one of four target designation transmitters for target acquisition.

The entire Mk 86 operation is controlled and monitored by a control officer and weapon controllers. The control officer's console displays all search radar returns on a PPI presentation. This is used for threat evaluation and selection of targets to be automatically tracked. When a target track has been established, the control officer assigns a specific target and weapon, or combination of weapons, to a weapon control console.

A B-scan and TV display are provided on the weapon control console, and laser and IR displays may be added if the appropriate sensors are fitted. The B-scan gives the weapon controller an expanded radar presentation of his assigned target area, and by examining the display gate around the target on the B-scan he can assess the quality of the track. During an air engagement, the B-scan monitor displays an SPG-60 train and elevation error, enabling the weapon controller to assess track quality. The TV monitor can be used for splash spotting and other functions. Each weapon control console provides a digital readout of target parameters such as bearing, range, course, speed and elevation, and a keyboard is provided for inserting ballistic, target and other data into the computer.

Several operational modes are available:
Radar Surface Fire
Upon target acquisition, a track-while-scan routine is used to track simultaneously multiple designated targets. Smoothed radar data, with appropriate ballistics data, are used to compute weapon orders.
Air Action
The computer automatically and adaptively controls search patterns to acquire and track air targets. Target data, plus a TV view along the SPG-60 boresight axis, are displayed on a weapon control console. The engagement with SM-1 missiles by ships so fitted is facilitated by virtue of continuous wave illumination injection to the SPG-60 tracking radar.

An air pre-action calibration of gun weapons can be initiated from the weapon control consoles.
Anti-Ship Missile Defence (ASMD)
The track-while-scan acquisition gate is expanded to a range sufficient for threat detection. (Full 360° coverage, or over a number of segments to provide surveillance of selected areas, can be chosen.) All targets passing through the acquisition gate are then automatically detected by the system. After target detection, the folowing functions are performed automatically:
(1) threat evaluation
(2) weapon assignment
(3) assignment of targets to tracking channels
(4) slewing of AA director and a weapon to the target
(5) scan of AA director and 3-D track of targets
(6) initiation of firing; transfer of fire to second target.
Visual Surface Fire
A future facility (Seafire **3727.281**) will allow the weapon controller to track the target visually with the TV system and fire the laser to obtain range data. Target range and angle data are entered into the system automatically, and ballistics are computed.
Indirect Shore Bombardment
For shore fire support missions or engagement of targets that are not within view of either radar or optical sensors, target and own-ship co-ordinates are entered at a weapon control console. The system automatically updates these inputs from the ship's compass and log, or by means of other navigational aids. Spotting data is entered at the keyboard. Automatic compensation for orientation of the target line by an on-shore observer is provided.
DEVELOPMENT
Initial in-house studies were started by Lockheed in 1961, and the first prototype was completed in 1966.
STATUS
Deliveries by February 1985 totalled 68 systems. The Mk 86 is used aboard the USN's new fleet of amphibious assault ships (LHA), 'Spruance' class destroyers (DD-963), the 'Kidd' class guided missile destroyers (DDG-993), and guided missile cruisers, CGN-36 and -38 classes. The Mk 86 is also installed in the DDG-15 modernisation programme, and is fitted aboard the new CG-47 class Aegis ships.

The Mk 86 constitutes an important element in the modernisation of three of the USN's DDG-15 class of destroyers; three similar ships for the West German Navy are also being fitted.

AN/USQ-81(V) COMMAND CONTROL SYSTEM

The AN/USQ-81(V) is a computer driven real-time tactical data display system which receives, processes, correlates, displays and prepares surveillance reports for transmission to similarly equipped units. Display systems are installed in submarines, surface ships, aircraft and command centres ashore and are designed for the requirements of each site.

The AN/USQ-81(V) collects and processes surveillance data from a variety of sensors and sources and converts this into near real-time information which is continuously updated. The information is designed to give the overall commander the maximum amount of information on the tactical situation on land, sea and air, as well as up-to-date data on the location and operational disposition of both his own forces and those that he is opposing.

The system operates in interactive real-time mode with an established data base that can be searched both forward and back in time. Manual data control is achieved by programme function and alpha-numeric keyboards in the operator's console. The operator can select a variety of reports, graphics and calculations to be displayed for briefing, editing, comparing documentation and transmitting. The information can be displayed in great detail or it can be filtered to display the specific data a commander wants to see.

A typical AN/USQ-81(V) configuration includes a central processing unit, an operator interface terminal containing the keyboards and display, the computer control panel, graphic display unit, fixed head memory disc, tape unit, paper-tape reader and a hard-copy unit.

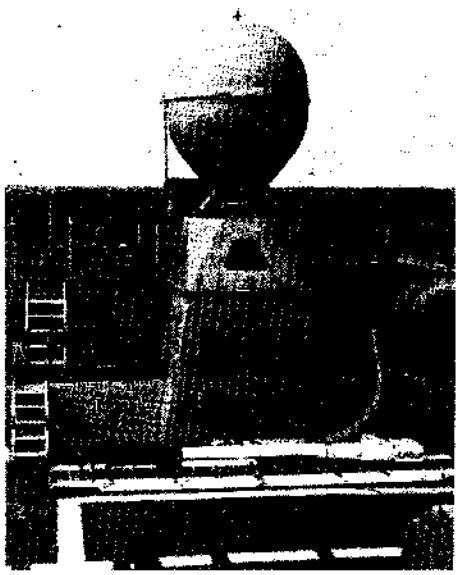
1835.281
FIRE CONTROL SYSTEM Mk 92

The Mk 92 FCS has been developed for fitting in two new classes of USN ships, the guided missile frigate (FFG) and patrol combatants missile (hydrofoil) (PHM), and for the US Coast Guard medium endurance cutter (WMEC). The PHM is also known as the NATO hydrofoil, since the overall programme of development and construction is being carried out in collaboration with West Germany and Italy, who planned to have essentially the same craft but differing in some aspects of weapon and sensor fits. One such variation is in respect of the fire control system: the Italian Navy will employ an Argo FCS, while the USN and German Bundesmarine will have virtually the same system, namely the Hollandse Signaalapparaten M28 which has been given the American designation Mk 92 Mod 1, produced under licence in the USA by the Sperry Division. Details of the M20 Series of HSA fire control systems will be found in **1259.281**, earlier in this section.

The Mk 92 is very similar to the M25 and M27 systems built by HSA for the Belgian, West German, and the Netherlands Navies, the former providing for control of air and surface engagements by guns and missiles, while the M27 additionally has provision for torpedo control. The Mk 92 is used for air and surface actions using guns and missiles, and there are a number of other changes from the basic M25/M27 configuration to suit USN requirements. In compliance with the differing sensor arrangements and armament in the three classes of US vessels fitted with the Mk 92 this system is produced in different versions, the Mk 92 Mod 1 for the PHM and WMEC, and the Mk 92 Mod 2 for the FFG. A further version, Mk 92 Mod 5 is in production for ships of the Saudi Arabian Navy. All versions have been built, tested and are in serial production.

Patrol Hydrofoil Missile

The USN variant of the PHM which employs a Mk 92 Mod 1, has as its armament eight Harpoon anti-ship missiles (**2641.221**), and a US-built OTO-Melara 76 mm dual-purpose gun (Mk 75). In addition to the co-mounted search and tracking radars which are a feature of the M20 Series fire control system, other sensors include an I/J-band navigation radar, inertial navigation system, and an electronic warfare suite.



Guided Missile Frigate

The new class of guided missile frigate (FFG) for the USN has as its principal operational roles anti-submarine warfare, anti-air warfare including both anti-aircraft and anti-missile capability, and anti-ship missions. These ships have a dual-purpose launcher able to launch either Harpoon surface-to-surface or Standard surface-to-air missiles. Other armaments include a US-built OTO-Melara 76 mm dual-purpose gun (Mk 75).

The Mk 92 Mod 2 FCS for this class of vessel will operate within a more elaborate environment than the Mod 1 version. In addition to its own search and tracking radars (with integral IFF), other sensor equipment includes an AN/SPS-49 search radar, AN/SPS-55 I/J-band navigation radar, and an AN/SPG-60 STIR (standard target illuminating radar). The complete Mk 92 Mod 2 is integrated with the ship's digital rapid reaction command and control system, Sperry Univac AN/UYK-7 computers being used for this and the Mk 92.

Medium Endurance Cutter

The WMEC employs a Mk 92 Mod 1 FCS which controls a US-built OTO-Melara 76 mm dual-purpose gun (Mk 75) and an optical sight. The ship also contains a Sperry collision avoidance system and command display and control system (COMDAC). This is a shipboard command display and control system which combines both weapons control and ship control. The COMDAC utilises the ship's radar and other sensors to detect and create a display of airborne and seaborne objects and land coastlines. The displays are used by operators to perform navigation/collision avoidance and mission requirements including search and rescue, enforcement of law and treaties, and military operations.

Mk 92 FCS radar unit (US Navy)

Hazeltine Corporation will supply three types of electronic equipments in various quantities for the COMDAC system: cue generators, digital scan converters, and a video sync generator for each installation. The cue generator and digital scan converter will generate composite, television-compatible data for display of radar and computer-generated information; the third unit provides the timing and synchronisation for all the electronic equipments in the COMDAC system.

CONTRACTOR

Sperry Corporation, Electronic Systems, Great Neck, New York 11020, USA.

4491.281
H-930 SERIES COMBAT/WEAPON CONTROL SYSTEMS

The H-930 Series of combat weapon control systems is designed to accept inputs from a wide variety of available and future surveillance and tracking sensors and provide outputs to a similar variety of weapon sub-systems for ships ranging from fast patrol boats to destroyers. Significant operational features of the H-930 Series include:

(1) automatic detection, tracking, threat analysis and display of targets from an air search radar (ASR)
(2) semi-automatic detection, and automatic tracking and display of targets from a surface search radar (TWS)
(3) precision tracking from up to two track radars (TR) and an optronic device (OD)
(4) split mode tracking utilising best combination of angle and range data from any pair of track data sources from the same target
(5) assignment of any of a ship's guns to any system track data sources simultaneously or all guns on a single track data source or any combination thereof
(6) assignment of a tracking and illuminating radar (TIR) to Standard missile (SM-1)
(7) assignment of a tracking radar to a surface-to-surface missile (SSM) system
(8) integration with IFF, EW and data link in various levels of intimacy
(9) integration with Mk 114 UBFC system (sonar, ASROC and OTS) (**3222.281**)
(10) tactical navigation aids such as intercept/manoeuvre calculations, CPA and time to CPA calculations, true or relative motion display, maintenance on earth grid, and manual or automatic compensation for set and drift
(11) manual, semi-automatic or automatic setting of shell splash spotting data
(12) automatic recommendation of tracker designations and weapon assignments including a means of quick operator acceptance of same
(13) automatic sequencing of tracker designation and weapon assignment as preset by the operator. Such sequences are triggered by an event pre-selected by the operator
(14) demonstrable gun pointing accuracy under realistic test conditions.

The various models within the H-930 Series include all or combinations of the above features. To achieve flexibility and still retain ease of operation, the H-930 operator interface features a common command and control syntax and, in most models, employs a plasma panel that is programmed to accommodate many operator actions and displays, yet preclude illegal actions.

The H-930 Series began with the production of the EX-93 gun fire control system for the USN's Coastal Patrol Interdiction Craft (CPIC) programme. This system was successfully evaluated by the USN and subsequently transferred to South Korea in 1974. Since then the H-930 Series has evolved and continually been improved over the years.

During the development of the Mod 0 system, it became apparent that the H-930 Series must be truly modular in order to be compatible with future technology developments as well as future applications. Accordingly, in the mid-1970s, Honeywell merged the benefits of a distributed computing development programme that had progressed for several years for the USAF into the H-930 Series. As a result, the Mod 1, 2, and 3 systems are the first operational modular ship-board control systems based on a distributed computing architecture for fast patrol boats, destroyer modernisation, and land-based coastal defense installations.

These systems are functionally modular and physically distributed. They have been installed, checked out, and formally accepted by a foreign navy after extensive, rigorous live firing and operational test exercises at sea. The H-930 programme has involved the integration of a wide variety of new and existing weapons and sensors from US and world-wide suppliers.

The most recent modular combat system (H-930 MCS) incorporates the latest technological improvements to realise the full potential of total physical and functional modularity for both new ship classes and modernisation programmes. This new system draws on Honeywell's experience in systems for foreign navies, as well as on research conducted and demonstrated for the USN.

Under the MCS concept, modularity is achieved through a module that is defined as a distributed computing unit (DCU) and the attached system devices that it serves, combined with an equally modular software architecture. The DCU consists of a set of circuit card assemblies, including processors and memory, that perform all of the processing, data routeing, signal conditioning, and protocol functions to allow the attached device(s) to perform effectively as a unit of the total system. These circuit cards, along with special power supplies and cabling connectors, are either mounted in a stand-alone, drip-proof, air-cooled module or are embedded in the cabinets of system control display consoles.

System data is routed as digital messages via the combination of a powerful operating system, local input output control (IOC) processors, and a multiple redundant data bus system. All addressing and local data transfers are accomplished by the IOC and the executive function of the resource processor. All inter-modular tranfers on the data bus system are effected by the global bus interfaces (GBI). The total data routeing system is not dependent on a central master control point that can fail and bring down the entire system. It is this degree of controlled autonomy that allows the system to tolerate the addition or deletion of a given module with the only immediate effect being the presence or absence of that module's function. Access to the global bus is allocated on a rotating basis such that addition of a module will require a slight adjustment, but the inherent intelligence of the bus system can recognise and recover from a non-responding module. Normally, the designed removal of a module will be accompanied by a compensatory change to the allocation sequence.

An area of significance to the shipbuilder is that of long-run cabling. In a recent study for the US Navy, it was determined that the implementation of a data bus in an FFG-7 class ship could eliminate almost 12 000 m of complex signal cables, or more than half of the total cable length. The weight saving was determined to be five tons.

STATUS

H-930 Series system fittings in service and projected and equipment configurations as at early 1983 are summarised in the following table:

CHALLENGER SA-2

This electro-optronic fire control system primarily designed for fast patrol boat installation provides precise gun orders or missile guidance functions for a large inventory of weapons. (It was originally introduced as Sea Archer 2 and re-named in late 1982.) Gun calibres accommodated range in size from 20 mm to 76 mm and surface-to-surface missile control includes both inertial and laser guided types. Having both surface and air target capability, SA-2 utilises infra-red (three to five micron and eight to twelve micron common module), TV, and laser sensors mounted on a remotely controlled director. An optional M-band (95 GHz) radar tracker module is also available for mounting on the director. Associated with the one-man total system operational concept is a below-deck control console which contains TV/IR radar and alpha-numeric displays as well as system control functions including weapon designation information and tellback information. Automatic operation is provided through an AN/UYK-502 militarised 16-bit computer utilising standard USN CMS-2 software compilation.

Since the line-of-sight stabilised director can support over 150 kg of payload and is trainable through 360° with elevation angle coverage of –30 to +85°, a wide variety of target sensors can be accommodated. Currently in use are a 3·4 to 4·2 micron thermo-electrically cooled imaging and tracking sensor, 7·75 to 11·75 micron common module IR with a new long-life Stirling cycle cooler, a low light-level TV with 10:1 zoom lens elements, and a 1·06 micron high repetition rate rangefinder laser. When laser illumination is required for missile guidance functions a high power coded laser with variable beam divergence is employed. In addition the 95 GHz radar tracker, which is mounted integrally with the E-O director, uses a narrow 0·5° beamwidth to minimise specular multi-path reflections and sea clutter returns. A power output in excess of 1 kW peak provides range and angle information compatible with the detection ranges and performance of the IR and TV sensors.

Processing of data from the available sensors utilises algorithms for edge, centroid, and correlation target tracking to generate angle error data for servo control. Automatically adjusted gate size

corresponding to target size and dynamics reduces track jitter and aids the many signal enhancement techniques used to reduce background clutter effects. Images from the TV and IR sensors as well as the radar module can be displayed simultaneously on the control console for operator interpretation.

Target designation for SA-2 can be accomplished from any of the ship sources such as search radar, other FCS equipment, CIC, or optical director. When initial designation is received, the FCS is programmed in automatic acquisition patterns dependent upon accuracy of the input data. Multiple input/output data channels provide the interchange of information between SA-2 and the controlled weapons.

The SA-2 above-deck equipment weighs 305 kg and below-deck equipment totals 422 kg. Other ship inputs required, dependent upon weapon order generation, include heading, roll, pitch and speed in either synchro or digital format.

STATUS

Land-based testing was carried out contractually by US Naval Surface Weapons Center, Dahlgren, Virginia in April 1981. Demonstrations of high-speed aircraft tracking by production-type equipment were conducted at the Paris Air Show in 1981. Reliability proved to be in excess of 600 hours MTBF over an operational period of 2500 hours. It was also marketed by the associated Sperry, UK Company (but now a division of British Aerospace Dynamics Group).

CONTRACTOR

Sperry Corporation, Electronic Systems, Great Neck, New York 11020, USA.

3727.281

SEAFIRE NAVAL FIRE CONTROL SYSTEM

Seafire is a projected development of a passive electro-optical naval fire control system for fitting and use aboard ships for directing gunfire against surface targets at sea or on shore. Employed aboard ships equipped with the Mk 86 gun fire control system (**1241.281**), the Seafire system will provide all-weather, day/night target acquisition and tracking facilities. Sensors will include a forward looking infra-red (FLIR) sensor, and the electro-optical package will also include a daylight television system for long-range target detection, digital video tracker and processor for automatic tracking, and a laser rangefinder and target marker. The latter will enable Seafire-equipped ships to employ laser-guided munitions against targets. Fine stabilisation of the system for precision fire control computations is incorporated.

STATUS

Honeywell was selected as prime contractor for the Seafire system by the USN in March 1980 when a contract for $17·2 million covering three full-scale engineering models was awarded. Most of the work was carried out at Honeywell's West Covina, California plant and at its Systems and Research Center in Minneapolis. Major sub-contractors were Northrop Corporation for platform stabilisation and certain E-O sensors, and Texas Instruments for the IR sensor package. A laser sub-system produced by Ferranti Ltd was also incorporated.

Originally a four-year development was envisaged, to be followed by a production facility but in 1982-83 the programme was thought to have been cancelled after which a fresh contract was awarded to Texas Instruments in November 1983 following a new Request for Proposals issued by the USN. At one stage it was expected that 12 classes of USN ships would be fitted with Seafire.

In April 1983 it was learned that Texas Instruments and Ferranti had decided to embark on a joint programme to market a system derived from Seafire to be known as Sea Tiger in international markets (**4489.281**).

CONTRACTOR

Texas Instruments Incorporated, PO Box 226015, Dallas, Texas 75266, USA.

1922.481

TRIDENT FIRE CONTROL SYSTEM Mk 98

General Electric Ordnance Systems Division has received a contract award for the development of US Navy fire control systems and guidance support equipment. The contract covers work extending over a four-year period for design and initial manufacture of fire control systems for the new Trident submarine and for the modifications required for Poseidon fire control systems currently deployed in order to accommodate a larger C-4 missile (**2840.411**).

As a key sub-system of the Trident strategic weapons system, the GE fire control technology will serve the primary purpose of preparing the missile guidance system for flight and controlling the missile launch sequence.

Support equipment will consist of: guidance system test equipment for shore-based activities and nuclear submarine strategic weapons facilities; guidance system containers and handling equipment; and equipment to support fire control and guidance operations at all maintenance levels. Deliveries of fire control systems and support equipment under this contract will continue into the 1980s. No further details were available at the time of publication.

CONTRACTOR

General Electric Company, Ordnance Systems Division, 100 Plastics Avenue, Pittsfield, Massachusetts 01201, USA.

1925.281

PASSIVE FIRE CONTROL SYSTEM Mk 105 (TAC)

The Mk 105 target acquisition console is a passive fire control system for the detection of targets radiating anywhere in the microwave spectrum and the direction of appropriate ship's weapons against those which are identified as threats. The main elements of the system are a broadband microwave antenna array with direction finding facilities, a countermeasures receiver, signal data processor, and an indicator control unit.

The antenna array consists of eight cavity-backed planar spiral elements with broadband balun feeds, these being disposed on a masthead mounting to permit direction finding by the monopulse amplitude technique.

The countermeasures receiver, derived from the AN/ALR-47 radar homing and warning system developed by IBM for the S-3A, Viking ASW aircraft (**1862.353**), is a four-channel, digitally tuned superheterodyne receiver with a fast-acting diode matrix switching head.

The signal data processor measures the characteristics of the video outputs of the receiver and converts the video pulses to digitised, monopulse, parametric data. All signal processing and system controls are handled by software that can be modified by the operator or by selection in advance of a mission. The processor performs all input/output signal conversions and storage, processes and filters the data, and transmits information to the display for use by the operator. All communication with external displays or interfaces with other of the ship's systems are handled by the signal data processor, which has two memories, the combined capacity of which may be as much as 24 K words. The computers are machines of IBM's System/4 Pi range, model SP-OA.

The indicator control unit is provided with an advanced CRT display for the presentation of emitter bearings, and the associated emitter signal characteristics in alpha-numeric form. Its operation and character generation functions are controlled by the signal processor computer. The operator is provided with a control panel on which are push-buttons and thumb-wheels that serve as data insertion devices. The buttons are illuminated internally and also act as indicators. System software can revise the function of each of the 28 push-buttons without affecting the hardware.

OPERATION

The Mk 105 is a programmable passive fire control system which automatically detects, sorts, identifies, and locates emitters. Multiple digital channels permit two-way communication with weapons direction systems, tactical data systems, and missiles. Several emitters can be processed at the same time, and the system has a large capacity emitter file, which permits operation in dense electromagnetic environments.

The system automatically scans the microwave frequency band, processes the emitter data gathered, displays the emitter signatures, priorities, identification data, and bearing. The operator's controls allow him to set receiver frequency scan limits and select emitter signals for further processing or designation as targets. Emitter data are used by the weapons system, under operator control, for target acquisition. Data can also be supplied to other surveillance systems to enhance target detection and identification.

As programmed at present, the Mk 105 TAC concentrates on short-duration radar transmissions, such as those associated with ship, submarine, and missile guidance radars, but other priorities may be assigned by software changes.

DEVELOPMENT

At the time of adaptation to the Standard anti-radiation missile for the surface-to-surface anti-ship role, in early 1972, the US Navy selected the IBM Mk 105 system to provide passive target acquisition, location, and identification, and weapon initialisation. In November 1972 two systems were delivered for installation aboard the USS *Grand Rapids* (PGM-98) and USS *Douglas* (PGM-100). The first successful launch of a Standard SSM was made from the former vessel in April 1973. In November 1973 IBM was awarded a production contract for 12 improved Mk 105 TAC systems for fitting in DDG and DEG class ships.

STATUS

The first of the production systems was delivered in spring 1974 and in 1976 delivery was completed for guided missile destroyers.

CONTRACTOR

IBM Federal Systems Division, Owego, New York 13827, USA.

3221.481

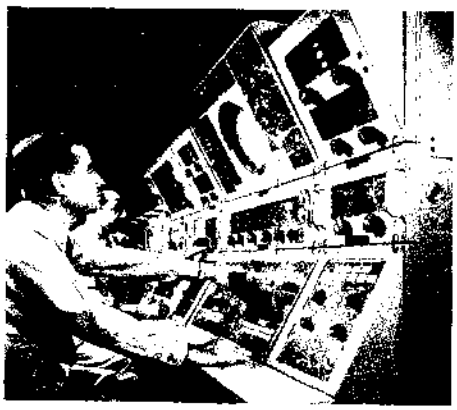
FIRE CONTROL SYSTEM Mk 113

The FCS Mk 113 is used in SSN 594 class submarines of the US Fleet. Target bearings from the BQQ-5 sonar suite are pre-filtered, and together with own ship motion data, are processed in the Mk 130 digital computer, the first electronic digital computer to be used aboard attack class submarines. With input of own ship state vector information, the target range, course and speed can be computed from passive bearings only. The operator interacts with the target motion analysis (TMA) function at the analyser console Mk 51.

The FCS Mk 113 consists of the following equipments:

(1) the attack director Mk 75 receives own-ship and target information to compute torpedo ballistics and wire-guide controls, and performs position keeping on both target and torpedo. The Mk 75 also supplies necessary data to levelling computer Mk 129 for Subroc ballistic computations
(2) the attack control console Mk 50 is the system firing panel, tactical display, and torpedo room status panel
(3) the levelling computer Mk 129 performs Subroc ballistic computations, and in conjunction with

the reference sensing element Mk 1, provides signals for levelling the Subroc inertial platform.



Addition of two torpedo control panels Mk 66, two tone signal generators Mk 47, together with major modifications to existing Mod 2 equipments, results in FCS Mk 113 Mod 6 and Mod 8 which accommodate the Mk 48 torpedo. Torpedo control panel Mk 66 (which represents the first application of MSI/LSI circuit technology on submarines) acts as a preset panel while TSG Mk 47 generates the signals for transmission of data to the torpedo. The Mod 6 is a field-modified Mod 2 while the Mod 8 comes directly from the factory with the modifications built in.

STATUS

The FCS Mk 113 has been operational since 1962. It is the weapon control system deployed aboard the USN's nuclear attack class and fleet ballistic missile submarines. In the late 1960s the additional equipments required for the torpedo Mk 48 were developed.

CONTRACTOR

The Singer Company, Librascope Division, 833 Sonora Avenue, Glendale, California 91201, USA.

Attack control console of Mk 113 fire control system

3222.281

ASROC Mk 114 FIRE CONTROL SYSTEM

Fire control system Mk 114 provides the means of solving the shipboard anti-submarine attack problem, generates launching orders, prepares the weapons for firing, and generates designation data for Asroc (**6001.241**) missile tracking by ship's radar. The ASW weapons controlled by FCS Mk 114 range from Hedgehog projectiles and older Mk 44 torpedoes to the newer Mk 46 torpedoes as well as the Asroc missile.

The FCS Mk 114 consists of the following equipments:

(1) the attack console Mk 53 consisting of an attack plotter and a ballistic computer
(2) a stabilisation computer Mk 134 which generates stabilised azimuth and depression orders for the ship's sonar
(3) the position indicator Mk 78 provides a continuous display of own ship's target and weapon tactical information including firing control to the commanding officer
(4) the relay transmitter Mk 43 tests Asroc readiness, and programmes and monitors the ignition and separation assembly of the selected Asroc missiles
(5) a relay transmitter Mk 44 which transmits train and elevation orders to the selected gun or missile fire control system for radar tracking of the Asroc missile.

These equipments employ a firing panel and transistorised, electromechanical analogue computer modules which combine automatic computation with graphic plotting on the Mk 53 console for target motion analysis, and ballistic computations.

STATUS

The Mk 114 FCS, and its predecessor the Mk 111 fire control group have been installed on US Navy destroyers and frigates, and on ASW ships in service with navies of Brazil, Germany (FR), Greece, Italy, Japan, Korea (S), Pakistan, Spain, Taiwan, and Turkey. Originally developed in the early 1960s, the USN maintains a refurbishment and repair facility for the Mk 114 at NTS, Keyport, Washington.

CONTRACTOR

The Singer Company, Librascope Division, 833 Sonora Avenue, Glendale, California 91201, USA.

3223.281

Mk 116 FIRE CONTROL SYSTEM

The Mk 116 Mod 4 is the latest version of this underwater fire control system (UFCS) to be fitted in USN anti-submarine warfare ships. The system has evolved during the period it has been in operation and the Mod 4 uses an AN/UYK-7 computer as the system central processor. It interfaces with the Mk 26 guided missile launch system to launch Asroc missiles against submerged targets at stand-off ranges, and with trainable Mk 32 torpedo tubes to launch the Mk 46 torpedo against submarines at close range.

The principal sensor is the AN/SQS-53 sonar set, with environmental inputs from the electro-magnetic log, wind indicator Type F, advanced design stabilised gyro, AN/SQQ-61 bathythermograph, AN/UQN-4 fathometer, and data from ship's command and decision system. The Mk 116 Mod 4 UFCS includes standard NTDS computers, displays, and interface equipment. It consists of two major sub-systems, the computer processing sub-system and the weapon control and setting sub-system (WCSS).

(1) computer processing sub-system: AN/UYK-7 digital computer with advanced ASW operational program; RD-358 magnetic tape unit; OA-7984 input/output console (paper tape and teletype)
(2) WCSS: weapon control panel, Mk 329, which is normally the only manned unit; missile setting panel Mk 330, one for each launch system; torpedo setting panel Mk 331; weapon status and approved panel Mk 332, installed at the bridge and combat information centre; bridge display panel Mk 333; and interface control panel Mk 377, which provides power distribution and signal routeing for missile/torpedo functions.

OPERATION

The underwater battery supervisor, stationed in the combat information centre, operates the UFCS from the weapon control panel and an adjacent display console. ASW team members are also located at the torpedo setting panel to facilitate local operations if required, and at the weapon status and approval panels to provide Asroc launch approval.

DEVELOPMENT

The WCSS was developed and produced by Singer-Librascope under contract to the Naval Ocean Systems Center, San Diego.

STATUS

The Mk 116 Mod 4 and its predecessor systems Mk 116 Mods 1, 2 and 3 have been installed in several classes of surface ships: Mod 1 on CGN-38 class cruisers, Mod 2 on DDG-993 class destroyers, Mod 3 on CG-26 with a single launcher, as part of its modernisation programme. Mk 116 Mod 4 is currently being installed on CG-47 'Aegis' class cruisers.

CONTRACTOR

The Singer Company, Librascope Division, 833 Sonora Avenue, Glendale, California 91201, USA. (WCSS)

4822.481

SUBMARINE COMBAT CONTROL SYSTEM Mk 2

The Singer company's Librascope Division has developed and is producing an improved version of the submarine fire control system (SFCS) Mk 1, that was initially produced for the Royal Australian Navy's modernised 'Oberon' class submarines and subsequently fitted in boats of the Canadian and other navies. The new system is also mainly for export applications, although its use in certain classes of US ship, or surface vessel fittings, should not be ruled out. The original Mk 1 SFCS Mod 0 was described in the Australian section of this part of *Jane's Weapon Systems* in previous editions under entry number **3220.481**.

The Mk 2 combat control system is a completely integrated action-information system for submarines, corvettes, and frigate-type ships. It provides comprehensive processing and evaluation of all combat data and co-ordinated operational control of all sensors, weapons, and combat manoeuvres. The system's unique and innovative architecture has resulted in lower costs, higher reliability, and easier operation and maintenance than its predecessors.

The system provides for surveillance of a large number of contacts and the simultaneous engagement of multiple threats. The surveillance process is highly automated due to the large amount of navigation, contact tracking, communication link, and weapon telemetry surveillance data that must be processed and evaluated. The results of the automatic processing are presented to system operators in user-friendly pictorial and natural language forms. The highly automated approach frees the operators from perfunctory tasks and allows them to manage by exception. This results in a reduction in the number of operators required for surveillance and allows the assignment of additional operators to the prosecution of contacts which are a threat to the ship's mission. The contact prosecution process, while operator intensive, includes the display of tactical options and recommendations to aid operators in attacking threats using torpedoes and missiles. In addition, the system provides support for performance monitoring and fault localisation, combat data recording and reconstruction, and operation and maintenance training.

The system hardware is completely redundant and can therefore sustain single failures of any type without any loss of tactical capability. The equipment is very compact and will fit down a 650 mm hatch. Central to the system are a set of distributed computers which are embedded in each of the hardware elements. The computer design is modular and therefore expandable by inserting additional processing and memory cards. The system is comprised of the following hardware elements: a sensor data converter/processor with two computers, multiple combat control consoles with one computer each, and a weapon data converter/processor with two computers, all interconnected by a dual combat data bus.

The sensor data converter/processor provides:

(1) interfaces with the navigation sensors, the tracking sensors (including passive/intercept/active sonar, radar, electronic support measures, TV, and periscopes), and the communication link
(2) automatic surveillance and support processing
(3) combat data recording.

Combat control consoles provide a truly multi-function display of sensor video and processor generated graphics and alpha-numerics. The main display surface is a 45 Hz non-interlaced raster scan colour CRT with 1280 × 1024 picture element resolution. Each console independently provides for the simultaneous display of video from any two sensor sources plus the overlay of graphic and alpha-numeric annotation. Radar, navigation charts, and annotation may be combined for use in combat navigation. The console contains a 17 × 8·5 inch (430 × 22 mm) touch interactive plasma display which is used as a tactical summary display and for interaction with the weapon launch compartment personnel during preparation for a launch.

The weapon data converter/processor provides:

(1) automatic contact prosecution and support processing
(2) interfaces with the launch tubes and weapons
(3) emergency weapon setting, launching, and control.

A plasma display like the one in the combat control console is included and is used for interaction with the console operators during preparation for a normal launch and for local control during emergency operations.

The combat data bus provides communication between the other elements of the system at a one million bit-per-second serial rate over each half of a dual bus in the Mil Std 1553B format. Data is broadcast on the bus from each computer to all other computers simultaneously so that all computers receive the data simultaneously. Each half of the bus has the capacity to provide all of the required system communication. The bus is available in both copper and fibre-optic forms.

The system software is written in Pascal and is completely redundant and stored in read only memory in order to eliminate the need of program loading during system initialisation or during casualty switching. In addition, the entire combat data base, which is used for interprocessor communication, is replicated in all processors in order to eliminate the need for selective communication between processors. The software is comprised of a sensor data converter/processor sub-program, a combat control console sub-program, and a weapon data converter/processor sub-program.

The sensor data converter/processor sub-program provides automatic surveillance and support processing. The surveillance processing includes:
(1) track data processing and correlation
(2) automatic contact motion analysis
(3) contact data processing and correlation.

The support processing includes:
(1) performance monitoring and fault localisation in conjunction with the weapon data converter/processor sub-program
(2) sensor simulation for training
(3) combat data recording.

The entire program is stored in both sensor data converter/processor computers with one computer executing the surveillance tasks and the other computer executing the support tasks. In the event of a failure of one of the computers, the surviving computer executes the surveillance tasks with support tasks being executed on a time available basis.

The combat control console sub-program provides surveillance, contact prosecution, and support displays. The surveillance displays include:
(1) contact detection and tracking video displays
(2) a track history display
(3) a geographical situation display.

The contact prosecution displays include:
(1) a classification video display
(2) a threat motion analysis display
(3) an engagement/avoidance display.

The support displays include:
(1) performance monitoring and fault localisation displays
(2) training displays
(3) combat data recording and reconstruction displays
(4) a combat navigation display.

The weapon data converter/processor sub-program provides automatic contact prosecution and support processing. The contact prosecution processing includes:
(1) threat classification
(2) threat motion analysis
(3) threat engagement/avoidance.

The support processing includes:
(1) performance monitoring and fault localisation in conjunction with the sensor data converter/processor sub-program
(2) weapon simulation for training.

The entire program is stored in both weapon data converter/processor computers with one computer executing the contact prosecution tasks and the other computer executing the support tasks. In the event of a failure of one of the computers, the surviving computer executes the contact prosecution tasks with support tasks being executed on a time available basis.

The sensor and weapon data converter/processor performance monitoring tasks combine to provide a double check on system failures and in conjunction initiate automatic switching to redundant hardware/software in the event of a single point of failure. Switching processors is simplified as program loading and data base updates are not required. Also, switching halves of the data bus is simplified by switching all communication from one half to the other in the event of any failure on the half that is providing system communication.

The Mk 2 combat control system is a completely integrated action-information system which can survive any single point of failure without any loss of tactical functions. It centres around multi-function colour display consoles, and the cost is low due to the simple and innovative design.

STATUS

The preceeding Mk 1 version was initially supplied to the Royal Australian Navy for fitting in modernised 'Oberon' class submarines, and was later adopted for Royal Canadian Navy boats of the same class, as well as being procured for West German-built 1500-ton submarines for the Indian Navy. The Mk 2 SCCS is in production for an unnamed navy.

CONTRACTOR

The Singer Company, Librascope Division, 833 Sonora Avenue, Glendale, California 91201, USA.

1493.261

US NAVAL TACTICAL DATA SYSTEM

NTDS (naval tactical data system) is the designation given to the combinations of digital computers, displays of various types, and data links which are installed on USN ships for the on-line collection, processing, storage, and presentation of information from sensors such as sonar, radar, optical, and aircraft or ship consorts, via data link. NTDS also is engineered to interface with ATDS (airborne tactical data system) and MTDS (marine tactical data system). All three systems have the prime function of providing automated organisation and display of information for command and control teams for such purposes as threat detection and assessment, and weapon-target allocation.

Although designed to a common concept, NTDS exists in a number of versions, varying in size and equipment complement according to the age of installation and the size of vessel fitted. The overall system has also been subject to a continuous process of updating since its introduction into service in the late 1950s. By 1969, for instance, three generations of display devices had been employed. The basic digital computer for the system, the AN/UYK-20, was preceded in some installations by other types, and later NTDS employ the Univac AN/UYK-7.

STATUS

In addition to USN fleet fittings of NTDS, installations aboard ships of the Australian, French, Italian, Japanese and West German navies now total more than 100.

In the early 1980s the USN selected the AN/UYK-43 and AN/UYK-44 computers to replace the AN/UYK-7 and AN/UYK-20 as 'standard' digital computers. It was also decided to replace the older machines progressively by UYK-43 and UYK-44 processors as requirements expand beyond the capabilities of the former processors, or other circumstances make appropriate. It was also decided to adopt the 'embedded' computer philosophy which provides distributed processing facilities with benefits in survivability, maintainability, flexibility etc. The NTDS has been the object of a programme of up-dating involving replacement of obsolete computers, displays and other equipment, and software modifications to reflect the integration of new sensors and weapon systems into the Fleet.

Hughes has delivered about 2500 displays (UYA-4 and UYQ-21) for these systems. As examples, in the USN, the AN/UYA-4 standard NTDS display system in an FFG-7 class ship includes seven consoles, while in CG-47 class vessels 17 consoles and the AN/UYQ-21 large screen are fitted. From 1973 to 1982, 87 UYA-4 systems were procured for the USN at costs that varied from $3·5 million for an FFG-7 to $9 million for the CG-47, with 42 AN/UYQ-21 systems procured in the period 1979 to 1982.

The total amount budgeted in fiscal year 1984 was $160 million: $50 million for UYA-4 systems and $110 million for the UYQ-21.

Combat information centre of the USS Spruance, *DD-963, showing part of the ship's NTDS*

1834.281

AEGIS COMMAND AND CONTROL SYSTEM

Aegis, formerly designated the Advanced Surface Missile System (ASMS), is a surface-to-air weapons system primarily designed to defend against anti-ship missiles. Major components of the Aegis system are the missile, its launching system, the fire control and weapons control systems, the multi-function array radar system with its computer control, the system command and decision, and the operational readiness test system.

The missile to be used is the SM-2 modularised Standard missile (**1122.231**). This is a semi-active radar terminal homing weapon with mid-course command guidance. It is launched from the Mk 26 fully automatic dual-purpose launcher which can also launch Asroc (**6001.241**) anti-submarine missiles.

This launcher has a digital interface with the Mk 1

weapons control system. One of the three computerised systems of Aegis, all of which use the AN/UYK-7 digital computer (**1467.063** in 1973-74 and earlier editions), the Mk 1 system accepts weapon assignment commands and special threat criteria from the Mk 1 command and decision system and tracking data from the multi-function radar system. These inputs are processed to determine the possibility of engaging the target and then to generate commands for the Mk 26 launcher and pre-launch orders for the missile, commands for the Mk 99 fire control system for target illumination, commands to the multi-function radar if mid-course guidance is required, and reports to the Mk 1 command and decision system.

The function of the Mk 99 fire control system is to illuminate the target. To do this it uses the AN/SPG-62 (slaved) radar. Inputs to the system come from the Mk 1 weapons control system which, in the case of slaved radar operation is passing on data from the multi-function radar system.

The multi-function phased array radar, the AN/SPY-1A (described in **1570.253**), is capable of surveillance and the simultaneous detection and tracking of multiple targets. Associated with it is a four-bay AN/UYK-7 computer, and this equipment with ancillaries makes up the radar control system. The primary function is, evidently, to search for and acquire targets and track them to whatever extent may be necessary. Beam scheduling for this and other tasks is organised by the computer. The system also handles the two-way link with the missile for mid-course guidance when requested by the Mk 1 weapons control system. Certain special facilities can be provided such as a 'burn-through' facility for use in ECM conditions or passive angle tracking. The system accepts general operational commands from the Mk 1 Aegis command and decision system and mid-course guidance commands from the Mk 1 control system; and its operational outputs are processed signals giving target detection data to the Mk 1 command system and target and missile track data to the Mk 1 control plus mid-course guidance commands to one or more missiles.

Together with the AN/SPY-1A radar system and the Mk 1 control, the Mk 1 command and decision system make up the detection and decision loops of the Aegis system. The Mk 1 system is the ship's command and control centre and targets enter the detection and decision loop from the AN/SPY-1A radar, from other ship's own sensors or from data supplied by other ships or aircraft. What happens next depends on which of the four Aegis operating modes has been selected. The modes are automatic special, automatic, semi-automatic, and casualty; in the automatic special mode targets meeting certain predetermined threat criteria are automatically fired upon unless manual override is invoked; in all other modes positive human action to initiate firing is needed.

In these three modes the Mk 1 weapons control system inserts targets into the engagement queue and schedules equipment for launching and terminal illumination. Trial intercepts are computed and a time to fire predicted. Resulting data are fed back to the Mk 1 command and decision centre which is also receiving target detection data from the radar control system, operational readiness data from the Mk 1 operational readiness test system and electronic warfare and other data from the command and decision centre. Incorporated in the Mk 1 system is another four-bay AN/UYK-7 computer and a comprehensive display system, the AN/UYA-4. On the basis of all this data, threat evaluation and weapon assignment processes are carried out so that the engagement decision can be taken.

STATUS

Fitting in CG-47 class missile cruisers and DDG-51 class missile destroyers.

CONTRACTORS

Prime Contractor: RCA Government Systems, Moorestown (three major RCA divisions are engaged in the project).

FCS Mk 99, radar SPG-62 and SPY-1 high power transmitter: Raytheon Co.

AN/UYK-7 computers: Univac Divison of Sperry Rand.

Mk 26 launcher: Northern Ordnance Division, FMC Corporation.

SM-2 missile: General Dynamics Corporation, Pomona Division.

Computer software: Computer Sciences Corporation.

Technical advice to USN: The Johns Hopkins University, Applied Physics Laboratory.

Also more than 600 other suppliers.

3514.261

W-1200 SERIES FIRE CONTROL SYSTEMS

The W-1200 Series fire control systems are designed to control guns, missiles and defensive measures for fast patrol-boats (FPBs) ranging in size from 60 tons up to 400 tons or more. Additional capability can be added to handle fire control requirements up to destroyer size ships.

The W-1200 Series systems have been optimised for FPB's offensive and defensive missions against air, surface and shore targets. Each system of the series is an integration of matched sensors, a versatile fire control computer and a display control console that has been organised for FPB operators. The elements of these systems are fully developed, off-the-shelf hardware. Each hardware element has been selected and integrated with interfacing to provide fire control based on boat size and requirements, enhanced target detection and acquisition, accurate tracking, and weapons direction. Each system provides operators with full and relevant target information. The systems feature quality performance, rapid data processing, high reliability, ease of maintenance, lightweight and rugged construction. Operation is straightforward, minimising the number of dedicated crew members required while sharply reducing the complexity and load of duties or tasks performed by operators. The W-1200 and W-1210 systems for FPBs up to 100 plus tons require one operator while the W-1220, -1230 and -1240 systems only require two operators.

STATUS

All components of the systems are currently operational on FPBs.

In late 1982, the W-160 pulse doppler monopulse radar replaced the W-120 as the principal tracking radar in the W-1200 Series of fire control systems.

CONTRACTOR

Westinghouse Electric Corporation, PO Box 1897, Baltimore, Maryland 21203, USA.

Systems of the Westinghouse W-1200 Fire Control Series

System	Sensors	Weapon Control	Application
W-1200	Navigation/search radar Optical director	One or more weapons, under computer-supported optical director or radar control, against an air, surface, or shore target.	FPBs from 30 to 60 tons with one or two powered gun mounts. Optical director is the primary fire control director.
W-1210	Navigation/search radar W-120 fire control radar	One or more weapons controlled by the W-120 against an air, surface, or shore target. One or more weapons controlled by search radar against a surface or shore target. System also directs chaff/flare launch.	Applies to FPBs from 60 to 100 plus tons with one to three powered gun mounts, and chaff-flare launchers. W-120 can direct weapons against a target of any type, particularly effective against small, fast, low fliers.
W-1220	Navigation/search radar W-120 fire control radar Optical director	One or more weapons under W-120 control, and one or two weapons under optical director control, thereby engaging two targets - air, surface, or shore. One or more weapons controlled by the search radar against surface or shore target. System also directs chaff/flare launch.	Applies to FPBs from 100 to 180 tons with one to three powered gun mounts and chaff-flare launchers. W-120 is the primary fire control director. Optical director supplements W-120 or enables divided fire.
W-1230	Navigation/search radar SPS-58 or W-611 air search radar W-120 fire control radar Optical director	One or more weapons under W-120 or W-160 control, and one or two weapons under optical director control, thereby engaging two targets – air, surface, or shore. One or more weapons controlled by the search radar against surface or shore target. System also directs chaff flare launch, and missile launch.	FPBs from 180 tons upward with one or more powered gun mounts, chaff flare launchers, and missile launchers. W-120 or W-160 and optical director split the fire control responsibility. SPS-58 or W-611 in MTI mode enables point defence against quick appearing, fast closing hostiles (pop-up threats).
W-1240	Navigation/search radar SPS-58 or W-611 air search radar W-120 fire control radar Optical director ESM equipment ECM equipment IFF	Same as W-1230 above, plus gun cueing during radar silence using ESM bearings, plus ECM jamming capability, plus IFF.	Same as W-1230 above.

NOTE: Later versions employ the pulse doppler monopulse W-160 tracking radar instead of the W-120.

JINDIVIK
The Jindivik continues to be a standard weapons target in Australia and the United Kingdom. The total value of orders, including associated equipment, exceeds $A 81 million, of which export orders exceed $A 52 million.
CHARACTERISTICS
Mk 4A Version
Power plant: 1 Rolls Royce Viper Mk 201 turbojet engine
Systems: Non-regenerative pneumatic system using air stored in accumulator. Engine driven 9 kW 30 V generator, 24 V battery
Remote control: Aircraft controlled from ground station, aircraft performance telemetered to ground constantly
Take-off and landing: Take-off from trolley, landing on retractable skid. 1800 m runway required
Max payload: 250 kg
Max speed: 981 km/h (Mach 0·86) short or intermediate span. Mach 0·82 full extended span
Manoeuvre capability: 70° bank turn, 7 *g* pull-up
Rate of climb: 4570 m/minute at sea level
Service ceiling: 16 500 m (short span), 18 500 m (intermediate span), 19 500 m (full span)
Typical endurance: 2 h
Auxiliary flight equipment: Tracking transponders, optical scoring system, radar or infra-red augmentation, radar or infra-red augmented recoverable towed targets, radar altimeter for low-level (16 m) operations
CONTRACTOR
Department of Defence, Canberra, Australia.

BRAZIL

CBT BQM-1 BR RPV
The first indigenous remotely piloted vehicle to be produced by Brazilian industry, the BQM-1 BR, has been designed and built by the Aeronautical Division of CBT (Companhia Brasileira de Tratores). Flight trials began in late 1983.

The general configuration of the vehicle can be gathered from the accompanying three-view drawing. Other physical characteristics are tabulated below. The cantilever low wing monoplane RPV is of conventional all-metal construction. It is powered by a small centrifugal flow turbojet engine developed by the PMO Mechanics Division of the Brazilian Ministry of Aeronautics and built by CBT. The power plant is housed in a small nacelle above the fuselage, at the base of the fin.

The BQM-1 BR takes off under its own power using a tricycle undercarriage which is jettisoned when the RPV is airborne. Details of vehicle recovery have not been specified but possibilities may include a parachute descent after engine shut-down. Operational uses foreseen include aerial target for weapons training and tactical reconnaissance by means of sensors such as TV and IR imaging payloads. A civil role of crop dusting has also been suggested. A six-channel VHF FM radio command link with an operating range of about 20 km is provided for guidance and control.

Three-view drawing Brazilian CBT BQM-1 BR RPV

CHARACTERISTICS
Length overall: 3·89 m
Fuselage length: 3·5 m
Wing span: 3·18 m
Height overall: 1·28 m
Tailplane span: 1·1 m
Power plant: 300 N PMO/CBT Tietê turbojet
Max launch weight: 93 kg
Max speed: Mach 0·7 at 6100 m
Endurance: 45 minutes
STATUS
Development.

CANADA

2034.351
CANADAIR AN/USD-501 RECONNAISSANCE DRONE
This is a short-range battlefield reconnaissance drone for day and night surveillance and artillery target acquisition purposes. It is known as the Midge in British Army service. Configuration of the vehicle is apparent from the illustration and its dimensions are: length 260 cm (plus 113 cm launch booster), diameter 33 cm, and wing-span 94 cm. Straight and level speed is 400 knots (740 km/h) and range is up to 160 km.

The reconnaissance sensor equipment is carried in a sensor pack located midway between the wings and the forward control fins. The sensor pack is capable of rapid removal and replacement. Two versions are in use at present, the Carl Zeiss KRG 8/24 camera and the British Aerospace Dynamics IR linescan Type 20.

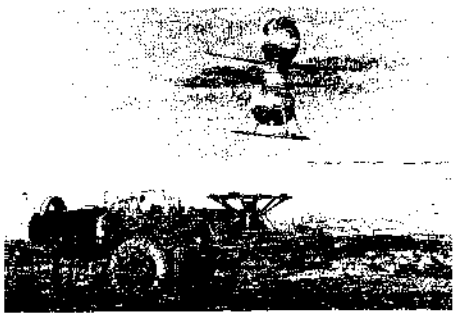
The AN/USD-501 is powered by a Williams WR2-6 single-stage turbojet which also drives an alternator giving electrical power during flight. Launching from a vehicle-mounted zero length launcher is assisted by a PERME Wagtail booster.

AN/USD-501 reconnaissance drone launch

OPERATION
After launch, the drone's subsequent flight path is pre-programmed and is maintained by DR navigation, aided by a propeller driven air-distance measuring unit, a directional gyro, and a vertical gyro. Height is controlled by reference to a barometric sensor. Operation of the reconnaissance sensor equipment is also pre-programmed, the results being recorded on film for rapid processing after the return of the drone. To the rear of the sensor pack, and on the upper side of the fuselage, is a flare pack containing 12 flares which are discharged under the control of a stepper switch. Normal operating height of the AN/USD-501 is between 300 and 1200 m above ground.

Recovery is assisted by a homing receiver working in conjunction with a beacon located at the recovery site. The drone may be equipped with a transponder of the user's choice to enable radar tracking for training flights during peace-time operations. Shutdown of the motor initiates parachute deployment and the drone is inverted to come to rest on a pair of air-inflated bags carried in containers in the upper part of the fuselage.

DEVELOPMENT
Development was initiated in 1959 by Canadair under the designation CL-89. In 1963 development contracts were awarded by Canada and the UK and the official designation of AN/USD-501 was allocated. In 1965 West Germany joined the programme, costs being shared equally between the three partners.



STATUS
The system is in service with the armies of Britain and West Germany, France and Italy. A total of over 2200 flights have been made to date from the 500-plus drones supplied. User states see the system remaining in service through the 1990s. A product improvement programme is being developed by Canadair in conjunction with user countries.

A developed version designated AN/USD-502, and also known by the manufacturer's number CL-289, is the subject of a joint Canadian, French and West German programme (see **3238.351**).

CONTRACTOR
Canadair Ltd, PO Box 6087, Montreal, Quebec H3C 3G9, Canada.

3010.351
CL-227 (SENTINEL) RECONNAISSANCE AND TARGET ACQUISITION RPV

This is a medium-range remotely piloted vehicle (RPV) designed by Canadair Ltd to acquire surveillance and target acquisition data for army brigade and division formations. It is also intended for use at sea from ships that are unable to carry conventional helicopters and can be operated tethered or untethered. It has a vertical take-off and landing capability and can provide real-time information from various types of electro-optical sensors such as TV, low-light level TV and thermal imaging systems. The range of interchangeable payload packages would include laser target designators. According to mission, it is possible that various electronic warfare sensor packages could be carried. It has a very low noise level and a low radar signature. The RPV, which flies itself, is directed from a mobile ground station manned by a flight controller and a sensor data observer/interpreter.

Canadair CL-227 RPV undergoing test flight

The configuration of the CL-227 is somewhat unusual and the vehicle resembles a dumb-bell, with its axis vertical. It consists of three modules, the upper and lower ones being of near spherical profile, while from the centre section two three-bladed rotors protrude. These are contra-rotating and all aerodynamic control over the vehicle is by means of these rotors which can be actuated to provide lift, hover, and transit modes of flight. The upper end section houses the propulsion motor and fuel, while the lower unit contains the sensor package and other vehicle electronic systems.

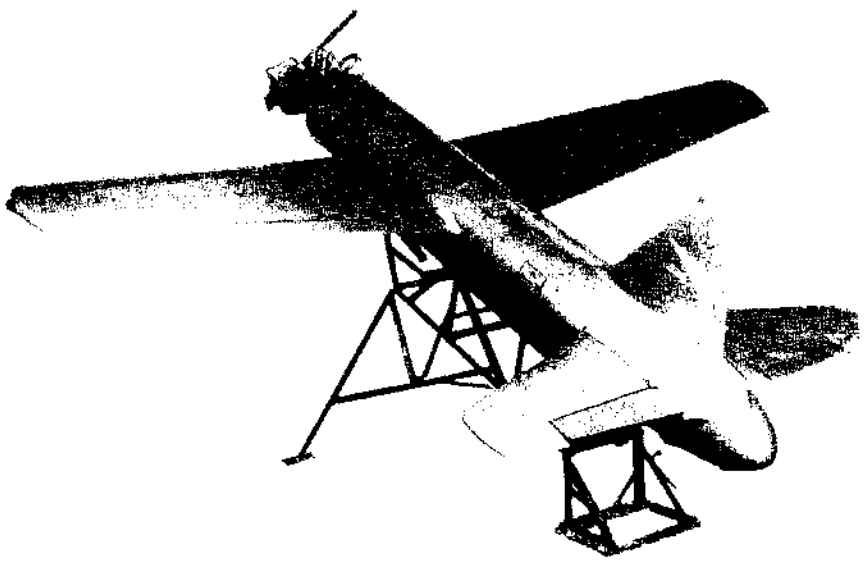
CHARACTERISTICS
Height: 1·64 m
Max diameter: 64 cm
Weight: 115 kg
Payload: 52 kg (fuel); 31 kg (disposable)
Operating radius: Typically 50 km, but LOS limited
Mission endurance: 4 h
Flight speed: Hover to 130 km/h
Flight altitude: Sea level to 3000 m

STATUS
Full-scale development. First free flight in 1980, more than 400 flights performed by early 1983.

CONTRACTOR
Canadair Ltd, PO Box 6087, Montreal, Quebec H3C 3G9, Canada.

CHINA

4591.391
CHANGCHENG B-2 TARGET DRONE



The B-2 radio-controlled target drone produced by the Changcheng Scientific Instrumentation Factory was first revealed in public at the Guangzhou Fair in 1982.

Constructed of lightweight glass-fibre reinforced plastic/honeycomb sandwich material, the B-2 has a rigid airframe of conventional configuration, as shown in the illustration. It can be launched from various surfaces using a zero-length launcher and rocket-assisted take-off.

Principal uses of the B-2 target drone are weapon system training and gunnery practice. For the second role two towed targets can be attached to the drone. Other devices which can be used include items that produce a realistic representation of descending paratroops. Additional roles can be accommodated to meet specific requirements.

The standard drone is equipped with a radio command guidance system and telemetry facilities operating in the HF and VHF bands respectively. The radio command guidance system operates in conjunction with the drone autopilot. The power plant is a flat-four, two-stroke engine driving a two-bladed fixed pitch propellor.

CHARACTERISTICS
Length overall: 2·55 m
Wing span: 2·7 m
Height overall: 0·6 m
Power plant: 16 hp Huosai flat-four two stroke engine
Max launch weight: 56 kg
Fuel weight: 6 kg

Changcheng B-2 target drone on zero-length launcher

Max level speed: 220 - 240 km/h at 1000 m
Endurance: 1 h
Max control range: 20 km

STATUS
In service.

TYPE D-4 RPV

Developed in the early 1980s by the Chinese Northwestern Polytechnical University (NPU) the Type D-4 RPV is understood to be intended for use as a radio controlled camera platform for reconnaissance purposes. The vehicle is of conventional high-wing monoplane configuration, powered by a nose-mounted Huosai-510 30 hp piston engine driving a two-bladed propeller. Honeycomb and glass-reinforced fibre construction is employed and an autopilot is incorporated as standard equipment.

The D-4 is launched from a zero length launcher using a rocket booster motor under the fuselage, with recovery by means of a parachute stowed in the tail.

CHARACTERISTICS
Power plant: 22·4 kW (30 hp) Huosai-510 piston engine
Payload: 25 kg
Max level speed: 170 km/h (at S/L)
Service ceiling: 3000 m
Endurance: 2 h 40 min

STATUS
Limited production.
CONTRACTOR
Northwestern Polytechnical University, Xian, Shaanxi Province, People's Republic of China.

Rocket motor beneath fuselage is used to launch Chinese Type D-4 RPV

AÉROSPATIALE CT 20

The CT 20 is a turbojet-powered radio-controlled target of medium performance, which can also be used as a tug for a towed target. It is standard equipment for training military units in the use of air-to-air and surface-to-air missiles, notably the Hawk, and over 1500 have been sold to French, Italian, Swedish, and other armed forces.

Three versions were developed, described in earlier editions of this book.

Derivatives of the CT 20 are the R 20 (**2127.351** in 1979–80 and earlier editions), and the M-20. The latter is an offensive missile specifically designed for ship launching. This was built for the Swedish Navy and was produced in Sweden as the RB-08 (**2366.221**).

CT 20 target drone on zero length launcher

CHARACTERISTICS
Length: 5·4 or 5·5 m
Wing span: 3·6 m
Take-off weight: 700 kg
Power plant: 1 Turbomeca Marboré II or VI turbojet engine
Remote control: From ground or airborne station. Automatic descent in case of radio control failure
Take-off: From launching carriage powered by powder rockets on a zero length launcher. 7·4 *g* acceleration
Max speed: At 10 000 m, 900 km/h with Marboré II or 950 km/h with Marboré VI
Rate of climb: Time to 10 000 m, 6 minutes
Service ceiling: 12 000 or 15 000 m with Marboré II or VI
Endurance: Mean 60 minutes
STATUS
Production is now completed but a considerable number of vehicles remain in service. The successor to the CT 20, the C 22, is operational (**3239.351**).
CONTRACTOR
Aérospatiale, Division Engins Tactiques, 2 rue Béranger, 92320-Chatillon Cedex, France.

3239.351
C.22 TARGET DRONE

The C.22 is a high-performance, subsonic aerial target, powered by a nacelle-mounted turbojet engine. It is designed for the testing of anti-aircraft weapons and for training air defence units armed with guns, surface-to-air missiles, or air-to-air missile systems. Sizeable dimensions, coupled with an extensive flight envelope and high manoeuvrability make it a realistic target capable of representing a sea-skimming anti-ship missile or a bomber at more than 12 000 m.

Aérospatiale C.22 target drone

Generous compartments and external load hardpoints are provided in the C.22 to house up to 135 kg of special equipment for radar/IR enhancement, active or passive countermeasures, and recording equipment for the assessment of weapon effectiveness during training. It can be equipped for towing one or two tow targets, weighing up to 30 kg each.

Plastic materials and lightweight aircraft techniques are extensively employed in construction of the C.22, which can be launched from the ground or ships by two jettisonable solid propellant rockets. Sustained flight is powered by a Microturbo TRI 60 turbojet of 350 kg thrust. Recovery on land or sea, is by parachute. An integrated system, called TTL, provides tracking, remote control and telemetry transmission. This system is developed by LCT.
CHARACTERISTICS
Length: 5·25 m
Wing span: 2·5 m
Diameter: 40 cm (fuselage); 34 cm (engine nacelle)
Launch weight: 610 kg (max)
Weight, empty: 300 kg
Service ceiling: 14 000 m
Rate of climb: 5 minutes to 12 000 m
Endurance at 12 000 m: 2 h 30 minutes
Max speed: Mach 0·95
Minimum altitude: <15 m
Manoeuvrability: Over 6 *g*
STATUS
Production.

GERMANY (FEDERAL REPUBLIC)

3779.351
TUCAN MINI-RPV

The experimental mini-RPV system Tucan RT-900 is under development for the Federal Republic of Germany MoD for use in the evaluation of various payloads on board a safe, small aircraft for battlefield tasks such as reconnaissance, target location and other similar operational roles. The system has been designed with these requirements in mind and is characterised by the following features:

A flying wing configuration has been adopted, with a medium to high aspect ratio. A rear-mounted engine drives a pusher propeller and the fuselage is of modular glass-fibre construction for maximum payload flexibility and minimum radar cross-section. The Tucan mini-RPV carries an on-board autonomous navigation system, which in conjunction with a ground control station equipped with command facilities permits the vehicle to be guided to its target area which it then systematically covers in an autonomous search mode. The payload can comprise TV and/or IR camera/tracker sensors mounted on a stabilised platform, LTDS/rangefinder etc, as well as the command, telemetry and video data

Tucan mini-RPV reconnaissance drone immediately after launch

link equipment. The integrated high-resolution FLIR camera with remotely changeable optics and stabilised platform ensures accurate location of targets. This part of the payload is housed in the nose of the mini-RPV and is capable of forward, rearward, downward and side-looking operation.

Launch is by means of a booster rocket and Tucan takes to the air direct from a short ramp within its container/launcher unit, which also provides environmental protection and storage facilities. The drones are stored and transported in pairs in these containers which can be mounted on any type of vehicle. Recovery is by means of a parachute, assisted by an inflatable airbag to cushion the shock of landing.

In addition to the container/launch system and the maintenance/overhaul truck, there is a ground control and guidance station and a ground data terminal forming the overall Tucan system. Here the mini-RPV acquired data transmitted in real-time via a jamming-resistant data link are displayed on a TV screen. Information may also be transmitted from the battlefield for presentation to other centres or simultaneously to artillery batteries.

KZO programme target acquisition RPV based on Tucan

CHARACTERISTICS
Wing span: 3·3 m
Overall length: 2·055 m
Launch weight: 100–140 kg
Payload: 30–50 kg
Fuel: 15 litres
Operating altitude: 3000 m

STATUS
Development was started in 1978 and the first flight took place in November 1979. The experimental Tucan RT-900 is under development for the German Federal Government and the hardware forms a basis for an operational target acquisition and location RPV proposal to meet the KZO (Kleinfluggerat fur Zielortung) requirement.

MBB and Matra have agreed on a common system concept known as 'Brevel' with similar system characteristics and they have signed a memorandum of understanding with the objective of carrying out a co-operative programme in the event of a Franco/West German government contract.

Sensor testing for the Tucan programme began in 1983, and by early 1984 250 test flights had been made without loss (some with two-thirds scale models).

No further progress had been reported by Spring 1985.

CONTRACTOR
MBB Marine and Special Products Division, Hünefeldstrasse 1-5, 2800 Bremen, Federal Republic of Germany.

4570.391
MBB-UM ATTACK DRONE (PAD)

MBB-UM (formerly VFW) continues the previous Locust mini-drone activities (see **3779.351** and **3166.351, 3604.391, 4037.391** and **4038.391** in 1983-84 and earlier editions) by directing them, and concentrating them towards a Combat Weapon System having as its two main tasks: anti-emitter (MHz and GHz bands), and anti-tank and similar battlefield roles.

The combat mini-drone was developed as a tailless, cruciform wing vehicle suitable for direct engagement of targets and consequently having high terminal phase accuracy at a high dive speed approach and broadly similar to a missile in design concept. A pre-requisite for such attacks is survival of the drone until the target is reached, and this is maximised in a number of ways; small size with low radar cross-section, minimal silhouette and small damage-sensitive surfaces; low-power engine with low IR and noise signatures; and a search phase flight altitude above the effective range of AA fire.

Locust mini-drone vehicle used in the MBB-UM attack drone (PAD) development programme

The attack drone dives at a steep angle on to its target. An integrated terminal guidance sensor directs the weapon with high accuracy, and the warhead is designed to destroy hardened targets. No details of the sensors available have been released but they can be expected to include passive IR homing and radar seeking types appropriate to the classes of target planned for PAD attack drones.

The anti-tank drones are operated in groups, 20 drones in a container can be made ready at one time. Such a container serves as a storage, transport, preparation and launch unit, it can be carried on any suitable truck, military or civil. Only a crew of two men are needed to launch 60 attack drones. A high launch rate is achieved through use of automatic launch sequence control, and only minimal prelaunch reconnaissance data input is required. Autonomous target acquisition and attack capability is complemented by a long-duration search phase and deep penetration features.

Launch is effected by a booster (zero length) which automatically detaches from the vehicle after burnout when the wings of the drone have unfolded after leaving the container. The container launch and vehicle flight characteristics, in particular the unbanked turns and steep dive, have been demonstrated in flight tests.

CHARACTERISTICS
Wing span: 2·26 m
Overall length: 1·81 m
Height: 1·03 m

Launch of PAD expendable attack drone from experimental container

Fuselage cross section: 0·26 m²
Weight: 100 kg
Payload and fuel: 50 kg
Speed: 140 – 250 km/h
Cruise altitude: Up to 3000 m
Duration: Several hours

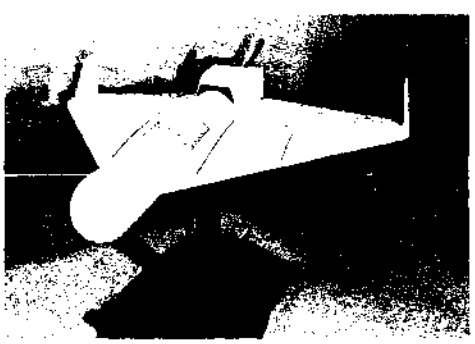
STATUS
Development project. This work apparently represents a continuation of the joint West German/US Locust programme of expendable combat mini-drone development (**4037.391** in 1983-84 and earlier editions) which has now been suspended.

CONTRACTOR
MBB Marine and Special Products Division, Hünefeldstrasse 1-5, 2800 Bremen, Federal Republic of Germany.

3602.351
DORNIER MINI-DRONE/RPV

This is one of the designs competing under Federal Republic of Germany Defence Ministry contracts for a mini-RPV for use in various battlefield applications, and which later was incorporated in the now-defunct US-FRG Locust harassment weapon programme. Roles examined include: reconnaissance, target location, fire control, target simulation, and point target engagement.

The airframe consists essentially of two fibreglass half-shells. The wing unit, integral with the fuselage, has elevons. The vertical tail unit carries the drogue parachute at the top. The keel protects the propeller during landing and also acts as a vertical tail surface. The payload compartment is of modular design and measures 600 mm in length and 200 mm in diameter. In the version with recovery system, the parachute container is in the fuselage centre, with the two fuel tanks to left and right of it. For one-way missions the parachute container can be replaced by an extra fuel tank to extend range, or by other equipment.



Dornier mini-drone experimental vehicle

The propulsion system is a two-cylinder, two-stroke opposed cylinder engine with a power of 22 hp, fitted at the rear end and driving a pusher propeller

For the reconnaissance and target acquisition and fire control missions the integration of a sensor package consisting of either a stabilised TV camera or a FLIR with autotrack facility coupled with a laser illuminator is under investigation.

Anti-radar missions and attacks on tanks/point targets are 'kamikaze' missions on which the vehicle homes on to and attacks the target out of a search flight, for example, using passive or active radar and/or IR seeker heads. For target demonstration missions, augmentation aids (such as smoke cartridges, flares or Luneberg lenses) can be integrated.

CHARACTERISTICS
Length: 2 m
Wing span: 2·1 m

Dornier mini-drone (Locust configuration)

Power plant: 22 hp 2-cylinder 2-stroke piston engine
Max launch weight: 70 kg
Payload: 15 kg
Max speed: 250 km/h (sea level)
Max operating height: 3000 m
Max endurance: 3 h

STATUS
No progress reported in 1984.

CONTRACTOR
Dornier GmbH, Postfach 1420, 7990 Friedrichshafen 1, Federal Republic of Germany.

3601.351
DORNIER EXPERIMENTAL SPÄHPLATTFORM

The Spänplattform is a small tethered rotor platform which needs no drive system. Its rotor is surrounded by a solid ring which, accelerated to a high speed on the ground, acts as an energy store and as a gyroscopic stabiliser. The stored energy is sufficient for a flight time of just over one minute, in which operating heights of 50 to 100 metres are reached.

The Spänplattform was designed as a carrier system for optical and electro-optical reconnaissance sensors. This experimental system was described and illustrated in the 1984-85 and earlier editions of *Jane's Weapon Systems*.

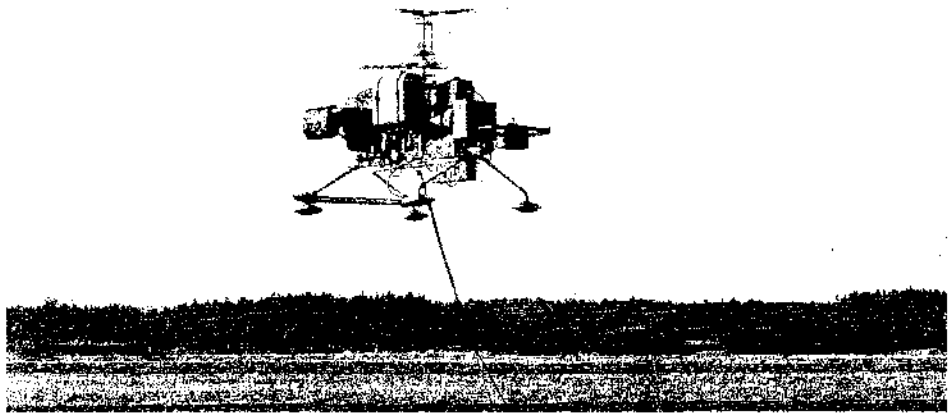
STATUS

Development undertaken by Dornier under private funding.

In addition to stand-off reconnaissance, an untethered version of the Späplattform is being examined as a sea-skimmer defence system which will operate from ship decks. No further progress has been reported.

CONTRACTOR

Dornier GmbH, Postfach 1420, 7990 Friedrichshafen 1, Federal Republic of Germany.



4294.351
DORNIER EXPERIMENTAL MINI-TELECOPTER

Based on the experience with the unmanned mini-helicopter MTC 1, a more powerful prototype, the MTC II, has been developed by Dornier and, after integration of an appropriate payload, can be used for battlefield reconnaissance, target acquisition and fire control, mine detection, detection of NBC contaminated areas, communication link jamming and decoying anti-ship missiles. Unmanned mini-helicopters are particularly effective for many of these types of mission because of their hover, vertical take-off and landing capabilities.

The MTC was designed as a helicopter with coaxial contra-rotating rotors of identical basic torque. This means that a tail rotor can be omitted and the total engine power serves the rotor drive. Each rotor is of three-blade design to decrease vibration. The rotor blades are rectangular and made of a wood/glass-fibre composite. They are connected to the rotor hub by flapping hinges. Lag hinges are not necessary.

The rotors are driven by a two-cylinder, two-stroke engine producing 29·5 kW power via a single-stage coaxial angle gearbox. The connection between the gearbox and engine is a centrifugal clutch ensuring a no-delay separation in the event of engine failure and giving an auto-rotation capability. The MTC II is fully stabilised and also equipped with a yaw damping control. A spider landing skid supports the flight vehicle on the ground and when landing.

In the operational role the MTC II can be equipped with a mission payload of up to 60 kg. Maximum take-off weight is 190 kg and endurance is two hours. For battlefield reconnaissance and target acquisition missions a sensor package consisting of a stabilised TV camera (or FLIR) with autotrack capability coupled with a laser designator is the probable payload. Mine detection missions and missions for detecting contaminated areas require high resolution thermal imagers or special detectors. Appropriate jammers and decoy transmitters can be fitted for ECM flights.

Dornier experimental mini-telecopter in flight

CHARACTERISTICS
(Prototype MTC II)
Width: 0·8 m
Length: 1·5 m
Height: 1·15 m
Rotor diameter: 3·2 m
No. of blades: 2 × 3
Max take-off weight: 190 kg
Max payload: 60 kg
Power plant: 1 Hirth 028 276 RO3 E 40 hp
Max speed: 140 km/h
Note: Operational systems may differ in data according to user specifications.

STATUS

Flight testing of the MTC II commenced in March 1987 followed by mission-oriented concept studies. Dornier is believed to have proposed an Argus II vehicle, based on the MTC II, to replace the cancelled Argus battlefield drone system, but no details have been received.

CONTRACTOR

Dornier GmbH, Postfach 1420, 7990 Friedrichshafen 1, Federal Republic of Germany.

INTERNATIONAL

3238.351
AN/USD-502 (CL-289) RECONNAISSANCE DRONE

The AN/USD-502 surveillance drone is a follow-on project to the Canadair AN/USD-501 (**2034.351**) adopted by Canada, France, West Germany, Italy and the UK. The designers of the latter, Canadair, several years ago planned an improved performance version of the CL-89 (AN/USD-501), which was designated CL-289. Based on this concept, the AN/USD-502 emerged in July 1976 as a formal international project between Canada and West Germany when Canadair was awarded a $68·3 million contract for the design, development and test of an AN/USD-502 prototype, with Dornier of FRG as the main sub-contractor.

The CL-289 is equipped with a Zeiss reconnaissance camera and a SAT IR linescan sensor with real-time data transmission. The navigation/control system comprises a Canadian Marconi doppler sensor and a Dornier system airborne digital computer in which is stored the mission program which generates the command signals required for navigation, altitude control and sensor activation. A KHD turbojet engine gives the drone a high subsonic cruise speed; a solid-fuel booster is used to accelerate the drone off the launcher.

In March 1977 France joined the programme, with Société Anonyme de Télécommunications (SAT) as the French sub-contractor. The three governments are sharing the funding of the project. Successful flight trials by the contractor were completed in April 1981. Customer evaluation and troop trials began at the beginning of 1982 and were completed early in 1983. Production is expected to commence in January 1987.

STATUS

The first successful test flight took place in March 1980. Pre-production was scheduled to start in July 1985.

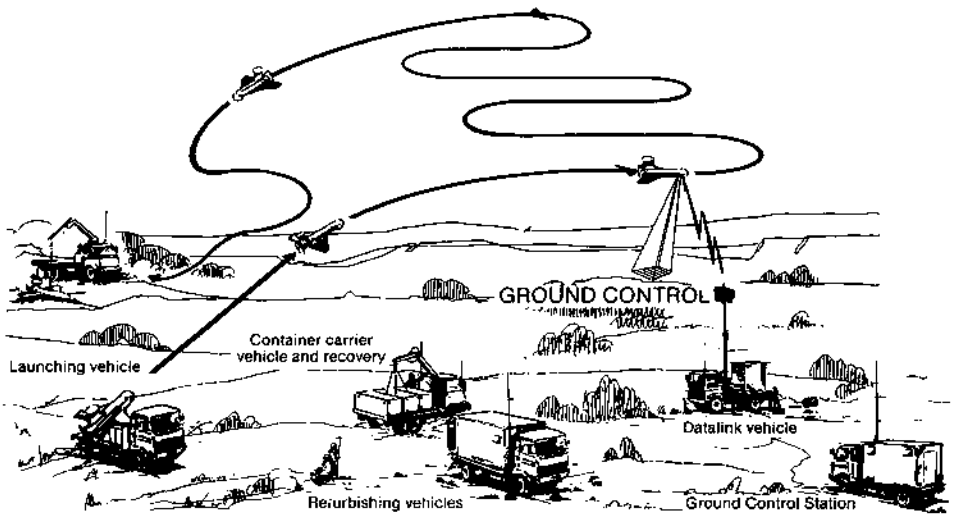
BREVEL RECONNAISSANCE DRONE

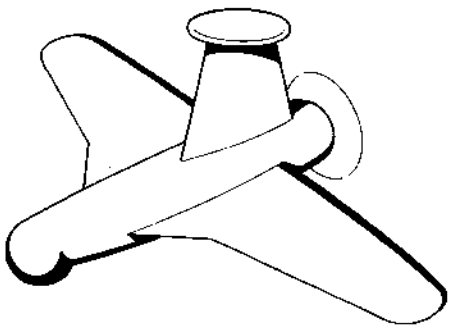
The West German company MBB is combining its experience with the Tucan programme (**3779.351**) with that of the French Matra concern's Scorpion project in a collaborative venture known by the name Brevel (derived from the parent companies' locations at Bremen and Velizy).

The joint Brevel programme combines the common features of the Tucan and Scorpion designs, and its objective is the development of an organised reconnaissance system with mobile, speedily deployed batteries including one or more firing vehicles and a command vehicle equipped with the requisite command, control and communications systems. The latter include data transmission facilities between the RPV and the control station for reconnaissance sensor information and for operating purposes etc. The vehicle is in the 100 - 150 kg class and will have a penetration range of about 50 km, several hours of autonomy, carrying a payload consisting of a TV camera or forward-looking infra-red sensor and recorder for deferred inflight transmission.



STATUS

The agreement for the development programme was signed in April 1983 and it is envisaged that the Brevel system could be operational in 1991.



CONTRACTORS

SA Matra, BP No 1, 78146 Vélizy-Villacoublay Cedex, France.

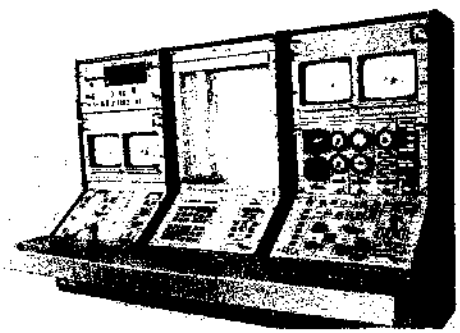
TADIRAN MASTIFF MINI-RPV Mk III

The Tadiran Mastiff Mk III is a mini-RPV of conventional miniature aircraft configuration, for use in reconnaissance, surveillance, target designation, artillery spotting roles and EW and communications relay missions. The 30 kg payload capacity permits a variety of sensors to be carried, including (in addition to other payloads) still or TV cameras mounted on gyro-stabilised gimbals.

High survivability is ensured by the small radar cross-section, negligible IR signature, low visibility and noise levels of the mini-RPV. All these factors make its detection by opposing forces extremely difficult. The mini-RPV generates 1 kW of electrical power, of which some 400 W are available for various payloads such as:

(1) a TV camera carried on stabilised gimbals operable in yaw (360°) and pitch (-88 to +5°) with remote control of both camera lens viewing angle and 1:10 zoom
(2) a TV camera on gimbals and miniature panoramic (mini-pan) film camera for detail photography
(3) various EW and ECM, or ESM packages
(4) certain other electro-optical (eg laser designator, mini-FLIR etc) payloads to suit specific missions.



Mastiff Mk III mini-RPV

The ground control station is housed in a standard S-280 type shelter which is normally carried on a 2·5-ton military vehicle. The functions of this unit are mainly those of vehicle and payload control, RPV tracking, video and telemetry data reception, with mini-computer processing of received data and display for real-time or subsequent analysis. There is a portable control station that permits RPV take-off and landing at a site remote from the ground control station, and this is used when the latter is located in terrain unsuitable for launch and recovery and/or when extended mission range is required. A vehicle-mounted hydraulic launcher is available for assisted launch when a take-off strip cannot be found. A tail-hook and arrester wire are used for landing and retrieval.

CHARACTERISTICS

Length: 3·3 m
Wing span: 4·25 m
Wing area: 2·16 m²
Height: 80 cm
Power plant: 22 hp 2-cylinder 2-stroke piston engine
Max take-off weight: 115 kg
Mission payload: 30 kg
Fuel: 33 litres
Max level speed: 180 km/h (sea level)
Cruising speed: 90 - 130 km/h (typical)
Max rate of climb: 305 m/minute (sea level)
Max altitude: 3660 m
Range: 100 km
Endurance: >7 h

A new ground control system, GCS-2000, able to operate Scout or Mastiff vehicles has been developed for the Israeli combined mini-RPV programme

STATUS

The drone/RPV activities of Tadiran Ltd and Israel Aircraft Industries Ltd, including their respective flight vehicles, Mastiff III and Scout, were pooled in 1984 in a new concern, Mazlat Ltd, which is a jointly owned subsidiary of the two originating companies. A new ground control station able to operate Scout or Mastiff vehicles has been developed, the GCS-2000.

CONTRACTOR

Mazlat Ltd, Kiryat Weizmann, Science Park, Ness-Ziona 70400, Israel.

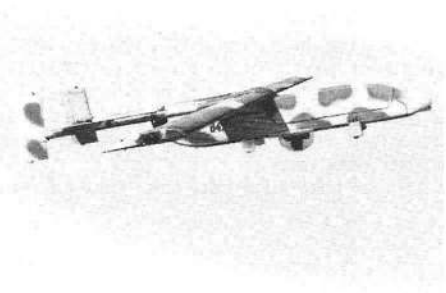
3736.391
SCOUT MINI-RPV

The IAI Scout is a miniature RPV designed to enable ground troops to control it for reconnaissance or surveillance missions, with minimum training requirements. To ensure this, the control system is organised so that the operator has merely to transmit flight-path demands to the RPV, such as changes in altitude or new headings, rather than using the link between RPV and ground station to convey signals for direct operation of the air vehicle's aerodynamic control surfaces. Instead, the demands transmitted to the air vehicle are fed to the autopilot which contains the necessary control logic to translate the demands into appropriate movements of the control surfaces. This method has an advantage over systems that rely on the ground operator being responsible for 'flying' the air vehicle by remote control; the latter technique requires almost continuous transmission from ground to air via the command link, whereas the alternative employed in the Scout system requires transmission only when a fresh flight demand has to be passed to the air vehicle. This is clearly less vulnerable to countermeasures actions and offers the possibility of a single operator controlling more than one air vehicle.

The configuration of the Scout can be seen from the accompanying illustration. The Scout fuselage is constructed of composite materials and aluminium with a small radar signature. Launching is assisted by a catapult from a truck-mounted ramp. A transparent dome on the underside of the fuselage houses a gyro-stabilised TV camera equipped with a 1:15 ratio zoom lens and a panoramic camera. The pictures obtained are relayed back to the ground station by data link for real-time display, and it is assumed that the operator has some remote control over the camera. For recovery the Scout is flown into a net set up at the ground station.

CHARACTERISTICS

Engine: 2-cylinder 22 hp
Wing span: 4·96 m (with wing extension)
Length: 3·68 m
Launch weight: 139 kg (fuel: 24 kg, payload: up to 30 kg)



Max speed: 157 km/h
Economical cruise speed: 100 km/h
Max altitude: 3000 m
Endurance: 7 h (approx at economical cruise speed)

STATUS

The drone/RPV activities of Tadiran Ltd and Israel Aircraft Industries Ltd, including their respective flight vehicles, Mastiff III and Scout, were pooled in 1984 in a new concern, Mazlat Ltd, which is a jointly owned subsidiary of the two originating companies. A new ground control station able to operate Scout or Mastiff vehicles has been developed, the GCS-2000.

ANDROMEDA RPV SYSTEM

The Andromeda RPV system is the result of considerable study and developmental work carried out by Meteor in relation to evolving a multi-role system capable of meeting most battlefield and training functions for land, sea and air forces. This is achieved by means of a range of unmanned aircraft which can be operated in conjunction with a self-contained mobile ground support and control system. The latter was described in some detail in the 1977 edition of *Jane's Weapon Systems*.

The overall Andromeda system is composed of the following sub-systems:

(1) the ground station for control of the RPV mission by the crew
(2) equipments for launch, recovery and maintenance of the RPV aircraft
(3) equipments for the preparation, recovery and maintenance, and operation and/or checkout of the payload and/or the data collected
(4) the RPV aircraft. This sub-system comprises a range of five vehicle types (see table) configured to specific operational roles.

The Meteor range of vehicles is known by the name Mirach and a suffix number to denote model/role. The manufacturers state that the Andromeda system may be used with other vehicles.

EYRIE MINI-RPV

The Eyrie is a multi-purpose mini-RPV designed to fulfil a variety of potential battlefield roles such as reconnaissance, surveillance, electronic warfare and artillery adjustment as well as fleet surveillance and rocket strike. It is a private venture.

The Eyrie is of modular design and the Warren-Young rhomboidal wing configuration has been adopted for its non-stalling and spinning flying characteristics. It is also rugged and has low observable signatures (radar, IR, noise). Construction is from precision moulds, the wing being of composite structure with a Kevlar skin and rigid PVC foam core. The main fuselage is integral with the wing, and the nose-cone houses the video and other electronic equipment and is detachable.

The Eyrie is powered by a 48 kW two-cylinder two-stroke engine driving a two-bladed pusher propeller. Launching is by zero-length launcher, hydraulic catapult or moving truck with recovery by means of a travelling catch net. The main part of flight control is under the management of the flight controller using a console in the mobile ground control station (MGCS) assisted by an auto pilot in the RPV providing automatic stabilisation in the lateral plane. The autopilot function can be overridden at the flight controller's discretion.

The payload includes two TV cameras, one fixed forward looking for navigation and strike and one port/forward/starboard slewing for target identification and back-up. The MGCS, launch and recovery subsystems, GPUs, antennas, maintenance and stores are mounted on five military trucks and two trailers.

Operational version of National Dynamics Eyrie mini-RPV

CHARACTERISTICS
Length overall: 3·49 m
Wing span: 4·27 m
Height overall: 1·26 m
Fuselage diameter: 0·55 m
Power plant: 47 kW Rotax 503 engine with tuned exhaust and silencer
Max level speed: 320 km/h
Weights: 110 kg (empty); 220 kg (max launch)
Endurance: 8·5 hours without rockets
STATUS
Fully developed

BTT-3 BANSHEE TARGET

The Target Technology Ltd BTT-3 Banshee has been designed as a basic training aerial target for use by crews of surface-to-air missiles and anti-aircraft cannon systems. Glass-reinforced fibre is used in construction of the delta-wing vehicle which is controlled by twin elevons, and powered by a 26 hp two-stroke piston engine driving a fixed pitch two-bladed pusher airscrew.

Banshee is launched from a vehicle-mounted catapult and recovery can be by either a conventional belly landing on land or water, using an under-fuselage stroke pod as a landing skid, or by means of a cruciform recovery parachute. A PCM radio command link operating in the VHF band is used for remote control of the Banshee, in conjunction with line-of-sight tracking aided by gyro-stabilised binoculars and an autostabilisation system with height lock in the flight vehicle. There is a long-range tracking system available for use at ranges up to 20 km.

Various payload options are available for the aerial target role, including a nine- or ten-shot smoke pod, IR flares, Luneberg lens and corner radar enhancing reflectors, and miss distance indicating equipment.

There is also a reconnaissance/ECM version of the Banshee designated Spectre which can carry various alternative E-O payload packages, including a data down link.

Launch of Target Technology Ltd BTT-3 Banshee target drone

CHARACTERISTICS
Length: 2·84 m
Wingspan: 2·49 m
Height: 0·71 m
Power plant: WAE 342 cc 28 BHP two-cylinder, two-stroke
Fuel capacity: 12 l
Payload: 15 kg
All-up weight: 54·4 kg
Speed range: 74 – 306 km/h
Duration: 1 – 15 min
STATUS
Production. In service with two Middle East countries.

STABILEYE MINI-RPV

Stabileye was designed as a mini-RPV for use in research programmes into a variety of battlefield roles such as reconnaissance and target location etc. A number of experimental payloads have been carried, including a BAe Dynamics IR linescan system. The prototype Stabileye (serial number 30) first flew in September 1980, and nine more vehicles were ordered by the UK MoD for use in a flight trials programme to evaluate the potential of RPVs and various payload/sensor combinations in a battlefield context.

These nine RPVs, ordered in December 1981, and later vehicles were known as Mk 1 and Mk 2 models, and the current version is the Mk 3, but Mk numbers have now been discontinued and the latest version is known as the BAe Stabileye.

The vehicle is configured as a high wing monoplane with constant chord wings supporting a rectangular cross-section fuselage and a twin-boom mounted tail assembly consisting of a tailplane, single fin and rudder. A hinged top to the fuselage provides access to the payload space, and the power plant is mounted at the rear end of the fuselage, driving a pusher propeller. The wings are of foam core construction and are equipped with conventional

ailerons. The power plant is a 25 hp two-cylinder, two-stroke Weslake Type 342 engine with a two-bladed airscrew.

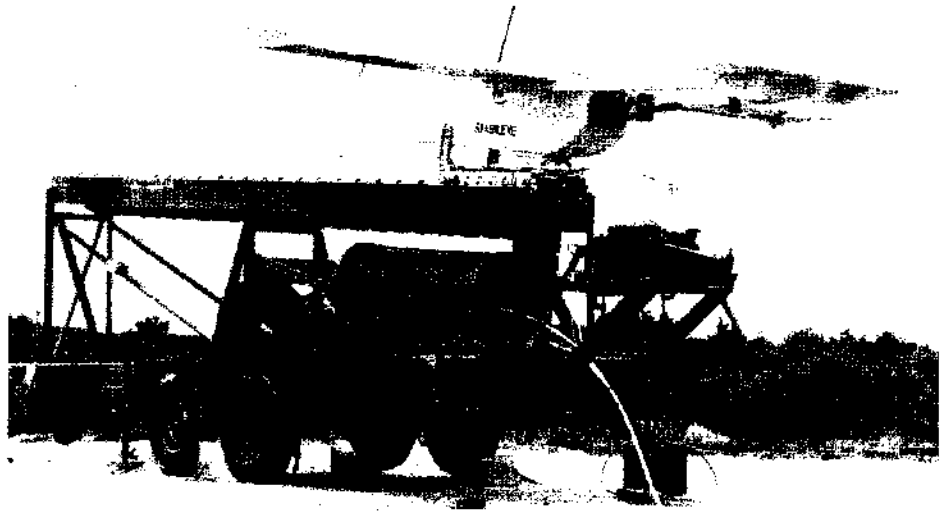
OPERATION

Stabileye is launched from a pneumatic catapault, and recovery is by means of a parachute assisted by an air bag inflated beneath the fuselage to cushion the vehicle against impact with the ground on landing. In the event of contact with the RPV being lost, the parachute and airbag are deployed automatically as a safety precaution to terminate the flight. Parachute release automatically switches off the engine and initiates air bag inflation.

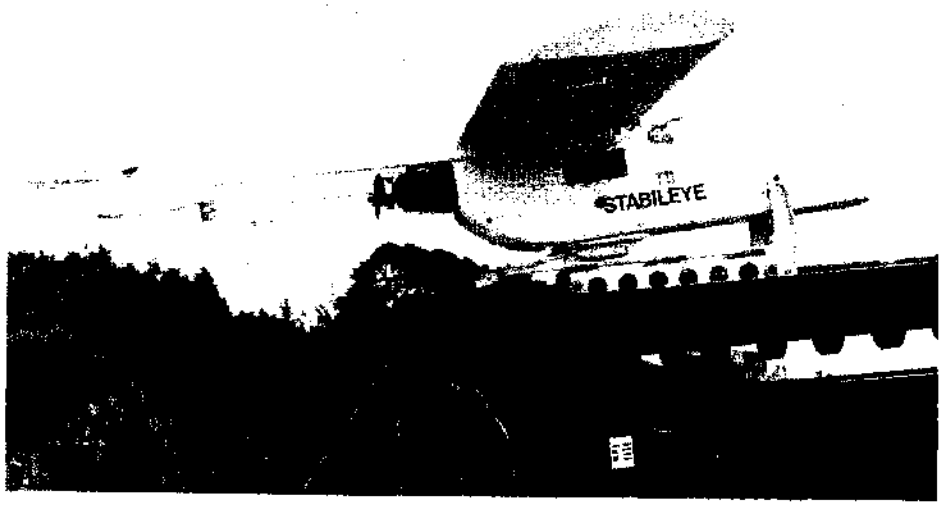
Guidance and control from the ground is by means of a radio telecommand link. The RPV is tracked by radar and other ground equipment includes a plotter unit that shows the position of the vehicle relative to a map of the area of interest and a TV screen on which the view from the Stabileye is displayed in real-time. The on-board flight control system interfaces with the pulse code modulation (PCM) telecommand system, and includes flight control electronics, vertical and yaw rate gyros, magnetometer, telemetry encoder and command receiver/decoder. Alternative payloads include still cameras and BAe Linescan equipment.

One complete Stabileye 'real-time' battlefield surveillance system consists of a ground control cabin, pneumatic launcher and six Stabileye RPVs with various payload options.

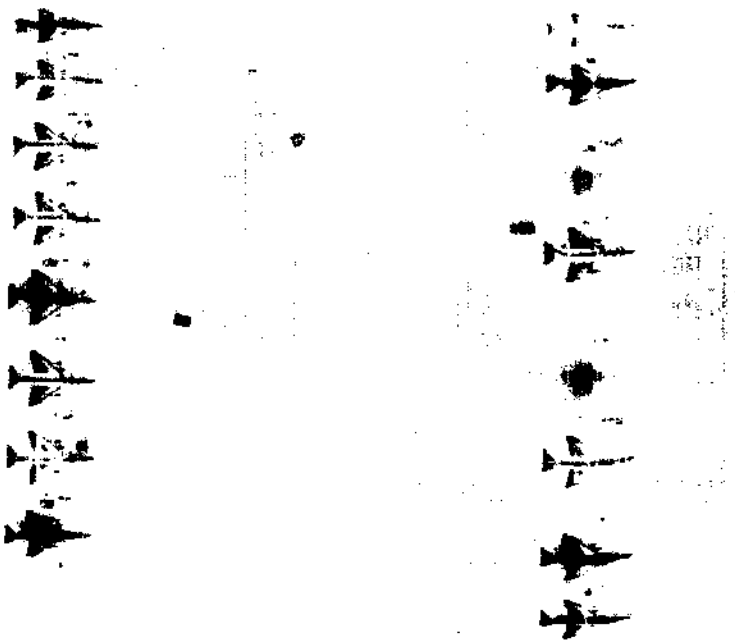
CHARACTERISTICS



Length: 2·87 m
Wing span: 3·65 m
Weight: 82 kg
Payload: 25 kg
Cruising speed: 96 – 180 km/h
Duration: 4 h



STATUS



The prototype Stabileye first flew in September 1980. Nine more RPVs were ordered for the UK MoD in December 1981. These are still used for flight trials and a further order for eight more vehicles was announced in May 1983. Another vehicle was later added to this order. In January 1984 construction of a new batch for an unnamed customer had commenced. A total of about 50 vehicles has been produced to date, the most recent using a revised pneumatic launcher.

FLIGHT REFUELLING TARGETS

Flight Refuelling Ltd has produced pilotless drones and target systems of a wide variety for many years. Its Rushton targets provide an airborne system which, in terms of altitude, air speed and tow length (up to 7·5 miles/12 km) cater for the needs of all types of modern air-to-air and surface-to-air weapons. Sleeve type targets for use with the older conventional weapons are also available. The Rushton target can be towed supersonically and incorporates radar, visual and IR enhancement devices together with facilities for miss-distance measurement. It is made up of easily put together sections and thus by selecting the appropriate modules can be quickly assembled to meet a variety of weapons requirements.

Rushton low-level height-keeping target

To augment this proven system, the Rushton LL height-keeping target has been introduced to simulate sea-skimming missiles' attacks to provide training for a variety of weapon systems. The target provides a facility to 'fly' over a range of pre-set heights from 500 feet (150 metres) down to 15 feet (4·5 metres) above sea level and is designed to give a

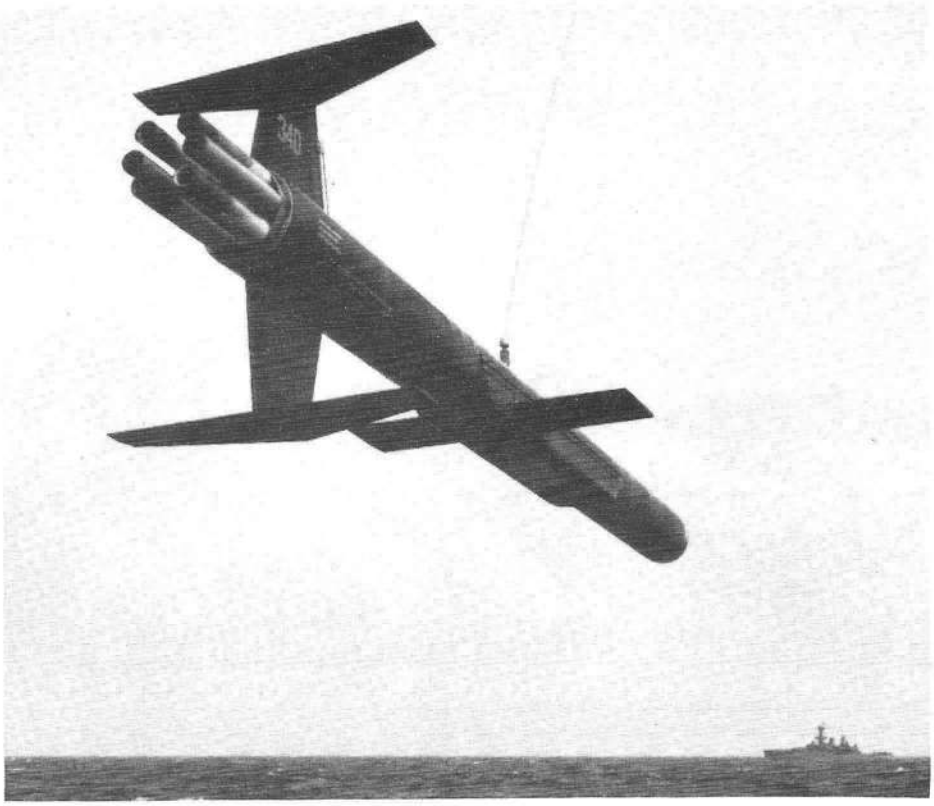
height keeping accuracy of within ±7 feet (2·1 metres). It is equipped with radar and visual augmentation, an infra-red output and MDI.

Seaflash

The Seaflash radio-controlled surface target has been manufactured to enable the Royal Navy and other services to carry out practice firings against high-speed surface targets and to simulate fast patrol boat attacks.

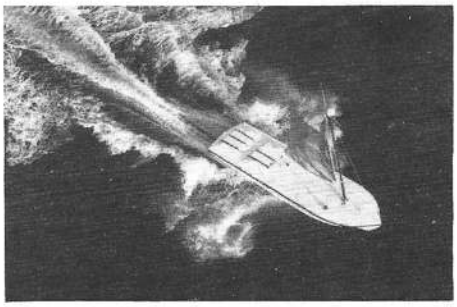
Seaflash has been in service with the Royal Navy since 1973 and provides a realistic target for surface-to-surface and air-to-surface practice with conventional or guided weapons. The hull is a deep V design, constructed in glass-reinforced plastics and fitted out to withstand hard usage under service trials conditions. The size of the boat enables it to be carried aboard fighting ships during exercises.

Seaflash has many features which render it efficient and economical as a surface target-training system. The following features have been found to be especially advantageous:



(1) facilities are provided to enable the boat to be fully tested with a crew aboard, in preparation for unmanned operation
(2) built-in buoyancy is provided to prevent the boat from sinking in the event of minor shrapnel damage, during firing trials
(3) reserve electrical power and adequate stowage space is available for specialised instrumentation and equipment, as required for weapon evaluation trials
(4) the control equipment is on a modular basis for ease of maintenance at sea
(5) an attack by a flotilla of fast patrol boats can be simulated by operating several Seaflash targets simultaneously
(6) visual enhancement of a Seaflash is achieved by fitting a large target flag. The targets can be controlled either from an accompanying vessel or from a helicopter.

CHARACTERISTICS



Length overall: 8·99 m
Max beam: 2·21 m
Height from waterline to command antenna (erected): 5·79 m
Weight (approx): 1800 kg
Engine: Mercruiser Type 470 or Volvo Penta
Speed, max: In excess of 30 knots
Operational endurance: 8 h
Control range: 20 000 m (dependent on height of transmitting antenna)

CONTRACTOR

Flight Refuelling Limited, Wimborne, Dorset BH21 2BJ, England.

Rushton Height Keeping Towed Target maintains stable level flight at heights between 150 and 4·5 metres to simulate anti-ship missiles

Seaflash radio controlled marine target is designed for training with ships' guns, coastal artillery and air-to-surface weapons

RAVEN MINI-RPV

The Flight Refuelling Ltd Raven system is designed to provide at low cost an RPV surveillance system capable of producing real-time TV imagery and a collection of still photographs in daylight, and also offer a means of evaluating alternative payloads and operational roles. Although not designed initially as a hardened military tactical system, it includes the primary elements of such a system (eg launcher, air vehicle, navigation system, payload management, telecommand etc), and could form the basis of military systems in the future.

The Raven air vehicle configuration can be seen from the nearby illustration. It is a small mini-RPV with an all-up weight of about 15 kg (see table for detailed characteristics), with a standard payload that comprises a video camera and a down-link transmitter for the return of reconnaissance/target data. Constant chord wings constructed of foam cored glass-fibre and obeche support a glass-fibre fuselage. This contains the payload compartment, which has a transparent camera window in the nose and downward-viewing panels for the still camera; the autopilot and radio equipment; fuel tank; and has a Webra 91 15 cc two-stroke engine driving a pusher propeller mounted at the rear. The high-T tail assembly is carried on a tubular boom structure extending from the underside of the fuselage.

The air vehicle is launched from a special trailer equipped with a folding launch rail and compartments for transporting two mini-drones in partially dismantled form. The launch is powered by elastic cord in which energy is stored by means of an irreversible hand-operated winch. Recovery is effected by an arrester net which can also be dismantled for transport. A recovery video camera is mounted behind the recovery net and aligned with the glide-slope so that the vehicle can be manually controlled into the net. Additional operating details appeared under this entry number in the 1984-85 edition of *Jane's Weapon Systems*.

Flight Refuelling Ltd Raven mini-RPV climbs over its home airfield

CHARACTERISTICS
Wing span: 2·7 m
Length: 2·1 m
Height: 0·5 m (over prop)
Launch weight: 15 kg (typical)
Max fuel: 1·5 litres
Endurance: 80 mins at 88 km/h TAS
Max operating altitude: 2500 m
Speed range: 74 - 126 km/h
Stall speed: 46 km/h
Range: Over 100 km
Typical payload: 2·5 kg
Power plant: Webra 91 15 cc two-stroke engine
Autopilot: Skyleader, with Skyleader SRC-4 servos
Telecommand: PCM digital
Radar transponder: Plessey WF3 (X-band)
Computer: HP 86 or equivalent
Tracking radar: Plessey WF3
STATUS
Deliveries under UK MoD contract were due to commence in 1984

AEL SPARROWHAWK

The Sparrowhawk reconnaissance drone system has been designed for field use to provide commanders with real-time information on which to base their decisions. In recent European trials a Sparrowhawk fitted with an AEL auto-stabiliser and command link demonstrated a proven radius of operations of more than 35 km.

Construction comprises a glass-fibre reinforced plastic fuselage, with foam core marine ply wing. The basic Sparrowhawk payload includes a TV camera and data downlink. Other payload options include still cameras, IR or thermal imaging packages, ESM/ECM or a chaff/flare dispenser. The command link employs a digital proportional PCM system providing independent control of all on-board equipment. The auto-stabiliser is a stick priority pressure-controlled, rate-stabilised two-axis unit with built-in control limits and height hold. Tracking of the vehicle is by means of a standard RDF system with an optional interface to a plotting table.

Sparrowhawk during European evaluation trials

CHARACTERISTICS
Wing span: 3·2 m
Length: 2·77 m
Weight: 59 kg (all-up)
Engine: 342 cc 2-stroke with electronic ignition
Duration: 90 minutes (average)
Max speed: Over 300 km/h
Max range: 50+ km
STATUS
Production.

AEL (RPV) Limited, Gatwick House, Horley, Surrey RH6 9SJ, England.

4296.391
AEL SNIPE TARGET DRONES
AEL 4700 Snipe Mk III

The Mk III meets the target requirements for large calibre defence guns and medium-range missiles. It is considerably larger and faster than Mk II, and many of the latter systems have been up-graded to Mk III standard by existing users to provide a comprehensive target system.

Construction of the Snipe Mk III is as for the Sparrowhawk (**4821.391**), and the same command link is used for both models.

The AEL autopilot gives the Snipe Mk III a proven out-of-sight range up to 35 km, as required for range operation of medium-range weapon systems. It can be tracked with the AEL tracking unit allowing deployment away from permanent installations. System reaction time is short and a target can be launched within 15 minutes of the crew arrival. Average turn-round time between sorties is less than 10 minutes. Target recovery is by normal belly-landing if there is sufficient space, or by parachute, if not.

A built-in fail-safe mechanism ensures that under conditions of lost command signal, severe interference, loss of main power or destruction of the receiver, the engine will be stopped and the parachute deployed automatically.

CHARACTERISTICS
Wing span: 3·14 m
Length: 2·5 m
Engine: 342 cc 2-stroke with electronic ignition
Fuel: 25:1 petrol/oil mixture
Duration: 60 minutes (average)
Max speed: Over 300 km/h
Max range: 50 km (tracking); 9 km (binoculars)

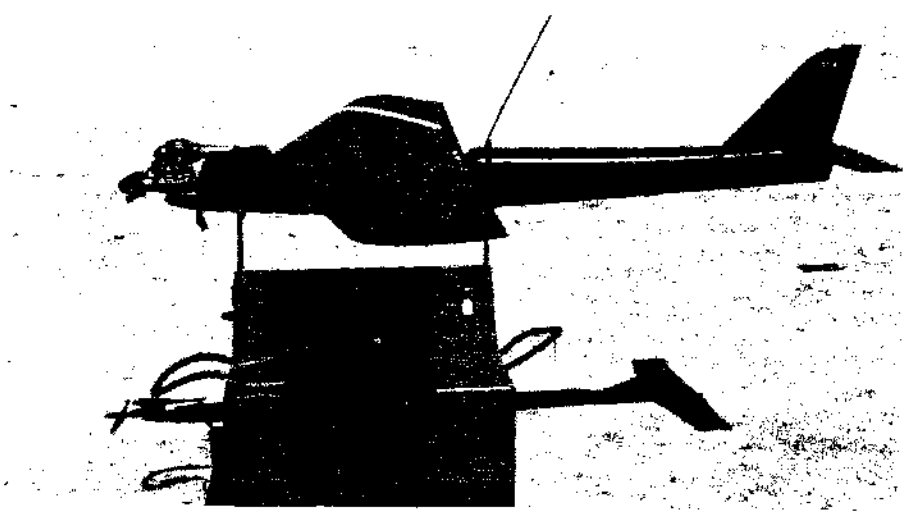
AEL 4111 Snipe Mk II

The Snipe Mk II is intended for use with large calibre weapon systems and ammunition (20 to 40 mm), and man-portable surface-to-air missiles. It is currently in service with 15 armed forces world-wide.

The ground support equipment comprises a self-contained trailer unit that carries a launcher (for use with both Mks II and III Snipe and Sparrowhawk vehicles), special tools, spares back-up for extended operational use, and is designed to be towed by a Land-Rover or similar vehicle. The launcher is powered by powerful rubber bungees, requiring no maintenance. The trailer will carry two flight vehicles and all equipment spares and tools for extended operations.

CHARACTERISTICS
Wing span: 2·44 m
Length: 2·1 m
Weight: 19 kg
Engine: 100 cc 2-stroke with electronic ignition
Fuel: 20:1 petrol/oil mixture
Duration: 40 minutes (average)
Max speed: 210 km/h
Max range: 15 km with autopilot and radar, 5 km with binoculars, 2 km by eye

Support trailer/launcher
Length: 5·18 m including draw-bar
Width: 1·79 m
Height: 1·75 m
Body dimensions: 3·048 × 1·79 × 1·07 m



The Snipe and Sparrowhawk systems have a number of common payload features, summarised below

45-second smoke
Attachment: Up to 8 in wing-tip pods
Colour: Red, orange, blue
Firing: Individual by operator command
Ignition system: Electrical
25-second IR flares
Attachment: 2 in wing-tip pods (Snipe Mk II); rear-mounted cluster (Snipe Mk III & Sparrowhawk)
IR spectrum: To customer specification
Firing: Individual by operator command
Ignition system: Electrical
(A variety of corner reflectors and/or Luneberg lens are available according to requirements.)
STATUS
Current production.
CONTRACTOR
AEL (RPV) Limited, Gatwick House, Horley, Surrey RH6 9SU, England.

4297.391
AEL 4600 STREEK TARGET DRONE

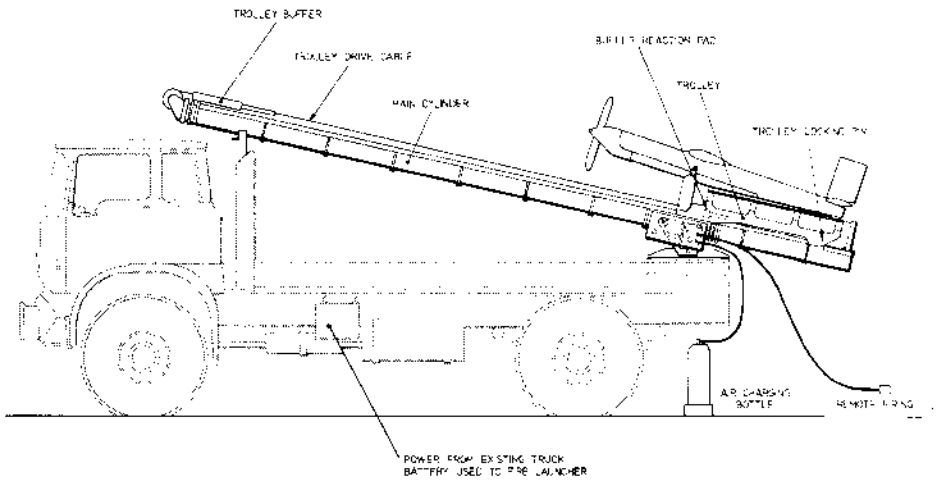
The Streek radio-controlled trainer/all arms air defence RPV is a cost effective and realistic target for small arms and machine guns used in air defence roles. It is also used as an *ab initio* trainer for personnel operating the larger Snipe target systems (**4296.391**), and as such it is in use with 15 armed services world-wide.

The Streek vehicle is constructed with a glass reinforced plastic (GRP) fuselage with a veneered polystyrene wing. The radio command link is crystal controlled and operates at customer-selected UHF/VHF frequencies. Ground support equipment is contained in a GRP box housing a 2·5-litre fuel container, electric fuel pump, electrical starter, a 12 V battery to power equipment and a selection of hand tools

AEL Streek target drone on launcher

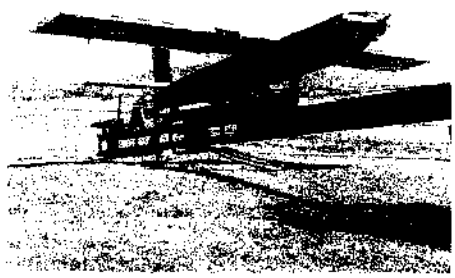
CHARACTERISTICS
Wing span: 1·7 m
Length: 1·385 m
Weight: 2·7 kg (all up)
Engine: Glo-fuel 10 cc
Fuel: 4:1 methanol/castor oil mixture
Duration: 20 minutes
Max speed: 140 km/h
STATUS
In current production and widely operated.
CONTRACTOR
AEL (RPV) Limited, Gatwick House, Horley, Surrey RH6 9SU, England.

3730.391
SKEET TARGET DRONE



Skeet is a compact, highly-manoeuvrable, radio-controlled aerial target for use in both target tracking and practice firings of close-range missiles and guns. The drone's 2·7 m long square-section fuselage is constructed of metal and glass-fibre and contains compartments for engine, recovery parachute, fuel, batteries and electronics. Its wings, fin and tailplane are constructed of fibreglass filled with polyurethane foam. Wing span is 3·35 m. Sixteen smoke flares for visual enhancement are carried in the landing skid and underwing pods may be fitted for customer's optional equipment. The radar returns are enhanced by a reflector mounted in the fuselage.

The aircraft is launched from a simple pneumatically-operated launcher which carries compressed air storage capacity for eight launches. Launching and flight can be carried out in crosswinds of up to 25 knots.



Operation is by radio-command in the 68 MHz band, using four information channels to control pitch, roll, throttle, stabilisation trim, height-hold and visual enhancement. Height-hold uses a simple barometric device to maintain the aircraft at the desired altitude. A visual control sight with binoculars is provided to assist the pilot in visually flying the drone over 5 km range and to enable repeat flight-paths to be flown. Recovery is by parachute or by conventional landing, utilising the fuselage underbody fairing as a skid. The parachute is deployed either by pilot demand or automatically in the event of engine, power supply or radio failure.

The target drone can be operated from land or on board ship and maintenance is minimal, being limited normally to refuelling, replacement of batteries, parachute and flares, and checks of the various control and ground equipment. Skeet is powered by a twin-cylinder 274 cc engine and has an endurance of 75 minutes at its maximum speed of 130 knots.

CHARACTERISTICS
Length: 2·72 m (including miss-distance antenna system)
Span: 3·35 m
Weight: 63 kg
Max speed: 130 knots
Endurance: 75 minutes
STATUS
Skeet is now in service with the British Army as well as with overseas customers.
CONTRACTOR
Short Brothers plc, Montgomery Road, Belfast BT6 9HN, Northern Ireland.

Variant of Shorts Skeet for vehicle mounting is under development

Skeet target drone on towed pneumatic launcher

3792.391
FALCONET ASAT

Flight Refuelling's ASAT (Advanced Subsonic Aerial Target), was designed in response to a UK MoD requirement. In British Army service this target is known by the name 'Falconet'. The development contract provided for the construction of eight flight vehicles, the first of which was flown in February 1982. Seven of the eight development vehicles had flown by the end of 1983, with the lead vehicle still serviceable after 10 flights. Trials included launch and recovery in wind speeds up to 28 knots and flight speeds in excess of 350 knots have been achieved, with non-visual control throughout. Operation of the system's 'Carousel' circular runway launch system, and the stability and control of the vehicle have been established. A zero-length launch system is also under development to provide added mobility including deployment in ships.

A maximum fuel load of 60 kg permits sortie times in excess of one hour. Approach and intercept legs of a typical target mission total about 10 km over the whole of which the target vehicle may be flown at more than 400 knots (740 km/h) at sea level. Ten such circuits can be repeated at 4½ minute intervals, but during less demanding operations, or where more time is required between presentations, the rate of fuel usage can be reduced by loiter at 3000 metres altitude. Maximum endurance with full allowances for take-off, climb, descent and recovery, is in excess of 90 minutes.

CONSTRUCTION
The ASAT subsonic target drone is configured as a cantilever low/mid-wing monoplane. The wings, tailplane and elevators are formed in folded flat aluminium sheet, without compound forming. The wings are interchangeable (left/right), have plain ailerons, and are attached to the fuselage by four bolts each. The tailplane is held in place by a GRP fin and two studs. A circular cross-section stressed skin fuselage of aluminium alloy has a frangible, expendable nose that is designed to absorb any nose-down ground impact. A cylindrical canister in the rear fuselage houses the recovery parachute, and there is a large equipment bay in the forward fuselage, aft of the nose cone. The engine pod is attached to the underside of the fuselage by two bolts.

The Ames Industrial Ltd 108 kg static thrust turbojet engine is supplied with fuel from an integral tank in the centre fuselage between the wings. Aft of the fuel tank is a smaller tank for oil which can be injected into the jet pipe by command from the ground, to produce smoke for visual enhancement. The fuel tank is pressurised to 1 bar (15 lb PSI) and has a capacity of 75 litres. Pressurisation for oil and fuel tanks is by engine compressor bleed air. The equipment compartment in the front of the fuselage houses avionics and optional target equipment such as miss-distance indicator and radio altimeter. The guidance and control system includes a radio command PCM sub-system with Skyleader receiver and Marconi Avionics autopilot, the latter effecting aerodynamic control by ailerons and elevators which have actuators located in the rear fuselage between the tanks and the parachute compartment. Control from the ground is by means of a microprocessor-

Falconet advanced subsonic aerial target in free flight

First zero-length launch of Flight Refuelling ASAT

based control station which utilises radar data for vehicle navigation and direction functions. The station is equipped with an operator's control console and there is a programmable ground-based control option using the microprocessor. The RPV has provisions for pylon mounting of optical or IR flares, radar enhancement devices, sub-targets, banners, or other external stores.

The ASAT vehicle takes off under its own power from a three-wheeled trolley tethered to a pylon in the centre of a 115 metre diameter circular track, running clockwise round the track for a distance of about three laps (equivalent to a straight line take-off run of 1000 metres). With this technique the launch can always be into wind. An alternative zero length launch stand was revealed by Flight Refuelling in late 1983 (see picture) which employs booster rockets to accelerate the vehicle, enabling a more rapid launch and/or eliminating the need for a take-off track. A phased-release Irvin parachute recovery system consisting of a drogue and single cruciform main canopy is pre-loaded into a cylindrical pack and deployed by tail-cone release.

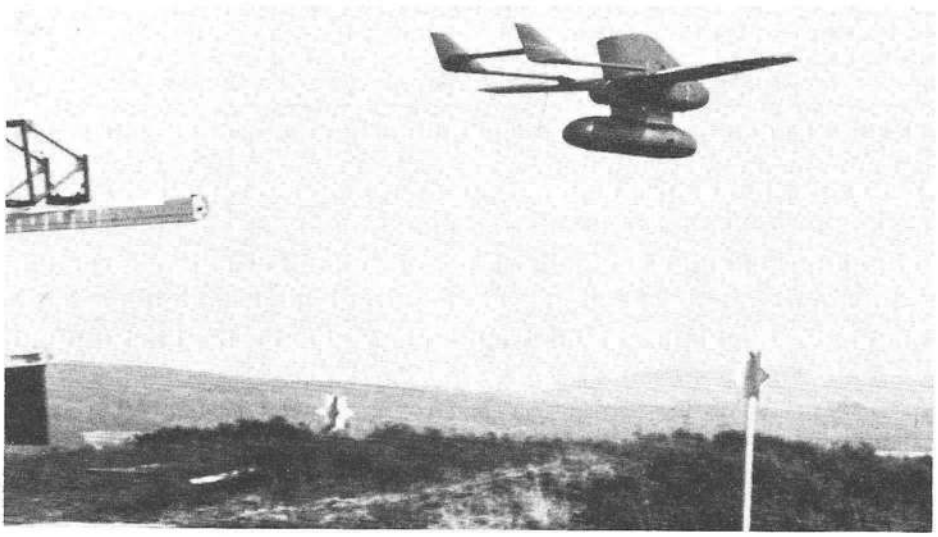
CHARACTERISTICS

Wing span: 3·05 m
Gross wing area: 1·4 m²
Aspect ratio: 6
Length: 3·5 m
Fuselage diameter: 387 mm (max)
Tail span: 1·32 m
Height: 1·32 m
Max launch weight: 205 kg
Power plant: Ames TRS 18-075 108 kg st turbojet
Max level speed: 834 km/h
Minimum loitering speed: 278 km/h
Max rate of climb (at sea level): 2600 m/minute
Endurance: 1 h (typical); 1·5 h (max)
Manoeuvring limit: ±4 *g*

STATUS

Design and development carried out under UK MoD contract awarded in 1978/79. First of eight flight vehicles delivered and flown in 1982 with entry into service in 1984.

CONTRACTOR



Flight Refuelling Limited, Wimborne, Dorset BH21 2BJ, England.

4592.351
PHOENIX RPV

The Phoenix RPV programme is concerned with the development of a surveillance and target detection/designation remotely piloted vehicle for use principally by the British Army in West Germany. A major function will be the location and acquisition of targets for medium- to long-range battlefield support weapons such as MLRS (**4060.111**) and heavy artillery.

Two teams drawn from British industry took part in a Ministry-funded competitive study which included flight trials. The Phoenix competition, which was in the CED (competitive engineering definition) phase from 1983 until late 1984, was won by the team headed by Marconi Avionics with Flight Refuelling as the major subcontractor and a fixed price contract of some £80 million for development and production was awarded in early 1985.

The programme evolved from the earlier Supervisor project that was cancelled in 1979, and the system envisaged will probably have an effective target detection/location range of about 50 km and an endurance of at least four hours.

Phoenix RPV in flight

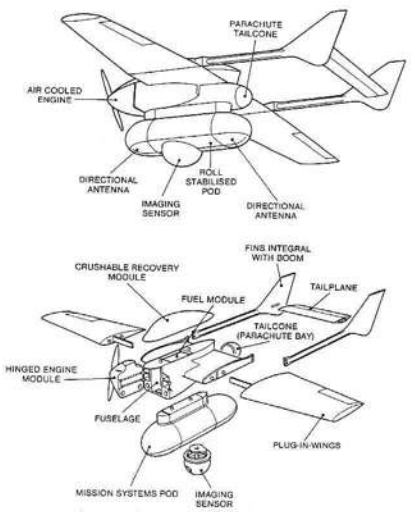


Diagram showing construction and major component locations of Phoenix RPV

The RPV payload includes a real-time surveillance and targeting system, for providing information by day and night which uses a GEC Avionics IR imaging sensor. The remotely-piloted surveillance aircraft will be supplied by Flight Refuelling Ltd, and utilises airframe parts of sandwich composite construction, manufactured by Herman Smith Hitco Ltd. Flight Refuelling Ltd is also responsible for the launch and recovery systems of the flight vehicle.

The flight control and navigation systems in the aircraft have been derived from the GEC Machan experimental RPV programme (**4298.391**) conducted with the Royal Aircraft Establishment. The surveillance data and RPV commands are transmitted via a data link supplied by Marconi Electronic Devices Ltd.

The computing system in the ground station will be interfaced with the Army's BATES battlefield command and control system (**2644.161**) and the ground station incorporates a specially developed digital map display unit by GEC Avionics.

STATUS

Entry into service is provisionally planned for 1988-89. Many aspects of the system's performance were demonstrated during the study phase, noted above, including trials with a full size air vehicle and fully representative control systems. The RPV was launched using ground equipment of pre-production standard. The IR sensor comprises thermal imaging common modules (TICM II) with a zoom telescope designed by Pilkington PE.

The demonstration programme successfully proved the launch and recovery system, the remote guidance and control system and the day/night imaging system. For the evaluation, a full scale mock-up of the ground station was assembled with its electronic systems, including the map display and these were demonstrated.

4480.391
SPRITE RPH

A new remotely piloted helicopter (RPH) design was revealed at the 1982 SBAC Exhibition at Farnborough under the name SPRITE, this being derived from the initial letters of the principal roles for which the vehicle is intended: surveillance, patrol, reconnaissance, intelligence gathering, target designation, and electronic warfare. As the adjacent photograph reveals, the helicopter configuration closely resembles the earlier Westland Wisp vehicle (**3243.351** in 1980-81 and earlier editions), but although the dimensions of Wisp and the later SPRITE are similar the latter is slightly larger in certain respects and has a significantly enhanced payload/range capability.

The general configuration can be seen from the nearby illustration, which shows a main body of oblate spheroid shape supported by a quadruped undercarriage constructed of radar-transparent materials and with counter-rotating twin helicopter rotor blades. There is a rotor head fairing made of similar composite materials as the undercarriage and the main body of the vehicle. The two-stroke petrol driven motor that powers SPRITE is housed within the body as are the sensor packages and four plastic fuel tanks. Other internal compartments house the

The shape and use of composite materials in construction of the SPRITE RPH result in minimal radar signature, and internal location of the power plant gives a very low IR signature. Battlefield surveillance roles are envisaged

guidance, autopilot and data link sub-systems. Typical sensor payloads might include: a stabilised TV camera, thermal imaging equipment, LTDS, ELINT and electronic warfare equipment.

CHARACTERISTICS

Body diameter: 0·65 m
Rotor diameter: 1·6 m
Power plant: 2-stroke flat twin Piper P2/80 engine
Fuel capacity: 6 kg
Sensor payload: 6 kg
Take-off weight: 36 kg
Endurance: Up to 150 minutes
Cruising speed: 110 km/h
Operating height: 250 – 500 m (typical)

An engine-driven 28 V 500 W alternator provides electrical power for sensors and autopilot, and SPRITE can be pre-programmed or operated under direct ground control via a data link. A typical mission radius of 32 km has been estimated.

STATUS

Developed as a private venture by ML Aviation, SPRITE made its first flight in February 1983. It was revealed publicly in September 1982. The manufacturers state that both military and civil applications have been considered and there is understood to be close UK MoD interest in the project.

2522.391
BEECH MODEL 1107 (AQM-37A)

This is a non-recoverable, supersonic, air-launched missile target system designed to simulate aircraft and missile threats for defence weapon system evaluation and crew training. The target provides both active and passive radar augmentation for radar acquisition and tracking, and a chemical flare is provided for IR homing. Two optical miss-distance systems are available.

CHARACTERISTICS

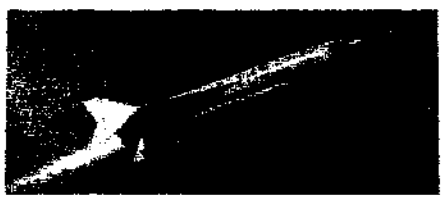
Power plant: 1 Rocketdyne/AMF LR64 P-4 dual-chamber liquid-propellant rocket-engine
Guidance: Programmed
Launching: Air-launched
Recovery: Non-recoverable. Automatic destruct system operates at end of flight or in case of major failure. Command destruct standby system for added range safety.
Operating speed: Mach 0·4 – 3
Operating height: 300 – 21 337 m
Endurance: 8 minutes (powered)
Special features: Approx 0·4 m³ of space in nose section for optional scoring and augmentation systems. Target compatible with non-co-operative scoring systems.

Model 1107 is the basic version of the AQM-37A target. Other versions built for the US services are:

Model 1019A: The US Navy contracted in 1975 with Beech to provide 20 AQM-37As capable of flying at 10 to 300 metres altitude for weapon system evaluation. These vehicles used an autopilot that incorporated a homing device for longitudinal guidance and radar altimeter for altitude control.

Model 1100, Model 1101: The US Army contracted with Beech to provide 48 AQM-37As for weapon system evaluation in 1975. These vehicles were the first production units to incorporate a two-stage parachute recovery system. Under the Army contract Beech produced two versions of the AQM-37A. One (the model 1101) is a supersonic, high-altitude target capable of operation to 2188 km/h and 21 340 metres altitude, the other (the Model 1100) a low altitude modification which can be flown to within 15 metres of the terrain. Both the 1100 and 1101 models are equipped with a radio-controlled guidance system enabling both longitudinal and vertical positioning. Smoke canisters were provided for visual acquisition.

Model 1104: This is an improved version of the Model 1107 series for Mach 3, 24 380 metre missions. It was ordered by the US Navy after a demonstration programme of ten vehicles in 1981. The Model 1104 (AQM-37C) incorporates a digital autopilot with improved flight control features, and greater range/endurance performance is obtained by an optimum energy management program. The command control facility permits dual launch and in-flight heading control. Initiation of dives of 15 to 65° and pull-out on ground command are available. Radar augmentation in several bands has been improved and a new nose incorporates a new radome and a nose-mounted pitot.



Apart from increased length due to the nose pitot, and an increase of about 40 per cent in the vertical stabiliser fin area, other details are as for the AQM-37A. 54 units have been delivered to the US Navy.

Model 1105: This is the Beech designation of a Mach 3·5, 27 430 metre version of the AQM-37C, which has aerodynamic control surfaces protected with thermal insulation. Beech Aircraft's US Navy contract to provide eight units for development and demonstration was completed in 1984.

In addition to the AQM-37A models built for the US services, five other versions have been built.

Model 1072 (Short SD.2 Stiletto): This is a version for the UK and is modified by Short Brothers to meet British requirements, including incorporation of telemetry and radar systems and control system changes. The vehicle is fitted by Beech with a single-chamber rocket motor to give Mach 2 performance at 18 300 metres. The Stiletto is launched from a Canberra PR Mk-3 aircraft. In the successful first test flight at Llanbedr in August 1968, the drone was released at 16 750 metres and flew for more than 28 nautical miles (52 km) at an average speed of Mach 1·4 before the flight was terminated by a commanded explosive destruct.

The principal modifications made by Shorts were the incorporation of a British EMI T44/1 telemetry system, provision of additional 15 V flight break-up system (WREBUS), installation of radio-active miss-distance indicator (RAMD) with associated radio link, introduction of Plessey IR 112A IR 310 tele-command system with heading and turns command circuitry and changes in the radar augmentation system. The current Stiletto system consists of the basic target vehicle plus a number of optional mission kits which can be either installed by Shorts or delivered separately for customer installation. To date 190 Model 1072 AQM-37As have been delivered to the UK.

US Navy Beechcraft AQM-37C target drone. AQM-37C is distinguished from earlier AQM-37A by nose-mounted pitot head and increased fin area

Model 1088: This is the manufacturer's designation of 11 targets supplied to Italy. Primarily used for weapon systems evaluation, vehicles had pre-programmed dive manoeuvre to give supersonic presentation at medium altitudes and were equipped with radio-controlled lateral manoeuvring capability to accurately position the target.

Model 1094: This is the manufacturer's designation of 50 targets supplied to the French Air Force. Primarily used for air-to-air weapon system evaluation they were modified by Matra to be compatible with weapon systems. Modifications include addition of scoring, radar augmentation, telemetry, and tracking beacon systems. Primary missions are Mach 1·6 at 16 750 metres and Mach 2 at 21 340 metres.

Model 1095: This is the manufacturer's designation of 40 targets delivered to the UK MoD. This version has been modified to the specifications of the MoD and will be used for crew training exercises on the Hebrides Range.

Model 1108: This is the manufacturer's designation of 30 targets delivered to the UK MoD. This version uses the single thrust chamber rocket motor developed for the Model 1072 'Stiletto' target. It also meets the specific requirements of the MoD and will be used for crew training exercises on the Hebrides Range.

STATUS

The AQM-37 is in service with the US Navy (1962), US Air Force (1968), US Army (1973), UK (1966), Italian Air Force (1969) and French Air Force (1974), with year of introduction shown in brackets. In total, more than 4000 AQM-37 targets have been built.

Beech Aircraft Corporation, Wichita, Kansas 67201, USA.

3240.391
VANDAL INTERIM ANTI-SHIP MISSILE TARGET (MQM-8G)

Vandal (MQM-8G) is the US Navy's interim supersonic target for ship defence against cruise missiles. It is a modification of RIM-8G Talos naval missiles to serve as a low cost target into the 1990s. The modifications to the normal Talos round include the provision of a tracking beacon, a radar altimeter, a destruct system, an on-board command receiver and telemetry, plus airframe and fuel system modifications to simulate a variety of threat altitudes and speeds. A simulated radar emitter and a scorer are also included. The basic configuration and dimensions are as for the Talos anti-aircraft missile (**1030.231**) in 1981-82 and earlier editions.

A simpler version, Fleet Vandal, has also been developed for use in fleet training exercises. In this version, the altimeter, scorer, telemetry, and simulated radar emitter are not provided.

DEVELOPMENT

The development contract was started in July 1976 and completed in May 1978; it included six flight tests. All test objectives were achieved. Fleet Vandal development took place between May 1981 and July 1982, and programmes are in progress to provide a higher altitude, higher speed Vandal, and a lower altitude, longer range Vandal version. Comparative performance figures of the various models are given in the following table:

	Altitude (m)	Speed (Mach)	Range (km)
Vandal/Fleet Vandal	18 280	2·54	270
Vandal	91	2·1	40
High altitude Vandal	21 330	2·8	304
ER Vandal	15	2·1	74

STATUS

By January 1983, 65 Vandals and 12 Fleet Vandals had been delivered to the US Navy, and 26 more Vandals and 23 Fleet Vandals were in production. The run is expected to continue throughout the 1980s.

1814.391

BEECH MODEL 1089 ARMY MQM-107A/C VSTT

Beech Aircraft Corporation was awarded a multi-year production contract in 1975 by the US Army for the Model 1089 variable speed training target (VSTT). The target was designated the MQM-107A Streaker.

The principal function of the Streaker is to provide a variety of threat situations for training of missile and automatic weapons crews. It is the primary subsonic missile training target for the US Army. It is also used for the research and development testing of weapon systems. The standard vehicle is a 4·87 metres long, swept wing, turbojet-powered 430 kg aerial target that operates at altitudes from sea level up to 12 200 metres and at speeds of up to 500 knots (927 km/h). It tows gunnery banners and tow targets out to 2438 metres. With wingtip augmentation and scoring devices the MQM-107A itself also serves as an aerial target for air defence systems such as Stinger, Chaparral, Redeye, Hawk, and Improved Hawk. It is a re-usable target with recovery by command using a two-stage parachute system.

The standard Beech Model 1089 is powered by a Teledyne CAE J402-CA-700 engine. With the pod-mounted engine configuration other engines are easily adapted and are being considered for the MQM-107. The fuel capacity is 65 US gallons (246 litres) with an additional capacity of 4 US gallons (15 litres) for a smoke oil visual identification system. Optional wing insert fuel tanks, supplied in kit form, add 30 US gallons (113 litres) to the total fuel capacity. The target may be surface-launched from a zero-length launcher using a JATO booster, or air-launched from manned aircraft. Thiokol has developed the TX-632 booster for launching MQM-107 vehicles.

The modular design employed throughout the system provides for ease of fabrication and for economy in operation and maintenance. The fuselage is cylindrical. One unique design feature is the flat aerofoil section of the wing and tail surfaces. Low-cost bonded honeycomb is used for the fixed aero surfaces while the aero control surfaces are constructed of aluminium skins and filled with poured-in-place foam. Support equipment is both minimal and lightweight providing for transportability and deployment of the system. Launch and checkout equipment is packaged in suitcase-sized containers.

Guidance and control systems, either analogue or digital, provide for both ground control and for pre-programmed flight. The flight controller is provided with all pertinent flight information by radio link from sensors located in the vehicle and the operator can command vehicle manoeuvres as well as recovery. In flight, the guidance and control system automatically stabilises around the roll, yaw, and pitch attitudes and provides an altitude-hold mode. A recently developed and tested autopilot extends the manoeuvring and high-g envelope of the vehicle. Either constant airspeed or constant altitude high-g manoeuvres can be selected by the flight controller. Another flight control development is a terrain following guidance capability which has demonstrated extremely low altitude flight profiles. To provide a greater internal payload carrying capacity an extended section is now available. This section also provides ease of access to the payload and vehicle electronics and has specialised waterproofing provisions for seawater recoveries.

The 999H version of this target incorporates the extended payload section and improved electronics, but retains the J402-CA-700 engine.

CHARACTERISTICS

Guidance: Radio command
Wing span: 3 m
Length: 5·13 m (extended version 5·51 m)
Height: 1·47 m
Body diameter: 0·38 m
Wing area: (total projected) 2·52 m²
Horizontal tail surface: 0·55 m²
Vertical tail surface: 0·43 m²
Launch weight: 460 kg (including booster)
Useable fuel: 173 kg
Endurance: >3 h

Beech Model 999E, 999H (Army and Air Force MQM-107B)

This new model reflects the incorporation of the various system improvements which had been tested and proven on the MQM-107A. The primary reason for redesignation is the incorporation of the French Microturbo TRI 60-2 Model 074 turbojet engine. The increased thrust of the TRI 60-2 results in speeds up to 530 knots (982 km/h). This model incorporates the increased length electronic payload section (38·1 cm added), along with improved electronic packaging, improved waterproofing, increased smoke oil tank capacity and provisions for the high-g manoeuvring autopilot.

Beech MQM-107B VSTT drone

STATUS

In addition to the use by the US Army and other Department of Defence agencies, the Army has supplied the MQM-107A system to Sweden (999A), Jordan and Iran (MQM-107A) under the Foreign Military Sales (FMS) programme. Taiwan (999F), Republic of Korea (999D) and the United Arab Emirates (999L) have purchased this system and are now operating the MQM-107. Egypt (999M) has contracted to buy the system and deliveries have been scheduled for mid-1984. Following successful evaluations by the US Army and Air Force, production orders have been placed, deliveries commenced in August 1984. The US Navy has also conducted evaluations of the MQM-107A.

CONTRACTOR

Beech Aircraft Corporation, Wichita, Kansas 67201, USA.

FIREBEE I (BQM-34A/BQM-34S/MQM-34D)

Firebee is a turbojet-powered remotely controlled drone used mainly for target purposes but with the capability of being used in a reconnaissance role (see following entries). Designation of the current standard version is BQM-34A by the US Air Force and BQM-34S by the US Navy, and there is also a version known as MQM-34D used by the US Army. Recent incorporation of the J85-GE-7 turbojet engine and the A/A37G-14 three-axis flight control system have enabled the target to execute flight manoeuvres at higher speeds and greater load factors than before.

CHARACTERISTICS

Power plant: 771 kg thrust Continental J-69-T-29 turbojet or the 1112 kg thrust General Electric J85-GE-7 turbojet

Guidance: Coded radar command control and tracking. US Navy BQM-34S version is fitted with Motorola integrated tracking and control system equipment. BQM-34A is equipped with the Vega drone tracking control system. BQM-34S versions have A/A37G-8A flight control system whereas current BQM-34A versions have A/A37G-14 three-axis system.

Launch: Air launch or ground launch with JATO rocket

Recovery: Parachute system deployed by remote command or in the event of loss of power, or guidance signal for a predetermined time

Max level speed: 1 124 km/h at 2286 m
Max diving speed: Mach 0·95
Max cruising speed: 1015 km/h at 15 240 m at 8 16 kg AUW
Rate of climb: 5080 m/minute at sea level
Operating height range: 15-18 300 m
Endurance: 75 minutes 30 s at 15 240 m
Flotation time: 24 h with 25% fuel
Special features: Adjustable TWT amplifiers for D, E, F, G, H, I-band radar signal enhancement. Continuous infra-red wing-tip propane pods for IR augmentation. Built-in 5-6 g turn capability

RALACS - Radar Altimeter Low Altitude Control System - available for precision low altitude flights at 5 m altitude over water or 30 m over land

CONTRACTOR

Teledyne Ryan Aeronautical, 2701 Harbor Drive, San Diego, California 92138, USA.

2616.391

FIREBEE II (BQM-34E/F/T)

The Teledyne Ryan Model 166 Firebee II is a supersonic target drone developed for the US Navy and Air Force as an advanced version of the subsonic BQM-34A drone described above. The US Navy designations are BQM-34E and BQM-34T, while it is the BQM-34F in the US Air Force. The Firebee II is designed to provide aerial target presentations above 18 300 metres altitude at supersonic dash speeds up to Mach 1·5 for a period of 18 minutes. With full fuel load, range time may be extended to 74 minutes. Among other improvements the drone is designed to carry much more in the way of radar enhancement and tracking aids than its predecessor.

CHARACTERISTICS

Power plant: 873 kg thrust Continental YJ69-T-406 turbojet engine

Guidance: Drone carried AN/DRW-29 radio control receiver DKW-1 ITCS (BQM-34T) or DTCS (BQM-34F) command guidance package and A/A37G-9A flight control system

Launch: Ground launch with JATO bottle, or air-launched from DP-2E Neptune or DC-130A or E Hercules.

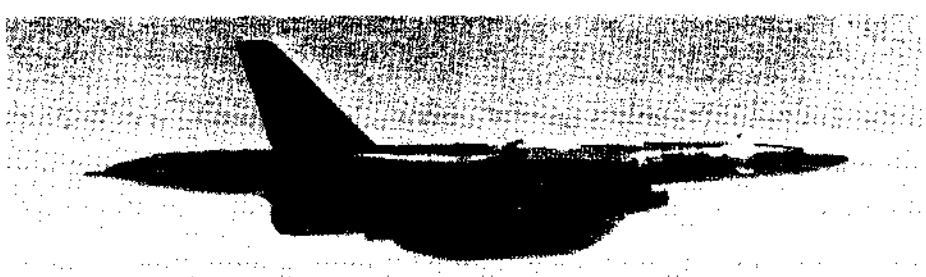
Recovery: Similar to BQM-34A, or MARS for BQM-34F

Max speed: Mach 1·8 at 13 715 m
Operating height range: 15-18 300 m
Endurance: 74 minutes total
Flotation time: 24 h
Special equipment: AN/DLQ-1, -2, and -3 ECM equipment

AN/DRQ-4 or AN/DSQ-24 (in BQM-34F) missile scoring system

RALACS - Radar Altimeter Low Altitude Control System

I-band and G/H-band tracking beacons



TWT radar augmentation for E/F, G/H, and I-band

Solid-state radar augmentation for B-band

Passive radar reflectors

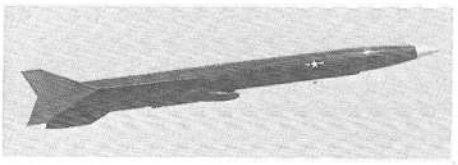
BQM-34E Firebee II supersonic target drone

4036.391
FIREBOLT MODEL 305 HAHST (AQM-81A)



The Teledyne Ryan Firebolt high altitude high speed target (HAHST) is being developed for the US Air Force Armament Division under a contract awarded in December 1979 following a competition with Beech Aircraft Corporation. This supersonic target drone is the outcome of development of the High Altitude Supersonic Target (HAST) programme to meet US requirements for highly advanced threat simulation, particularly at high altitudes and speeds. Flying at altitudes of around 30 000 metres at speeds of up to Mach 4, Firebolt vehicles will be used to authenticate the performance of new weapon systems.

In addition to the guidance and control equipment, the payload can include a point source radar augmentation system and a miss-distance indicator system. Flight manoeuvres can be remotely controlled via a radio link from the ground, or may be pre-programmed before flight utilising a digital control system. The vehicle is capable of between 5 *g* at 10 000 metres and 1·15 *g* at 27 400 metres.

The target is powered by a hybrid rocket engine using solid fuel and liquid (nitric acid) oxidizer. This engine provides thrust from under 200 lb to over 1200 lb. Electrical power and oxidizer pumping is provided by a ram-air driven turbine in the mid-fuselage section.

Launching is normally from an aircraft flying at between Mach 1·2 and 2·5, with recovery from land or sea following a parachute-controlled descent, or the vehicle can be retrieved in mid-air during its parachute descent.

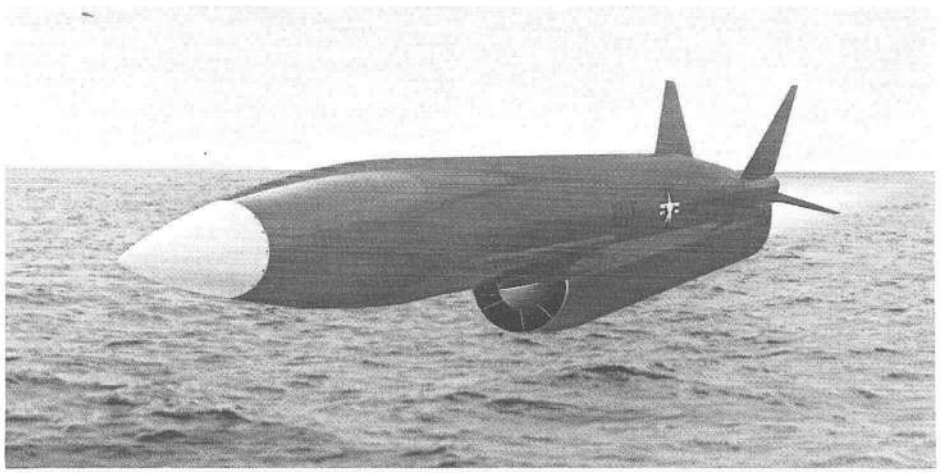
CHARACTERISTICS
Type: AQM-81A
Length: 5·18 m
Wing span: 1·02 m
Diameter: 33 cm
Launch weight: 558 kg
Performance: Mach 1·2 at 12 200 m to Mach 4 at 30 500 m
Propulsion: Variable thrust rocket motor
Guidance: Radio command
Endurance: 5 minutes at Mach 3

Teledyne Model 305 high altitude high speed target drone (AQM-81A)

STATUS
Teledyne was awarded a contract for nine test vehicles in December 1979, following a competitive procurement bid against Beech. Flight testing was nearing completion in 1984-85, with operational use by the US Air Force and Navy expected to follow soon after.

CONTRACTOR
Teledyne Ryan Aeronautical, 2701 Harbor Drive, San Diego, California 92138, USA.

4852.391
INTIMIDATOR SLAT (YQAM-127A)



Teledyne Ryan Aeronautical, United Technologies (Chemical Systems Division) and Brunswick Corporation are collaborating in the design of a new target drone to meet a proposed US Navy requirement for the YQAM-127A Supersonic Low Altitude Target (SLAT), which is intended to simulate realistic anti-ship missile threats for Navy ships and their defence systems. The proposal has been given the provisional company name Intimidator. No details or specifications have been revealed yet but performance is expected to allow for flight at Mach 2·5 at a height above the sea of about 30 feet (9 m).

STATUS
Development project.

CONTRACTORS
Teledyne Ryan Aeronautical, 2701 Harbor Drive, PO Box 80311, San Diego, California 92138, USA.

4477.391
NV-151 AERIAL TARGET

In 1984, Northrop completed a successful flight test programme of a new target drone to serve as a high performance supplement to the BQM-74C (**3731.391**). This private venture target has been designed to meet the US Air Force and various foreign military services requirements for a large, low-cost, subsonic vehicle that is capable of both air and surface launches. The new vehicle is designated the NV-151 (although first known as the NV-144) and it will be able to carry large payloads at lower costs than current targets of comparable performance. It has been designed to take advantage of many new developments incorporated into the BQM-74C and will use the same avionics. The latter include the Northrop-developed digital avionic processor computer system that performs on-board guidance and control functions as well as being compatible with programmed missions. NV-151 will also have common ground support and other sub-systems with the current BQM-74C aerial target. Various low-cost plastics are being used in the NV-151 construction.

Air launches can be made from tactical aircraft and the target is expected to be used for weapon system testing and evaluation of air-to-air and surface-to-air missiles as well as acting as a cruise missile simulator.

CHARACTERISTICS
Length: 5·95 m
Wing span: 3·29 m
Fuselage diameter: 51 cm
Power plant: 440 kg st turbojet
Gross weight: 635 kg (approx)
Fuel capacity: 180 kg
Max speed: 1100 km/h (approx)
Range: 1450 km (approx)
Altitude range: 15 - 16 800 m

STATUS
Private venture development. First flight completed successfully on 24 February 1984 after air launch from US Navy A-6 aircraft.

CONTRACTOR
Northrop Corporation, Ventura Division, Newbury Park, California 91320, USA.

Production of NV-151 aerial target drones at the Northrop-Ventura plant

---

3731.391
BQM-74C AERIAL TARGET

Northrop's BQM-74C air-launchable aerial target is an improved version of the company's successful MQM-74C Chukar II (**2732.391**) target aircraft, used by the US Navy and 11 allied nations, that can also be used as a cruise missile simulator. The Navy uses the target for numerous missions, including anti-aircraft gunnery, surface-to-air missile, and air-to-air missile training, as well as weapon systems evaluation. It is capable of air or surface launching and has retained the flexibility of the MQM-74C Chukar II for deployment aboard naval vessels and from remote unimproved shore sites. Increased performance of the BQM-74C is under development and this includes a 240 lb (108·9 kg) thrust power plant. Initial deliveries are planned for 1986.

The BQM-74C target system also includes pylon adaptors for air launch from A-6 and A-4 aircraft and payload kits for the Mobile Sea Range Operations. The BQM-74C target was derived mainly through changes in the fuselage and avionics section of the MQM-74C. The fuselage is 8 cm longer and the shape is modified to provide additional space for mission payload. Air launch capability was achieved through modification of the centre fuselage section.

The equipment area incorporates a Northrop-developed digital avionics processor, a micro-processor-based digital autopilot which has significantly more capability and system reliability than analogue autopilots now used in most aerial targets. The device also simplifies both maintenance and checkout tasks associated with the operation of aerial targets.

The BQM-74C is equipped with a radar altimeter for low-altitude flights, a seeker simulator to duplicate cruise missile emissions, a radar transponder for IFF, a miss-distance indicator for weapons system scoring, and/or command over-ride system to assure

target ship safety during simulated attack. The target's mission profile can be pre-programmed, including recovery via parachute. It is a mid-wing monoplane with detachable aluminium wings. Flight equipment, powerplant and fuel tanks are housed in the fuselage.

CHARACTERISTICS

Length: 3·95 m
Body diameter: 0·35 m
Wing span: 1·76 m
Engine: Williams International WR24-7B turbojet rated at 86·2 kg thrust
Speed: 300 – 926 km/h
Altitude: Over 7656 m
Flight time (average): >1 h
Max range: 833 km
Max launch weight: 205 kg
Guidance: Radio command or pre-programmed

STATUS

The BQM-74C completed US Navy technical and operational evaluation tests successfully in 1980. The target is now in full production and in early 1984 more than 700 were on order.

CONTRACTOR

Northrop Corporation, Ventura Division, Newbury Park, California 91320, USA.

BQM-74C Chukar III loading under wing of US Navy A-6 Intruder

---

2732.391
NORTHROP CHUKAR II

The Chukar II (MQM-74C) is a lightweight target drone designed for anti-aircraft gunnery, surface-to-air missile, and air-to-air missile training and weapon systems evaluation. Radio-controlled, it is turbojet powered and is recoverable by parachute. It is readily deployed and operated from aboard naval vessels.

CHARACTERISTICS

Wing span: 1·76 m
Length: 3·87 m
Height: 0·71 m
Launch weight: 233 kg

MQM-74 Chukar II after launch

Service ceiling: 12 200 m
Power plant: Williams International WR24-7B turbojet, two NR4113 or Mk-91 JATO rockets for launching
Guidance: Radio control, automatic stabilisation, and altitude hold
Launch: Rocket-assisted from zero-length launcher
Recovery: Parachute system operating on ground command or automatically on loss of power or radio guidance failure
Max level speed: 886 km/h at sea level; 926 km/h at 6000 m
Economic cruising speed: 463 km/h at sea level
Rate of climb: 1780 m/minute at sea level with full fuel
Endurance: 60 minutes at sea level to 102 minutes at 9200 m (at max endurance speed); 30 minutes at sea level to 60 minutes at 9200 m (at max speed)
Range: 370 – 750 km according to speed and height

The Chukar II employs a selection of passive and active augmentation devices fitted to the target or deployed as a tow to enhance the infra-red and varied radar cross-section spectrum signatures. In operation, the tow targets are attached to the wing tips and sequentially released for the firing presentations. The tows are deployed from 15 to 150 metres behind the Chukar II dependent upon the weapon system operational characteristics.

STATUS

The internationally deployed Chukar II target system is used extensively within NATO for missile training evaluation exercises at the NAMFI range, Crete, Greece, the Salto di Querre Range, Sardinia, Italy, the French ranges of Centre d'Essais des Landes (CEL) and Centre d'Essais de la Mediterranée (CEM), the UK Aberporth range, and is the standard target for various European, Middle-East and Far-East nations for both land-based and shipborne air defence weapons training. The production of the Chukar series target began in 1968 with more than 4000 targets manufactured for international users, the US Navy and Northrop operated target flight service operations. Production of the Chukar II will continue in addition to the air launchable BQM-74C (**3731.391**) known internationally as the Chukar III.

The international version designated Chukar III was operated for French authorities at CEL, Biscarrosse for proof testing of Thomson-CSF's modified Naval Crotale missile system and the Shahine missile at target altitudes of 30 feet and less. Spain first procured the Chukar III in 1984 and other countries are expected to follow.

CONTRACTOR

Northrop Corporation, Ventura Division, Newbury Park, California 91320, USA.

1819.391
PQM-102 TARGET DRONE

In March 1974 it was announced that the US Air Force was about to make its first purchase of 22 F-102 Delta Dagger interceptor aircraft converted for use as unmanned target drones, in which form they bear the designation PQM-102. One of the main functions of this class of target drone was for the testing and evaluation under realistic conditions of the latest types of air-to-air weapons and the new generation of fighter aircraft. F-102s have been withdrawn from reserve service and deep storage and the PQM-102 inventory was established from this source.

The US Air Force had planned to build up a force of up to 128 of these drones at an annual rate of 22. Although classified as drones, the PQM-102 qualifies for the US Air Force RPV definition. A pilot sitting in a van at the end of the runway carries out the preflight checks remotely and then flies the aircraft off the ground and clear of the airfield area for handing over to the range radar mission controllers. If the drone survives the mission, the procedure is carried out in reverse to recover the target vehicle.

DEVELOPMENT

Sperry was awarded a $5·5 million contract in spring 1973 for the conversion of an initial batch of eight Convair F-102 aircraft for the target drone mission. Of the eight, two retained the manual pilot facilities and were designated OF-102; the other six were configured for full unmanned operation.

STATUS

The first PQM-102 was flown in August 1974 and a total of 213 aircraft were brought to this configuration. About 12 remained in service until mid-1984, by which time there had been a total of 762 unmanned flights ('Nullos') for an expenditure of 196 PQM-102s. Missiles or rockets directed at PQM-102s to October 1983 numbered 1393. The last delivery was made in March 1982.

CONTRACTOR

Sperry Flight Systems Division, Sperry Corporation, PO Box 21111, Phoenix, Arizona 85036, USA.

3652.391
QF-100 FULL-SCALE AERIAL TARGET (FSAT)

In August 1979 the US Air Force issued a $6·7 million contract to Sperry Flight Systems for full-scale engineering development of the QF-100 full-scale aerial target (FSAT) based on the North American F-100 fighter-bomber airframe. Airframes are drawn from storage at Davis-Monthan AFB, Arizona.

The QF-100 is a multi-service target for air-to-air and ground-to-air missile evaluation and combat crew training. It uses current PQM-102 ground control and test equipments as well as many PQM-102 airborne sub-systems. A digital flight control computer replaces four analogue computers used in the PQM-102 system, offering ease of testing and operational mode growth capability.

Having a versatile performance and manoeuvring capability, the QF-100 can attain Mach 1·3 and fly at altitudes from 200 feet (60 metres) above ground level to 50 000 feet (15 240 metres) above mean sea level. It can perform -2 to +8 *g* manoeuvres. Drone formation flight capability for flying up to six QF-100s at one time has been developed with the US Army. Each QF-100 has a life expectancy of ten missions before a 'kill' occurs.

The QF-100 aerial target is designed to be remotely controlled and is equipped with a destruct system in event of control loss. Take-offs and landings are controlled by a mobile control station located next to the FSAT runway. After the QF-100 reaches the 'handover box' a 3 × 5 mile (5 × 8 km) area seven miles (11 km) from the runway, control of the aerial target is switched to a drone tracking control station.

Both the mobile and ground fixed control station require two skilled controllers for a QF-100 mission. Each mission is a highly co-ordinated effort between the ground controllers.

STATUS

QF-100 drones are replacing PQM-102s in US Air Force service, the supply of airframes for the latter having been used. Delivery of 81 QF-100 drones to the US Air Force was completed under contract by early 1985. A production contract for subsequent conversions was let to Flight Systems Inc, a subsidiary of Tracor Inc by the US Air Force.

AQUILA (YMQM-105) MINI-RPV

The Lockheed Aquila mini-RPV is the successful contender for the US Army's requirement for a small battlefield RPV to undertake reconnaissance, laser target marking, ranging, and similar high-risk operations. The objective was to achieve a unit cost low enough to permit use of the mini-RPV as expendable items where the mission priorities justified, but measures are incorporated for recovery. Simplicity and ease of operation are additional requirements of the system which was formerly known as 'Little R' and is a development of the US Army RPAODS programme.

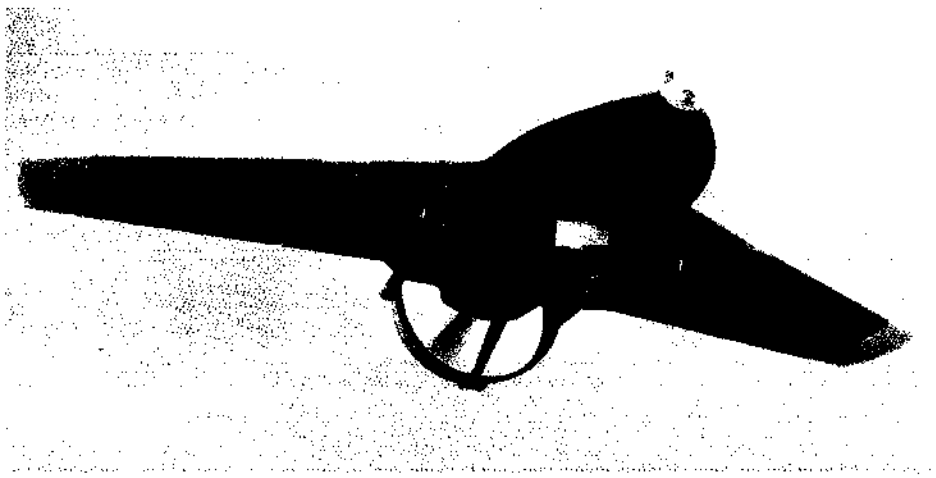
The aircraft is a flying-wing craft powered by a rear-mounted, two-cylinder engine driving a pusher propeller and the vehicle can fly a pre-programmed flight profile, entirely controlled by an on-board computer. The latter can be overridden by the ground operator who can modify the computer programmed profile as well as being able to select loiter or search modes as required.

The payload is provided by Honeywell and contains a stabilised TV camera and an International Laser Systems laser. The Aquila can also carry a Perkin Elmer mini-panoramic camera. Real-time TV pictures are relayed by a data link to three operators in a distant ground control van. A forward looking infra-red (FLIR) payload to provide a night/adverse weather capability is being developed. The Aquila system is designed to acquire and locate targets for artillery and also provides laser designation for precision-guided missiles and shells.

Steady development of the US Army requirement and the Aquila payload package has led to a sophisticated tactical application known as the TRAAMS mini-RPV C³/CM sensor concept. This relies upon the time reference angle-of-arrival measurement system (TRAAMS) anti-radiation sensor used in conjunction with the Aquila vehicle to form a flexible and effective command, control and communications (C³) countermeasure system. TRAAMS is a signal processing device that can measure extremely small delays between the times of arrival of two signals at a single frequency. A combination of surface acoustic wave resonators and a microprocessor, together with simple broadband antennas and an RF receiver, it forms the basis of an interferometer which will provide very accurate directional information about emitters.

TRAAMS is not restricted in frequency and is not dependent on antenna radiation patterns, and the system has the potential of giving accurate emitter location data when used in platforms (such as surveillance drones) which have limited antenna base lines. In the TRAAMS mini-RPV concept the former system is used to 'set on' the drone's TV system to the emitter's line-of-sight to permit remote visual identification of the target. On confirmation of the target, the RPV illuminates it or uses a laser target marker for the use of co-operative weapons such as laser-guided bombs or laser homing missiles. TRAAMS could also be employed for the initiation and direction of ECM against certain categories of target.

CHARACTERISTICS



Wing span: 3·89 m
Length: 2 m
Wing chord: 1·21 m (approx)
Leading edge sweep: 28°
Take-off weight: 54·4 kg
Payload weight: 16·3 kg
Max speed: 222 km/h (approx)
Endurance: 3 h (max)
Ceiling: 3600 m, plus
Power plant: Two-cylinder air-cooled piston engine developing 26 hp at 8000 rpm
Fuel: 6·8 kg

STATUS

The Aquila RPV is in full scale engineering development, with early fielding of two prototype systems scheduled for 1986. Flight tests continued in 1984 and of 86 flights to early 1985, 75 were completely successful, seven ended with parachute recovery, and four crashed. The Army fielded an 'Early Operational Capability' system at Fort Hood. The US Army RPV programme was re-arranged in eary 1985 to run for 79 months instead of 70 months to reduce programme risk by eliminating any need for concurrent development testing and operational testing.

4040.391
***E*-SYSTEMS MULTIPLE MISSION RPVS**

E-Systems, Melpar Division has developed miniature RPVs for multiple missions both expendable and recoverable. Manufacturing capabilities currently exist for three weight configurations of the same basic airframe, 90, 175 and 260 lb (40·9, 79·3 and 117·9 kg respectively). The design features shoulder wing, single tail boom, fuselage and a pusher engine. The wings, horizontal stabiliser, payload nose pod and engine are removable for transportation and maintenance, mission flexibility is achieved by allowing interchangeable payload pods. The main characteristics of the respective models are summarised further on in this entry.

A lightweight and simple autopilot not requiring a vertical gyro has been developed for flight path control. It is capable of real-time data link update by a ground operator or can be pre-programmed to carry out an autonomous mission. The autopilot has three independent feedback loops that are used to stabilise the aircraft and uses a barometric pressure transducer, angle-of-attack vane, magnetometer, rate gyros and velocity transducer as sensor inputs. The autopilot controls throttle, elevator and ailerons or rudder.

OPERATION

Omega (VLF) or Navstar/GPS (Global Positioning System) are the two recommended means of navigation for the RPVs, although other techniques such as Loran, inertial, area correlation, or beacons may be considered. RPV launch is accomplished from the top of a moving vehicle, by a catapault or with a boost rocket. Recovery methods include autopilot-assisted skid landing and recovery net which can stop the aircraft without damage within a distance of 12 metres. Recoverable RPV missions cover roles such as real-time TV reconnaissance, communications relay, and intelligence collection while expendable missions include radar strike, decoys, jamming, radio relay, and false target generation. Payloads appropriate to these missions have been developed, among them an RF sensor consisting of a microwave dual-axis RF homing system which can intercept and recognise radar signals and provide guidance information for the RPV to enable it to home on to the emitter.

For remote real-time reconnaissance Melpar has designed and produced a low cost TV camera system in a gimballed mount. Remotely controlled camera functions are from horizon to -45°, ±90° in yaw, and camera ON/OFF. The camera is illustrated nearby and can be used for numerous remote control applications. For higher resolution a stabilised TV camera or FLIR may be installed in the RPV using an interchangeable nose cone technique.

An RPV jammer also has both height and power advantages over ground-based systems under certain circumstances and at Fort Huachuca, Arizona, Melpar has demonstrated the effectiveness of a 25 W jammer operating against a typical enemy VHF communications net. Three types of jammers are available as RPV payload packages: (1) barrage; wide-band noise and tone, (2) spot; narrow-band noise and tones with remote running or on-board look-through, (3) DART (delay and repeat transmitter); which combines the best features of barrage and spot jamming at low cost.

CHARACTERISTICS

Model	E-90	E-175	E-260
Wing span	3·04 m	3·65 m	4·41 m
Length	2·31 m	2·52 m	3·23 m
Launch weight	40·8 kg	79·3 kg	117·9 kg
Payload	9·0 kg	18·1 kg	22·6 kg
Fuel	6·8 kg	13·6 kg	24·0 kg
Engine capacity	13 hp	18 hp	24 hp
Cruise speed	177 km/h	193 km/h	160 km/h
Range	338 km	482 km	482 km
Endurance	3 h	4 h	5-6 h

E-260 RPV in flight

E-90

The E-90 is an upgraded version of the original low cost expendable RPV which was first flown in October 1977. The power plant is a 13 hp 2-cycle, 2-cylinder piston engine. The E-90 has been designed for light payload expendable applications. It is a very low cost airframe to be used by a two- or three-man launch team where high quantities are required.

E-90 RPV

E-175

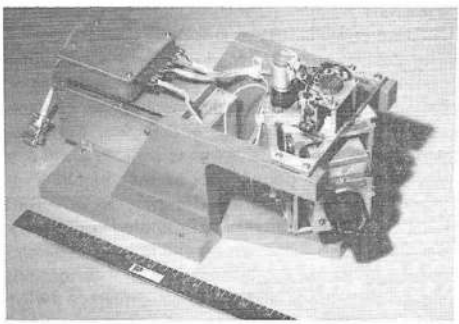
The E-175 is an upgraded version of the earlier E-130. This was accomplished by enlarging the wing surface area and utilising a slightly larger 18 hp engine.

Expendable strike and EW are the principal applications. The E-175 is adaptable to other applications and payloads which are also expendable.

The E-175 has been fully wind tunnel tested at the University of Washington, Seattle, Washington. A photo shows the E-175 configured for radar strike.

E-260

The E-260 is the latest model of E-Systems family of RPVs. The design allows for interchangeable payload nose cones allowing a basic E-260 airframe to accommodate a number of different reconnaissance missions all of which are recoverable. Endurance versus payload capacity tradeoffs can be accomplished with a typical payload configuration of 54 lb (24·5 kg) having over five hours' endurance. The electrical power generation system provides over 1500 W.



Launching can be accomplished by pneumatic catapault. The E-260 is designed for a minimum radar, IR, acoustic and visual signature. Recovery is accomplished using the autopilot and shock absorbing skids.

The E-260 is a cost effective vehicle for low-level reconnaissance without risk to aircrew.

Melpar also provides the total ground system support equipment including mission planning, mission operations, exploitation, and system maintenance.

Launch of E.175 for strike application

SKYEYE R4E-40

Developmental Sciences, since April 1984 part of the Astronics Division of Lear Siegler Inc, designed and developed the R4E as a mini-RPV capable of undertaking a variety of roles that may be required for such missions as patrol, tactical reconnaissance, and battlefield surveillance. The R4E, also known as Skyeye, is capable of remaining airborne for eight hours or more, carrying a nose-mounted payload of 63 kg, or a three hour mission with 54 kg of underwing stores plus an 18 kg nose compartment payload. Tactical uses that thus come within the Skyeye's capabilities are: defence suppression, artillery spotting, laser target designation, reconnaissance, various EW missions, data relay etc.

Three-view drawing of R4E Skyeye multi-role RPV

The R4E airframe is constructed of composite materials and the configuration can be seen from the adjacent drawing. In addition to driving a pusher propeller, a 40 hp twin-cylinder engine powers a 1000 W alternator for electrical supplies for the RPV avionics and payload packages. These power plant components are designed for reliable operation over extended periods of continuous operation. RPV avionics include a three-axis autopilot, and a data link that provides for command and control as well as a downlink for transmission of information to the ground station. An autonomous waypoint navigation system allows beyond visual range and 'radio silent' operation, and a jam detection/protection system ensures fail-safe operation in hostile environments.

Other features that provide Skyeye with optimum self-protection include a special wing form, low silhouette, low radar cross-section, and a special paint finish that gives a low visual signature. Effective engine silencing has made acoustic detection difficult and there is a low IR signature also.

The RPV is launched from a self-contained mobile launcher vehicle, and recovery is by means of a landing skid that permits semi-automatic landings on hard runways, sand, grass or other reasonably flat surfaces. The R4E also has a 12·8-metre diameter parachute for soft landings or emergency use. For short landings a low net can supplement the landing skid recovery. A mobile command station is employed and all RPV and payload operations are conducted from this facility housed in an air-conditioned portable S-280 shelter. Several tracking and RF data link options are available for command, telemetry and wideband data, depending on operational requirements.

As noted above, various payload options can be accommodated, among them is the 'Eyeball' real-time high resolution (800 lines TV) imaging system produced by Developmental Sciences which provides ±90 degrees azimuth and +30 to -55 degrees elevation coverage with a variable (10:1) instantaneous field of view. This system is gyro-stabilised (two-axis) to an accuracy of better than one milliradian. It is available with daylight and low-light level TV camera tubes. Among the other payload options are FLIR, reconnaissance cameras, EW passive and/or active sensors, video recorders etc.

CHARACTERISTICS

Length: 3·75 m

Wing span: 5·36 m

Max launch weight: 241 kg

Max speed: 230 km/h (no pods); 198 km/h (with pods)

Ceiling: 4600 m + (no pods)

Max endurance: 8 + h (no pods, 63 kg payload); 3 + h (pods and 72 kg payload)

Range: 80 - 270 km depending on equipment options

STATUS

Reportedly deployed on operational tests by the US Army and contractors from Honduras in 1984-85.

RS SYSTEMS AERIAL TARGETS

RS Systems has organised its miniature aerial target production into five main categories following some four years of supplying almost 40 000 targets for the US Army and foreign forces. In those four years the product range has been expanded from a single flying wing gunnery target to three-dimensional 1/9 and 1/7 scale targets carrying a jam-resistant command and control system, a two-axis stabiliser, electronic or pyrotechnic IR, fail safe system and hit indicator. Previous RS models have been described in entries **3740.391**, **4298.391** and **4475.391**, the following paragraphs summarise the current range.

(1) **FQM-117A** radio controlled miniature aerial target (RCMAT). This has been produced in quantity for the US Army and is a non-scale flying wing design to meet the requirements of small arms and light anti-aircraft artillery live-fire requirements. With the appropriate electronic or IR source, it is used for IR and radar tracking training.

(2) **FQM-117B** this 1/9 semi-scale RCMAT is a three-dimensional representation of the MiG-27, and a replacement for the FQM-117A delta. Augmented with an on-board pyrotechnic or electronic IR source, this target can also provide tracking for Redeye, Chaparral and other IR homing missile systems.

RS Systems 1/9 scale MiG-27 3-D aerial target

(3) The standard Highly Expendable Aerial Target (HEAT), produced so far as the MiG-27 and F-16, is designed to provide a larger size profile target visible at longer range, having a longer flight duration, and able to carry a significant payload.

(4) The extended range HEAT basically differs from the standard HEAT in that the structure is hardened to ensure missile warhead detonation on contact, but certain applications have called for additional facilities such as: IR augmentation, stability augmentation, a hit indicator, air-to-ground rockets, adaptation of MILES laser training equipment, a jam-resistant 140 MHz radio, a fail safe system for flight on

ranges where this is demanded, and catapult launcher or runway take-off cart launcher for heavy payloads.

(5) The three-dimensional target features replication of full-scale target shape and dimensions about all axes, and 3-D aircraft developed so far for the MiG-27 and F-16 are also faster and have greater payload capacity. Rugged construction of a composite material structure withstands heavy use and permits repair in the field. The engine used provides an IR signature for use with the Chaparral system. When equipped with stability augmentation and IR source(s), the 3-D target is capable of operation at ranges of more than three kilometres. However, visibility of the target to the naked eye is more appropriate to a 1/7th scale range of about 1500 m.

Among the enhancements available with the 3-D target are air-to-ground rocket and bomb simulation facilities; a runway cart that has demonstrated an ability to achieve take-off weights of up to 20·4 kg at over 1200 m altitude; a catapult launcher using bungee rubber cord; a visual hit indicator that can use either engine exhaust plume augmentation or a colour smoke cartridge operated on command; radar return enhancement; and four levels of IR augmentation. Both single axis and dual axis stabilisation units are available from stock, capable of ensuring stable, straight and level flight and damping of excursions. These are intended for use with targets that will be operated beyond visual range where binocular tracking or possible night operations are carried out.

A MILES aerial target system is being developed and this will interface with existing MILES ground transmitters to detect MILES hit(s), and initiate either a target hit indication or a fire-back mode. RS Systems has also developed an advanced command and control link operating at 140 to 165 MHz that is highly resistant to interference, compared to all other RCMAT command links. The standard RS Systems command link is a PPM-AM link operating at 25 to 76 MHz.

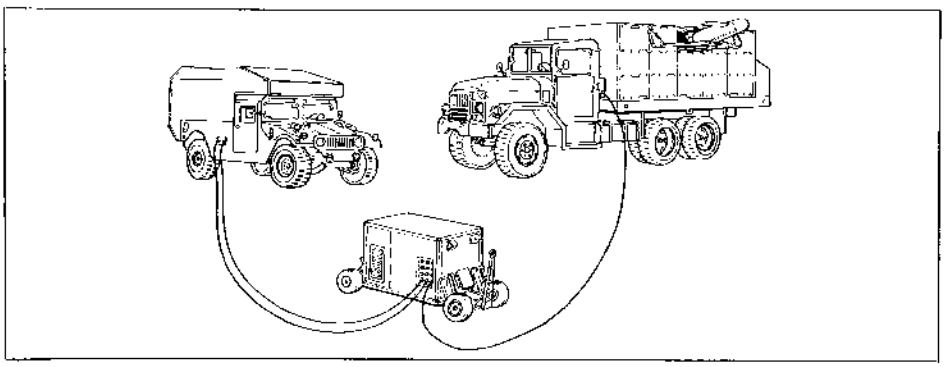
BRAVE-200 TACTICAL RPV

The Boeing Robotic Air Vehicle (BRAVE)-200 series tactical RPV system is a follow-on project stemming from the company's years of work on the Pave Tiger programme for the US Air Force YCGM-121A mini-drone (**4481.391**) which failed to gain continued funding support. The BRAVE project is maintained as a company-sponsored product development programme.



The flight vehicle remains essentially the same as that designed for the USAF programme, a low cost composite structure with a swept wing canard configuration and equipped with a digital autopilot and guidance system. The wings can be folded back to allow the RPV to be stowed in the launch cells of a multiple missile container which can be carried on a flat-bed truck to house up to 30 RPVs. Each cell also contains a zero-length launcher that is extended prior to vehicle launch to enable the RPV wings to fold out to their flight position and the two-cycle, air cooled engine to start before the rocket booster motor is ignited for launch.

The multiple missile (RPV) container vehicle is linked via cables to an auxiliary power unit on a trailer, and thence to a separate command and control vehicle. Using a microprocessor, BRAVE RPVs can use either pre-programmed mission control or the tactical command can re-programme missions in the field. The field launch controller can carry out rapid go/no go checks and transfers the mission programme into each flight vehicle. A two-man crew can fuel, test, and automatically launch a flight of vehicles in rapid sequence. When the vehicles are ready for deployment, the crew fuels them, and connects the electrical power. The launch controller is activated, RPVs checked, missions selected and the launch sequence begins. Typical missions include electronic warfare (disruptive and/or destructive), reconnaissance, deep attack (surface), and data relay.

The BRAVE flight vehicle is equipped with a digital autopilot, three-axis control plus controllable throttle and dead-reckoning navigation. A 1·1 kW power generation on-board system provides electrical power for the RPV's avionics and payload. The latter varies according to the RPV role, consisting of either sensors for reconnaissance or surveillance, data transmission and/or relay, EW sensors, or warheads and seeker equipment for defence suppression missions.

General arrangement drawing of BRAVE-200 RPV

Complete BRAVE-200 tactical RPV unit showing command and control vehicle and multiple cell launcher vehicle, linked via auxiliary power unit

CHARACTERISTICS

Length: 2·12 m
Wing span: 2·56 m
Canard span: 1·12 m
Fin height: 61 cm
Gross weight: 120 kg
Payload (fuel): 49·8 kg
Power plant: 438 cc 28 hp Cuyuna, two-cycle air-cooled engine + RATO
Electrical generator: 1·1 kW
Airspeed: 225 km/h (cruise), 144 km/h (loiter)
Altitude: Up to 3000 m

HAYES TARGET SYSTEMS

The Hayes International Corporation produces a wide range of air target systems and aircraft drone augmentation systems for air-to-air and surface-to-air missile and gunnery testing and training. Augmentation devices include both IR and radar types. The main Hayes systems are listed in the following paragraphs.

Model TA-7E (USAF TDU-22B/USN TDU-37B)

This is the standard supersonic tow target used by US forces for simulating threat aircraft for semi-active radar guided missiles. Four Luneberg lenses provide I/J-band radar augmentation for tracking, lock-on, and fuzing. Towing speeds between 150 knots and Mach 1·5 can be employed. The USN TDU-37B incorporates structural changes which strengthen the body and fins for aircraft carrier use.

Model TA-7 CIR (USAF TDU-25B)

The TA-7 CIR (continuous infra-red) provides a continuous heated stainless steel IR source of about one hour duration. Passive radar augmentation in the I/J- and D-bands is provided by means of Luneberg lenses. Towing is possible at speeds between 250 and 500 knots. Recent modifications provide a DIGIDOPS scoring capability instead of the older BIDOPS system.

HUTTS

The Hayes Universal Tow Target System (HUTTS) consists of the Universal Target Launcher, Model LTC-2 with Hayes radar, IR, smoke, or visual tow target. The launcher fits any aircraft pylon with standard NATO 14 or 30 inch (35·56 or 76·2 cm) lugs and is compatible with all Hayes towbodies.

The modular LTC-2 launcher can be mounted on any aircraft equipped with bomb shackles, and allows utilisation of the target system on all aircraft without modification of airframe or wiring system, thereby precluding any requirement for a dedicated tow aircraft. Adaptation to aircraft without pylons is also possible. Multiple target carriage is possible when mission requirements so dictate.

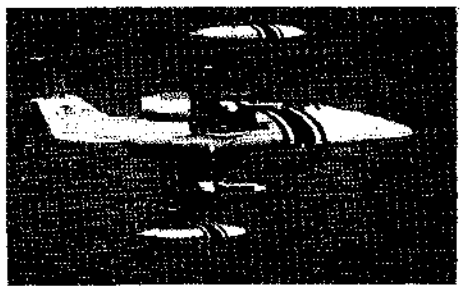
The LTC-2 launcher is constructed of glass-fibre and steel and is aerodynamically shaped. Weight of the launcher varies from approximately 31·5 to 39·25 kg depending on the configuration in use. Because of its simple modular mechanical construction and minimum electrical parts, maintenance of the launcher can be expected to be minor, easily accomplished and completely compatible with current field maintenance shop capabilities.

Major assemblies of the LTC-2 launcher are the pylon unit, the ignition module, the suspension and

release unit, the remote control module and the nose cone units.

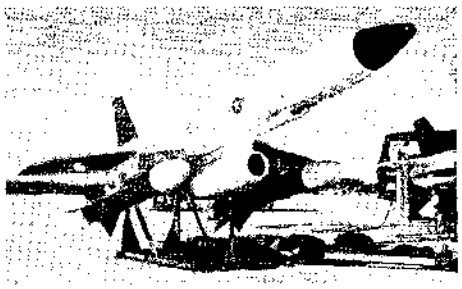
The pylon unit which interfaces with the aircraft pylon is designed so that it will accommodate a 35·56 or 76·2 cm spacing and the configuration may be varied in such a manner that the 35·56 cm lug spacing may be from the forward lug position or from the aft lug position by rotation of the hardback assembly and centre lug receptacle. This unit employs standard 450 kg class bomb lugs and no electrical interface is required between the pylon unit and the aircraft bomb rack. The pylon unit houses the battery for electrical operation of the launch and release bellows actuator carried in the suspension and release unit.

Immediately forward of the extension unit or pylon, in those cases where the extension unit is not used, an ignition unit may be placed as required for ignition of the propane CIR augmentation sources carried in the TIX series of IR targets. The ignition unit contains a solid-state, 20 kV spark generator operating at a PRF of approximately 1 kHz. The ignition unit operates from the pylon unit battery.



Ahead of the ignition unit or pylon unit, is the suspension and release unit which provides for a two-point suspension of the HUTTS family of targets and for the towing of these targets. Suspension is accomplished by a scissor type mechanism which grasps the suspension lugs of the HUTTS target. A similar arrangement is employed to grasp the towing end of the towline. Four individually operated sway braces are employed to make the launcher/target interface rigid. The release of the target from the launcher is accomplished by detonation of a pyrotechnic bellows actuator. Actuation of the bellows actuator unlocks a four-ball lock and moves a tapered rod aft between the scissor arm allowing the scissor to open and release the target. Release of the towline is accomplished by a second pyrotechnic bellows actuator and a similar release mechanism. The two functions of the suspension and release unit require one electrical command for each function.

Immediately forward of the suspension and release unit is the remote control unit which receives the coded commands from the command transmitter carried in the aircraft cockpit and operated by the pilot. Each remote control unit is equipped to receive either left- or right-hand launch and release commands from the command transmitter. These commands close the appropriate relays which connect the pylon unit battery to the appropriate actuator. The command receiver of the remote control unit operates on a separate battery contained within the remote control unit and is a flush-mounted receiving antenna for reception of the command frequency.



The LTC-2 command transmitter is a small solid-state, hand-held RF unit which the pilot carries in the cockpit of the tow aircraft. Switches on the transmitter allow the pilot to select the functions of launch and jettison of either right or left targets. Transmitter commands are controlled by a separate switch to prevent inadvertent operation. Weight of the transmitter is less than 1 kg.

The command transmitter operates on a frequency of 72·9 MHz. Each transmitter contains eight channel encoders. Two channels are dedicated to each of four command functions enabling the launch and jettison of the targets from two launchers on the same aircraft should dual carriage be a mission requirement.

Five types of targets have been developed to date for the HUTTS concept: radar, IR, plume, visual and smoke augmented targets. The radar augmented targets, designated TRX series, feature different arrays of passive radar lens and reflectors which provide the desired augmentation for the needed purpose. IR augmented targets feature propane fired burners/emitters and are designated TIX. Plume augmented targets, designated TPT, provide an all-aspect IR target capability. Two configurations of visual/radar targets have been developed. One is light augmented, the other is smoke augmented and are designated TGX and TVX, respectively.

HUTTS TRX-3 radar augmented and TGX-1 light augmented targets mounted on the 35A Learjet

Beech MQM-107 with TRX-4 radar augmented targets for Hawk SAM test and training

Each of the five series of targets has or is capable of being configured in several ways depending on mission requirements and the desired payload. Having scoring provisions changes model nomenclatures.

TRX Radar Augmented Targets

The basic fuselage and tail fins of the TRX are constructed of impact resistant thermoplastic. Nose and tail cones adapt to the fuselage with aluminium/steel bulkheads to support mounting of fore and aft lenses. Additional lenses or metallised reflectors can be mounted in the tow body to provide beam coverage for radar augmentation. A tow reel with pre-wound towline is located at the centre of gravity of the target. Variable towline lengths from 100 to 6000 metres of either constant- or stepped-diameter cable is wound on the reel during target assembly at the factory depending upon mission requirements. The braking system of the reel controls target reel-out rate. Depending upon the number, type and location of the radar lens, radar cross-section varies from 17 m² monostatic to 5 m² bistatic. Weight of the target, which is approximately 25 kg, will vary depending upon the number of radar lenses.

When required, a low-cost scorer/counter is mounted in the middle section of the TRX fuselage with the antenna located in a specially designed boom protruding through the nose cone. Scorer power is provided for by a battery pack located adjacent to the scorer. Scoring information is telemetered to a telemetry pod where it is re-transmitted to a ground receiving station where display and/or recording is accomplished.

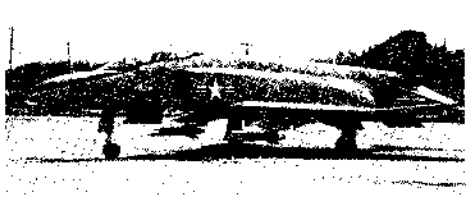
TIX IR Augmented Target

The TIX series of targets are the IR augmented targets of the HUTTS family. Like the TRX series, they are constructed of thermoplastic and are augmented with an IR emitting, propane-fired burner which operates at approximately 1135°C. The IR emitting surface is 21·59 cm in diameter and 22·86 cm long. The approximate output of the IR augmenter is 400 W per steradian in the 1·8 to 2·8 micron band and 250 W per steradian in the 3 to 5 micron band. Liquid propane fuel is carried in a stainless steel cylindrical tank of such capacity to provide for at least 30 minutes of CIR output. The duration of burning is dependent upon altitude of operation.

The nose cone has a 6 cm diameter opening to allow ram air to flow through the target to provide air for the proper fuel-air mixture needed to support fuel combustion. Ignition is attained through electrical spark that is controlled by an ignition module in the LTC-2 launcher.

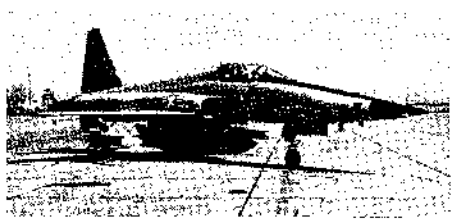
Tow reel provisions for the TIX target are similar to the TRX targets. Towlines up to 6000 metres in length can be provided with TIX targets. TIX targets are 232·41 cm long and the standard 22·86 cm in diameter. All HUTTS targets are stabilised with six fins that give the targets a maximum fin span of 60·32 cm. Weight of TIX targets is a nominal 25 kg but varies depending on length of towline.

TGX Series Targets



The TGX series of targets and the visual/radar augmented targets of the HUTTS family are used primarily in point defence weapons systems training. Coaxial visual/radar augmentation is provided forward along the flight axis by a trihedral radar reflector constructed of extremely fine mesh wire cloth through which the beam of the visual augmentation lamp passes. Visual augmentation is accomplished by use of incandescent lamps with an input of approximately 600 W at 31 V dc. Various beamwidths can be selected from the available augmentation lamps providing naked eye visual contact ranges up to 9 km. Electrical power for operating the on-board electrical system is provided by a generator unit which is turned by a ram air driven turbine wheel at the rear of the target tail cone. Additional radar augmentation may be provided in the beam areas if required, and the target is capable of carrying optional scoring equipment which will provide a missile scoring capability of approximately 15 metre radius and bullet counting for the 20 mm class bullets to approximately five metres. The TGX series of targets are equipped with deployment reels for self-deployment on towlines up to 6000 metres in length. These targets are 22·85 cm in diameter, cylindrical in shape and 223·52 cm in length. They are stabilised with six fins with a maximum fin span of 60·3 cm.

TVX Series Targets



The TVX series of tow targets are visual/radar targets designed for employment where visual/optical tracking of a target is required. Visual augmentation is provided by five smoke generators internally mounted which discharge smoke through a 10·16 cm discharge tube coaxial with the tail cone. Each flare will burn for approximately two minutes. Ignition of the smoke generators is accomplished by radio command. Each generator is ignited by a separate coded command from the command transmitter. A command transmitter operating at a frequency of 72·4 MHz radiates 15 W minimum thus enabling reliable command at all ranges to ten nautical miles at low altitude, and slightly longer range as the target altitude increases.

Radar augmentation is provided by a 17·78 cm monostatic radar reflecting lens which provides approximately 4 m² J-band, over a conical angle of 160° coaxial with the longitudinal axis of the target. A command receiver and battery are mounted on a tray accessible through the nose cone of the target and equipped with flagged safety plug. The TVX targets may also be equipped with the capability of scoring surface-to-air and air-to-air missiles. The TVX target is deployable from either droned or manned aircraft utilising its own internally mounted tow reel which has towlines to 6000 metres in length.

Bullet counting provisions are available for each series of HUTTS targets. Antenna and sensor installation varies for the different types of configuration so as to provide the optimum and desired scoring area. The sensitivity of the system can be varied for scoring out to approximately 15 metres. Scoring is achieved when a projectile such as a bullet or missile passes through an RF field which is produced by the sensor transceiver. The frequency shift (doppler effect) created when the projectile transgresses the RF field is detected by the sensor and electronically transmitted through a telemetry link to the tow aircraft then to a ground receiving

F-4 aircraft with TRX and TGX targets

Dual-carriage, radar augmented TRX-3 targets with passive lens and reflectors for basic air gunnery training

station. The bullet count is digitally displayed at the ground station. For record purposes the bullet count may be recorded at the ground station. All features of the scoring system for HUTTS can be provided without modification to the towing vehicle. Power for the target scorer and LTC-2 launcher is supplied by the battery packs. Standard telemetry frequencies for the scoring sensor and relay pod are 1775 and 235 Hz, respectively.

STATUS

Earlier target systems, such as the TA-8A/B, TJT-1, TDU-30/B, and TGT-1C MiniMIG, although no longer in production are still widely used; they are described in previous editions of *Jane's Weapon Systems*.

The HUTTS is currently the company's main programme and contracts are in force for supplies to Brazil, UAE and Yugoslavia. The US Army and Navy are using versions of HUTTS and Egypt, Saudi Arabia, Italy, Taiwan, Korea and Japan are considering adoption of HUTTS for sea, air and ground applications. In addition to aircraft types listed in previous editions, the following have been flown with HUTTS: A-4, A-7, Gates-Learjet 35A, MiG-21, T-33/T-34, Mirage 5, MB326, F-100 and MQM-107 drones.

IR plume augmentation for the MQM-107 and BQM-34A drones is under development and test.

Hayes International Corporation, Targets Division, PO Box 707, Leeds, Alabama 35094, USA.

NAVAL GUNS AND BOMBARDMENT ROCKETS

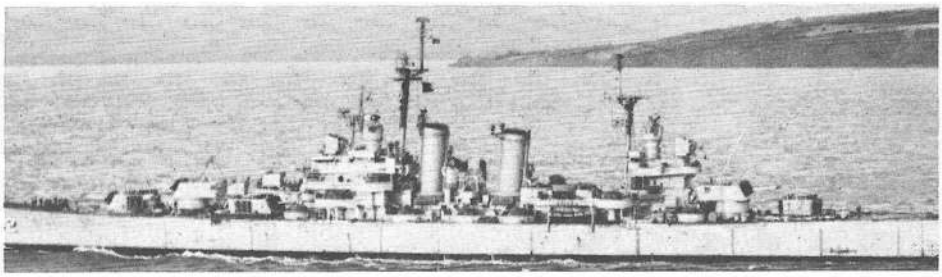
CANADA

6053.203
TWIN 3 inch AA MOUNTING

Certain of the frigates of the Canadian Navy are fitted with twin 3 inch (76 mm) Vickers Mk 6 AA guns (**6016.203**) manufactured in Canada. This is a 70-calibre weapon in a light turret and it replaced the forward 3 inch/50 calibre American mount (**6030.203**), the aft mount being left unaltered.

STATUS

Fitted in the 'Mackenzie' and 'Restigouche' class frigates. The latter class are in reserve.



Twin 3 inch 70-calibre guns on the destroyer escort Chaudière (Canadian Maritime Command)

CHILE

6054.203
SINGLE 5 inch MK 27 DUAL-PURPOSE GUN MOUNTING

Eight of these guns are fitted to the ex-US 'Brooklyn' class cruiser *O'Higgins*. They are believed to be of US manufacture but 5 inch guns of this type are no longer in service in the US Navy.

The cruiser O'Higgins. *Triple 6 inch Mk 16 gun turrets can be seen forward and aft and four of the eight 5 inch dual-purpose guns can be seen in single mountings abreast of the superstructure* (Chilean Navy)

4846.203
TRIPLE 6 inch/47 Mk 16 GUN TURRET

These mountings were originally installed on the US Navy's 'Brooklyn' class cruisers, only one of which remains in active service with the Chilean Navy (*O'Higgins*). Originally five turrets were fitted to each ship on the centreline. All turrets were similar with the principal difference being in the ammunition hoist to each. On trials the USS *Savannah* fired 128 rounds in the first minute during a ladder type barrage with a 600 yard (549 m) spread. Subsequent practice was to use split salvo firing to decrease the spread of the fall of shot, losing only 10 to 15 per cent of the rate of fire.

Each turret carries the three guns in a built up slide. They are elevated, depressed, and trained as a unit but may be fired separately or together, electrically or by percussion. Ammunition is manually served to loading trays from endless conveyor hoists. Each turret is eight feet (2·4 m) high, and has case ejection ports located at the base behind the barbette structure which is 17 feet (5 m) in diameter. Three types of projectile are used - the Mk 34 FCL(VT)/HC; the Mks 35, 36, 37, or 42 AP; or training rounds. Powder case Mk 6 was standard, using either full charge (60 pounds) or reduced charge (51 pounds).

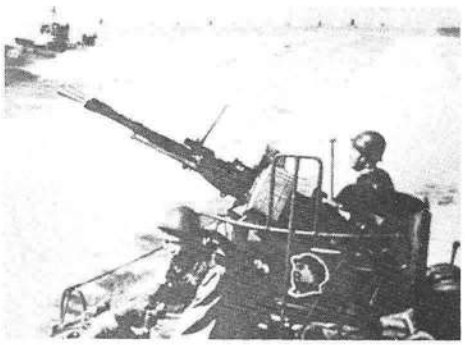
Twelve guns were installed on the 'Cleveland' and 'Fargo' class cruisers in the US Navy. All used the Mk 16 gun with slight weight variations from the 'Brooklyn' class.

CHARACTERISTICS

Calibre: 152 mm
Length of barrel: 50 calibres
Elevation: -5° to +60°
Traverse: 288° to 300° depending on siting
Muzzle velocity: 762 m/s(AP), 790 m/s(HC)
Max range: 23·9 km(AP), 21 km(HC)
Max altitude: 10·4 km
Assembly weight: 165 to 173 tons
Weight of gun: 4370 kg
Ammunition: AP, HC and drill

STATUS

Originally installed on all light cruisers of the US Navy's 'Brooklyn', 'Cleveland' and 'Fargo' classes. Only the USS *Oklahoma City* remains in Pacific Fleet reserve (logistic support only) and all other units have been scrapped. The Chilean cruiser *O'Higgins* is the last remaining ship with this gun.



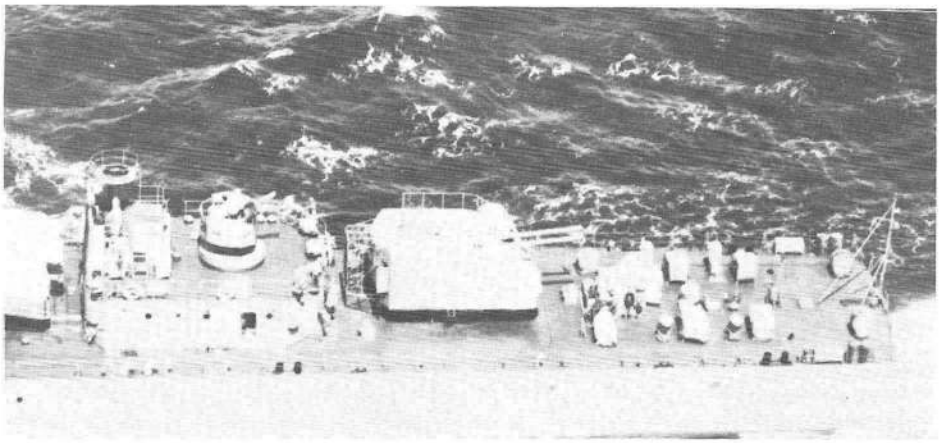
CHINA (PEOPLE'S REPUBLIC)

6055.203
CHINESE NAVAL ORDNANCE

Much of the Chinese Navy is made up of vessels originally designed and constructed in the Soviet Union and subsequently transferred to China. A further section - but one of diminishing importance - consists of ex-Japanese and Second World War ships inherited by the present regime from that of Chiang Kai Shek. Most of these latter vessels are now at least obsolescent if not obsolete.

Since the mid-1950s, however, the Chinese have been building many of their own fighting ships. At first these were mainly built from parts supplied by the Soviet Union, but since the two countries have become estranged the Chinese have had to rely increasingly on their own resources.

Because of this overlapping supply it is not possible to say exactly for which vessels the guns have been built in China, or which of those have been entirely manufactured in China. It seems probable, however, that there are Chinese-built guns of at least the following types currently in service: 100 mm dual-purpose (twin and single mounts), 57 mm (twin), 37 mm AA (twin mounts), and 25 mm AA (twin mounts). It is also certain that 130 mm guns (in twin mountings) are being built in China for incorporation in the new 'Luda' class destroyers. 100 mm single mountings too continue to be installed in new Chinese ships. Guns of several other calibres are in service with the fleet, and must therefore be being serviced in Chinese yards, but it cannot be said with certainty that they have been built in China.



14·5 mm calibre AA (twin) mount on P4 Class torpedo boat of Chinese Navy

4513.203
TWIN 130 mm DUAL-PURPOSE GUN MOUNTING

This gun mounting is a copy of the original gun system and mounting used on the Soviet 'Kotlin' class destroyers. Blueprints for the system were probably received prior to 1960, but the Chinese were unable to effect production of the mounting until ten years later when the first of the 'Luda' class destroyers was laid down. The gun houses differ slightly in having rounded edges and do not include the fitting of a ranging radar as installed on Soviet units.

CHARACTERISTICS
Calibre: 130 mm
Length of barrel: 58 calibres
Elevation: 85° max
Projectile weight: 33·4 kg
Muzzle velocity: 945 m/s
Max range: 29 300 m
Rate of fire: 15-17 rounds/minute

Twin 130 mm gun mount on Chinese 'Luda' class destroyer. Note open rear to turret and basket on back (G Jacobs)

4514.203
SINGLE 130 mm GUN MOUNTING

This is an old gun mounting originally received with the Soviet 'Gordy' class destroyers transferred to China in 1954-55. Two mountings are also installed in the ex-British 'Castle' class patrol frigate still in Chinese naval use and may possibly have come from spares provided for the 'Gordy' class as it seems unlikely that they were ever built in China. Although very elderly and relying on the equally elderly Soviet Post Lamp fire control radar for ranging information, the mountings may remain in service for some years since the 'Gordy' class have been fitted with SSMs and this may indicate an extension of their lives beyond the normal length.

CHARACTERISTICS
Calibre: 130 mm
Length of barrel: 50 calibres
Elevation: 45° max
Projectile weight: 33·4 kg
Muzzle velocity: 875 m/s
Max range: 25 000 m
Rate of fire: 12 rounds/minute
Soviet designation: Model B-13-2C

4515.203
SINGLE 100 mm DUAL-PURPOSE GUN MOUNTING

This single mounting was introduced into Chinese naval service in 1956-57 during the assembly of four Soviet 'Riga' class frigates at Hudong shipyard, Shanghai. It was extensively used in the 1960s in rebuilding ex-British and ex-Japanese frigates where all, except for the 'Castle' class, were re-armed with this gun system manufactured in China from blueprints originally sold by the Soviet Union in the late 1950s. It has also been installed in the locally designed 'Jiangnan' class frigates, and also appears to continue to be fitted in the more modern 'Jiangdong' and 'Jianghu' class frigates.

CHARACTERISTICS
Calibre: 100 mm
Length of barrel: 56 calibres
Elevation: 85° max
Projectile weight: 15·9 kg
Muzzle velocity: 875 m/s
Max range: 21 900 m
Rate of fire: 15-18 rounds/minute
Soviet designation: Bu-34

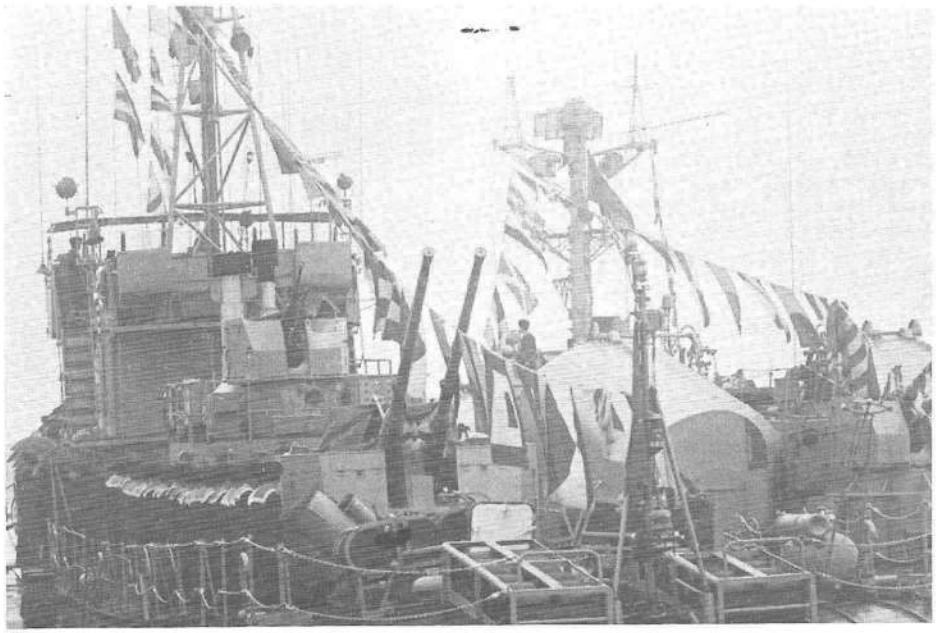
100 mm single dual-purpose mount on stern of a Chinese 'Jianghu' class frigate. Note small size of twin 37 mm mountings where twin 57 mm mounting may have been intended (G Jacobs)

4516.203
SINGLE 85 mm DUAL-PURPOSE GUN MOUNTING

This single 85 mm mounting was first placed in Soviet naval service in 1948 and is controlled by optical directors only. It can be considered obsolescent despite its use in a number of Communist countries. It is fitted to China's 20 'Kronstadt' class patrol vessels.

CHARACTERISTICS
Calibre: 85 mm
Length of barrel: 52 calibres
Elevation: -5 to +85°
Elevation rate: 8°/s
Projectile weight: 9·6 kg
Muzzle velocity: 760 m/s
Max range: 15 000 m
Rate of fire: 15-18 rounds/minute
Soviet designation: Model 90K

4517.203
SINGLE 75 mm DUAL-PURPOSE GUN MOUNTING



The 75 mm dual-purpose gun mounting first became available from captured Nationalist escorts and landing craft after the Civil War. It may subsequently have been manufactured locally from captured blueprints as quantities continue to be seen on refitted American LSTs.

CHARACTERISTICS
Calibre: 75 mm
Length of barrel: 50 calibres
Elevation: -13 to +85°
Projectile weight: 13·05 lb (5·92 kg) (AA); 13·07 lb (5·93 kg) (AP)
Muzzle velocity: 2650 ft/s (808 m/s)
Max range: 14 000 yards (12 800 m)
Rate of fire: 18 rounds/minute
Total mounting weight: 7500 lb (3400 kg) (Mod 17); 8310 lb (3769 kg) (Mod 2)
US designation: Mark 22 Mods 2 and 17

4518.203
TWIN 57 mm AA GUN MOUNTING

This is a water-cooled adaptation of the Soviet 57 mm SIF-31B model. Some 'Luda' class destroyers were initially armed with it as the AA defence system intended for all units of the class. It is, however, now only standard on the 'Hainan' class patrol craft, four of which have been exported to Pakistan. A lead computing optical sight is used for fire control. The magazine on an escort holds about 1600 rounds. The Chinese indicate that they have high explosive, fragmenting, and tracer rounds available.

CHARACTERISTICS
Calibre: 57 mm
Length of barrel: 70 calibres
Elevation: -10 to +85°
Projectile weight: 6·31 kg
Muzzle velocity: 1000 m/s
Max range: 12 000 m
Rate of fire: 2 × 105-120 rounds/minute

Twin 57 mm AA mount on 'Hainan' class escort. Note twin 25 mm 'over-and-under' mounting amidships (G Jacobs)

4519.203
TWIN 37 mm AA GUN MOUNTING

Both single and twin mountings are standard throughout the Chinese Navy and are currently used by all destroyers, frigates and fleet minesweepers, and some landing ships. Both mounting and ammunition are available for export and equip a number of vessels sold to Bangladesh, Pakistan and Sri Lanka. Only local fire control is available.

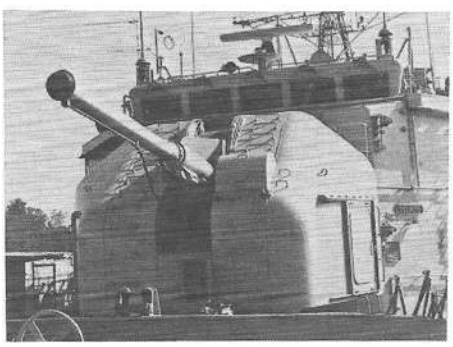
CHARACTERISTICS
Calibre: 37 mm
Length of barrel: 63 calibres
Elevation: -10 to +85°
Projectile weight: 1·416 kg
Muzzle velocity: 875 m/s
Max range: 8500 m
Rate of fire: 2 × 160-180 rounds/minute
Soviet designation: B-11-M (twin); Model 70K (single)

Twin 37 mm and twin 25 mm 'over-and-under' mounts on Chinese 'Shanghai' class gunboat (G Jacobs)

4520.203
TWIN 14·5 mm GUN MOUNTING

A light AA mounting fitted in the 'Chengdu' class frigates, the 'Kronstadt' class patrol vessels, the 'Huchuan' torpedo-armed fast attack craft, and the T-43 minesweepers. It is not certain that it is still in production although 'Huchuan' class vessels continue to be built. The ammunition however is available for export. Local fire control only is available.

CHARACTERISTICS
Calibre: 14·5 mm
Length of barrel: 93 calibres
Elevation: -5 to +85°
Projectile weight: 0·06 kg
Muzzle velocity: 1000 m/s
Max range: 7000 m
Rate of fire: 2 × 600 rounds/minute
Soviet designation: 2M-7



FRANCE

6064.203
SINGLE 100 mm DUAL-PURPOSE GUN MOUNTING MODEL 1968-II

The gun mounting Model 1968-II represents the latest version of French 100 mm turret and is a lightened and completely automatic version derived from the Models 1953, 64 and 68-I. This calibre is considered optimum by the French authorities for engaging air targets and surface vessels, as well as shore bombardment. Among the intended targets are missiles, including sea-skimming types.

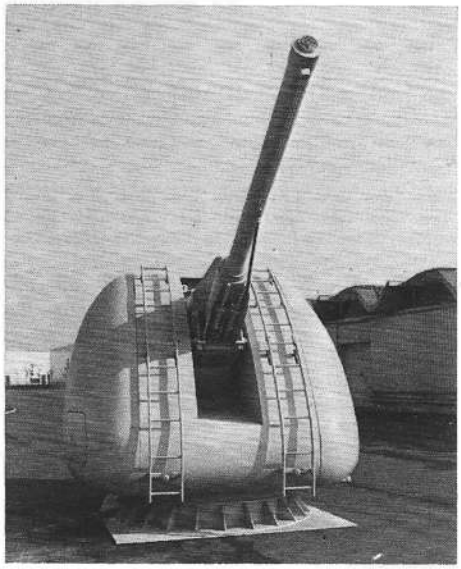
Features of the Model 1968-II 100 mm gun which suit it for multipurpose roles include: fully automatic remote operation, with the option of autonomous operation with a crew of two; high rate of continuous fire; replenishment of magazine when firing is in progress for long engagements; a container-based munition re-supply system; long bore life due to air purging and water cooling after each round is fired. Both a multipurpose and a prefragmented shell can be used. The multipurpose shell uses either a time or a proximity fuze while the prefragmented shell was primarily designed for proximity fuzing.

CHARACTERISTICS
Calibre: 100 mm
Length of barrel: 55 calibres
Elevation: -15 to +80°
Max speed in elevation: 25°/s
Max acceleration (elevation): 80°/s²
Max slewing speed: 40°/s
Max acceleration (slew): 50°/s²
Projectile weight: 13·5 kg (1·05 kg charge)
Round weight: 23·6 kg
Muzzle velocity: 870 m/s
Max range: 17 000 m (9 nautical miles)
Max practical range against air target: 6000–8000 m
Rate of fire: 60 rounds/minute (80 rounds/minute on recent models)

Model 1968-II 100 mm dual-purpose turret

STATUS

Operational with the French Navy since 1960, this equipment has subsequently undergone several modernisation programmes. It also serves in the navies of the Federal Republic of Germany, Belgium, Portugal and Argentina.



Creusot-Loire is developing a 100 mm Compact, derived from the 100 mm French Navy version, which is entirely automatic and which has essentially the same performance characteristics. Its weight of 17 tons allows installation aboard small ships. A reversible ammunition feed system is provided which also permits the use of several types of ammunition with instantaneous selection. Rate of fire is variable between 10 and 90 rounds/minute. Other significant characteristics include maximum speed and acceleration in elevation of 33°/s and 95°/s² respectively, and maximum slewing speed and acceleration of 50°/s and 57°/s². It has been ordered by Saudi Arabia and Malaysia.

CONTRACTORS

Overall responsibility for the 100 mm Model 1968-II guns and mounts rests with the Direction des Constructions Navales (DCN), 2 rue Royale, 75200 Paris Navale, France, with manufacture undertaken by:

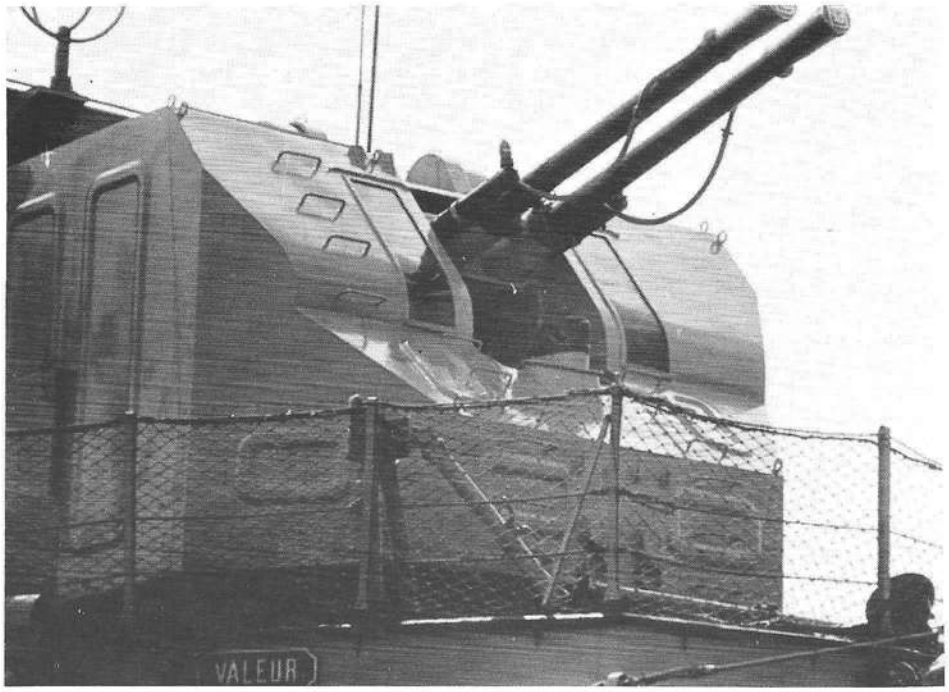
Turret: Société Creusot-Loire, 15 rue Pasquier, 75383 Paris Cedex 08, France; and ECAN Ruelle, 16600 Ruelle, France (a DCN establishment).

Control gear: CSEE, 2-8 rue Caroline, 75850 Paris Cedex 17, France.

Prototype Creusot 100 mm Compact

6065.203

TWIN 57 mm AA GUN MOUNTING



This 57 mm gun is now only fitted in the French Navy in the old cruiser *Colbert*. It consists of twin Bofors guns carried on a mount of French design. Each gun is provided with an ammunition reserve of 80 rounds, which can be replenished from a transfer chamber located below the mount. The gun and mount are normally operated under remote control but autonomous operation is also possible.

CHARACTERISTICS

Calibre: 57 mm
Length of barrel: 60 calibres
Elevation: -8 to +93°
Projectile weight: 2·96 kg
Muzzle velocity: 865 m/s
Max range: 13 km (7 nautical miles)
Practical range (air targets): 5000 m (3 nautical miles)
Rate of fire: 2 × 120 rounds/minute
Weight: 16 tons

CONTRACTOR

Direction des Constructions Navales (DCN), 2 rue Royale, 75200 Paris Navale, France.

French version of the Bofors 57 mm mount

2135.203

RAP 14 NAVAL BOMBARDMENT ROCKETS

The multiple unguided rocket bombardment system known as RAP 14 is now firmly proposed for naval applications.

The land-based version, which is at a much more advanced stage, was described in detail in **2024.103**, in *Jane's Weapon Systems 1982-83*, so that it is necessary here to draw attention only to those features that are peculiar to the naval version.

The naval version will have a 2 × 9 rocket launcher on a remotely controlled mounting with provision for automatic reloading from below deck with the launcher in the vertical position. Each of the two magazine drums will contain 36 rockets, giving a total capacity, with a full launcher and full magazine, of 90 rockets.

CHARACTERISTICS

Weight: Complete launcher assembly, less rockets: 10·4 tons. Complete assembly with rockets: 15·09 tons
Magazine dimensions: 5·9 × 2·5 × 2·5 m
Launch combinations: Any number from 1 to 18
Range: Max for standard rocket: 16 km
Rate of fire: 9 s for 18-round salvo
CEP: 90 m
Rocket calibre: 140 mm
Weight: 54 kg
Warhead: 19 kg HE standard. Special warheads possible
Speed: Max Mach 2

CONTRACTORS

System: CNIM (Constructions Navales et Industrielles de la Méditerranée), 50 avenue des Champs-Elysées, 75008 Paris, France.

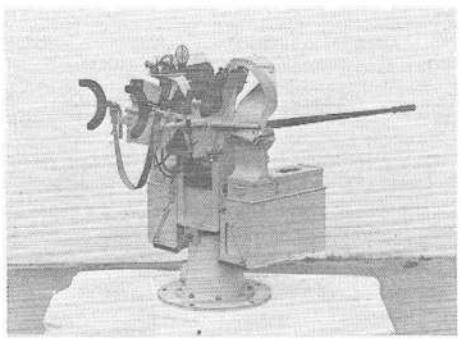
Mounting: in co-operation with Creusot-Loire, Groupes Marine Schneider, 15 rue Pasquier, 75008 Paris, France.

3655.203

TYPE A NAVAL MOUNTING FOR 20 mm F2 GUN

This naval mounting is installed in small, lightweight ships, and carries the French F2 20 mm automatic cannon which is also employed in land-based and airborne roles. It is designed for one-man operation, and elevation and slewing motions are manually powered. Two types of ammunition can be employed, carried in a pair of magazines on the mount with a combined capacity of 300 rounds. Continuous, limited burst and single-shot firing can be selected, and the mount can be used for both air or surface target engagement.

CHARACTERISTICS



Calibre: 20 mm
Elevation: -15 to +60°
Muzzle velocity: 1050 or 1250 m/s*
Effective range: 2000 or 1200 m*
Max range: 10 020 or 6770 m*
Rate of fire: 720 rounds/minute
Power requirement: 26 V, 7 A
Weight: 470 kg (360 kg without ammunition)
*Depending upon type of ammunition: explosive or armour-piercing.

STATUS

In series production for 'Tripartite' mine-hunter vessels of the Belgian, Dutch and French Navies. This gun also exists on a mobile land mounting for army use (**5599.103** in 1982-83 and earlier editions).

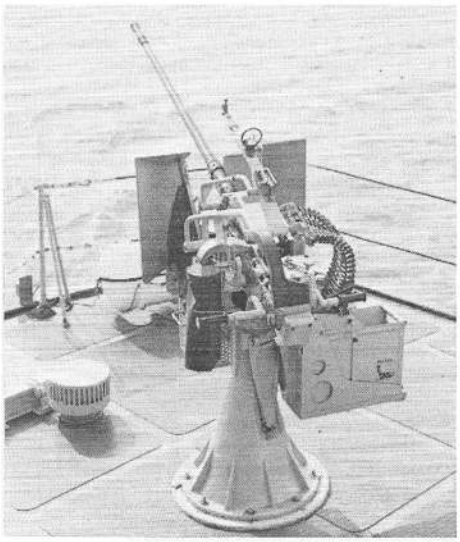
CONTRACTOR

Direction des Constructions Navales (DCN), 2 rue Royale, 75200 Paris Navale, France.

Type A naval mounting for 20 mm F2 gun

GERMANY (FEDERAL REPUBLIC)

3177.203
SINGLE 20 mm NAVAL GUN S20



This is the naval mount version of the Rheinmetall Mk 20 Rh 202 20 mm automatic cannon described in **5600.103**(in 1982-83 and earlier editions). S20 naval guns are primarily intended for installation on small and fast ships and as secondary armament on larger vessels as well as for static applications ashore. Low weight and one-man body aimed actuation of the mount assure rapid response for the effective engagement of surface and air targets, whereby the gunner always remains in an upright position.

The weapon itself is the Rheinmetall 20 mm automatic cannon Mk 20 Rh 202 which is particularly suited for these purposes because of its low recoil forces. The Mk 20 Rh 202 is also renowned for its functional safety and reliability in spite of restricted lubrication, sea water contamination, heavy fouling and other extreme environmental conditions. Mount and weapon can be dismantled into their major components without the use of any tools.

CHARACTERISTICS
Type: Mk 20 Rh 202
Calibre: 20 mm
Elevation: -10 to +55°
Traverse: Unlimited
Muzzle velocities: HEI-T, TP-T 1050 m/s; API-T 1100 m/s; APDS-T 1150 m/s
Recoil force: 550 - 750 kgf
Tactical range: 2000 m
Rate of fire: 1000 rounds/minute
Firing: Mechanical
Type of fire: Single or sustained fire
Ammunition supply: 200 rounds belted in exchangeable ammo box
Sight: Mechanical AA sight with parallelogram linkage and shoulder rest. Night vision device and telescope sight are optional
Weight: Mount complete: 334 kg; ammunition: 74 kg
Length: 3070 mm
Width: 1230 mm
Height: 1570 - 1785 mm

STATUS
In production.

Rheinmetall single 20 mm gun mount S20

ISRAEL

3729.203
TCM 30 TWIN 30 mm NAVAL GUN

The TCM 30 naval air defence weapon consists of two automatic 30 mm cannons and their feed systems mounted on a high angular acceleration, electrically-driven stabilised turret. The guns are Oerlikon 30 mm automatic cannons which with their respective 125-round ammunition feed boxes, are carried on a unique barrel-support system which reduces shot dispersion to a minimum. The cradle is carried on an electrically-driven mount which is fitted with rate gyros that provide signals to stabilise the guns against ship's motion. The turret has an elevation angle of -20 to +85°, and both positioning and velocity can be controlled from the ship's fire control system, which in Israeli vessels is generally based on the EL/M-2221 naval fire control radar (**3709.253**).

Five different types of ammunition provide flexibility against various classes of target. Two 125-linked round ammunition boxes are mounted on the gun cradle so that they move with the guns in elevation and traverse. Semi-rigid chutes guide the linked rounds from the boxes to the gun's bolt feed mechanisms, thus ensuring smooth feed paths which do not strain the belt's flexibility. Two back-up magazines provide a 40-round reserve.

TCM 30 twin 30 mm mount used for naval air defence

The TCM 30 is also adaptable to towed carriage mounts and armoured vehicles, as well as both large and small classes of warship. The same twin gun, on mountings suitable for land-mobile applications, is employed also in the Spider II air defence artillery system (**4508.131**).

CHARACTERISTICS
Main armament: 2 × Oerlikon 30 mm automatic cannon
Traverse: ±160°
Elevation: -20 to +85°
Acceleration (azimuth and elevation): 10 rad/s²
Max speed (azimuth and elevation): 1·5 rad/s
Muzzle velocity: 1080 m/s
Rate of fire: 2 × 650 rounds/minute
Overall length: 3550 mm

CONTRACTOR

ITALY

5534.203
SINGLE 127/54 GUN MOUNTING

The 127/54 is a dual-purpose gun mount of an intermediate calibre which has been designed for use as the main armament for frigates and destroyers.

Design work started in October 1965 as a joint venture with the Italian government. The first prototype was completed in May 1969.

Ready use ammunition is held in three drums just below the turret. A central elevator hoists the ammunition, chosen from one drum, and delivers it to the turret where two oscillating arms perform the final movement to the loading trays. The three drums are automatically reloaded through two hoists manually loaded in the magazine.

This three drum layout makes it possible to stow three different types of ammunition in the ready use magazine from which ammunition can be selected appropriate for the type of action. Remote-controlled fuze setters are provided in the oscillating arms.

The reloading, feeding, loading, and firing sequence is controlled by a control console operated by a single man.

The electrically-operated remote control servo-system is of modular construction using silicon controlled rectifiers. The modules are the same as those used on other modern OTO Melara weapon systems.

127/54 OTO single barrel naval mount

The main technical features are the light alloy construction, the compact installation, and the lightweight control mechanism.

The barrel is fitted with a muzzle brake. The shield is of fibreglass and is watertight.

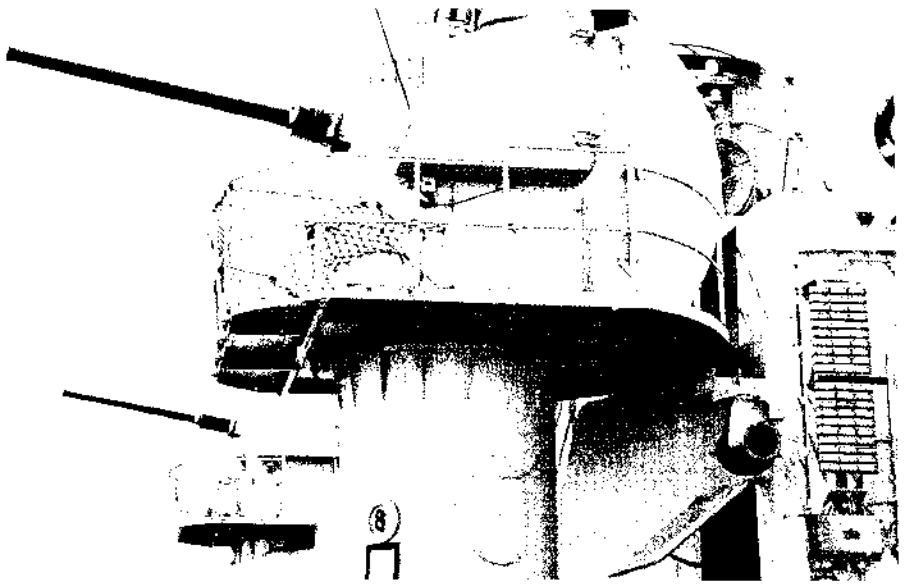
CHARACTERISTICS
Calibre: 127 mm
Elevation: -15 to +83°
Elevation speed: 30°/s
Elevation acceleration: 40°/s²
Traverse: 330°
Traverse speed: 40°/s
Traverse acceleration: 45°/s²
Rate of fire: 45 rounds/minute
Weight: 37·5 tons
Ready ammunition: 69 rounds (3 × 22 + 3)
Trunnion thrust: 24 000 kg

STATUS
In production and in service with Canada on four DD 280 class destroyers (1 turret); Italy on two 'Audace' class destroyers (2 turrets), eight 'Maestrale' class frigates (1 turret), and four 'Lupo' class frigates (1 turret); Argentina on four Blohm and Voss frigates (1 turret); Nigeria on one Blohm and Voss frigate (1 turret); Peru on four 'Lupo' class frigates (1 turret) and Venezuela on six 'Lupo' class frigates (1 turret). Note: this includes ships currently on order or building.

CONTRACTOR
OTO Melara, Via Valdilocchi 15, La Spezia, Italy.

5532.203

SINGLE 76/62 OTO MMI GUN MOUNTING



The 76/62 OTO MMI single barrel automatic gun was developed to a government contract for ships of the frigate and corvette types as a dual-purpose weapon. It was the forerunner of the successful 76/62 OTO Compact (**5533.203**) described below, which has superseded it.

The gun is a single barrel, water-spray cooled, on a powered mounting. It is protected by a watertight splinterproof shield, which also houses the one man required to direct the gun in the local control mode. Great efforts have been made to reduce the crew, and all operations are performed automatically.

Ammunition is fed from the magazine up to the loading trays, from where it is rammed into the breech. This feed system can vary in length from a minimum of 2·5 m to a maximum of 11 m, and will therefore accommodate a wide range of alternative deck and magazine locations.

The gun has a high rate of fire for its calibre, the maximum being about 60 rounds/minute. Ammunition is fixed, and the empty cases are ejected automatically.

Elevation and traverse is by electric and hydraulic control, with an emergency manual operation. The whole system can be controlled remotely or the fire director can exercise local control from his position beside the gun.

OTO 76/62 MMI single gun mountings

CHARACTERISTICS

Calibre: 76 mm
Elevation: -15 to +85°
Elevation speed: 40°/s
Elevation acceleration: 70°/s²
Traverse: 360°
Traversing speed: 70°/s
Traversing acceleration: 100°/s²
Rate of fire: 55 - 65 rounds/minute
Ready to fire rounds: 59
Overall weight: 12 tons

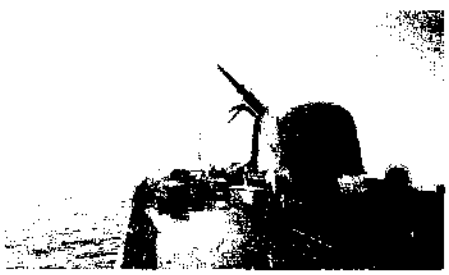
STATUS

No longer in production. There are many in service with the Italian Navy.

CONTRACTOR

OTO Melara, Via Valdilocchi 15, La Spezia, Italy

5533.203



SINGLE 76/62 COMPACT GUN MOUNTING

The 76/62-OTO compact is a light, small calibre gun mount intended for installation in ships of any type and class down to motor gun boats and hydrofoils as a dual purpose anti-aircraft and anti-ship weapon system.

The gun and mounting were developed from the 76/62 OTO MMI mounting (**5532.203**), the design study being started in 1964, and the first production units came into service in March 1969.

The mounting may be considered in two parts; the shank which is below the weather deck, and the turret which is installed on deck. The shank contains the ammunition feed system, which consists of a rotating platform and a hoist.

It can fire 80 rounds without reloading, and the rate of fire is adjustable from 10 to 85 rounds per minute. A version is available with a rate of fire up to 100 rounds per minute. Existing guns can be modified with a special kit.

OTO 76/62 compact gun mount

Generally, the system is controlled remotely; optionally it can also be fitted with a stabilised line of sight local control system. A reaction time of 2·8 seconds is quoted.

The shield is made of fibreglass, and is watertight. It offers complete protection against nuclear fall-out. The gun barrel has a small multi-hole muzzle brake and a fume extractor.

CHARACTERISTICS

Calibre: 76 mm
Elevation: -15 to +85°
Elevation speed: Max 35°/s
Elevation acceleration: 72°/s²
Traverse: Unlimited
Traverse speed: Max 60°/s
Traverse acceleration: 72°/s²
Rate of fire: 85 rounds/minute
Overall weight: 7·5 tons

STATUS

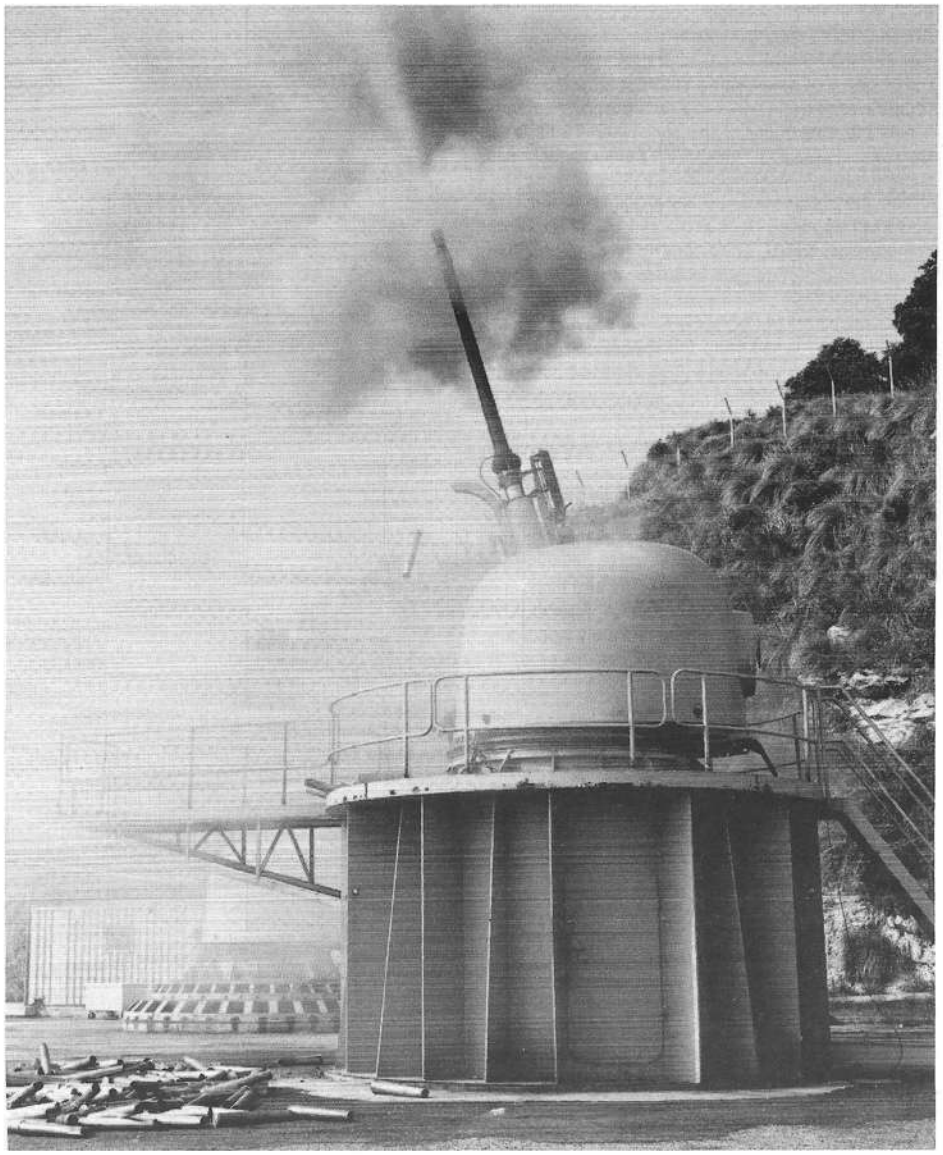
In service with, or being delivered to, 37 navies. In the USA this gun is produced under licence by FMC Corporation for the US Navy with which service it has designation 76 mm/62 calibre gun mount Mk 75 (**3175.203**), and is also being manufactured in Japan for the Japanese Navy. Production under licence is also undertaken in Australia, and in Spain for 'Lazaga' and 'Descubierta' classes of ship.

CONTRACTOR

OTO Melara, Via Valdilocchi 15, La Spezia, Italy.

4843.203

SINGLE 76/62 SUPER RAPID GUN MOUNTING



Development of the 76/62 super rapid gun mounting began in mid-1980 as an evolution of the 76/62 OTO compact gun mounting (**5533.203**). Its main role is anti-missile defence but it is also effective in either anti-aircraft or anti-ship fire. The new mounting maintains the same architecture and aspect and has identical mechanical and electrical interfaces but it can sustain continuous firing of all 80 ready-use rounds at more than 120 rounds per minute. In addition it incorporates a local stabilisation system for better aiming and firing accuracy and can be provided with an optional dual-feed mechanism that allows a rapid change from anti-air/anti-missile automatic fire to anti-surface and semi-automatic fire, and vice versa. The electronic portions of the gun have also been updated with safety firing arcs, pointing accuracy check, status display and BITE functions under mini-computer control.

Two ammunition developments have also been completed. The MOM ammunition is a pre-fragmented projectile designed for use against air targets, with high specific weight tungsten cubes and very high ejection velocity ensuring effective penetration of the target even at large miss-distances. It is fitted with a proximity fuze which is highly effective against sea-skimming missiles and aircraft and can also be used in an anti-personnel role during shore bombardment. The proximity fuze can be paralysed to allow the fuze to operate with impact delay.

SAPOM anti-ship ammunition is semi-armour piercing and optimised against hard surface targets. It is fitted with a base-detonating delayed action fuze and the projectile is made of high quality steel for maximum penetration capability.

Two further types of ammunition are also under development; one based on guided-projectile techniques for anti-missile/anti-aircraft fire and the other an anti-surface extended range round.

CHARACTERISTICS
Calibre: 76 mm
Elevation: -15° to +85°
Elevation speed: 35°/s
Elevation acceleration: 72°/s²
Traverse: Unlimited
Traverse speed: 60°/s
Traverse acceleration: 72°/s²
Rate of fire: greater than 120 rounds/minute
Trunnion thrust: 10 tons (constant)
Overall weight: 7·5 tons
STATUS
Series production started at the end of 1984.

BREDA COMPACT TWIN 40 mm L/70 NAVAL MOUNTING TYPE 70

This twin 40 mm L/70 naval mounting has been developed by Breda Meccanica Bresciana in close co-operation with Bofors in Sweden as part of the Breda/Bofors System 75 (see also **2349.131**) which is particularly intended for point defence against aircraft and anti-ship missiles.

Claimed to be the lightest and smallest 40 mm mounting currently available, the compact mount is fully automatic in operation, employs new remote controlled servo-systems of high performance to improve accuracy – which is also improved by the reductions in weight, inertia, and recoil disturbance resulting from the exceptionally small separation between the two barrels – and features a high rate of fire and a substantial supply of ready-use ammunition.

The weapon is available in two versions, Type A and Type B, the difference residing in the quantity of ready-use ammunition contained in the magazine (736 or 444 rounds) and in some consequential weight and dimension changes which are indicated below. In each type the magazine is divided into two halves each with a hoist serving one barrel. Without manual intervention the two hoists operate in synchronism.

Horizontally, the mounting is also divided into two parts. The upper part contains the cradle, the elevating mass, the automatic feeders, the servo-motors, and associated electronics and the firing, aiming, and limiting devices. The lower structure mainly comprises the magazine and hoists. The magazine is made up of several horizontal layers, there being seven of these in Type A and four in Type B. Before firing and during firing intervals these layers are packed with ammunition in four-round clips.

CHARACTERISTICS
Calibre: 40 mm
Elevation: -13 to +85°
Elevation speed: 60°/s
Elevation acceleration: 120°/s²
Traverse: Unlimited
Traverse speed: 90°/s
Traverse acceleration: 120°/s²
Swept radius: 3 m
Muzzle velocity: 1000 m/s
Rate of fire: 2 × 300 rounds/minute
Ammunition type: AP tracer, HE direct action, HE proximity fuze
Ready-to-use ammunition: 736 or 444
Power supplies: 440 V 60 Hz 3-phase; 115 V 400 Hz single-phase; Peak demand 13 kW; Mean demand 4·5 - 8 kW
Weight
Mounting without ammunition: Type A 5500 kg; Type B 5300 kg
Mounting with ammunition: Type A 7300 kg; Type B 6300 kg

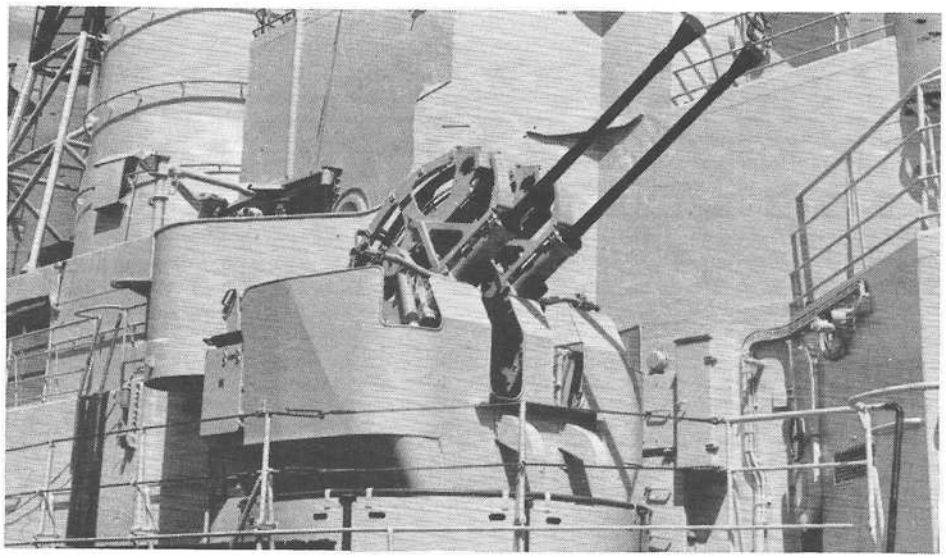
Breda 40 mm L/70 twin mountings

STATUS
The mounting is in mass production and entering service with more than 20 navies.
CONTRACTOR
Breda Meccanica Bresciana SpA, Via Lunga 2, 25100 Brescia, Italy.

2558.203
TWIN 40 mm NAVAL MOUNTING TYPE 106

This Breda/Bofors 40 mm L/70 mounting comprises two guns and two 32-round magazines. It can be controlled remotely, locally by means of the 'cloche' on the left of the mount, or manually. Ammunition feed may be either automatic by means of the Breda 32-round feeder or manually by inserting a four-round charger into the auto-loader of the elevating mass. The aiming device is either the NIFE type SRS-5 or the Mirasole line-of-sight type.

CHARACTERISTICS



Generally as for other 40 mm L/70 mountings
Elevation speed: 95°/s
Training speed: 95°/s
Acceleration: 125°/s²
Recoil force: 2 × 2700 kg
Power required: Elevation and training 4 kW each
Gun weight: With feeder and battery, less ammunition 6510 + 100 kg

STATUS

In service but no longer in production.

CONTRACTOR

Breda Meccanica Bresciana SpA, Via Lunga 2, 25100 Brescia, Italy.

Breda Type 106 twin 40 mm AA mount aboard the West German 'Hamburg' class ship Bayern (Stefan Terzibaschitsch)

2557.203
BREDA/BOFORS NAVAL MOUNTINGS

Breda Meccanica Bresciana make a range of single and twin naval anti-aircraft gun mountings incorporating a variety of different automatic feed systems and Bofors elevating mass. Breda also manufacture a 40 mm field mounting, details of which will be found in entry **2603.103** (in 1982-83 and earlier editions).

Set out in the following entries are brief details of current mountings. All use the 40 mm L/70 increased rate of fire pattern of Bofors gun (**2360.203**) which has the following general characteristics (which are not repeated in the individual entries below).

CHARACTERISTICS

Calibre: 40 mm
Length of barrel: 70 calibres
Elevation: -10 to +85°
Traverse: Unlimited
Weight of shell: 0·96 kg
Muzzle velocity: 1005 m/s (range 12·5 km max)
Rate of fire: 300 rounds/minute (per barrel)

STATUS

In service.

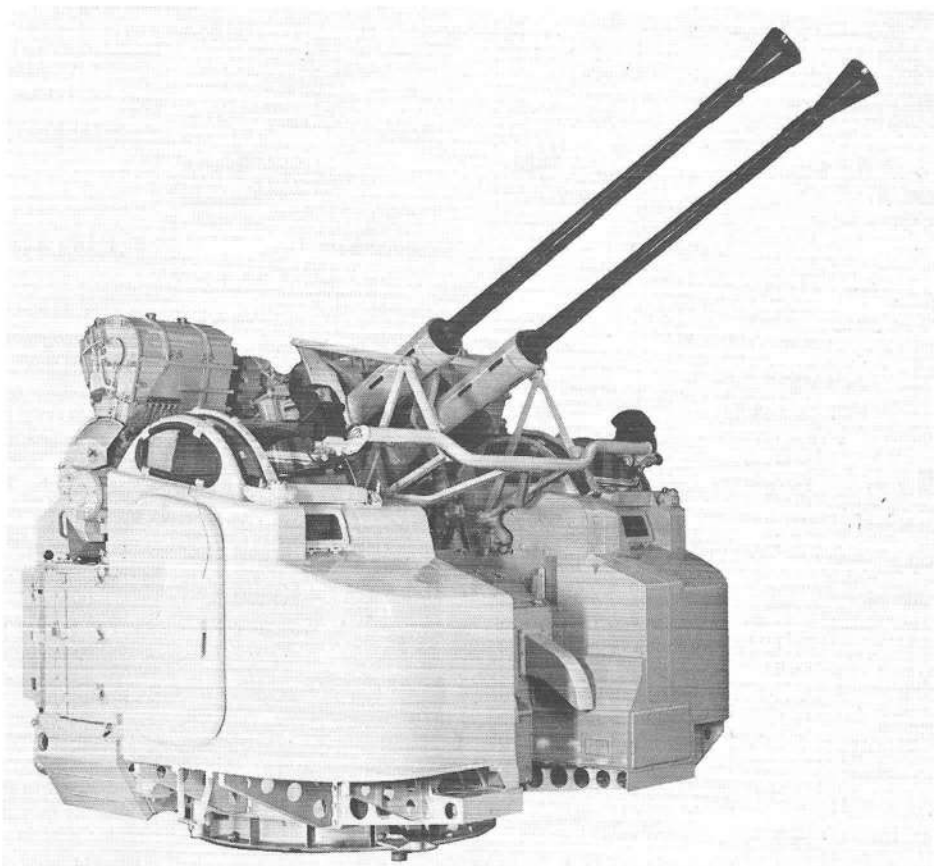
CONTRACTOR

Breda Meccanica Bresciana SpA, Via Lunga 2, 25100 Brescia, Italy.

2556.203
TWIN 40 mm NAVAL MOUNTING TYPE 64

This is a sophisticated Breda/Bofors mounting comprising two 40 mm L/70 guns and twin 100-round automatic magazines. It can be controlled remotely or locally. A graticule, Mirasole, or NIFE reflection sight can be fitted. Special features of this mounting include barrel cooling arrangements and an automatic fuze-setting device.

CHARACTERISTICS



Generally as other 40 mm L/70 mountings
Elevation speed: 95°/s minimum
Elevation acceleration: 125°/s² minimum
Training speed: 85°/s minimum
Training acceleration: 110°/s² minimum
Rate of fire: 2 × 300 rounds/minute
Power requirement: 6 kW each for training and elevation motors plus 1·6 kW for the feeder motor
Total weight: Excluding ammunition 7900 + 150 kg

STATUS

In service but no longer in production.

CONTRACTOR

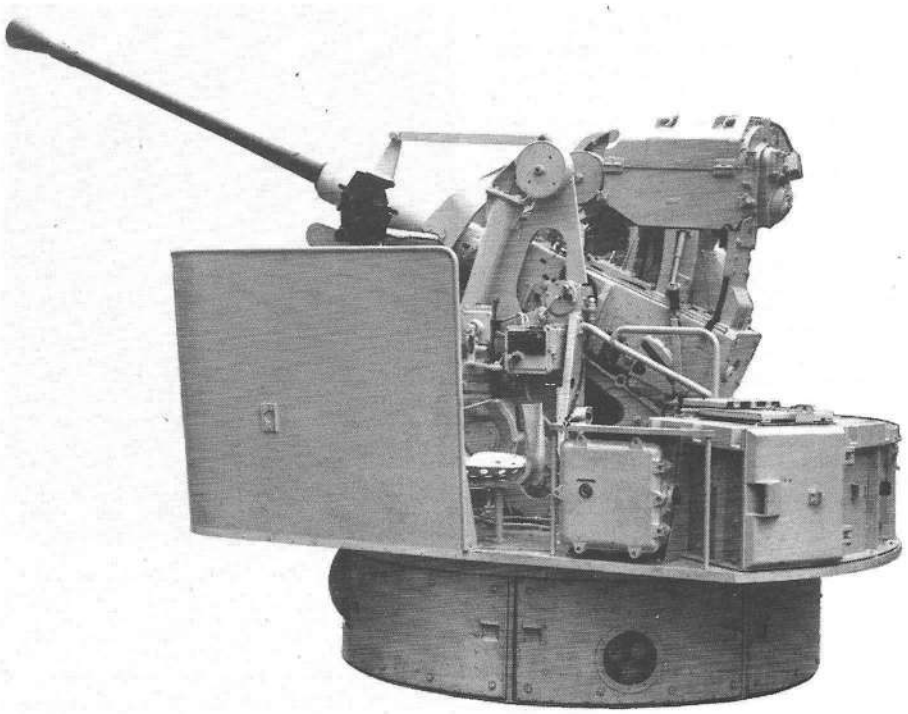
Breda Meccanica Bresciana SpA, Via Lunga 2, 25100 Brescia, Italy.

Breda/Bofors twin mounting Type 64

2554.203
SINGLE 40 mm NAVAL MOUNTING TYPE 564

This mounting differs from earlier Breda versions of the Bofors L/70 gun in being equipped with a Model 1971 144-round automatic feed of compact design. This permits a more effective use of the gun's high rate of fire and reduces the number of men required on the mount to two, with a third on standby near the mount to reload the automatic feed. A version requiring only one man on the gun is also available. The feed reloading operation can obviously be carried out during lulls in the firing, but with a little practice it is possible to reload while the gun is firing.

A further advantage of this feed system is that it can be fitted retrospectively to gun mountings which incorporate earlier types of feed. Complete modification kits are available to enable a purchaser having access to reasonable engineering facilities to arrange for the modification to be carried out, under Breda supervision, at any convenient location.



It is also known under the designation Breda/Bofors 350P.

CHARACTERISTICS

Generally as for other 40 mm L/70 gun mountings
Elevation speed: Local or remote control 45°/s
Elevation acceleration: 130°/s²
Training speed: Local or remote control 80°/s

Training acceleration: 120°/s²
Power consumption: 6 + 8 kW
Gun weight: With automatic feeder and with battery but excluding ammunition 3300 + 100 kg
STATUS
In service and in production.

Manufacture of the automatic feed device has been licensed by Breda to Bazan for Spanish naval production, incorporated with the Bofors SAK 350.
CONTRACTOR
Breda Meccanica Bresciana SpA, Via Lunga 2, 25100 Brescia, Italy.

40 mm Breda/Bofors mounting Type 107

5535.203
TWIN 35 mm OE/OTO MOUNTING

The 35 mm OE/OTO mounting has been produced as a private venture and is intended for use in any type of ship down to motor gun boats and hydrofoils, or as local defence for merchant ships in time of war. It is primarily for close anti-aircraft defence, with a secondary anti-ship and anti-shore role.

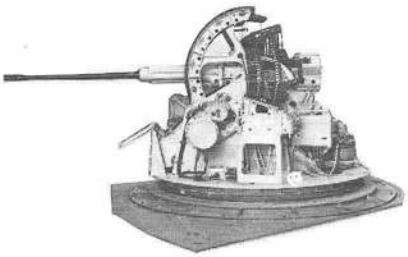
The mounting utilises a high proportion of light alloys in its construction. The shield is made of fibreglass and is watertight.

The mounting is remotely controlled without local aiming and is fitted with modular servo-systems of very light weight using electric motors with controlled rectifiers developed by OTO Melara.

The Oerlikon KDA 35 mm gun has a high rate of fire and is belt fed. An interesting feature is that two belts are fed to each gun, and either may be selected in about two seconds. Thus the mounting can switch very rapidly from firing, for example, anti-aircraft ammunition to armour-piercing. Each gun is provided with EVA at the muzzle to measure muzzle velocity, and this information is fed back into the computer to permit corrections in laying to be applied.

The Oerlikon guns used are similar to the KDC 35 mm cannons employed in the Oerlikon GDM-A twin 35 mm naval mount described in entry **6036.203** in the Swiss pages of this section. The GDM-A mount carries KDC cannons while the slightly lighter KDA guns are fitted in the Oerlikon/OTO mount, which has the Swiss designation GDM-C. The two versions of the gun have the same muzzle velocity, rate of fire, barrel length, and gas pressure. The KDA has twin belt feed, selectable left-hand or right-hand; the KDC has automatic clip ammunition feed, independent of the cannon.

OE/OTO 35 mm naval twin mount



Other details will be found in **6036.203** later in this section.
CHARACTERISTICS
Calibre: 35 mm
Length of barrel: 90 calibres (3·15 m)
Elevation: -15 to +85°
Elevation speed: Max 70°/s
Elevation acceleration: 130°/s²
Traverse: Unlimited
Traversing speed: Max 110°/s
Traversing acceleration: 100°/s²
Max recoil: 55 mm
Max range: 6000 m (surface targets); 5000 m (aerial targets)
STATUS
This turret is fitted in Libyan 670 ton corvettes built in Italy.

3994.203
BREDA TWIN 30 mm COMPACT NAVAL MOUNTING

Breda has designed and developed this mounting, using two Mauser MK 30 mm × 173 guns, set in a Breda twin cradle. Advanced design features of the twin 40 mm L/70 find their place in the new twin 30 mm, features not hitherto evolved in this calibre. Reaction time is cut to the minimum through complete automation, and both training and elevation velocities and accelerations are high (see characteristics). There are large ammunition reserves to meet saturation and successive attacks without human intervention in replenishment. Maximum accuracy is assisted by barrel proximity and mounting rigidity. The mounting is protected against the environment by a fibreglass dome, with one access hatch at the rear, and special attention has been given to sealing the mantlet plate and bearing assembly for watertightness.

The Breda patented magazine structure, containing an exceptionally large number of rounds, trains with the mounting, maintaining a constant relation to the feeders, and is divided into two halves, one half supplying each gun independently. The belted rounds are suspended in vertical folds, each fold being advanced as its predecessor is fired off. Replenishment can take place without firing off all the ammunition.

The mounting is supplied in four versions, designed for siting arrangement in various classes of ship. Dimensions are reduced to the minimum possible, aided by barrel proximity, and weight is contained by employing light alloys to the greatest practicable extent. The gun fires GAU-8 ammunition: HE(I), or armour piercing discarding sabot (APDS), with depleted uranium or swaged tungsten penetrator for missile warhead penetration and detonation. Also a frangible round for anti-aircraft fire.

Breda twin 30 mm compact naval mounting with 2000-round magazine and shown with and without the glass-fibre gunhouse

CHARACTERISTICS
Elevation limits: -13 to +85°
Elevation speed: 75°/s
Elevation acceleration: 100°/s²
Training limits: Unlimited
Training speed: 120°/s
Training acceleration: 150°/s²
Muzzle velocity: 1040 m/s (APDS M50)
Rate of fire (combined): 1600 rounds/minute
Ready-to-fire rounds: 2000 (1000/gun)
Distance between barrels: 260 mm
STATUS
Development complete. Production line being set up.

4575.203
BREDA SINGLE 30 MM MOUNTING

This completely new single mounting was exhibited for the first time at the 1984 Genoa Naval Exhibition, and uses one Mauser Model Mk 30 mm × 173 gun, set in a Breda cradle.

The mounting has been designed to provide the lightest vessels with a modern and effective gun, or to give a good auxiliary armament to larger major ships. Its main attributes are: remote control; rate of fire up to 800 rounds per minute; double ammunition feed system; capability for remote control in case of interruption in the power supply; complete protection against environmental conditions; lightweight (1200 kg) due to the extensive use of aluminium alloys; small dimensions and compact design.

The on board installation is simple because it is completely above deck. The ready to fire rounds are contained in two boxes that may be easily reached through two replenishing doors placed on the two sides of the shield. Ammunition of GAU-8 type includes: practice rounds (TP), high explosive incendiary (HEI), armour piercing incendiary (API), high explosive incendiary with self destruction device (HEI-SD), frangible rounds and armour piercing discharging sabot rounds (APDS).

CHARACTERISTICS
Elevation arc: -13 to +85°
Elevation acceleration: 300°/s²
Elevation velocity: 80°/s
Training arc: Unlimited
Training acceleration: 300°/s²
Training velocity: 140°/s
Muzzle velocity: 1040 m/s (1150 m/s ROF APDS)
Rate of fire: 800 rounds/minute
Weight (without ammunition): 1200 kg
Weight (fully loaded):1330 kg
Deck ring (outer diameter): 800 mm
Swept radius: 2720 mm
STATUS
Development complete. Ready for production.

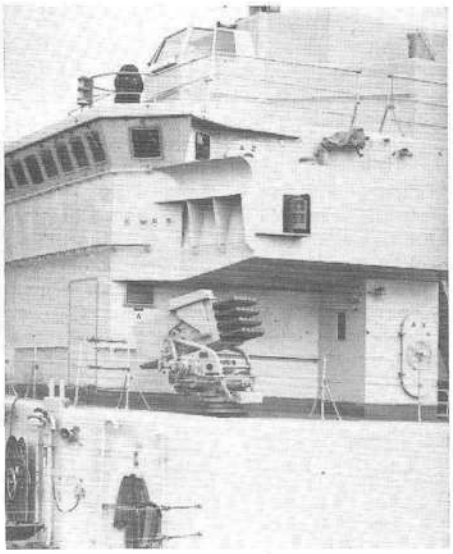
3995.203
BREDA MULTIPURPOSE NAVAL ROCKET LAUNCHER

The Breda multipurpose naval rocket launcher system normally consists of two Breda rocket launchers for 105 mm countermeasures or assault rockets, an Elsag control unit, and a supply of SNIA rockets. The 20-tube launchers are mounted on each side of the ship and they can be trained and elevated by remote control from the control unit. The latter is connected to the ship's radar and a control panel in the ECM compartment from whence it receives the necessary operating signals. The data needed to stabilise the two launchers against pitch and roll are provided by the ship's gyro-compass. (The Elsag control system is described in greater detail under entry **1823.281** in the Naval Fire Control Systems section of the 1982-83 and earlier editions.)

The SCLAR 105 mm rocket launcher system is intended to provide passive defence against radar and IR homing missiles, confuse enemy radars, and provide illumination for visual fire control at night. To meet these requirements provision is made for loading different types of rockets in mixed arrangements (long range chaff, medium range chaff, illuminating) to permit mixed salvoes. Automatic selection of the rockets to be fired is possible from the

Close-up view of Breda 105 mm rocket launcher

remote fire control unit and the time fuzes and launch sequence may be similarly controlled.



A 105 mm rocket, designed and developed by SNIA Defence and Aeronautical Division, is used by the Italian Navy and the various types are listed in the table of characteristics below.

CHARACTERISTICS
Elevation arc: -5 to +60°
Elevation velocity: 30°/s
Elevation acceleration: 50°/s²
Training arc: ±150°
Training velocity: 60°/s
Training acceleration: 60°/s²
Rate of fire: 1 round/s (approx)
Max ready-to-fire rounds: 20/launcher
Ammunition
Chaff distraction: 105LR-C (max range 12 000 m)
Chaff seduction: 105MR-C (max range 5000 m)
Illumination: 105LR-I (max range 4000 m)
Launcher weight: 1150 kg (empty); 1750 kg (with 20 rockets)
Trunnion height: 1170 mm
Tubular guide length: 1460 mm
Main power supply: 3 kW

STATUS
Production. About 100 mountings have been installed in ships of the following navies: Argentina, Ecuador, Federal Republic of Germany, Italy, Nigeria, Peru and Venezuela.

CONTRACTORS
Launcher: Breda Meccanica Bresciana SpA, Via Lunga 2, 25100 Brescia, Italy.

Rockets: SNIA Viscosa, Defence and Space Division, Via Sicilia 162, 00187 Rome, Italy.

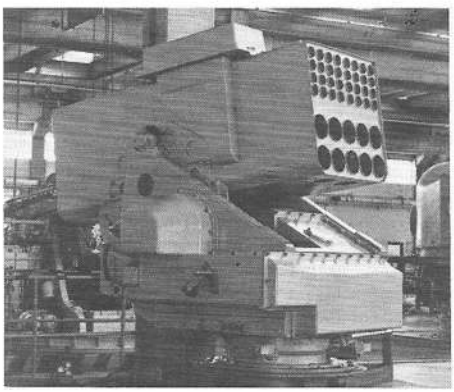
3996.203
BREDA MULTI-CALIBRE ASSAULT LAUNCHER



The Breda assault launcher is a special and improved version of the Breda multipurpose rocket launcher (**3995.203**) of which all the main characteristics are retained. It is specifically designed for conducting coastal bombardment.

This launcher is intended more particularly for installation in landing craft providing these ships with the capability for bombarding longer range targets with 105 mm rockets and those at closer range with 51 mm rockets. The assault launcher differs from the standard multipurpose rocket launcher in the following details: the launching tubes are longer in order to provide guidance necessary for the 51 mm rockets, and there is protective covering of the servo system to improve reliability and maintainability in adverse sea conditions. The ECM and illumination capability remains available with the 105 mm rockets.

STATUS
In production.

CONTRACTORS
Launcher: Breda Meccanica Bresciana SpA, Via Lunga 2, 25100 Brescia, Italy.

Rockets: SNIA Viscosa, Defence and Space Division, Via Sicilia 162, 00187 Rome, Italy.

NORWAY

4041.203
KV-SK/20 DUAL-PURPOSE 20 mm NAVAL MOUNTING

To meet the need for a light anti-aircraft and surface target gun for use aboard ships or shore bases, A/S Kongsberg Våpenfabrikk has developed a naval mounting for the Rh 202 gun (**3177.203**). Development was carried out in co-operation with the Ordnance Section of the Norwegian Naval Logistic Command.

The basic concept was to use the Mk 20 × 139 DM 5 gun (Rh 202) in a slightly modified version of the cradle used in the FK20-2 field gun, and to assemble these on a simple pedestal mount, thereby producing a gun which has approximately the same effect as the present field version, FK20-2. It is very reliable since it extensively uses previously developed and proven components and is quickly available because of its use of standard components. The gun is intended mainly for installation aboard naval vessels such as MTBs and mine-sweepers, fishing boats, and in the

Kongsberg KV-SK/20 20 mm naval mounting

defence of coastal forts. The gun can engage fast approaching and slower crossing aircraft and can be used against both land and sea targets.

The pedestal mount consists of the cradle with ammunition feed, the pedestal itself with a fixed base and a rotatable upper part, bowed shoulder-supports and sights. The cradle is basically similar to the existing FK20-2 field gun but where necessary certain components are redesigned, especially those concerned with loading, handling, and servicing. The cradle is supported in bearings at the centre of gravity of the elevating part of the gun and may be locked in four elevation settings (minimum, max, 0° and +30°) for loading and servicing. The elevation locking control is located on the right-hand side of the rotating part of the pedestal. The adjustable shoulder supports are placed at the rear of the cradle. The trigger is located on the left cradle handle and the selector for single shot/automatic fire is located on the right-hand side of the cradle. The complete cradle can be demounted from the pedestal without special tools.

The pedestal is made of aluminium alloy castings comprising a fixed lower part and rotating U-shaped upper part. The lower part consists of a simple hollow pillar fixed to a baseplate. The baseplate is designed for existing mountings with a diameter between 515 and 670 mm, but can be supplied for larger diameters on request. The baseplate is encircled with protruding footrests for use during aiming. The pedestal's upper part can be locked, by means of a lever, parallel to the ship's longitudinal axis and is also equipped with adjustable rotational stops. The upper part also carries an armoured shield and a box for collection of spent rounds and clips. Both box and shield can easily be removed and replaced.

The sights are of the cross hair and ring type and are fitted to the shoulder supports so that they follow the supports when they are adjusted in height. The sight can be adjusted sideways and in height with respect to the supports, and can also be raised up during servicing of the gun and locked in place again in its previous setting. Other types of sights may be adapted if required.

CHARACTERISTICS
Elevation: -15 to +70°
Traverse: 360°
Ammunition capacity (cradle): 2 boxes 100 rounds each
Spent round capacity: approx 200 rounds
Weight: 400 kg (with gun, without ammunition)
Total length: 2870 mm
Max radius: 1730 mm (from end of barrel to axis of rotation)
STATUS
The series produced version is in service on a large number of Norwegian vessels and shore establishments.

40 mm AUTOMATIC GUN SAK L/70 BOFORS-BREDA 144 MOD 76
This is a version of the Bofors L/70 gun (**2360.203**) with Breda automatic feeder, built under licence in Spain.
CHARACTERISTICS
Calibre: 40 mm
Length of barrel: 70 calibres
Elevation: -10 to +85°
Elevation speed: 45°/s
Traverse speed: 85°/s unlimited
Range: 12 km max
Rate of fire: 300 rounds/minute
Weight: 3·3 tons
Power consumption: 440 V, 60 Hz, 3-phase; 115 V, 60 Hz
STATUS
Operational in ships of the Spanish Navy.
CONTRACTOR
Empresa Nacional Bazán, San Fernando, Spain.

3176.203
MEROKA NAVAL AIR DEFENCE SYSTEM
The Meroka system is a multi-barrelled 20 mm gun system of Spanish design for close-in air defence of ships and like its US counterpart, Vulcan-Phalanx (**2858.203** in 1982-83 and earlier editions and **2543.231**), Meroka features a high rate of fire, comprehensive autonomous fire control provisions and rapid reaction. It is understood that the Spanish specification calls for similar performance characteristics to those of Vulcan-Phalanx.

The naval Meroka is derived from an experimental Spanish Army system (Meroka 12-203). Both consist of a multi-barrelled non-rotating machine gun with 12 barrels arranged in two horizontal rows of six. All three versions of the standard Oerlikon 20 mm round can be fired with salvoes in four groups of three in a way which minimises the effects of the recoil on aiming. A sub-calibre kinetic energy round is also under development. In the Spanish Navy, Meroka is associated with the Selenia RAN-12L surveillance radar intended to detect 0·1 square metre targets, flying at 300 metres per second at heights of 10 metres or less. Fire control is provided by a Lockheed Electronics AN/VPS-2 I-band monopulse doppler radar (**2547.153**) with the antenna mounted on the gun turret. Multi-path effects in tracking are minimised by using an offset tracking technique which places the target in the lower part of the radar beam. A secondary low light television tracking system is also provided.

System reaction is entirely automatic and takes under four seconds in normal conditions. Theoretically, ten to twelve salvoes are needed for each incoming missile target, so a single Meroka system can deal with at least five or six engagements without reloading. Considerable attention has been paid to avoiding flexing and resonance in the design with a mean salvo dispersion of less than 2 milliradians. This is claimed to give a 90% chance of a hit from a 12 round salvo.

CHARACTERISTICS
Calibre: 20 mm
Length of barrel: 120 calibres
Number of barrels: 12

Meroka multi-barrelled naval air defence weapon at test site in Spain

Elevation arc: -20 to +85°
Elevation speed: 1·5 rads/s
Traverse: 360°
Traverse speed: 2 rads/s
Muzzle velocity: 1215 m/s
Range: 2000 m+
Max rate of fire: 2700 - 3600 rounds/minute
Re-aiming time (12 barrels): 0·2 s
Time to fire 12-round salvo: 0-60 s
Ready use ammunition: 720 rounds
Ammunition type: HE, AP and incendiary. Sub-calibre KE under development
Reloading time: 3 minutes approx
Weight: 4·5 tons
Dimensions: 3·2 m high, 2·2 m wide at deck, 2·9 m swept radius
DEVELOPMENT
Development was carried out by CETME.
STATUS
In addition to the two prototypes, it is probable that the system will be fitted in the new aircraft carrier *Principe de Asturias*, the 'Roger de Lauria' class destroyer, and 'FFG7', 'Descubierta', and 'Baleares' class frigates.

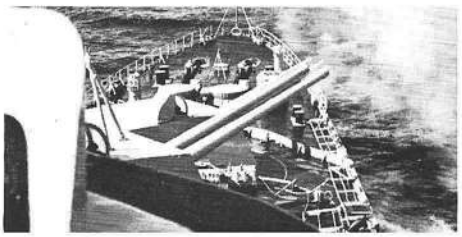
6070.203
TRIPLE 6 inch GUN MOUNTING

These 6 inch (152 mm) Bofors guns were first introduced in 1942 and were last seen as a triple mounting only in the cruiser *Latorre* of the Chilean Navy (formerly the *Göta Lejon* of the Royal Swedish Navy). This ship was the last survivor of two cruisers programmed in 1941, laid down in 1943, launched in 1945, completed in 1947 and disposed of in 1984.

CHARACTERISTICS
Calibre: 152 mm
Length of barrel: 53 calibres
Projectile weight: 46 kg
Muzzle velocity: 900 m/s
Rate of fire: 10 rounds/barrel/minute

CONTRACTOR
AB Bofors, Ordnance Division, Box 500, 691 80 Bofors, Sweden.



The cruiser Göta Lejon *(now transferred to the Chilean Navy and renamed* Latorre*). The triple 6 inch gun mounting forward can be seen clearly in this picture; less clearly seen are the two twin mountings aft* (Royal Swedish Navy)

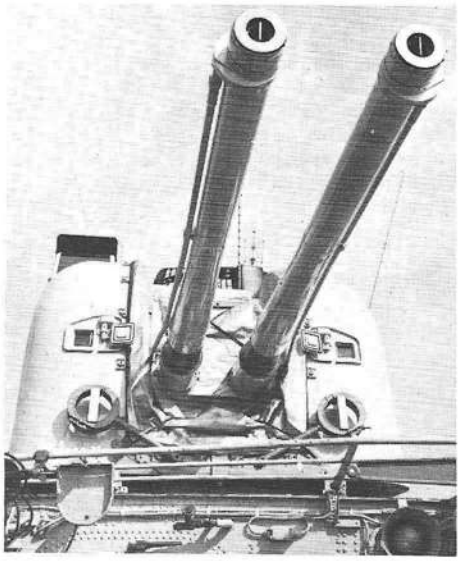
6085.203
TWIN 6 inch GUN MOUNTING

The Bofors 6 inch (152 mm) guns described in **6070.203** were seen as twin mountings in the *Latorre* (two twin mountings aft) and are still in the cruisers *Almirante Grau* and *Aguirre* of the Peruvian Navy (formerly the Royal Netherlands Navy cruisers *De Ruyter* and *De Zeven Provincien*).

The guns are fully automatic and radar controlled.

CONTRACTOR
AB Bofors, Ordnance Division, Box 500, 691 80 Bofors, Sweden.

6 inch guns at firing practice (Royal Netherlands Navy)



6086.203
TWIN 120 mm DUAL-PURPOSE AUTOMATIC GUN MOUNTING

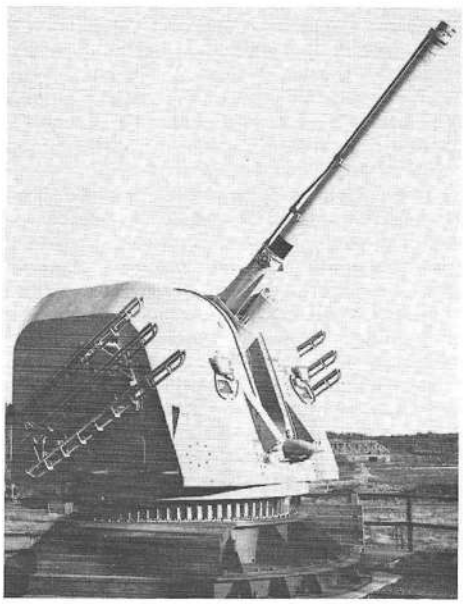
These 50-calibre Bofors 120 mm guns are mounted in twin mounts in the 'Halland' class destroyers of the Royal Swedish Navy (2 ships), 'Tromp' class destroyers (2 ships) of the Royal Netherlands Navy, 'Holland' class destroyer (1 ship) and 'Friesland' class destroyers (7 ships) of the Peruvian Navy and modified 'Halland' class (2 ships) of the Colombian Navy.

Introduced in 1950, the guns are fully automatic and radar controlled. The complete twin mounting weighs 67 tons.

CHARACTERISTICS
Calibre: 120 mm
Length of barrel: 50 calibres
Elevation: To 85°
Projectile weight: 23·5 kg
Muzzle velocity: 850 m/s
Rate of fire: 40 rounds/barrel/minute
Max range: 20·5 km (11 nautical miles)
Max altitude: 12 500 m

CONTRACTOR
AB Bofors, Ordnance Division, Box 500, 691 80 Bofors, Sweden.

Twin 120 mm gun mounting (Royal Netherlands Navy)



6073.203
SINGLE 120 mm/46 AUTOMATIC GUN MOUNTING

The Bofors L/46 120 mm automatic gun is designed for use against both surface and airborne targets and has a very high rate of fire.

Housed in a 4 mm steel turret mount the gun has two magazines, mounted on the elevating cradle, which are manually filled from a fixed-structure motor-driven rod hoist. Electro-hydraulic remote control is standard with the alternative of gyro-stabilised one-man local control. Telescope sights are also fitted and the hoist and the elevation and traverse mechanisms can be operated by hand. The gun barrel is liquid cooled and has an exchangeable liner.

CHARACTERISTICS
Elevation: -10 to +80°
Elevation speed: 32°/s
Traverse: Unlimited
Traversing speed: 40°/s
Muzzle velocity: 800 m/s
Time of flight to 10 km: 21·7 s
Range: 18·5 km
Rate of fire: 80 rounds/minute
Number of rounds in magazine: 52
Power supplies: 440 V, 3-phase, 60 Hz
Power consumption: (mean when firing) 60 kW
Weight of round: 35 kg
Weight of shell (HE): 21 kg
Weight of charge: 3·15 kg
Weight excluding ammunition: 28·5 tons

STATUS
Installed on Finnish and Indonesian corvettes.

Bofors 120 mm/46 automatic gun mounting

CONTRACTOR
AB Bofors, Ordnance Division, Box 500, 691 80 Bofors, Sweden.

2362.203
SINGLE 3 inch AUTOMATIC GUN MOUNTING

The Bofors L/50 3 inch (76 mm) automatic gun is designed for surface fire.

This is a sturdy, simple, remotely-controlled single gun. Weighing only 6500 kg and requiring only two loaders in the ammunition room, it is suitable for installation in small ships and is currently in service on 'Storm' class fast patrol boats of the Norwegian Navy.

Electro-hydraulic remote control is used. The gun is mounted in a 6 mm steel gun house and has a fixed motor-driven hoist with lifting link levers and a five-round feed device. The gun has a monoblock barrel.

CHARACTERISTICS
Elevation: -10 to +30°
Elevation speed: 25°/s
Traverse: ±175°
Traversing speed: 25°/s
Muzzle velocity: 825 m/s
Time of flight to 6 km: 13 s
Range: (30° elevation) 12·6 km
Rate of fire: 30 rounds/minute
Number of rounds in hoist and ammunition room: 100

Power supplies: 440 V 3-phase 60 Hz
Power consumption: (mean when firing) 60 kW
Weight of round: 11 kg
Weight of shell: (HS, Mk 27) 5·9 kg
Weight of charge: 0·54 kg
Weight, excluding ammunition: 6·5 tons
Minimum operating crew: 2

STATUS

Designed and developed as a private venture by Bofors, this gun was first conceived in 1962 and went into service with the Norwegian Navy in 1965. It is no longer in production.

CONTRACTOR

AB Bofors, Ordnance Division, Box 500, 691 80 Bofors, Sweden.

Bofors 76 mm mounting aboard the Sovereignty (Singapore Navy)

6087.203
TWIN 57 mm AA GUN MOUNTING

Introduced in 1950 these 60-calibre guns were at one time widely fitted. Now, however, they are to be found only in the 'Halland' class destroyers of the Royal Swedish Navy. The same gun in a slightly different twin mounting is still in service in the French Navy (**6065.203**).

The complete turret of the Swedish installations weighs some 24 tons.

CHARACTERISTICS

Calibre: 57 mm
Length of barrel: 60 calibres
Elevation: -10 to +90°
Projectile weight: 2·6 kg
Muzzle velocity: 900 m/s
Rate of fire: 130 rounds/barrel/minute
Max range: 14·5 km
Max altitude: 10 300 m

STATUS

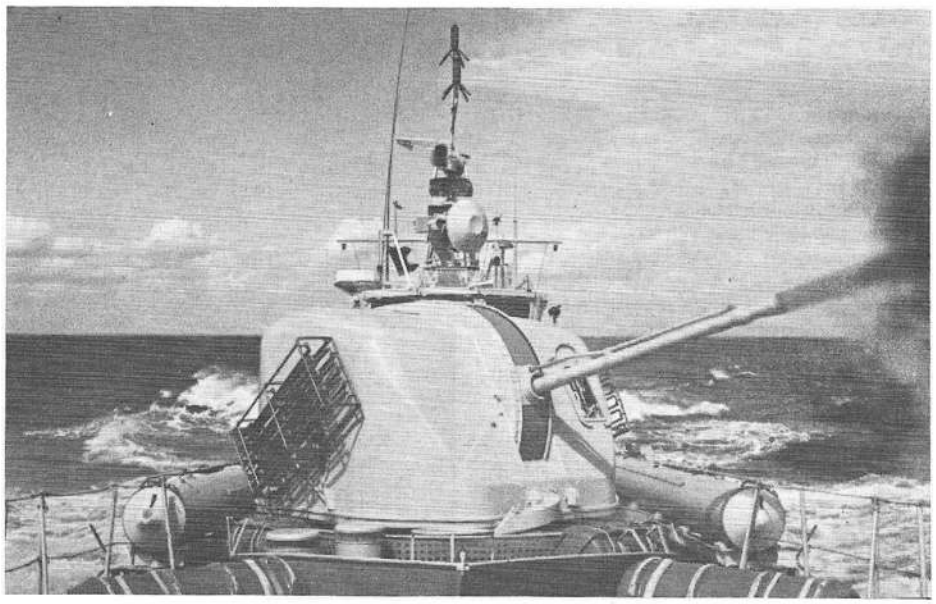
No longer in production.

CONTRACTOR

AB Bofors, Ordnance Division, Box 500, 691 80 Bofors, Sweden.

2361.203
SINGLE 57 mm L/70 AUTOMATIC GUN MOUNTING

This 57 mm Bofors single gun in a plastic cupola is designed for both surface and anti-aircraft fire.



Alternatives of electro-hydraulic remote control or gyro-stabilised one-man local control are available. The gun feed system contains 40 rounds of ready-use ammunition with 128 rounds stowed in racks within the cupola, and there are dual step-by-step fixed supply hoists. The barrel is liquid-cooled. The Mk 2 version incorporates a new servo system giving a dispersion of less than 0·5 mrad and high accuracy even in rough seas.

Two types of ammunition are available: one is a proximity-fuzed prefragmented shell for use against aerial targets; the other is a special surface target shell which penetrates the target and is detonated after a short delay.

The gun can be equipped with rocket-launching rails for two-inch (57 mm) rockets.

CHARACTERISTICS

Elevation: -10 to +75°
Elevation speed: 40°/s
Traverse: Unlimited
Traversing speed: 55°/s
Muzzle velocity: 1025 m/s
Time of flight to 3 km: 3·8 s
Range: 17 km
Rate of fire: 200 rounds/minute
Power supplies: 440 V 3-phase 60 Hz
Power consumption: (mean, when firing) 8 kW
Weight of round: 5·9 kg
Weight of shell: (HE: DA or proximity fuze) 2·4 kg
Weight, excluding ammunition: 6 tons

Bofors 57 mm L/70 automatic gun mounting on board 'Spica T-131' fast attack craft

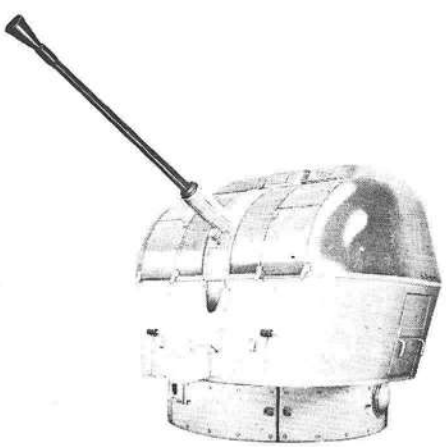
STATUS

In production, and in service on the Swedish Navy 'Spica R 131' (12 boats), 'Hugin' class (16 boats) fast attack craft, the 'Nordkapp' class Norwegian coast guard vessels, and with several other navies.

CONTRACTOR

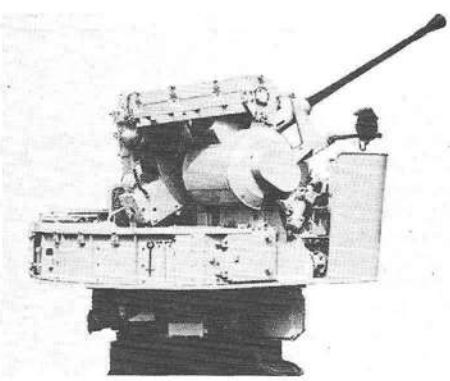
AB Bofors, Ordnance Division, Box 500, 691 80 Bofors, Sweden.

2360.203
SINGLE 40 mm L/70 AUTOMATIC GUN MOUNTING



Bofors make a number of different mountings for their shipborne 40 mm L/70 gun for use against both surface and airborne targets.

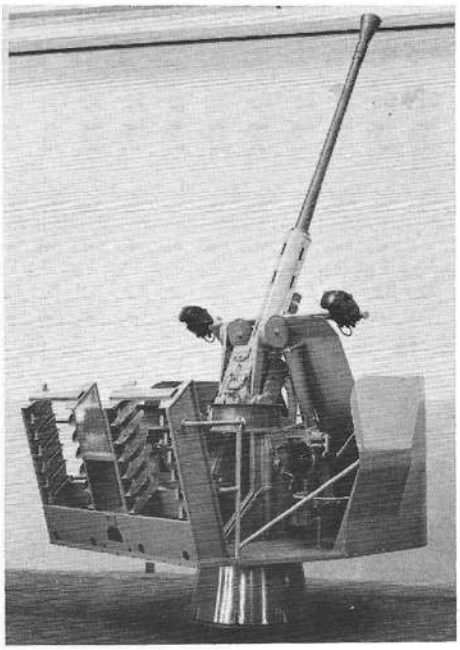
Three guns are shown here. All of these have electro-hydraulic laying machinery, and can be supplied with both remote and local control. In local control the guns are gyro-stabilised, and reflex sights with speed rings are used for aiming. All three types of gun can be provided with a light plastic cupola for weather protection. A fully automatic gun with a new 100 round magazine is also available. This gun can also be operated by local control and is described in more detail in **2557.203**.



The proximity-fuzed ammunition can be used in all Bofors 40 mm L/70 guns.

CHARACTERISTICS

Elevation: -10 to +90°
Elevation speed: 45°/s (powered mounts)



Power-operated 40 mm Bofors gun with plastic cupola

Automatic gun with Breda 144 round feed

Traverse: Unlimited
Traversing speed: 85°/s (powered mounts)
Muzzle velocity: 1005 - 1025 m/s, depending on ammunition type
Range: Tactical range 4000 m (12 km max)
Rate of fire: 300, or 330 rounds/minute
Power supplies: 440 V 3-phase 60 Hz
Power consumption: 5 kW
Weight, excluding ammunition: 2·8, 3, or 3·3 tons
Ammunition: PFHE Mk 2 (principal type), HCHE, APC-T, HE-T, TP-T
STATUS
Operational with more than 30 navies, including the Swedish Navy.
CONTRACTOR
AB Bofors, Ordnance Division, Box 500, 691 80 Bofors, Sweden.

Hand-operated 40 mm Bofors gun

4031.203
ALL-PURPOSE 57 mm Mk 2 NAVAL GUN
This unmanned 57 mm all-purpose gun in a compact plastic cupola and with low radar signature is designed for combating both surface and aerial targets. The gun comprises an improved, extremely accurate, electro-hydraulic remote control system with microprocessor-controlled aiming and firing limitations. The new, completely automatic, reloading system allows for 120 rounds available in the cupola, and there are dual step-by-step fixed supply hoists.

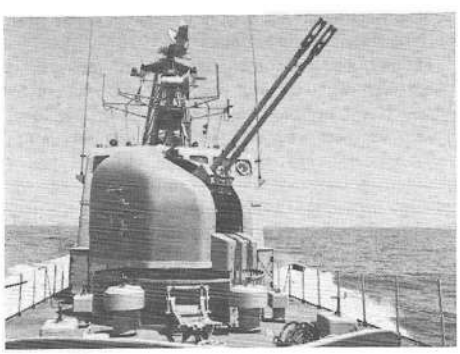
Two types of ammunition are available: one is a proximity-fuzed and prefragmented shell for use against aerial targets; the other is a special surface target shell which penetrates the target and is detonated after a short delay.
CHARACTERISTICS
Elevation: -10 to +75°
Elevation speed: 40°/s
Traverse: Unlimited
Traverse speed: 55°/s
Muzzle velocity: 1025 m/s
Time of flight to 3 km: 3·8 s
Range: 17 km
Rate of fire: 220 rounds/minute
Power supply: 440 V 3-phase 60 Hz
Power consumption: 8 kW (mean when firing)
Weight of round: 6·1 kg
Weight of shell: 2·4 kg (HE:DA or proximity fuze)
Weight, excluding ammunition: 6 tons
STATUS
In series production and in service with the Swedish Navy. Also selected for the Canadian Patrol Frigate programme.
CONTRACTOR
AB Bofors, Ordnance Division, Box 500, 691 80 Bofors, Sweden.

Bofors 57 mm Mk 2 naval gun on board Swedish 'Hugin' class fast attack craft

6088.203
SINGLE 40/60 AA GUN MOUNTING
This 60-calibre version of the well-known Bofors 40 mm AA gun was introduced in 1942 and is still in service in many places. Its performance is, as one would expect, somewhat inferior to that of the modern 70-calibre weapon.

CHARACTERISTICS
Calibre: 40 mm
Length of barrel: 60 calibres
Elevation: To 80°
Projectile weight: 0·9 kg
Muzzle velocity: 830 m/s
Max range: 10 km
Tactical range: 3 km
Rate of fire: 120 rounds/minute
STATUS
In service and still fitted in reconditioned form but no longer in production.
CONTRACTOR
AB Bofors, Ordnance Division, Box 500, 691 80 Bofors, Sweden.

SWITZERLAND



6036.203
35 mm TWIN ANTI-AIRCRAFT GUN TYPE GDM-A
This gun is similar in concept and design to the successful Oerlikon field gun. It is primarily intended for convoy or self-protection against air attack, but can also be used to engage sea and land targets.

It is an all-weather weapon system with a bi-axial stabilised mount on deck, and its electronic control-unit below deck. High laying accelerations and speeds are an important feature of the design.

Both 35 mm cannons type KDC are completely interchangeable without the use of additional parts as are the hand cocking devices and the barrels.

Three modes of operation are possible:
(1) automatic operation, electrically controlled from fire control equipment or an optical aiming mechanism with auxiliary computer
(2) local operation, electrically controlled from the gun with joystick and the gyro-stabilised gunsight
(3) emergency operation, mechanically controlled from the gun with two hand wheels and the gunsight.

CHARACTERISTICS
Gun type GDM-A
Elevation
Arc: -15 to +85°
Speed: 100°/s
Acceleration: 120°/s²
Traverse
Arc: Unlimited
Speed: 120°/s
Acceleration: 130°/s²
Ready-to-use ammunition: 2 × 56 = 112 rounds
Reserve container: 2 × 112 = 224 rounds

Oerlikon 35 mm twin naval AA gun type GDM-A

Weight
Gun without ammunition: 5950 kg (approx)
Ammunition (336 rounds): 570 kg (approx)
Servo amplifier cabinet: 272 kg (approx)
Thyristor control unit: 130 kg (approx)
Power supply
Drive voltage: 440 V, 60 Hz, 3-phase
Stabilisation: Bi-axial by gyroscopes
Cannons type KDC
Calibre: 35 mm
Length of barrel: 90 calibres
Muzzle velocity: 1175 m/s
Rate of fire: 2 × 550 = 1100 rounds/minute
Weight
Barrel: 120 kg
Cannon complete: 430 kg (approx)

STATUS

In production. The GDM-A mount is known to be in service with the following countries: Ecuador, Greece, Iran, Libya and Turkey. In collaboration with OTO Melara of Italy, Oerlikon also supplies the OE/OTO 35 mm twin naval mount, the Swiss designation being GDM-C. Additional information can be found in entry **5535.203** in the pages of this section covering Italian naval guns. The gun employed varies slightly and is the slightly heavier type KDA, but the main performance characteristics of both types (KDA and KDC) are the same.

CONTRACTOR

Machine Tool Works Oerlikon-Bührle Ltd, 8050 Zurich, Switzerland.

2395.203
30 mm TWIN NAVAL ANTI-AIRCRAFT GUN TYPE GCM-A

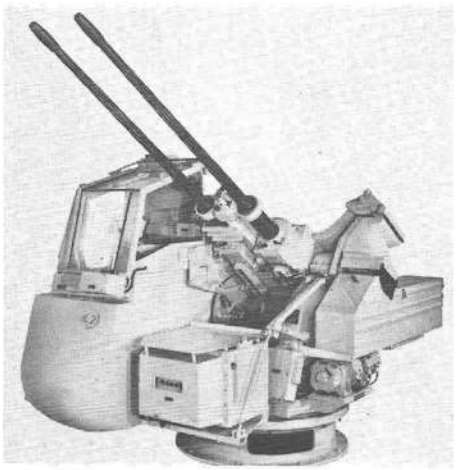
Because of its low weight, this modern 30 mm twin gun can be used to provide small fighting ships with an effective weapon of the type whose fire power and ammunition effectiveness were previously reserved for larger ships only. Fast patrol boats, for example, can be equipped fore and aft with this gun. The limitation of weapon use at sea due to environmental effects (sea movement) is considerably reduced since the gun is gyro-stabilised. In addition to its use on fast patrol boats etc, the gun can also be used effectively on large ships for short-range anti-aircraft defence.

Three modes of operation are possible:

(1) automatic operation, electrically controlled from a fire control system or an optical aiming mechanism with auxiliary computer
(2) local operation, electrically controlled from the gun with joystick and gyro stabilised gunsight
(3) emergency operation, mechanically controlled from the gun with two hand wheels and the gunsight.

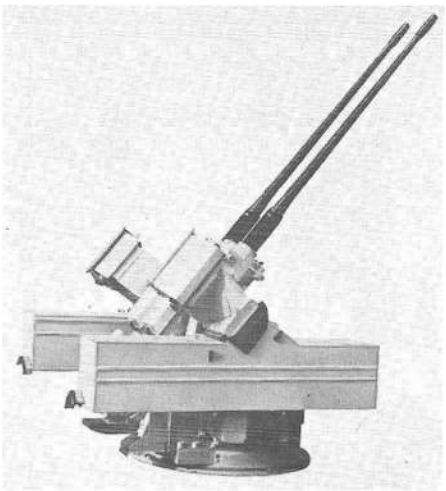
The GCM-A is also manufactured in the United Kingdom by the British Manufacture and Research Company Limited and this model is fitted with Ferranti gyroscopic lead angle computing sight.

Oerlikon twin 30 mm mounting GCM-AO3-3



The gun is produced in three different versions:
AO3-1 with enclosed cabin for remote and local control and with 320 or 500 rounds
AO3-2 with open gunner's station for remote and local control and 500 rounds
AO3-3 without gunner's cabin and with remote control only and 640 rounds of ammunition.

CHARACTERISTICS



Elevation
Arc: -10 to +75°
Speed (max): 50°/s
Acceleration (max): 90°/s²
Traverse
Arc: Unlimited
Speed (max): 75°/s

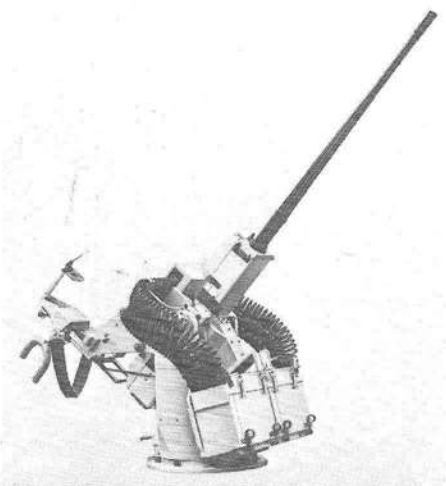
Oerlikon twin 30 mm mounting GCM-AO3-1

Oerlikon twin 30 mm mounting GCM-AO3-2

3657.203
25 mm NAVAL GUN TYPE GBM-AO1

This Oerlikon multipurpose naval mount carries a type KBA-CO2 25 mm automatic cannon and its low weight with simple installation make it suitable for use aboard ships of all tonnages. It can be used against land, sea, or air targets, and is designed for one-man operation. Sighting is by simple ring and bead and night sights are available. No electrical power is required and the gun is laid by the gunner using a shoulder harness. Two different ammunition types can be fired at the same time.

CHARACTERISTICS



Gun type GBM-AO1
Elevation: -15 to +50°
Traverse: Unlimited
Weight: 585 kg (ready to fire)
Ready-to-use ammunition: 200 rounds
Cannon type KBA-CO2
Calibre: 25 mm
Length of barrel: 80 calibres (2173 mm with muzzle brake)
Muzzle velocity: 1100-1360 m/s, depending on ammunition
Rate of fire: 570 rounds/minute

STATUS

Production.

CONTRACTOR

Machine Tool Works Oerlikon-Bührle Ltd, 8050 Zurich, Switzerland. This weapon is also manufactured in the United Kingdom by the British Manufacture and Research Company.

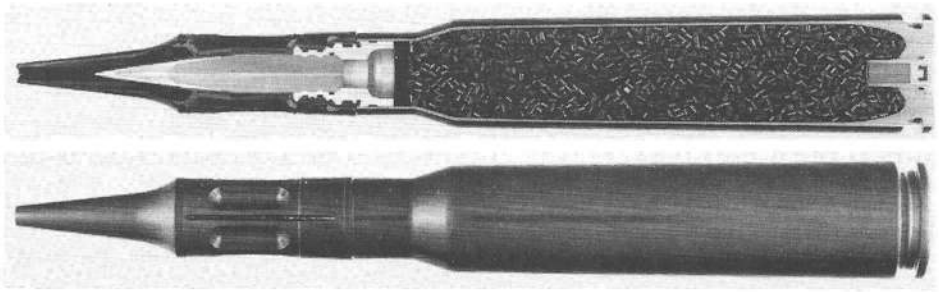
25 mm Oerlikon naval gun type GBM-AO1

4017.203

SEA ZENITH 25 mm MOUNT TYPE GBM-B1Z

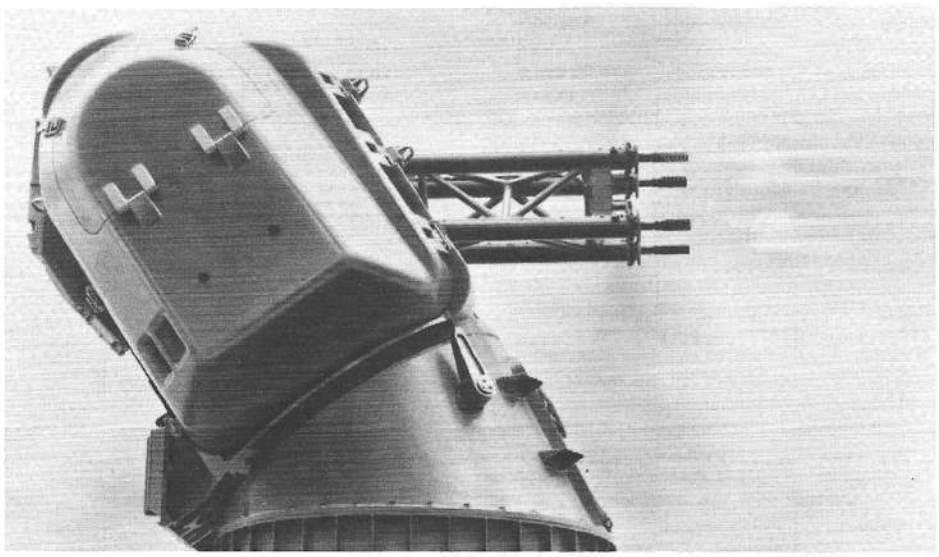
Sea Zenith is the name of the four-barrelled 25 mm gun mounting employed in the Contraves/Oerlikon Seaguard close-in weapon system (**4016.231**). It is named from its ability to bear on targets at the zenith by virtue of a slewing axis which is inclined at 35° to the horizontal. Its function is the close-in destruction of anti-ship missiles using special AMDS ammunition with a forged tungsten core designed to ensure that a single hit will be sufficient to destroy a missile target by exploding its warhead. It also has a performance against aircraft using more conventional ammunition.

The four 25 mm guns have a combined rate of fire of 3400 rounds/minute, each gun being independently fed from ammunition drums which may either be mounted below decks or by the side of the gun. The ready-use supply of 1660 rounds is sufficient for 18 engagements of missile targets. Reloading can be achieved during the firing cycle.



The KBB-RO3/LO3 gun is a positively locked gas operated weapon with two breech locking catches and is ruggedly built to ensure operational reliability under extremely adverse environmental conditions.

CHARACTERISTICS



Gun type: Sea Zenith KBB-RO3/LO3
Calibre: 25 mm
Length of barrel: 2300 mm
Elevation
Arc: -15 to +127°
Speed and acceleration: 2·5 rad/s, 10 rad/s²
Traverse
Arc: ±180°
Speed and acceleration: 2·5 rad/s, 10 rads/s²
Muzzle velocity: 1335 m/s
Ready-to-use ammunition: 1660 rounds (415 per gun)
Weight
Mounting with ammunition: approx 4600 kg
Ammunition feed system: 2150 kg

STATUS

In full series production following a contract from a West German shipyard for Seaguard systems to be fitted in four frigates under construction for the Turkish Navy. Other contracts were under discussion in May 1985.

Seaguard CIWS 25 mm KBB AMDS ammunition

Seaguard CIWS gun module (Sea Zenith)

2397.203

20 mm NAVAL GUN TYPE GAM-BO1

The Oerlikon GAM-BO1 is a simple, modern, and efficient 20 mm naval mounting, embodying the well-proven KAA cannon.

All-up weight is low enough to permit installation on any type of naval vessel. The gun can be used for either surface- or AA-fire. No electrical power is needed. The gun is laid by the gunner using a shoulder harness. Sighting is by simple ring and bead and a night sight is available.

CHARACTERISTICS

Gun type GAM-BO1
Elevation
Arc: -15 to +60°
Speed and acceleration: Manual
Traverse
Arc: Unlimited
Speed and acceleration: Manual
Ready-use ammunition: 200 rounds
Weight
Gun without ammunition: 410 kg (approx)
Ammunition (200 rounds): 90 kg (approx)
Gun complete: 500 kg (approx)
Cannon type KAA (former design: 204 GK)
Calibre: 20 mm
Length of barrel: 85 calibres
Muzzle velocity: Approx 1050 m/s
Rate of fire: 1000 rounds/minute
Weight
Barrel: 26 kg approx
Cannon complete: 92 kg approx

STATUS

Known fittings include Spanish 'Lazaga' and 'Barceló' classes, a number of British ships, and ships of several other navies.

20 mm Oerlikon naval mounting type GAM-BO1

CONTRACTOR

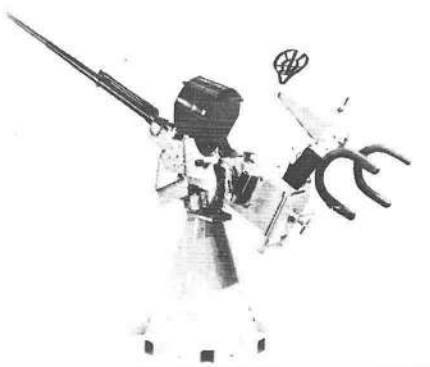
Machine Tool Works Oerlikon-Bührle Ltd, 8050 Zurich, Switzerland. This weapon is also manufactured in the United Kingdom by the British Manufacture and Research Company.

2396.203

20 mm NAVAL MOUNTING TYPE A41/804

This widely used Oerlikon mounting incorporates the type 804 drum-fed cannon. Suitable for small and very small naval vessels it is operated entirely by one man and can be used for either AA or surface fire. Sighting is by ring and bead.

CHARACTERISTICS



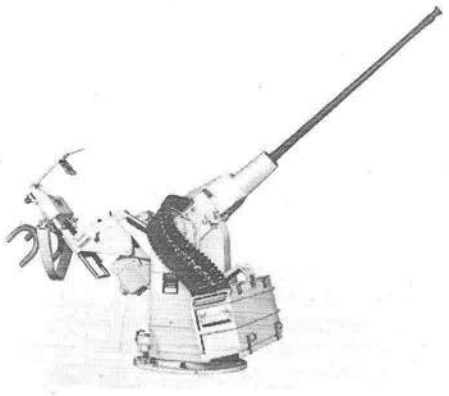
Calibre: 20 mm
Muzzle velocity: 835 m/s
Rate of fire: 800 rounds/minute
Ready rounds: 60 in drum magazine
Weight: Including ammunition 240 kg

STATUS

In production and widely used.

CONTRACTOR

Machine Tool Works Oerlikon-Bührle Ltd, 8050 Zurich, Switzerland.

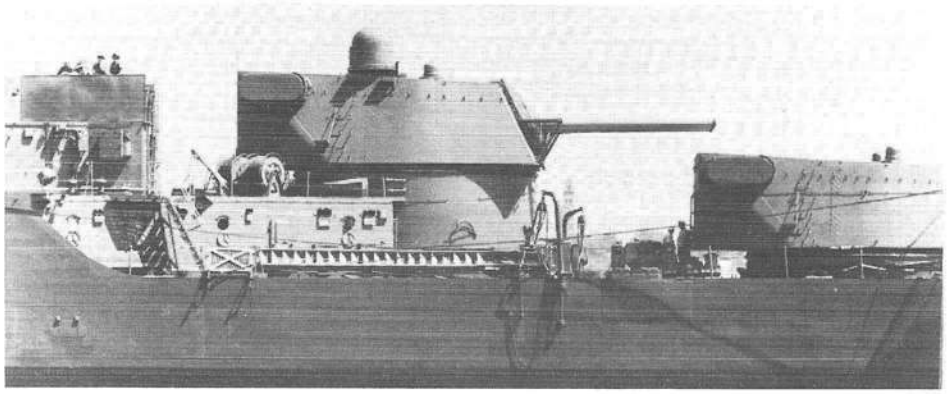


20 mm Oerlikon naval mounting type A41/804

3656.203
20 mm NAVAL GUN TYPE GAM-CO1
The Oerlikon GAM-CO1 is very similar to the type GAM-BO1 (**2397.203**), employing the same kind of sighting with the addition of an optional night sight, and gun laying by means of a shoulder harness. However, in place of the GAM-BO1's KAA 20 mm cannon, the GAM-CO1 uses the 20 mm automatic cannon type KAD-B13-3 (formerly designated HS820).

CHARACTERISTICS
Gun type GAM-CO1
Elevation: -15 to +60°
Speed and acceleration: Manual
Traverse: Unlimited
Ready-to-use ammunition: 200 rounds
Weight: 510 kg (ready to fire)
Cannon type KAD-B13-3 (formerly HS820)
Calibre: 20 mm
Length of barrel: 1906 mm
Muzzle velocity: 1050-1150 m/s, depending on ammunition
Rate of fire: 900 rounds/minute

CONTRACTOR
Machine Tool Works Oerlikon-Bühle Ltd, 8050 Zurich, Switzerland. This weapon is also manufactured in the United Kingdom by the British Manufacture and Research Company.



20 mm Oerlikon naval gun type GAM-CO1

UNION OF SOVIET SOCIALIST REPUBLICS

6038.203
TRIPLE 152 mm GUN MOUNTING
These guns are in service with several of the older cruisers of the Soviet fleet. The 'Sverdlov' class cruisers each carry 12 guns in four triple mountings, except for three ships which have been modified to carry SA-N-2 or SA-N-4 missiles, and have had one or two turrets removed.

Guns in the turrets are mounted in separate sleeves, thus permitting individual elevation to at least 50°. Projectile weight is believed to be about 50 kg and muzzle velocity 915 m/s so that maximum range is probably in the region of 27 km. The gun is 50 calibres long, semi-automatic, and can fire ten rounds/minute. An eight-metre rangefinder is incorporated in each turret.

The triple 152 mm gun mounting is often described as a 150 mm triple mount.

Triple 152 mm gun turrets of Soviet 'Sverdlov' class cruiser

6039.203
TWIN 130 mm GUN MOUNTING
There appear to be two types of twin 130 mm mounting in service in the older destroyers of the Soviet and associated navies. One type is to be found in the older (unmodified) 'Skory' class destroyers, including those supplied to Egypt.

It is believed that the gun is 50 calibres long and fires a 27 kg shell with a muzzle velocity of 875 m/s. The mountings are semi-automatic and a rate of fire of ten rounds/minute can be achieved. Range is about 25 km.

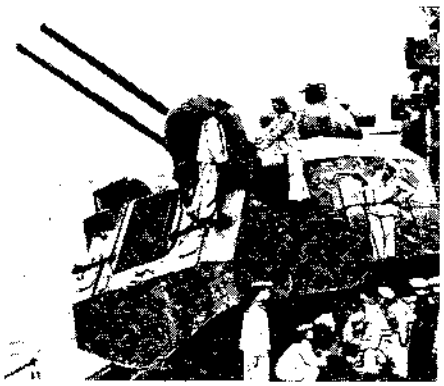
Twin 130 mm guns mounted on the 'Skory' class destroyer Svobodnyi

6040.203
TWIN 130 mm DUAL-PURPOSE GUN MOUNTING
It is believed that this mounting is common to the modified 'Skory' class and the 'Kotlin' class destroyers.

On these vessels, assuming that all the installations are indeed similar, the 130 mm guns, in two twin turrets including firing directors are fully stabilised. The guns are dual-purpose, semi-automatic, and are believed to be 58 calibres long and to fire a 27 kg projectile at ten rounds per minute with a muzzle velocity of 875 m/s. The two guns in the mounting can be independently laid and can be elevated to 70°. They are used with 'Wasphead' stabilised directors with radar.

Twin 130 mm gun mounting, two RBU 2500 ASW launchers, and quadruple 45 mm AA mounting on 'SAM Kotlin' class Vozbuzhdenny (G Jacobs)

4522.203
TWIN 130 mm DUAL-PURPOSE GUN MOUNTING



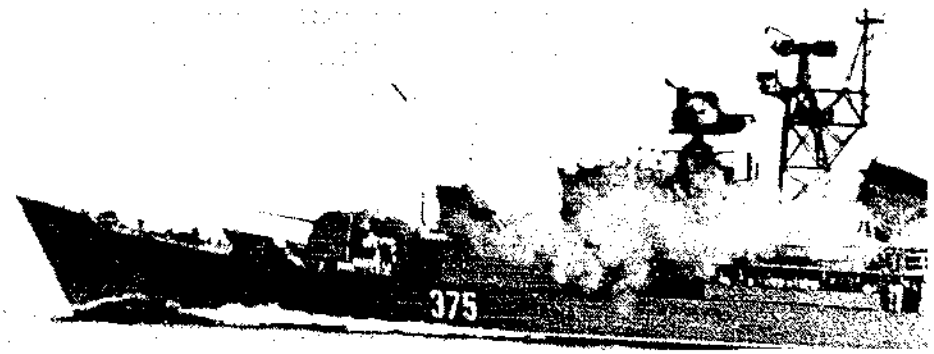
A new design of automatic, water cooled, twin 130 mm mounting was first seen on the 7500-ton cruiser *Sovremenny* and is probably controlled by the Kite Screech director radar. It is also fitted in the 'Slava and later 'Kirov' class cruisers. Guns of this large calibre have not been fitted in the Soviet fleet since the 'Kotlin' class destroyers were built in the mid-1950s.

CHARACTERISTICS
Calibre: 130 mm
Length of barrel: 58 calibres
Elevation: 0 to 85°
Traverse: 270° estimated
Muzzle velocity: 950 m/s estimated
Max range: 29·5 km estimated
Rate of fire: 35 to 45 rounds/minute
Ammunition: HE, SAP

6042.203
TWIN 100 mm DUAL-PURPOSE GUN MOUNTING

Guns of this type are in service with the Soviet Navy on the 'Sverdlov' class cruisers (including the *Dzerzhinski*), on which they are associated with Egg Cup and Sun Visor fire control systems.

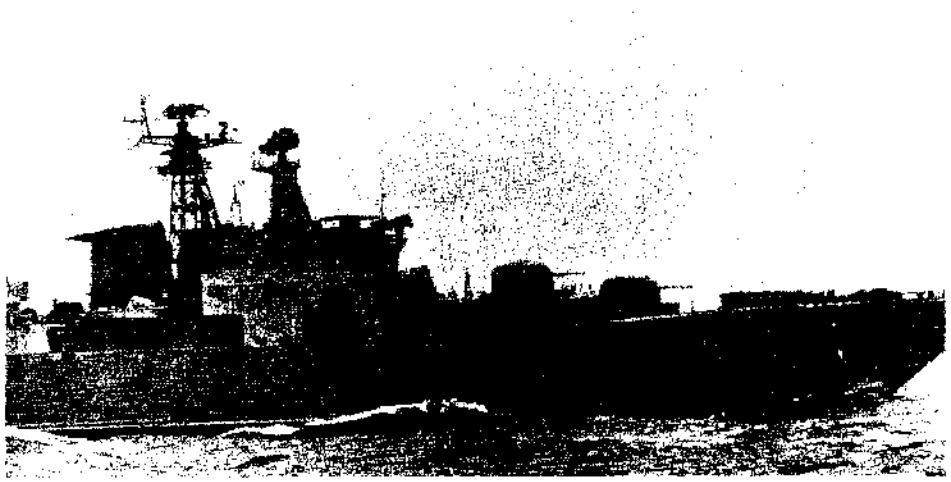
These guns are of more modern type than the single 100 mm gun fitted on the 'Riga' class destroyers (**6041.203**). They are reported as being capable of firing their 16 kg projectile with a muzzle velocity of 900 m/s at 20 rounds/minute. Maximum surface range is understood to be 18 km and maximum AA engagement height 12 000 m (at 80° elevation). Barrel length is 60 calibres. The turret is stabilised and has been said to weigh 35 tons. It is believed that the trunk of the turret extends downwards for at least one deck and contains the ammunition hoist.



Stabilised twin mountings for 100 mm dual-purpose guns on a cruiser. The top of the fire director can be seen to the rear of the gun mounting

6041.203
SINGLE 100 mm DUAL-PURPOSE GUN MOUNTING

This gun mounting is found on the many 'Riga' class destroyers in the navies of the Soviet Union and its client countries, the 'Don' class support ships and one 'Purga' class patrol ship.



These guns are all believed to be the 1947 model, to be 56 calibres in length, and to fire a 13·5 kg projectile with a muzzle velocity of 850 m/s. Surface range is believed to be some 16 km and maximum AA engagement height 6000 m. They are manually operated and obsolescent.

Anti-submarine rockets being fired from a 'Riga' class destroyer. Two single 100 mm dual-purpose gun mountings can be seen. Note the elevation angle of the gun nearer to the rocket launcher (Novosti)

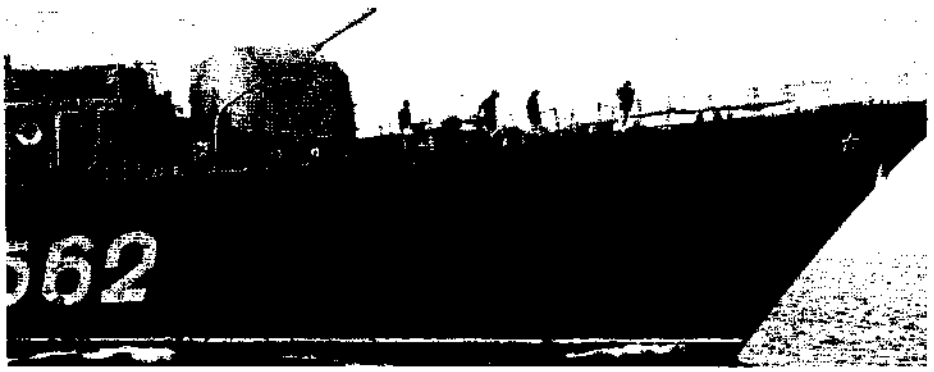
4521.203
SINGLE 100 mm DUAL-PURPOSE GUN MOUNTING (AUTOMATIC)

A new type of single 100 mm dual-purpose mounting, of which little is known, is fitted in the 'Krivak II' frigates, the large destroyer *Udaloy*, and the battle cruiser *Kirov*. It is totally enclosed and is almost certainly automatic unlike the earlier guns of this calibre described in **6041.203**. Control is from Kite Screech radar.

Single automatic 100 mm mountings on the cruiser Udaloy (Federal German Navy)

6043.203
SINGLE 85 mm DUAL-PURPOSE GUN MOUNTING

Fitted on 'Kronstadt' class coastal patrol vessels which are now only in full service in foreign navies and are being converted to torpedo recovery vessels in the Soviet Navy. This gun is presumed to be obsolescent.

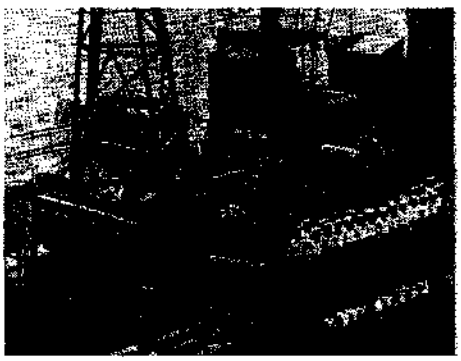


CHARACTERISTICS
Soviet designation: 90-K
Calibre: 85 mm
Length of barrel: 4435 mm
Elevation: 5 to +85°
Elevation rate: 8°/s
Traverse rate: 12°/s
Weight of round: 16·17 kg
Muzzle velocity: 800 m/s
Horizontal range: 15·5 km
Rate of fire: 15 to 18 rounds/minute

2865.203
TWIN 85 mm AA GUN MOUNTING

This is an elderly semi-automatic heavy AA weapon believed to be installed now only in the unmodified 'Skory' class destroyers. Barrel length is about 52 calibres, muzzle velocity about 800 m/s, maximum range and height about 10 000 and 5000 metres respectively. Maximum barrel elevation is 75°. Rate of fire is about 15 rounds per minute.

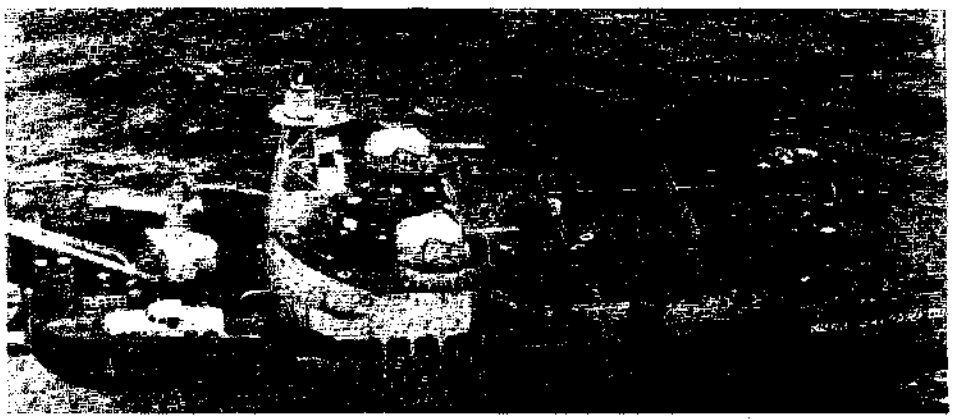
6044.203
TWIN 76 mm DUAL-PURPOSE GUN MOUNTING
This mounting seems to have first appeared on the 'Kynda' class cruisers in 1962 and is now widely fitted in the Soviet fleet in 'Kiev' class aircraft carriers, 'Kara' and 'Kynda' class cruisers, 'Kashin' and modified 'Kildin' class destroyers, 'Krivak I', 'Koni', 'Mirka' and 'Petya' class frigates and 'Ivan Rogov' amphibious ships as well as in a number of foreign navies. Doubtless it has been updated during this long period.



The 60-calibre gun can be elevated to about 85°, and this, with a muzzle velocity of about 900 m/s, means that air targets can be engaged at slant ranges up to 14 000 metres. Maximum range is 15 km. Rate of fire is said to be 60 rounds per minute. It is normally associated with Owl Screech or Hawk Screech fire control.

Twin 76 mm dual-purpose gun turret on the 'Kashin' class missile destroyer Odarenny (G Jacobs)

4315.203
SINGLE 76 mm DUAL-PURPOSE GUN MOUNTING
This new mounting has appeared recently in the 'Nanuchka III' and 'Tarantul' classes of corvette and the 'Matka' class of missile hydrofoil. It is totally enclosed and therefore most probably automatic, can clearly achieve high elevations, and is suitable for fitting in small craft since 'Matka' displaces no more than 215 tons fully loaded.

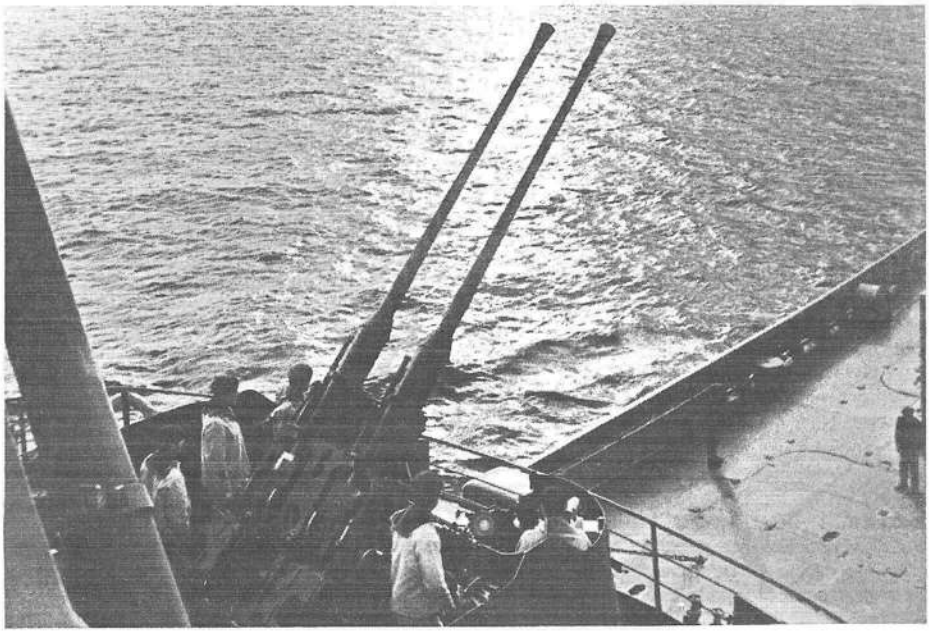


6047.203
QUADRUPLE 57 mm AA GUN MOUNTINGS
Quadruple 57 mm mountings are installed in the 'Kanin' and 'Kildin' class destroyers and the 'Lama' class supply ships. The guns are arranged as two pairs mounted vertically one above the other and it is believed that the pairs are essentially similar to the twin 57 mm guns described below (**6046.203**), except that the barrels of the quadmounted guns do not have muzzle brakes. Fire control is by Hawk Screech.

Two of four quadruple 57 mm AA gun mounts aboard a now obsolete Soviet 'Krupny' class destroyer

2869.203
TWIN 57 mm AUTOMATIC AA GUN MOUNTING
Several of the most modern classes of Soviet ships are equipped with fully-enclosed, fully-automatic 57 mm guns in twin mountings. With 80-calibre barrels and muzzle velocities around 1000 m/s, these guns have maximum horizontal and vertical ranges of 12 000 and 5000 metres respectively. Rate of fire is believed to be 120 rounds per minute per barrel. Maximum elevation is around 85°.

Guns of this type are found in at least ten different classes of ship including the 'Moskva', 'Kresta', 'Grisha', 'Nanuchka', 'Poti', 'Ugra', and 'Chilikin' classes. Radar control is normally by Muff Cob (**1611.253**).



Twin 57 mm automatic guns on the submarine tender Ivan Vakrhrameev (G Jacobs)

6045.203
SINGLE 57 mm DUAL-PURPOSE GUN MOUNTING
This 57 mm gun is fitted only to the 'Sasha' class coastal minesweepers and the modified 'Skory' class destroyers. It is believed that the gun performance is the same as that of the twin-mounted 57 mm gun described in **6046.203** but the gun barrel is not fitted with a muzzle brake.

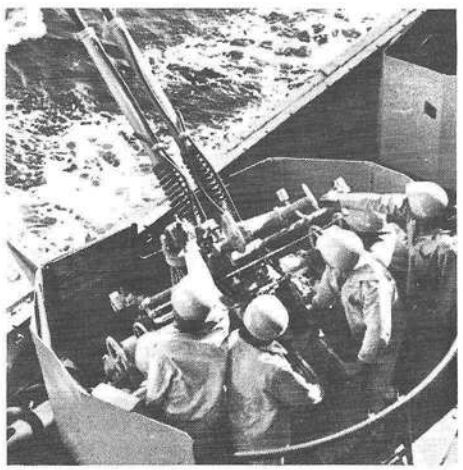
6046.203
TWIN 57 mm AA GUN MOUNTINGS
Twin 57 mm AA guns are fitted to many of the more modern or recently modernised Soviet ships. The guns have 70-calibre barrels with muzzle brakes and a rate of fire of some 120 rounds per minute per barrel is believed to be possible. Muzzle velocity is about 1000 m/s, vertical range is believed to be about 6000 metres, and horizontal range about 9000 metres; the weight of the shell is about 2·8 kg.

Guns of this type are installed in 'T-58', 'Don', 'Oskol', and 'Alligator' classes of ship. Although primarily AA weapons, the 57 mm guns are in some cases the sole armament of a ship and must therefore be intended for use in a dual-purpose role.

CHARACTERISTICS
Soviet designation: SIF-31B
Elevation: -10 to +85°
Elevation rate: 25°/s
Traverse rate: 30°/s
Weight of round: 6·6 kg
Muzzle velocity: 1020 m/s
Range: 8·4 km
Range of fuze: 6950 m
Rate of fire: 100 - 120 rounds/minute

Twin 57 mm AA guns (Novosti)

6048.203
QUADRUPLE 45 mm AA GUN MOUNTS



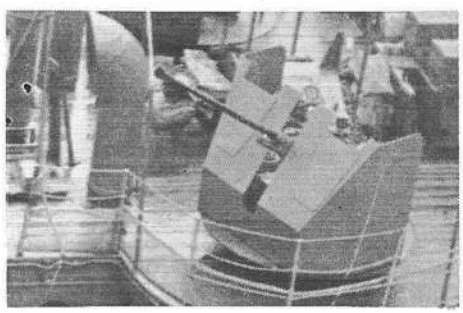
These mounts are very similar in appearance to the quadruple 57 mm AA gun mounts described above. The only remaining mountings are in the 'Kotlin' class destroyers.

Semi-automatic and with an 85-calibre barrel, each gun can fire about 160 rounds per minute with a muzzle velocity of about 1000 m/s, and vertical and horizontal ranges of some 7000 and 9000 metres.

2870.203
TWIN 37 mm AA GUN MOUNTINGS

Twin 63-calibre AA mountings of various types are found on many of the older cruisers, destroyers, and auxiliaries of the Soviet Navy. The 37 mm AA calibre was first introduced for naval use, adapted from the army weapon, in 1943, but the twin mountings date from some five years later. Fitted in 'Sverdlov', 'Skory' (modified), 'Riga' and 'T43' class.

CHARACTERISTICS
Soviet designation: W-11-M
Elevation: -10 to +85°
Elevation rate: 13°/s
Traverse rate: 17°/s
Weight of round: 1·5 kg
Weight of shell: 732 g
Muzzle velocity: 880 m/s
Range: 4000 m (horizontal), 3000 m (vertical)
Rate of fire: 2 × 160 to 180 rounds/minute



Twin 37 mm AA guns (Tass)

2883.203
SINGLE 37 mm AA GUN MOUNTING 70-K

Derived from an army weapon of the same calibre this gun was introduced for naval use in 1943 and is to be found in open mountings on the older 'Skory' class destroyers, and on 'Kronshtadt' class submarine chasers and in turret mountings on 'T-301' class coastal minesweepers which are now only in service in other navies.

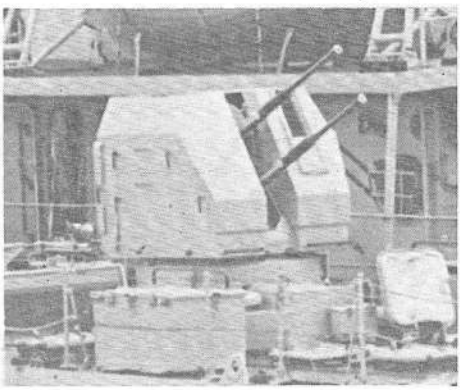
It is also in use in ships of other Warsaw Pact navies.

CHARACTERISTICS
Calibre: 37 mm
Elevation: -10 to +85°
Elevation rate: 15°/s
Traverse: 360°
Traverse rate: 20°/s
Muzzle velocity: 880 m/s
Max range: 4000 m
Rate of fire: 160 - 180 rounds/minute
Weight: 1750 kg
Crew: 6

Single 37 mm AA mountings

2896.203
TWIN 30 mm AA GUN MOUNTING

Widely fitted in many classes of ship including missile boats and other small craft, this is a fully automatic remote-controlled weapon. Barrel length is 65 calibres, muzzle velocity around 1000 m/s, range about 3000 to 4000 metres, and rate of fire around 500 rounds per minute per barrel. Maximum elevation is about 85°.

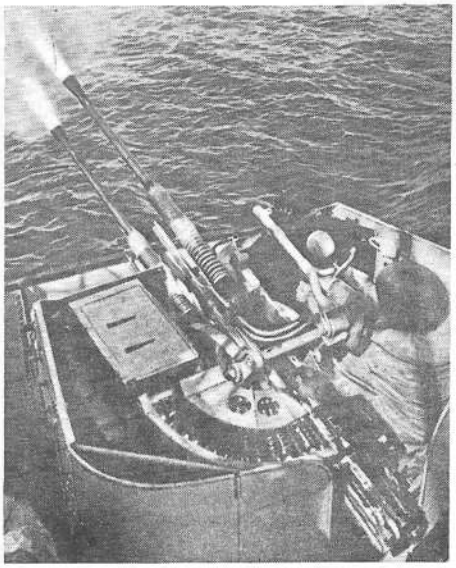


The gun was first introduced in 1960. It is most commonly associated with the Drum Tilt fire control radar (**1330.253**) or more rarely with Muff Cob (**1611.253**).

Twin fully-automatic 30 mm AA mounting as mounted on missile boats and other small vessels

2897.203
TWIN 25 mm AA GUN MOUNTINGS

LAA guns of this type are mounted in many of the smaller ships of the Soviet Navy and other friendly navies. At least three versions of mounting exist, the simplest being the open type 2-M-3 110PM. This is essentially for local control with visual sighting, although hydraulic power is provided for training and elevation. Later versions, however, may provide for varying levels of remote control.



Later twin 25 mm gun mounting, probably aboard a riverine gunboat

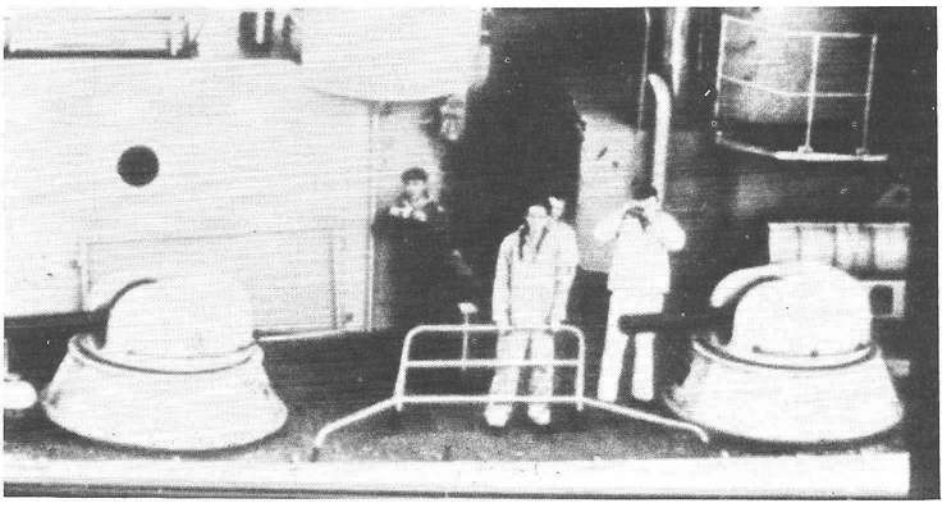
CHARACTERISTICS
Calibre: 25 mm
Length of barrel: 80 calibres
Elevation: -10 to +85°
Traverse: 360°

Rates:	Hydraulic	Manual
Elevation	2 - 40°/s	15°/s
Traverse	2 - 70°/s	25°/s

Muzzle velocity: 900 m/s
Rate of fire: 270 - 300 rounds/minute (theoretical)
Overall length: 2·845 m
Overall weight: 1500 kg
Crew: 2

This data refers to the open mounting type 2-M-3 110PM; the performance of the alternative versions is likely to be broadly similar.

Twin 25 mm AA guns in 2-M-3 110PM open mounting



2899.203
122 mm and 140 mm ROCKET LAUNCHERS

For the past 30 years and more the Soviet Army has been using and arranging for the development of a wide range of unguided barrage rockets (**5555.111**). It is not surprising, therefore, that the Soviet Navy should also use these weapons, indeed it is surprising that they have not made greater use of them.

Systems are fitted in some amphibious ships. The 'Ivan Rogov' class has two 122 mm 20-barrelled launchers, the Type 3 and 4 'Alligator' class have two launchers each and the 'Polnochny' class have two 18-barrelled 140 mm launchers with a range of about 9 km.

2973.203
30 mm CLOSE-IN WEAPON SYSTEM

This 30 mm six-barrel Gatling type weapon is the new close-in weapon system for the Soviet Navy for defence against cruise missiles and 'smart' weapons. In concept it is similar to the American Vulcan-Phalanx system (**2543.231**). This weapon is controlled by a Bass Tilt radar and is mounted on at least 18 different classes of ship ranging from the battlecruiser *Kirov* to the 210-ton fast attack craft *Slepen*. It is probable that this weapon has a cyclic rate of fire of at least 3000 rounds per minute.

Barbette mountings on 'Kresta II' cruiser

UNITED KINGDOM

6012.203
TWIN 4·5 inch GUN MOUNTING Mk 6

This twin-barrelled remotely controlled power operated 4·5-inch (113 mm) naval gun mount was introduced shortly after the Second World War. Electro-hydraulic power control is normally remotely controlled, but can be locally controlled by a joystick. The loading cycle is semi-automatic, shell and cartridge being separately hoisted and then manually loaded into the loading tray. The complete turret weighs about 45 tons.

CHARACTERISTICS
Calibre: 113 mm
Length of barrel: About 45 calibres
Elevation: To 80°
Projectile weight: About 25 kg
Muzzle velocity: About 750 m/s
Max range: About 19 km (10 nautical miles)
Rate of fire: 20 rounds/barrel/minute

STATUS
Operational in British and Commonwealth navies.

CONTRACTOR
Vickers Shipbuilding and Engineering Ltd (a subsidiary of British Shipbuilders), Barrow Engineering Works, PO Box 12, Barrow-in-Furness, Cumbria LA14 1AF, England.

6011.203
SINGLE 4·5 inch GUN MOUNTING Mk 8

This fully-automatic single-barrelled 4·5-inch (113 mm) gun has been designed for the RN by the Royal Armament Research and Development Establishment (RARDE). It is modelled on the British Army's Abbot gun (**5503.103** in 1982-83 and earlier editions) and is fitted with muzzle brake and fume extractor. A range of fixed ammunition has also been developed for use with this mounting.

The gun mounting, designed by Vickers at Barrow, features a simple ammunition feed system with the minimum number of transfer points, and a remote power control system with large stability margins that requires a stiff mounting structure with low inertia. To this end the revolving structure has been kept as light as possible and a sandwich construction glass-reinforced plastic gun-shield fitted. To keep the trunnion height as low as possible the gun is mounted front heavy, balance being restored by an oil spring. To reduce inertia the training gear is fitted to the fixed structure, the training motors are fitted inside the mounting pedestal, and the driving motors are secured vertically to the ring bulkhead which is part of the ship's structure.

The loading system is hydraulically operated from one power plant sited below decks. The system employs only four transfer points between the gunbay (ready use magazine) and the gun, and is designed so that the nature of ammunition may be changed without unloading or firing off a large number of rounds. A stockpile of ammunition is accommodated within the feed system and may be fired remotely from the operations room with no crew closed up at the mounting.

Fail-to-safe interlocks are included in all major operations to safeguard equipment and ammunition, and facilities are arranged for manual control of the power drives for maintenance purposes.

CHARACTERISTICS
Performance data for the gun has not been published, but the following suggestions are offered by way of general guidance.
Calibre: 4·5 inch (113 mm)
Length of barrel: 55 calibres
Elevation: -10 to +55°
Training: ±340°
Muzzle velocity: 870 m/s
Max range: 22 km
Rate of fire: 25 rounds/minute continuous
Ammunition: HE, Illuminating, Smoke, Chaff dispensing

STATUS

The equipment is currently in service with several navies. It is the standard medium calibre gun in the Royal Navy and is fitted to the Type 82 destroyer HMS *Bristol*, the Type 21 and later Type 22 frigates, and the Type 42 destroyers. It will also be fitted in the Type 23 frigate. The Mk 8 is also in service with Argentina on the Type 42 destroyers (1 turret), Brazil on the six 'Niteroi' class frigates (1 or 2 turrets depending on ship), Iran on the four 'Saam' class frigates (1 turret), Libya on the single Vosper Thornycroft Mk 7 frigate (1 turret) and Thailand on the single 'Yarrow' frigate (2 turrets). During the South Atlantic conflict in 1982, the 4·5-inch Mk 8 gun was used to advantage, particularly for naval gunfire support and earned the confidence and commendation of British naval and land forces for its accuracy and effectiveness.

CONTRACTOR

Designed and manufactured by Vickers Shipbuilding and Engineering Ltd (a subsidiary of British Shipbuilders), Barrow Engineering Works, PO Box 12, Barrow-in-Furness, Cumbria LA14 1AF, England.

Vickers 4·5-inch Mk 8 gun mounting on the Brazilian Mark 10 frigate Liberal

6014.203

TWIN 4 inch GUN MOUNTING Mk 19

Designed by Vickers, this is a twin-barrelled, hand loaded, remotely controlled naval gun mount which is electrically trained and elevated. Normally laid by remote control it can also be locally controlled using joysticks. Fuze setting devices are located alongside each trunnion support. A good gun crew can achieve a rate of fire of up to about 16 rounds per barrel per minute.

CHARACTERISTICS

Calibre: 102 mm
Elevation: To 80°
Projectile weight: 15·9 kg
Muzzle velocity: 760 m/s
Max range: 19·5 km (10·5 nautical miles)
Max altitude: 13 500 m
Rate of fire: Up to 16 rounds/barrel/minute
Date introduced: 1935

STATUS

Operational in Commonwealth and other navies. No longer in production.

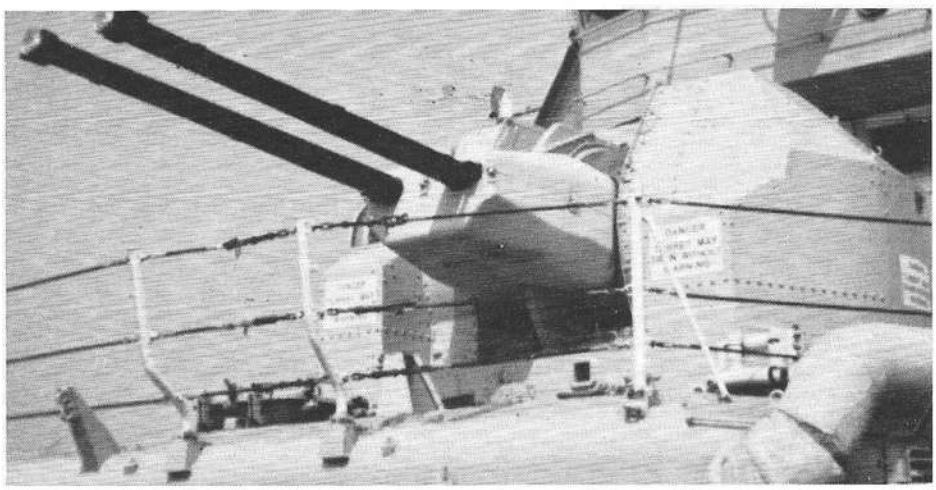
Twin 4-inch Mk 19 gun mounting

6016.203

TWIN 3 inch GUN MOUNTING Mk 6

This is a twin-barrelled 3-inch (70 calibre) automatic dual-purpose, remotely controlled naval gun mount. Local control arrangements are provided but the mounting can be operated unmanned. The rate of fire is about 90 rounds per gun per minute and the barrels are water cooled to allow sustained fire. Turret weight is about 38 tons.

CHARACTERISTICS



Calibre: 76 mm
Length of barrel: 70 calibres
Elevation: To 90°
Projectile weight: Probably about 7 kg
Muzzle velocity: 1000 m/s
Max range: Approx 17 km (9 nautical miles)
Rate of fire: 90 rounds/barrel/minute

STATUS

Operational in Canadian Navy. British ships which were fitted have been disposed of or are in reserve.

CONTRACTOR

Vickers Shipbuilding and Engineering Ltd (a subsidiary of British Shipbuilders), Barrow Engineering Works, PO Box 12, Barrow-in-Furness, Cumbria LA14 1AF, England.

Twin 3-inch Mk 6 gun mounting on HMS Tiger (Stefan Terzibaschitsch)

6010.203

SINGLE 4·5 inch GUN MOUNTING Mk 5

This single-barrelled, remotely controlled, and manually loaded gun mounting is to be found in the 'Tribal' class frigates of the RN and in similar vessels elsewhere. As an alternative to remcte control, local control by joystick is possible. Charge and shell are separate and automatically rammed.

CHARACTERISTICS

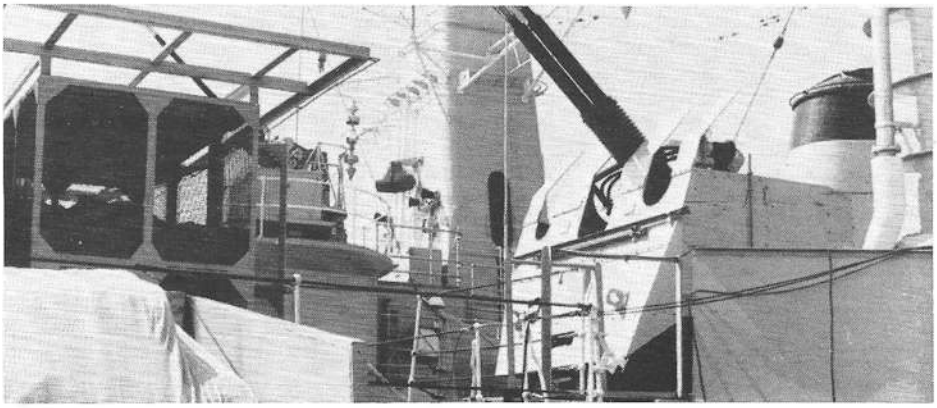
Calibre: 113 mm
Length of barrel: 45 calibres
Elevation: To about 50°
Projectile weight: About 25 kg
Muzzle velocity: About 750 m/s
Max range: About 19 km (10 nautical miles)
Rate of fire: 14 rounds/minute with a good crew
Date introduced: 1937

STATUS

No longer operational in the British fleet but used by certain other navies.

CONTRACTOR

Vickers Shipbuilding and Engineering Ltd (a subsidiary of British Shipbuilders), Barrow Engineering Works, PO Box 12, Barrow-in-Furness, Cumbria LA14 1AF, England.



4·5-inch Mk 5 gun mount in the frigate HMS Ashanti

6015.203
TWIN 40 mm (BOFORS) GUN MOUNTING Mk 5
This is a remotely or locally controlled twin Bofors 40 mm 60-calibre close-range naval gun mount. A splinter protection shield to the front of the mounting is installed. It requires one 'on mounting' loader per gun and one operator to lay and train the gun in 'local control' operation. Separate emergency manual laying and training arrangements using two men are provided. Rate of fire is about 120 rounds per minute per barrel.

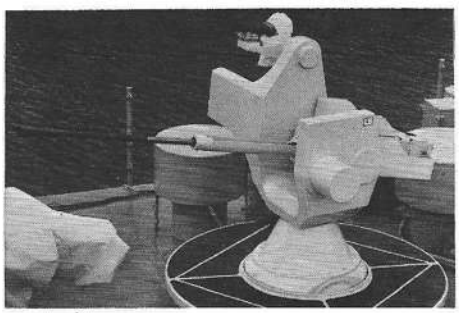
CHARACTERISTICS
Weight: Approx 3000 kg
Rate of fire: 2 × 120 rounds/minute
Tactical range: 3000 m

STATUS
Operational in many British and Commonwealth naval vessels.

40 mm Bofors twin mount, British pattern (Stefan Terzibaschitsch)

6013.203
SINGLE 40 mm (BOFORS) Mk 7 GUN MOUNTING
This is a single-barrelled Bofors 40 mm power operated ship's gun mounting. It is a lightweight mounting suitable for fitting in FPBs as well as larger vessels. One-man control is by joystick and uses a gyro sight for aiming. One man is necessary 'on mounting' for loading and rate of fire is about 300 rounds per minute.

For details of the gun in this mounting see **2360.203**.



STATUS
No longer in production but widely fitted in British and Commonwealth naval vessels.

Bofors 40 mm gun on Mk 7 mounting

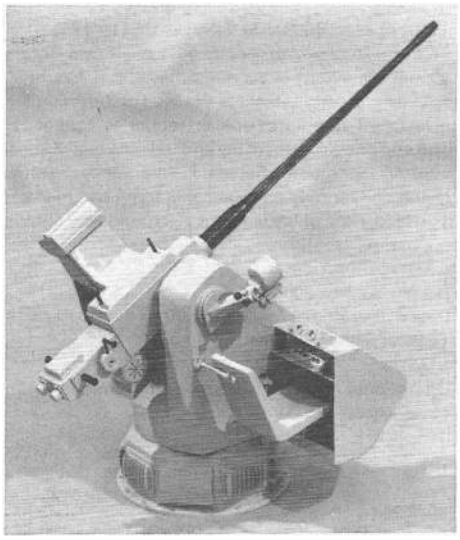
3658.203
LS30R 30 mm (RARDEN) NAVAL GUN MOUNTING
Laurence, Scott (Defence Systems) Ltd (KSDS) have developed a lightweight naval mounting for use aboard small vessels, based upon the technology employed in the company's optical fire director (OFD) (**3055.293**) described in the Electro-Optical section of this volume. The electronic and servo system package is similar to that used in the OFD, and the LS30R mounting is both power-driven and line-of-sight stabilised. It is designed to accommodate the Rarden 30 mm gun, and all subsequent description refers to this version, although guns of other types can be fitted.

The Rarden 30 mm gun was conceived by the Royal Armament Research and Development Establishment (RARDE) and is a lightweight cannon featuring low trunnion loads and good power and accuracy. It is in use on armoured fighting vehicles such as the Fox and Scimitar, and notes on its land-based uses will be found in entry **5504.103**, in earlier editions of *Jane's Weapon Systems*.

Laurence, Scott LS30R stabilised 30 mm gun mount

CHARACTERISTICS
Mounting type: LS30R
Elevation: -20 to +70°
Elevation speed and acceleration: 35°/s; 120°/s²
Training: ±160° standard
Training speed and acceleration: 30°/s; 120°/s²
Weight: 800 kg (complete)
Gun type: Rarden 30
Calibre: 30 mm
Length of barrel: 2440 mm
Muzzle velocity: 1100 m/s (HE); 1080 m/s (APSE); 1200 m/s (APDS)
Rate of fire: 90 rounds/minute (max)
Max continuous burst: 6 rounds (22 rounds with extra magazine)
Optional extras: Predictor; image intensifier; IR camera and/or TV camera for remote control

STATUS
A private venture development introduced in September 1979. Extensive trials have successfully been carried out by the Royal Navy. The gun mounting is in production but no ship fit details have been released.



CONTRACTOR
Laurence, Scott (Defence Systems) Ltd, PO Box 25, Kerrison Road, Norwich, Norfolk NR1 1JD, England.

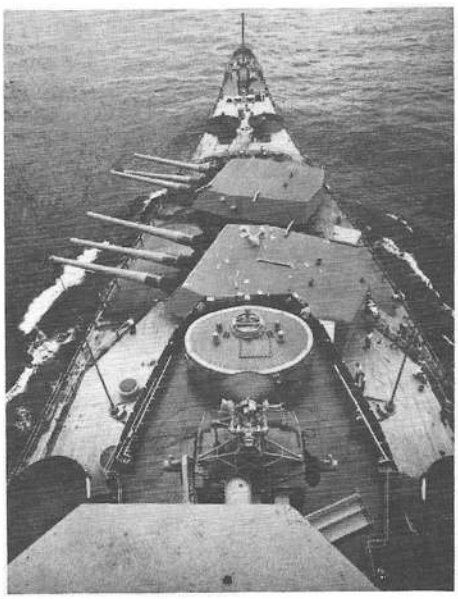
4567.203
LS30 SERIES SEATED OPERATOR GUN MOUNTS
The LS30 series is a family of powered and stabilized naval gun mountings for seated operator control, and is designed to suit weapons of high accuracy and rates of fire. They are compact and lightweight and readily adaptable to different installation requirements. In action, they are easily controlled, convenient for wash-down in NBC conditions, and both the structure and ammunition have a low magnetic signature. The LS30 series can thus provide a credible air defence and surface engagement capability for a wide range of warships and patrol craft.

A further advantage of the LS30 series is that, although intended primarily for local manning, they can readily be used in remotely directed and emergency hand powered modes. When locally manned the seated operator controls the mounting with a thumb joystick while following the target through a sight attached to the mounting. Local control sighting is by a binocular and disturbed sight line arrangement with the sight being offset to provide tangent elevation and lead angle correction. On-mount prediction facilities can be fitted.

CHARACTERISTICS
Operational elevation arc: -20 to +65°
Operational training arc: -155 to +155°
Trunnion height: 1·075 m
Slew velocity (training and elevation): 60°/s
Acceleration (training and elevation): 120°/s²

STATUS
Advanced development.
CONTRACTOR
Laurence, Scott (Defence Systems) Ltd, PO Box 25, Kerrison Road, Norwich, Norfolk NR1 1JD, England.

Seated operator version of LS30 gun mount



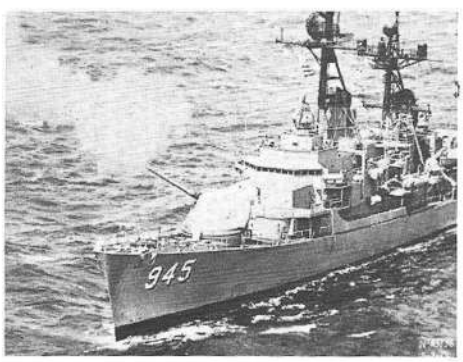
UNITED STATES OF AMERICA

4523.203
TRIPLE 16 inch GUN TURRET Mk 7

With the US Navy decision to re-activate and modernise four 'Iowa' class battleships in 1982, the US fleet re-introduced the powerful 16-inch calibre naval gun to the world's navies. *Iowa*, *New Jersey*, *Missouri* and *Wisconsin* (BB61/2/3/4) all saw action in the Second World War and later during the Korean conflict, and in the case of USS *New Jersey* also in the course of the Viet-Nam war. The latter ship is the first of the four to be re-activated, this process involving the changing of some lighter armament, the addition of some new weapons (eg Tomahawk cruise missiles and Phalanx close-in weapon systems), but the nine Mk 7 16-inch guns remain the main conventional armament, arranged in three triple turrets.

These major calibre gun turrets are constructed with armour plate which is 43 cm thick at the sides and front, 30 cm at the rear, and with 18 cm tops. The gun was designed to be removed without dismantling the turret; barrel length is 50 calibres, weighing (without breech block) approximately 108 480 kg. A range of about 40 km has been achieved with a shell weighing 1225 kg with a barrel elevation angle of 45°, and for use against surface shipping, 'Iowa' class 16-inch guns are seen as complementing the Harpoon anti-shipping missiles being fitted in these ships with their typical maximum range of about 60 nautical miles.

In mid-1981 it was estimated that there were over 21 000 projectiles for Mk 7 16-inch guns in store, of which about 13 000 were then probably still serviceable. Their number includes: 15 400 high capacity (HC) projectiles, 3200 armour piercing (AP), 2300 target projectiles, and 138 Mk 19 projectiles. All of the last listed are thought to be unserviceable, while all of the target projectiles and some 90 per cent of the AP rounds are fit for use. Slightly over half the HC projectiles are regarded as serviceable. In the case of charges for these rounds, about 80 per cent of exisiting stocks of 12 400 full charges and almost 12 600 reduced charges are thought to be fit for use. Each ship of the 'Iowa' class has a magazine load of 1220 projectiles, and the combined weight of round and full charge is approximately 1525 kg. The HC projectile has a payload of 70 kg of explosive 'D' and the AP round has about 18 kg of the same explosive. US assessments calculate that existing ammunition stocks will be adequate for training and structural test purposes until the end of 1991, after which procurement of target projectiles will be required. There are considered to be about 18 000 war rounds available without any need for refurbishing, and it will take about six months to start up the 16-inch/50 calibre projectile loading facility in the USA.



The two forward triple 16-inch guns aboard USS New Jersey *which was recently re-activated (again), retaining the largest naval guns in service together with new missile armament and other improvements for a new commission* (US Navy)

CHARACTERISTICS
Calibre: 16 inch (406 mm)
Length of barrel: 50 calibres
Elevation: +45° max at 12°/s
Traverse: 300° at 2°/s
Projectile weights: 862 kg(HC); 1225 kg (AP and drill)
Muzzle velocity: 820 m/s (HC); 739 m/s(AP)
Max range: 38 km (HC); 36·75 km (AP)
Rate of fire: 2 rounds/minute
Weight of gun: 108 510 kg
Assembly weight: 1701 - 1708 tons
STATUS
In service on board USS *New Jersey* and *Iowa*. Recommissioning work is in progress on USS *Missouri* at the Long Beach Naval Shipyard, California. Initial funding to activate the USS *Wisconsin* is included in the FY86 appropriations.

6094.203
SINGLE 8 inch MAJOR CALIBRE LIGHTWEIGHT GUN MOUNT Mk 71

The major calibre lightweight gun (MCLWG) development programme is intended to provide US Navy ships of destroyer size with a high-performance 8-inch (203 mm) gun capable of fitting where a gun of 5-inch (127 mm) calibre would be more usual. Operational roles are anti-ship engagements and shore bombardment in support of amphibious operations. A single operator (below deck) can fire the gun, single shot or at rates up to 10 to 12 rounds per minute, and there is a ready-use capacity of 75 rounds on the prototype 8-inch/55 calibre Mk 71 Mod O. This can be increased by use of specially designed ready-to-use magazines for selected classes of ships. A centre-line ammunition hoist may be used to replenish the ready-use magazine from a lower deck magazine. In that case an additional crew of four loaders is required.

The loading, aiming and firing operation is fully automatic and there is automatic selection of any of six different types of round. All 8-inch/55 calibre semi-fixed ammunition with projectile weights up to 260 lb (118 kg) maximum can be used and two different lengths of projectile are automatically accommodated. Misfire removal, also, is automatic. In addition to standard Mk 25 projectiles, the Mk 71 Mod O gun is capable of firing guided projectiles, and extended range projectiles with a rocket motor.

FMC Mk 71 8-inch major calibre lightweight gun mount aboard USS Hull

Control of the gun can be effected by either the existing analogue fire control systems such as the Mk 68 as fitted in the USS *Hull* used for sea firing trials of the Mk 71 Mod O, or the digital Mk 86 GFCS being fitted to new constructions.
CHARACTERISTICS
Calibre: 8 inch (203 mm)
Length of barrel: 55 calibres
Elevation: -5 to +65° at 20°/s
Traverse: 300° at 30°/s
Acceleration: 60°/s² in traverse; 40°/s² in elevation
Projectile weight: 118 kg (max)
Rate of fire: 12 rounds/minute
Ready use: 75 rounds
Mount weight: 78 425 kg
Barrel weight (tube and liner): 9008 kg
DEVELOPMENT
The concept of providing ships of destroyer size with a major calibre gun capability originated in the US Navy during the early and mid-1960s, and at one time it was proposed to develop a gun able to use ammunition in common with US Army 175 mm rounds. The latter project was dropped however, and the US Navy then decided to convert the prototype

175 mm gun to use existing 8-inch ammunition. The resultant weapon was the 8-inch/55 calibre gun mount Mk 71 Mod O.

STATUS

The Mk 71 Mod O was delivered to the US Navy Surface Weapons Center Dahlgren Laboratory for shore testing in 1969, following tests at the manufacturer's (Northern Ordnance Division, FMC) plant. Evaluation at Dahlgren was completed by March 1971, followed by a limited scope operational evaluation from November 1971 to January 1972. Installation in USS *Hull* for sea trials took place between April 1974 and April 1975 and sea firing tests began later that year. In December 1975 favourable results were reported but the Mk 71 was dropped from DoD procurement plans in 1979. The evaluation mount in USS *Hull* was removed and returned to the US Naval Surface Weapons Center Dahlgren Laboratory and is maintained in firng condition as a test and demonstration mount.

CONTRACTOR

FMC Corporation, Northern Ordnance Division, Minneapolis, Minnesota 55421, USA.

4847.203

SINGLE 5 inch/54 CALIBRE GUN MOUNTING Mk 39

The 5-inch/54 calibre Mk 39 is a single enclosed base-ring type mounting and is designed for semi-fixed ammunition. The gun is incorporated in the 5-inch housing Mk 4 with a vertically sliding wedge breech-block mechanism. Ammunition is power-rammed after being placed manually in a loading tray. Gun crews can maintain a rate of fire of 20 rounds per minute.

The single and twin 5-inch/54 calibre Mk 39 mountings were designed during the Second World War as successors to the Mk 32 and Mk 39 dual-purpose guns then in widespread use. One of the earliest proposals for the new mounting's use was installation on a 1940 design of an 8 100 ton cruiser, and later proposals included installations on the 'Montana' class battleships and late-war anti-aircraft cruiser designs. Ultimately the single Mod 0 mounting was installed on the 'Midway' class aircraft carriers. Later they were removed from these ships, and transferred to Japan for installation on five destroyers. Other mountings are held in US Naval reserve.

CHARACTERISTICS

Calibre: 5 inch (127 mm)
Length of barrel: 54 calibres
Elevation: -10 to +85°
Traverse: 300° plus
Projectile weight: 31·8 kg
Muzzle velocity: 762 m/s
Max range: 23 km
Max altitude: 14·8 km
Rate of fire: 20 rounds/minute max
Gun weight: 2432 kg
Assembly weight: 33 530 to 35 739 kg
Ammunition: AAC/HC, Common, and Illuminating

STATUS

In service in Japanese Navy on 'Akizuki' and 'Murisame' class destroyers. Held in reserve by US Navy.

6026.203

TWIN 5 Inch/38 CALIBRE GUN MOUNTING Mk 32

This is the oldest design of the 5-inch mounting still in service with the USN, but it is also one of the most widely used. The 5-inch/38 calibre gun has indeed been described as 'the prototype of the conventional US naval gun'.

The Mk 32 mounting contains two Mk 12 5-inch/38 calibre guns and an enclosed mounting with ammunition-handling room beneath. It requires a crew of 13 on the mounting and 26 in all. Remotely-controlled, semi-automatic, and dual-purpose, it also has local laying facilities on the mounting. Normal rate of fire is 15 rounds per barrel per minute but the gun's capacity for sustained fire is in excess of this and a good crew can achieve 22 rounds per minute over short periods. Train limits are 300° apart and elevation limits from -15 to +85° but train and elevation velocity and acceleration are significantly lower than those of the later 5-inch mountings.

Semi-fixed ammunition is used, consisting of a projectile weighing about 25 kg (varying according to type) and a case assembly weighing about 13 kg including a full powder charge of 6·8 kg. With a full charge the muzzle velocity is 792·5 m/s giving a maximum horizontal range of 16·5 km (9 nautical miles) and a ceiling of 11 400 m. The ammunition is raised to the gun house by hydraulically powered hoists. The complete mounting weighs about 53 tons.

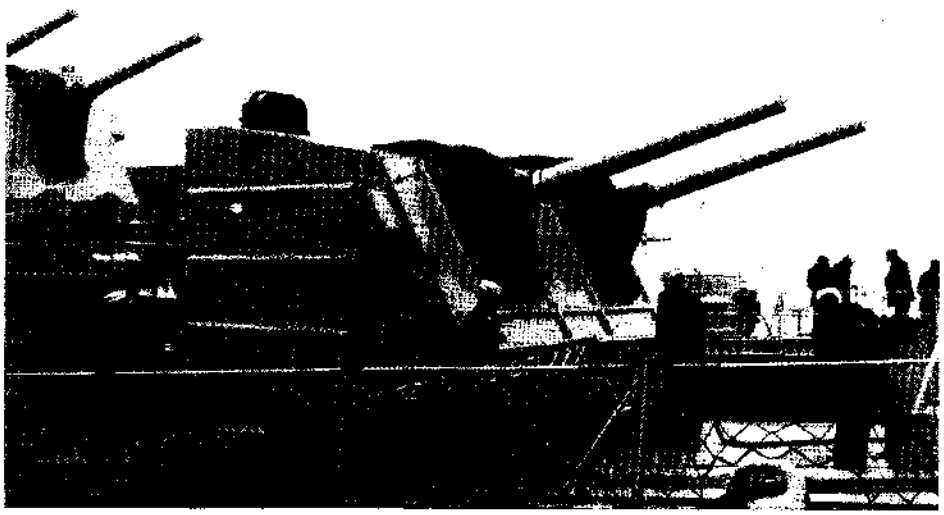
CHARACTERISTICS

Calibre: 5 inch (127 mm)
Length of barrel: 38 calibres
Elevation: -15 to +85°
Traverse: +150°
Projectile weight: About 25 kg
Muzzle velocity: 792·5 m/s
Max range: 16·5 km (9 nautical miles)
Max altitude: 11 400 m
Rate of fire: 15 - 22 rounds/minute
Date introduced: 1935

STATUS

Twin mountings were installed in the 'Iowa' class battleships where they are currently in service in USS *Iowa* and *New Jersey*, many heavy cruisers, and a great many destroyers. Some of these are still in service in both the active and reserve fleets of the USN as well as in ex-US ships of other navies. They are also in service with one Spanish-built ship, and aboard certain Italian-built destroyers and Danish frigates.

4844.203



TWIN 5 inch/38 CALIBRE GUN MOUNTING Mk 38

The 5-inch/38 calibre gun installed in the Mk 38 mounting was designed primarily for destroyer-type ship installation with a base ring and an open or enclosed mounting. It became one of the most widely used gun mountings in the US Navy and was installed on destroyer and auxiliary-type ships throughout the Second World War. It remains in widespread foreign service, mostly on transferred 'Sumner' and 'Gearing' class destroyers.

The Mk 38 mounting contains two 5-inch Mk 12 Mod 1 guns in a semi-automatic dual-purpose mounting with separate ammunition and cartridge hoists for each gun. In automatic control the mounting is operated by a remote fire control director. Four gun shields are provided - the Mks 41, 48, 53 or 62 - and although similar in their fabrication they differ in their degree of thickness for splinter protection with weights from 14 500 to 24 400 pounds (6577 to 11 068 kg).

CHARACTERISTICS

Calibre: 5 inch (127 mm)
Length of barrel: 38 calibres
Elevation: -15 to +85°
Traverse: 328·5°
Projectile weight: 25 kg
Muzzle velocity: 762 m/s
Rate of fire: 15 rounds/barrel/minute practical; 22 theoretical

Twin 5 inch/38 calibre gun mounting Mk 38 aboard USS Zellers (Stefan Terzibaschitsch)

Assembly weight: 43 466 to 44 600 kg
Gun weight: 1810 kg (Mk 12 Mod 1)
Ammunition: AAC/HC, Illuminating, Drill

STATUS

In service with US Naval Reserve destroyers and in the navies of Argentina, Brazil, Chile, Greece, Denmark, Ecuador, Iran, Italy, South Korea, Mexico, Pakistan, Spain, Taiwan, and Turkey.

6093.203

SINGLE 5 Inch/54 CALIBRE GUN MOUNTING Mk 39

This gun mounting is an intermediate stage between the 5-inch/38 mountings (**6026.203** and **6092.203**) and the 5-inch/54 Mk 42 mountings (**6027.203**, **6028.203**, and **6029.203**). It can be regarded as a 5-inch/38 calibre single enclosed mounting Mk 30 with the Mk 12 38 calibre gun replaced by a Mk 16 54 calibre gun. This gun fires a heavier shell (about 32 kg instead of about 25 kg) with a slightly higher muzzle velocity and thus a longer range.

It may be noted that in this mounting an amplidyne all-electric power drive is used, whereas in both the 5-inch/38 mountings and the 5-inch/54 Mk 42 mountings the drive is electro-hydraulic.

STATUS

Operational as a single enclosed mounting in seven ships of the Japanese 'Murasame', 'Akizuki' and 'Harukaze' classes.

6092.203
SINGLE 5 inch/38 CALIBRE GUN MOUNTINGS

In addition to the enclosed twin mounting of the 5-inch/38 calibre gun (**6026.203**) there have been three other general types of mounting for this gun. They are:

(a) Enclosed single mount with ammunition-handling room below. Originally on destroyers, destroyer escorts, and auxiliaries. Now mainly found on auxiliary vessels of the USN, these single mounts are also the main surface armament of the ex-US 'Fletcher' class destroyers which are still in service in some navies.
(b) Open single mount with ammunition-handling room below. Auxiliary vessels. Probable designation: Mk 30 Mod 24.
(c) Open single mount without ammunition hoists or handling room. Converted merchant vessels. Probable description: Mk 37.

In performance there is essentially no difference between the first two of these and one gun of the enclosed twin mounting. The third arrangement is necessarily less efficient in terms of ammunition handling but otherwise the gun characteristics are the same.

Single 5-inch/38 calibre gun aboard the Spanish Navy ship Legazpi (J I Taibo)

The most widespread model is the Mk 30 which carries a single Mk 12 barrel. There are numerous versions, and those of 'Fletcher' class destroyers are referred to as Mods 19, 30 and 31, depending upon the position of the mount aboard ship.

4468.203
155 mm VERTICAL LOAD GUN SYSTEM (VLGS)

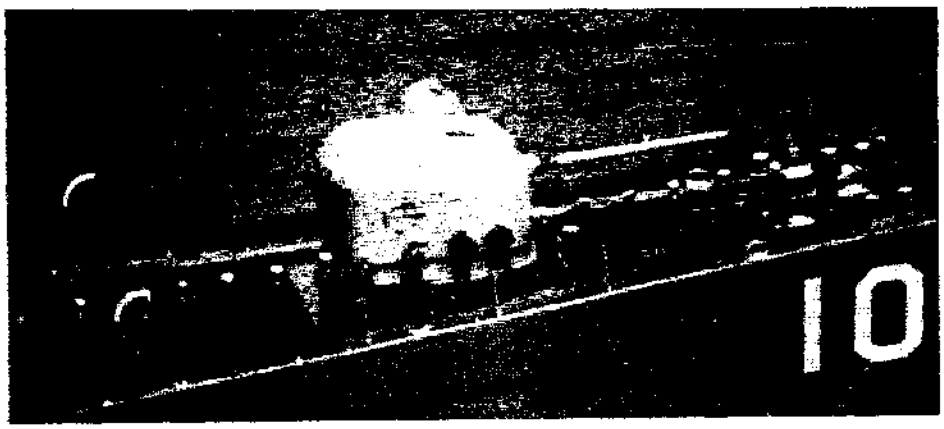
This concept was aimed at developing a gun specifically designed for guided projectiles but also capable of using the wide range of 155 mm ammunition available throughout NATO including high explosive ballistic projectiles and nuclear shells. It was designed for air and surface engagements in a mounting that is lighter, less complex, and more effective than existing 5-inch guns.

The basic concept is of a single barrel which is always brought to the vertical before being loaded by a powered vertical hoist. Similarly after firing the gun is brought to a fixed elevation to align with an empty case door before extracting the used cartridge case. Complex machinery is thus avoided and the simple design is intended to give maximum reliability, ease of maintenance, availability and reduced life cycle costs. The system has 40 per cent fewer parts than the 5-inch/54 calibre gun mount Mk 45 and a predicted mean rounds between failures of 2100 rounds. Installation on board ship is also intended to be simple and achieved, together with the check-out, in a week with mounting replacement, when needed in three days.

CHARACTERISTICS
Elevation: -10 to +75°
Traverse: Unlimited
Projectile weight: Conventional 46·7 kg, guided 102 kg
Rate of fire: 10 rounds/minute (sustained)
Mounting weight: 22 680 kg total
Power requirements: 440 V, 60 Hz, 3-phase. 40 kW stand-by load, 120 kW average firing load
Ammunition types: Conventional high explosive, illuminating, smoke, and incendiary. Existing nuclear rounds. Guided projectiles

STATUS
The concept was developed under the direction of Naval Sea Systems Command but was not pursued further.

CONTRACTOR
FMC Corporation, Northern Ordnance Division, Minneapolis, Minnesota 55421, USA.



6027.203
SINGLE 5 inch/54 CALIBRE GUN MOUNTING Mk 42

The 5-inch/54 calibre Mk 42 gun mounting was adopted to replace the pre-Second World War 5-inch/38 and wartime 5-inch/54 Mk 39 (**6093.203**), and is the most widely adopted post-war US gun mounting. It is a single-barrel rapid-fire base-ring type mounting used with either local or remote fire control. The Mods 1, 5 and 6 were for command ships (CLC) and the Mod 3 for DL/DLG class ships. Mod 7 was the most common and included CVA, CG, DLG, and DD installations.

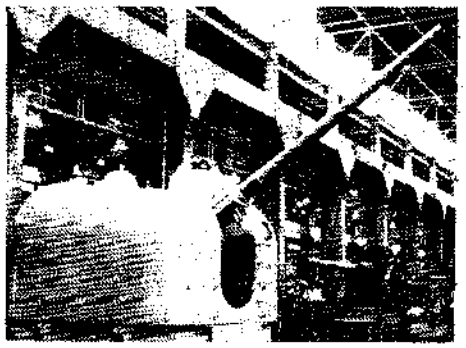
All Mods use the 5-inch/54 calibre Mk 18 Mod 0 gun housed in a vertical sliding breech-block. A bayonet type joint attaches the gun to the housing and the entire gun assembly is supported on rollers in the slide. A separate rammer is mounted on the slide. The mounting is fully power driven with an automatically controlled loading system capable of maintaining a sustained rate of fire of 40 rounds per minute. Ammunition is loaded by a dual system with projectiles supplied automatically to the slide alternately from the right and left.

The mounting is enclosed in an armour plate shield assembly with early mountings using the shield Mk 61 Mod 1 and the Mks 7 to 10 mountings using Mod 1 or Mod 4 shields. The weights of the mountings vary from the 145 930 pounds (66 193 kg) of the Mod 1 to a maximum of 210 196 pounds (95 343 kg) in the CVA installation. Ammunition includes the Mk 41 AAC/HC, Mk 42 common, and Mk 48 illumination rounds, all of which weigh 70 pounds (32 kg) and have a muzzle velocity of 2650 ft/s (808 m/s).

The Mk 42 Mod 10 is an improved version of the Mod 7 gun mount and over 100 are at sea. A modernisation and overhaul programme substitutes updated control and operating components to incorporate the improved reliability and maintenance features of the Mk 42 Mod 9 gun mount (**6028.203**) into the earlier Mod 7 and 8 gun mounts. The full gun crew complement is reduced to 12 men. Ready-to-use ammunition capacity is 40 rounds and firing rates of 20 or 40 rounds per minute are possible. The associated fire control system is the Mk 68 Mod 11.

5-inch/54 calibre Mk 42 gun on USS Thomas C Hart (Stefan Terzibaschitsch)

CHARACTERISTICS
Calibre: 5 inch (127 mm)
Length of barrel: 54 calibres (269 in)
Elevation: -7 to +85°
Traverse: 360° potential
Muzzle velocity: 2650 ft/s (808 m/s)
Max range: 23 690 m
Max altitude: 14 847 m
Rate of fire: 20 rounds/minute practical; 40 rounds/minute rated max
Assembly weight: 145 930 lbs (66 193 kg) (Mod 1); 146 400 to 183 630 lbs (66 406 to 83 293 kg) (Mod 7)
Weight of gun: 5 615 lbs (2547 kg) (Mod 1); 5 508 lbs (2498 kg) (Mod 7)



STATUS
Operational in ships of the US Navy and elsewhere. Foreign users of the Mk 42 gun include the Royal Australian, Federal German, Japanese and Spanish navies.

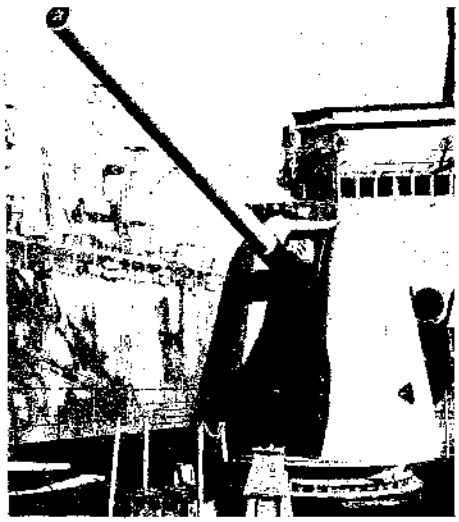
6028.203
SINGLE 5 inch/54 CALIBRE GUN MOUNTING Mk 42 (Lightweight Mod 9)

Functionally similar to the Mk 42 Mod 7 gun mount described above, the Mk 42 Mod 9 is an improved design featuring lower mount weight (58 700 kg), nearly ten per cent lower power consumption and a smaller crew requirement. Improvements incorporated include replacement of all electronic components of the earlier mount by solid-state devices. Only two men are needed on the mount as against four for the Mod 7, and the total crew requirement is 12 men instead of 14. The only respect in which the Mod 7 performance is known to be superior is that of elevation acceleration (60°/s² against 40°/s²).

STATUS
Fifty-one units of the above-decks portion of the mount were manufactured by Northern Ordnance and supplied for use on DE-1052 class ships. The below-decks portion was produced by the US Navy Naval Ordnance Station, Louisville.

CONTRACTOR
FMC Corporation, Northern Ordnance Division, Minneapolis, Minnesota 55421, USA.

Lightweight (Mod 9) version of the 5-inch/54 calibre gun mounting Mk 42 in production



6029.203
SINGLE 5 inch/54 CALIBRE LIGHTWEIGHT AUTOMATIC GUN MOUNTING Mk 45

This gun mounting represents a major step forward in medium calibre ordnance for the US Navy. It has been designed primarily for installation in new ships and was required to embody all relevant improvements developed over some 30 years since the 5-inch/38 was first introduced (**6026.203**). It was also required to be light, easily maintained, and exceptionally reliable. The result is a weapon which requires only one-third of the crew of a 5-inch/38 and with which a single man in a control centre can fire a drum load of 20 shells without help. It is also certainly the lightest naval gun mount of its size in the West and probably the lightest in the world.

Specifically, the major characteristics of the Mk 45 mountings are:
Max elevation: 65°
Rate of fire: 20 rounds/minute
Ready service rounds: 20
Mount weight: 25 tons
Crew: Reduced from 14 to 6
Crew on mounting: None

The gun is used with the lightweight Mk 86 GFCS (**1241.281**), the Mk 68 digital upgrade, and the Mk 160 GCS of the DDG-51 class. The Mk 45 has also been integrated with the Hollandse Signaalapparaten WM25 weapon control system.

DEVELOPMENT
Development of the Mod 0 weapon started in 1964 on a contract placed with the Northern Ordnance Division of the FMC Corporation. Initial production was by Northern Ordnance, who continue to make the mounting, and General Electric Company Ordnance Systems were brought in as a second source in the early 1970s but are no longer active in medium calibre gun production.

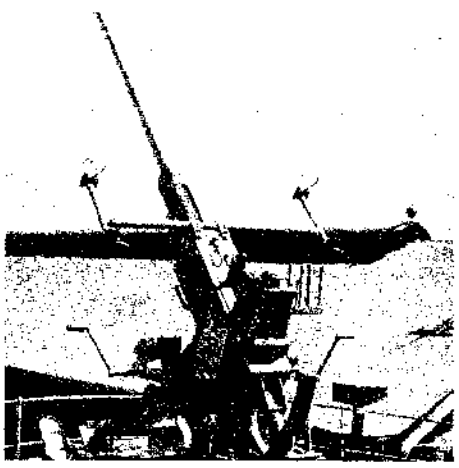
5-inch/54 calibre Mk 45 gun aboard USS Briscoe

The Mod 1 gun system entered production in 1983. The new gun has the capability to automatically select, load, and fire all existing types of 5-inch/54 calibre semi-fixed ammunition, including guided projectiles.

Northern Ordnance were also the developers and the sole manufacturers of the Mk 6 ammunition hoist, which is an integral part of the Mk 45 installations on CGN-41, CGN-36, DD-963, LHA, DD-993 and CG-47 ships. Gun barrels are produced by US Government ordnance factories.

STATUS
Over 115 Mk 45 guns have been delivered to the US Navy. Initially, FMC produced 33 mounts, and later General Electric produced 56 mounts. Since the late 1970s FMC has delivered an additional 25 systems. In 1984 FMC was awarded a multi-year contract for 25 Mod 1 guns to be supplied over a three year period. Each of the CG-47 'Aegis' cruisers will be fitted with two Mk 45s, while ships of the DDG-51 'Burke' class will carry one gun each. In 1984 the Turkish Navy purchased four Mod 1 systems for each of their 'Meko 200' class ships.

A Mk 45 gun system product improvement programme is currently being considered by the US Navy. Advanced controls and mechanical simplification are expected to lead to further increases in reliability, maintainability and mission availability. The improved Mk 45 would enter production in 1989 or 1990.



CONTRACTORS
FMC Corporation, Northern Ordnance Division, Minneapolis, Minnesota 55421, USA.

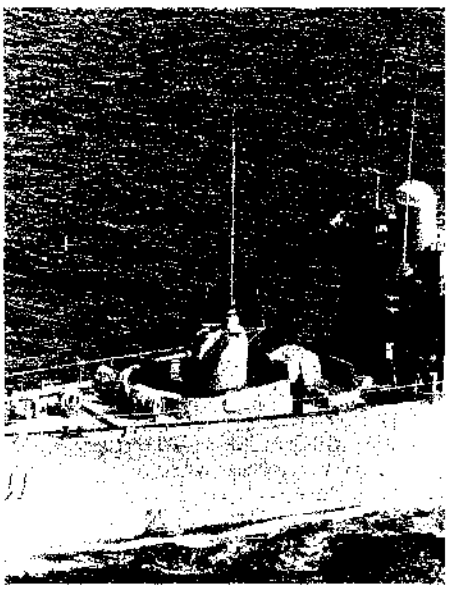
6031.203
40 mm ANTI-AIRCRAFT GUN MOUNTINGS

There are single, twin, and quadruple barrelled versions of the 40 mm automatic recoil operated gun in service in the US Navy. The twin model is the Mk 1, the quadruple version is the Mk 2, and both types are water-cooled. The single barrel Mk 3 is air-cooled. Most mounts can be either locally or remotely controlled, and are power operated, with emergency hand operation. The gun is derived from the Bofors design and the accompanying photograph shows a single barrel mount.

CHARACTERISTICS
Calibre: 40 mm
Length of barrel: 56 calibres
Projectile weight: About 0·9 kg
Muzzle velocity: About 820 m/s
Max range: About 11 km but tactical range much less
Rate of fire: 140 to 160 rounds/barrel/minute

40 mm Bofors single mount US pattern



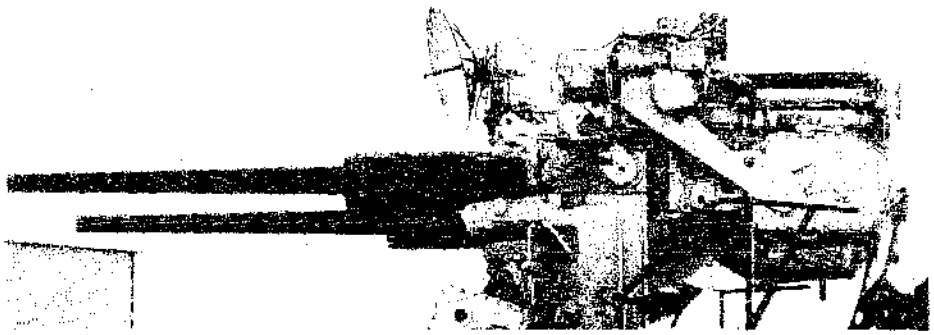
6030.203
SINGLE 3 inch/50 CALIBRE GUN MOUNTING Mk 34

This gun mounting was designed as a dual-purpose weapon with an automatic loader for use with Gun Fire Control Systems Mks 56, 57, or 63 Mods 11 and 22. It can be controlled locally or from a 3-inch Gun Director Mk 51 Mod 3. Installations were intended for destroyer escorts, patrol gunboats, attack transports and other auxiliaries. Many of these mountings were later transferred to US Naval 'Asheville' class fast attack craft and a majority of those still otherwise in use are to be found in former US Naval vessels in service with other navies.

The Mk 34 mounting is commonly found with an environmental shield for protection against icing and bad weather as the Mk 34 Mod 2 version. With a loader Mk 2 it can handle up to 50 rounds per minute in an installation which is identical to US Naval twin 40 mm mountings, designed for easy interchangeability.

CHARACTERISTICS
Calibre: 3 inch (76 mm)
Length of barrel: 50 calibres
Elevation: -15 to +85°
Traverse: 355°
Projectile weight: 5·93 kg
Muzzle velocity: 808 m/s
Max range: 12·8 km
Max altitude: 1492 m
Rate of fire: 50 rounds/minute
Assembly weight: 8677 to 9557 kg
Weight of gun: 564 kg

STATUS
Fitted to US Naval 'Asheville' class and a few other US Naval ships. Also in service with the navies of Indonesia, South Korea, Norway, the Philippines, Thailand, Tunisia, and Turkey.



Single 3-inch/50 calibre Mk 34 Mod 3 mounting on Indonesian frigate Samadikun (G Jacobs)

4845.203
TWIN 3 inch/50 CALIBRE GUN MOUNTING Mk 33

This mounting was originally designed as a heavy anti-aircraft gun to replace the 40 mm and 20 mm weapons considered inadequate during the Second World War. Installations did not begin until after the war with the 'Des Moines' and 'Worcester' class cruisers being among the first.

The Mk 33 mounting differs from the earlier Mk 27 in that the slide has been modified to allow the gun barrel to be removed out of the front of the slide to facilitate barrel changing. In addition it has faster training and elevation speeds but without an alternative hand drive. The guns used are the Mk 22 Mods 4 to 9 and each has an automatic loader Mk 2 capable of handling up to 50 rounds per minute. Either drum or vertical type ammunition magazines are available. The Mods 4 and 7 mountings have environmental shields, which have been made from both grp and aluminium, designed for protection against icing and bad weather. These include provision for a fire control radar to be fitted outside the shield.

CHARACTERISTICS
Calibre: 3 inch (76 mm)
Length of barrel: 50 calibres
Elevation: -15 to +85°
Traverse: 310°
Muzzle velocity: 808 m/s
Max range: 12·8 km
Max altitude: 8951 m
Rate of fire: 50 rounds/minute max
Ammunition: AA, AP, and Illuminating

3-inch/50 calibre twin mounting (US Navy)

STATUS
Installed in the US Navy's 'Des Moines' (CA 134), 'Bronstein' (FF-1037), and other classes as well as in various large auxiliaries. Also installed in the navies of Argentina, Canada, Chile, Colombia, Greece, Italy, Japan, Norway, Portugal, Spain, Taiwan, and Turkey.

3175.203
76 mm/62 CALIBRE GUN MOUNT Mk 75

FMC Corporation, Northern Ordnance Division, supplied gun mounts to the United States Government under licence from OTO Melara SpA of La Spezia, Italy. The gun is identical to the single 76/62 compact gun mounting described in entry **5533.203.**

Based on a 1960s design, it is a single barrel, lightweight, rapid fire, remote controlled, dual-purpose gun and has been installed on US PHM hycrofoils, FFG-7 frigates and Coast Guard cutters.

STATUS
Five mounts (of which only one was used) were delivered by OTO Melara for comprehensive tests on USS *Talbot* and technical evaluation on board this ship was completed in early 1975 with favourable results. 75 guns had been delivered by December 1983. The US Navy continues to buy small numbers of mountings to support Coast Guard and overhaul requirements. The gun mount is not currently planned for any new US Naval construction shipbuilding

2584.203
EMERLEC-30 TWIN 30 mm MOUNTING

Emerlec-30 is a twin 30 mm naval ordnance system currently in production at Emerson Electric Co, St Louis, USA. The Emerlec-30 was originally developed as the EX-74 MOD 0 for the coastal patrol and interdiction craft under a USN programme. The system incorporates design improvements that have resulted from land-based and sea testing of the EX-74. Designed for anti-missile, anti-aircraft and surface fire the system comprises two Oerlikon 30 mm cannon, daylight reflex or night image intensifier sight with gyroscopically-assisted hand grip assembly, an integral below-deck magazine with substantial ready-use ammunition and an enclosed environmentally-controlled cabin for the operator. The mount can be operated by remote control and will interface with standard fire control systems. Ship's power supplies are used in normal operation, but an on-mount battery provides sufficient power to operate the guns and fire a full complement of ammunition in an emergency. Traditional hand crank mechanisms provide further back-up.

CHARACTERISTICS
Calibre: 30 mm
Elevation: -15 to +80°
Traverse: 360°
Projectile weight: 0·35 kg
Max range: 8 km
Rate of fire: 600 rounds/barrel/minute
Ready rounds: 985 rounds/gun
Total weight of system (less ammunition): 1905 kg

STATUS
In series production since 1976 and known to be in service with or on order for Ecuador, Greece, Malaysia, Nigeria, Philippines and South Korea.

CONTRACTOR
Government & Defense Group, Emerson Electric Company, 8100 W Florissant, St Louis, Missouri 63136, USA.

4042.203
SEA VULCAN 30 LIGHTWEIGHT 30 mm NAVAL GUN MOUNT

The Sea Vulcan 30 lightweight 30 mm naval gun mount designed and developed by the General Electric Company, USA, is a high performance mount embodying the seven-barrel GAU-8/A Gatling gun. It has been designed to provide naval craft with an effective close-in defence against air and anti-ship missile threats.

The production ammunition consists of a ballistically matched set of 30 mm HEI, API, and target practice rounds. The ammunition feed/storage drum is mounted vertically and rotates in the train axis. This configuration minimises unbalanced loads and inertia changes as the ammunition is expended and the total amount varies, reduces the above-deck profile of the mount, and minimises the swept radius required below deck. The below deck location of the feed drum also provides a protected environment for reloading and maintenance of the ammunition replenishment and feed system.

Particular design emphasis was placed on the positioning of the GAU-8/A relative to the mount's train and elevation axes, to ensure reliable ammunition feed to the gun's transfer unit. The elevation axis of the gun passes through the centre of the transfer unit, which minimises chute distortion as the gun is elevated or depressed. Gun firing torque about the elevation axis is eliminated by having the centroid of the firing pressure pulse coincident with the centre-line of the elevation trunnion bearings. The longitudinal axis of the gun assembly is displaced 102 mm from the centre of the train bearing, which positions the firing barrel coincident with the mount's train axis.

General Electric Sea Vulcan 30 lightweight 30 mm naval gun mount set up for shore firing tests

CHARACTERISTICS
Gun type: 7-barrel Gatling GAU-8/A
Calibre: 30 mm
Muzzle velocity: 1021 m/s
Rate of fire: 2100/4200 rounds/minute
Drive: Electric
Ammunition types: HEI, API, TP, APDS
Capacity: 1190 rounds
Feed: Linkless
Mount
Weight (loaded): 5295 kg
Height above deck: 1613 mm
Depth below deck: 2200 mm
Max diameter: 2529 mm

STATUS
The prototype system EX-83 was test fired in late 1979 in Den Helder, and used with the Signaal Flycatcher all-weather fire control system (**2301.181**) for a demonstration programme code-named Shortstop. This combination is the basis of the autonomous naval air defence system called Goalkeeper (SGE-30) (**3516.261**). In early 1983 demonstrations were given to representatives of ten countries in the course of trials at Burlington of the Goalkeeper system which is to be fitted in ships of the Royal Netherlands Navy. Simulated engagements included a replica missile of the same size as the Exocet anti-ship weapon, and various attack profiles.

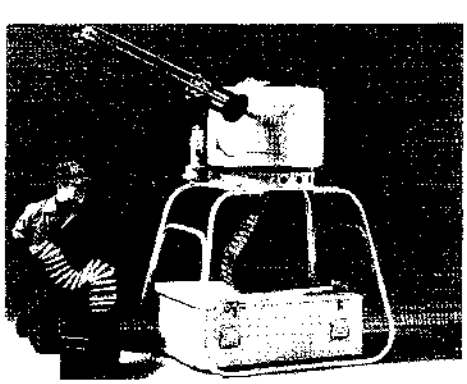
4043.203
SEA VULCAN 20 20 mm NAVAL MOUNT



The Sea Vulcan 20 is a lightweight, low profile mount developed to provide firepower for small naval craft. It is designed to accept and fire the 20 mm M197 gun, the XM188E1 gun, the M134 7·62 mm gun, the M19 40 mm grenade machine gun, the Stinger AA missile and other selected weapons. An engineering model, the EX-84, was constructed and tested under a US Navy prototype programme.

The Sea Vulcan 20 mount has many components that are common with the UTS turret as used on the AH-1 Cobra helicopter, and the system is a remotely controlled flexible gun mount with four main elements: a microprocessor-based gun corrector module, mount electronics, ammunition storage and feed system and the mount structure.

The gun corrector is a fire control computer which makes the Sea Vulcan 20 mount self-sufficient, and in addition to the microprocessor it has the necessary components to provide memory and analogue and digital input/output facilities. The corrector compensates for velocity jump, gravity crop, parallax, target motion, and provides self-testing for the whole system.

The ammunition feed and storage system comprises a box assembly and a cover assembly with booster. The box has a capacity of 750 20 mm rounds. This electrically primed ammunition can be handled and stored in a RADHAZ environment. The gun feeder is designed to remove the ammunition from regular links or links with radiation tabs. Flexible chuting provides for transfer of ammunition from the container to the feeder assembly.

The structural components of the mount are the lower support, upper support, and the saddle assembly. The lower support provides the ship interface and mounting. The upper support is mounted to the lower support through a train bearing and drive, and contains an integral gear drive for the elevation axis. The saddle is a frame that supports the weapon which is mounted through the recoil system. The Sea Vulcan 20 is arranged to accept a ring sight, a reflex sight, night vision sight, or any director system.

Components of Sea Vulcan 20 universal naval mount, shown with M197 20 mm gun mounted in turret

CHARACTERISTICS
Mount: Sea Vulcan 20 (with M197 gun)
Gun type: 3-barrel Gatling
Calibre: 20 mm
Elevation: -10 to +55°
Elevation rate: 60°/s
Traverse: ±110°
Traverse rate: 80°/s
Muzzle velocity: 1030 m/s
Recoil force: 545 kg
Rate of fire: 750/1500 rounds/minute
Position accuracy: 3 mils (static in either axis)
Dispersion: 12 mils max (80% rounds fired)
Ammunition: 20 mm M50 series
Capacity: 500 rounds
Weight: 318 kg (empty); 465 kg (loaded with 500 rounds)
Height above deck: 609 mm
Turret diameter: 609 mm
Swept radius: 1676 mm

STATUS
Development and test.

20 mm THREE-BARREL DECK MOUNT Mk 10

Designed for installation on a wide range of sea-going and riverine craft, this three-barrel 20 mm gun can provide a small vessel with very substantial fire-power.

The system comprises an M197 three-barrel 20 mm gun and ancillary equipment mounted on a USN Mk 10 stand. The gun and its associated delinking feeder (M89) are currently in use by the USMC in helicopters and in US naval aircraft.

The M197 weapon is electrically operated and power for this is supplied by a battery mounted on the gun stand. Twenty complements of ammunition can be fired without battery recharging; the battery can conveniently be connected to a main power source to provide a 28 V trickle feed, thus maintaining the battery in a charged condition.

The three-barrel gun is derived from the six-barrel M61 (Vulcan) gun (**5547.103** in 1982-83 and earlier editions) and has alternative rates of fire of 600 and 1200 rounds/minute. The M89 delinking feeder includes a declutching arrangement which, when the trigger is released, automatically stops the supply of ammunition to the gun but permits the gun to continue firing long enough to clear the barrels.

The Mk 10 gun mount provides convenient room for the installation of the 300-round ammunition can behind the right-hand shield, the battery and control box being mounted behind the other half.

CHARACTERISTICS

Deck-mounted on Mk 10 mount

Weapon: 3-barrel M197 20 mm

Elevation: -15 to +75°

Traverse: ±180°

Muzzle velocity: 1030 m/s

Rate of fire: 600 or 1200 rounds/minute

Dispersion: 80% in 8 mil circle

Ammunition: M50 series

Feed: XM89

Ready rounds: 300

Battery fire out capability: 6000 rounds

Weight: (Without ammunition) 500 kg approx

AIRCRAFT ARMAMENT

ARGENTINA

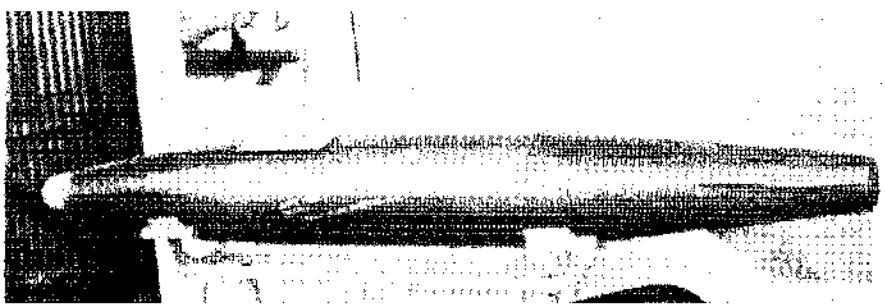
3806.303
CBAS-1 ALBATROS AIRCRAFT ROCKET
The Argentinian CBAS-1 Albatros is an unguided aircraft rocket used for typical air-to-surface tactical roles but primarily in naval applications for which it was originally designed. The rocket is of 70 mm calibre and the solid rocket motor case is constructed of aluminium. A peripherically inhibited double-base extruded propellant weighing 5·5 kg is used in the rocket motor, and the wrap-around forged steel tail fins are provided with a mechanical opening device which operates after launch.

CHARACTERISTICS
Calibre: 2·75 inch (70 mm)
Propulsion: Solid rocket motor
Launch weight: 8·7 kg
Warhead
Training (smoke): 2·9 kg
Anti-tank/anti-personnel (ATAP): 4·45 kg
Fragmentation: 4·65 kg
Anti-personnel/anti-light material: 4·8 kg
(Production of a submunition warhead was due to begin in March 1984)
Range: 8000 m

DEVELOPMENT
The CBAS-1 was designed by the Argentinian Scientific and Technical Research Institute of the Armed Forces (CITEFA) and produced by EDESA.
STATUS
Operational with the Argentinian Navy since 1973. More than 78 000 rockets have been exported. The contractor (EDESA) also produces integrated weapon systems which employ this 2·75 inch rocket.
CONTRACTOR
Empresa de Desarrollo Especiales Sociedad Anonima (EDESA), Corrientes 1642, Buenos Aires, Argentina.

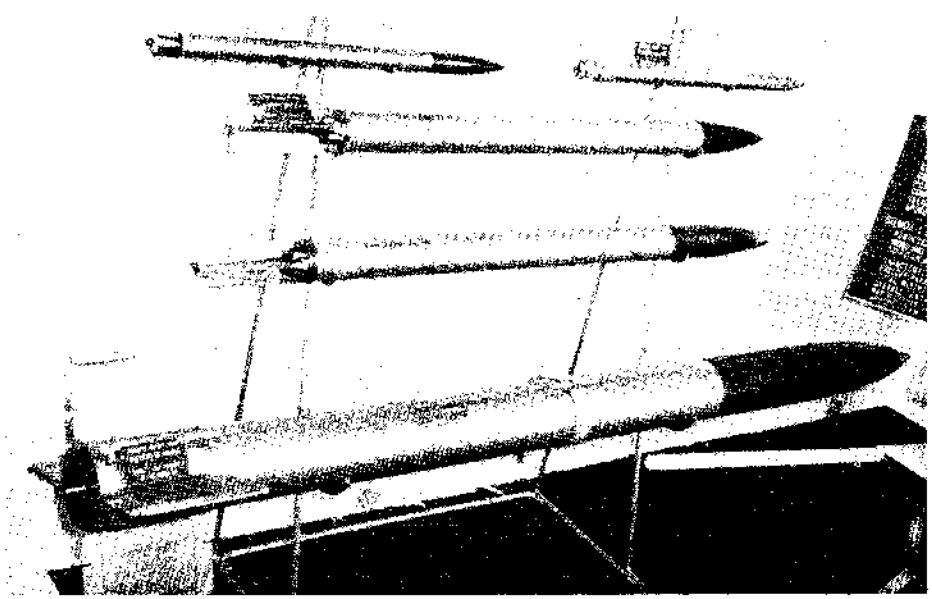
BRAZIL

4145.303
AIRCRAFT ARMAMENT
A number of aircraft armament systems have been developed in Brazil, and are currently in production and in local service and abroad. Brief details follow:
37 mm SBAT-37 rocket
This spin-stabilised air-to-ground rocket is fired from the seven-round LM-37/7 launcher, and can be fitted to light aircraft and helicopters.
70 mm SBAT-70 rocket
This solid-propellant air-to-ground folding-fin rocket is similar to the US-made 2·75 inch FFAR, and can be used with re-usable multiple launchers of two (LM-70/2), four (LM-70/4), seven (LM-70/7) or nineteen (LM-70/19) rounds. A disposable 19-round launcher is also available.



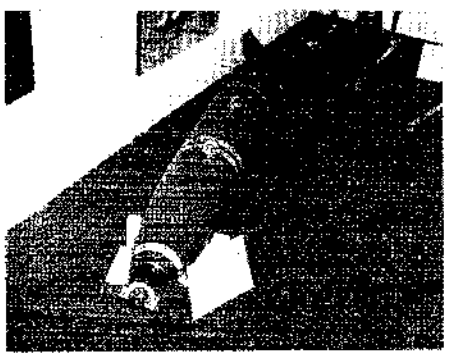
SBAT-70 rockets are produced in two main versions: the SBAT-70 M1 non-spinning type generally used with high-speed aircraft; and the SBAT-70 M2 spinning model for low-speed aircraft and helicopters, but also providing greater accuracy and longer stand-off ranges for fighter-bombers etc.

The current range of warheads for these rockets is as follows:

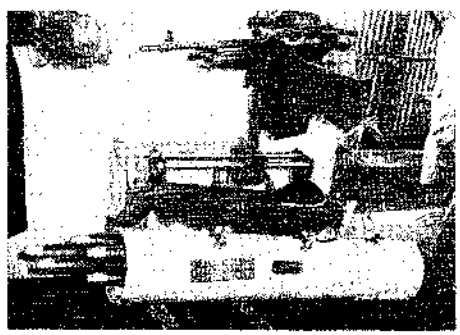


Warhead	Type
AVC-70/AC	HEAT anti-tank
AVC-70/AP	HE fragmentation anti-personnel
AVC-70/AC/AP	Combined anti-armour/anti-personnel
AVC-70/F	Flechette anti-personnel/anti-material
AVC-70/FB	Smoke WP (white phosphorus)
AVC-70/EF	Smoke practice
AVC-70/E	Inert practice (dummy)

The double base motor weighs 4·98 kg, has a thrust of 470 kg, a burn time of 1·2 seconds and uses BD-108 propellant; the alternative composite motor weighs 5·15 kg, has a thrust of 525 kg, a burn time of 1·2 seconds and uses CV-7 propellant.
127 mm SBAT-127 rocket
In the same class as the US-built five inch (127 mm) HVAR and Zuni Mk 16, this air-to-ground rocket has a 20 kg warhead and cruciform fins at the tail. It may use two- or four-rocket launchers.



Helicopter armament system
This consists of a flexible mounting for a 7·62 mm FN MAG machine gun and rack for an LM-70/7 launcher for seven SBAT-70 70 mm FFARs. In Brazilian use this system has been fitted to Air Force Bell UH-1D/Hs and to Navy Helibrás Esquilos (locally-built Aérospatia e Écureil), Westland Wasps and Westland Lynx. It has been exported to several countries.
7·62 mm machine gun pods
Pods for two 7·62 mm machine guns for aircraft use are operational and in production for local use and export.



Avibras 500 lb general-purpose bomb (Ronaldo S Olive)

Avibras aircraft rockets (top to bottom) SBAT-37, SBAT-70, SBAT-127 (Ronaldo S Olive)

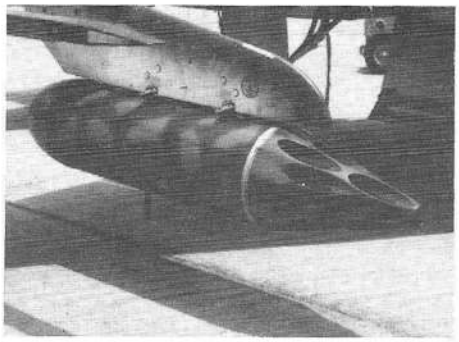
AV-BAFG-120 250 lb low-drag general-purpose bomb (Ronaldo S Olive)

Avibras helicopter armament system combining 7·62 mm machine gun mounting and 7-round rocket launcher pod (Ronaldo S Olive)

Avibras twin machine-gun pod for 7·62 mm machine guns (Ronaldo S Olive)

Aircraft bombs

Five types of aircraft bomb are known to be in production in Brazil for its air forces and for export:



CHARACTERISTICS

AV-BAFG-120
Length: 1·8 m
Body diameter: 230 mm
Total weight: 120 kg (equivalent to US Mk 81)

AV-BAFG-250
Length: 2·2 m
Body diameter: 270 mm
Total weight: 250 kg
(equivalent to US Mk 82)

AV-BI-200
Length: 1·81 m
Body diameter: 420 mm
Total weight: 177 kg
(equivalent to US 400 lb fire bomb)

AV-BI-250
Length: 3·46 m
Body diameter: 400 mm
Total weight: 271 kg
(equivalent to US BLU-32)

Avibras LM-70/19 multiple launcher on Brazilian Air Force F-5E (Ronaldo S Olive)

AV-BI-375
Length: 3·63 m
Body diameter: 480 mm
Total weight: 362 kg
(equivalent to US BLU-27)

Avibras LM-70/7 multiple launcher on Brazilian Navy Wasp helicopter (Ronaldo S Olive)

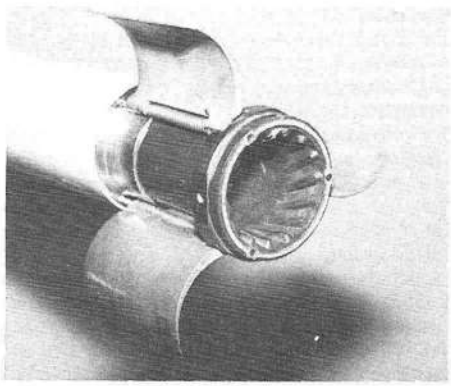
CANADA

4539.303
CRV7 AIRCRAFT ROCKET

Designed and developed by the Canadian Department of National Defence, the CRV7 2·75 inch (70 mm) wrap-around fin aircraft rocket operated by Canadian Forces aircraft is claimed to possess a number of advantages compared with similar rockets such as the Mk 4/40 series. These include: higher velocity, giving a flatter trajectory and three times the impact energy; greater stand-off range; more precise control of rocket motor ignition timing, giving reduced dispersion and enhanced accuracy; and improved aerodynamic stability through decreased deployment time for deployment of the wrap-around fins.

The CRV7 rocket weapon system has two motors: the RLU-5001/B (C14) and RLU-5002/B (C15). The C14 consists of a case-bonded high energy composite propellant which uses a hydroxyl-terminated polybutadiene (HTPB) binder with an 88 per cent solids content of ammonium perchlorate, aluminium and ferric oxide. This is primarily for fixed-wing use. The C15 motor is the same as the C14 with the exception that the aluminium powder is omitted. Consequently the production of primary smoke has been virtually eliminated. This is intended primarily for helicopter use. Weight of the assembled motor is 14½ pounds (6·6 kg). The propellant for both motors is an internal burning cylinder 83·8 cm long with a bore diameter of 20·5 mm.



The fibreglass/phenolic moulded nozzle has metallic inserts to provide strength, electrical contacts and a shear pin release system. Integrally moulded vanes induce spin prior to exit from the launcher. Aluminium wrap-around fins are fully deployed within 36 cm of exit from the launcher and further stabilise the rocket in flight.

Complete CRV7 rocket fitted with practice warhead

Loading CRV7 rockets into LAU 5002A/A launcher on BO-105 helicopter

Deployed wrap-around tail fins of CRV7 aircraft rocket and integrally moulded vanes in motor exit cone to induce spin

Operationally the CRV7 is fired from the 19-tube LAU-5003 A/A launcher. In training roles the CRV7 is fired from the six-tube LAU-5002 A/A. The SUU-20 bomb/rocket dispenser has been modified so that it is compatible with the CRV7.

The launchers are compatible with the standard 14-inch (35·6 cm) suspension systems, use standard intervalometers and the standard five-pin electrical connections all of which conform to STANAG 3763AA.

CHARACTERISTICS

Calibre: 70 mm
Length: 104·2 cm (without warhead)
Rocket weight: 6·6 kg (without warhead)
Action time: 2·2 s
Max thrust: 7 KN
Spin: 40 cycles/s (with 4·5 kg warhead)
Max velocity: 1250 m/s (a/c speed 540 KTAS, 4·5 kg warhead); 1500 m/s (a/c speed 540 KTAS, 3 kg warhead)
Effective range: Air-to-ground 6500 m; ground-to-ground 18 km

Launchers

LAU 5002A/A 6-tube re-useable training/operational launcher
LAU 5003A/A 19-tube disposable combat launcher
SUU 5003A/B 4-tube training dispenser

Warhead weights: 3, 4·5, 7 kg

A practice warhead, WTU 5001/B, has been developed specially for spinning 2·75 inch rockets. The design eliminates dynamic instability problems. It weighs about 4·25 kg and is also able to penetrate light and medium armour.

DEVELOPMENT

Development and flight proving was carried out by the Canadian Department of National Defence. Primary research was performed by the Valcartier Defence Research Establishment in association with Bristol Aerospace Ltd.

STATUS

The Canadian Forces have chosen the CRV7 as a replacement for earlier versions of the 2·75 inch rocket. In full production.

CONTRACTOR

Bristol Aerospace Limited, PO Box 874, Winnipeg, Manitoba R3C 2S4, Canada.

CHILE

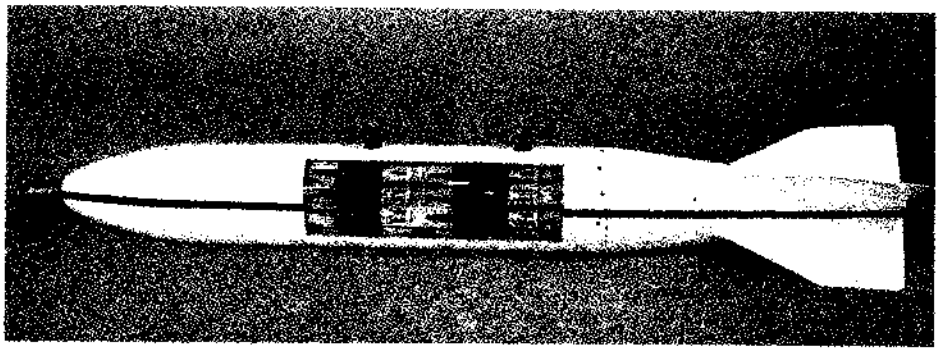
4426.303
PJ-1 MANUALLY OPERATED BOMB

The PJ-1 is a manually dropped bomb which can be used from almost any type of aircraft or helicopter and also allows civil aircraft to be used in an emergency. It measures 500 mm long by 85 mm in diameter and weighs 3 kg including 800 grammes of high explosive. The main explosive charge is surrounded by 110 steel fragments which are projected to an effective operating range of 35 metres.

The bomb is of simple construction and safety is ensured through safety locks which do not allow the fuze to activate until three seconds after leaving the aircraft. The head may be copper covered to allow perforation of armoured vehicles or installations, or alternatively fitted with a hollow charge device to give considerable anti-armour effect.

CONTRACTOR

Cardoen Explosivos, Providencia 2237, Santiago, Chile.



Cardoen PJ-1 bomb with storage and transportation container

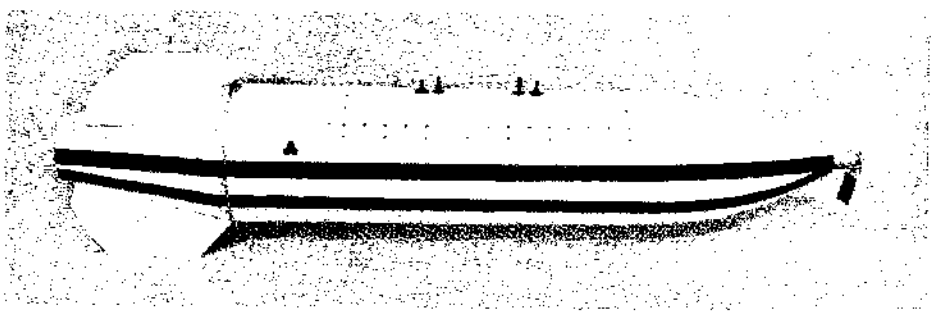
4598.303
CB 130 & CB 500 CLUSTER BOMBS

Promising experience with the earlier Cardoen 100 lb and 500 lb cluster bombs (**4427.303** and **4487.303** in the *1983-84* edition) led the company to embark on development of improved models, the CB 130 and CB 500 which are 130 lb and 500 lb cluster bombs respectively. Both feature bomblets of a new indigenous design and a new programmable fuze designed by Cardoen.

Using these bombs, low or high altitude attacks can be made at high aircraft speeds against targets dispersed over wide areas without the need for extreme delivery accuracy. After release, the bombs are opened in mid-air by an electronically programmed fuze, and a number of armour-piercing bomblets are dispensed; 50 from the CB 130, and 240 from the CB 500. The surface area covered by the bomblets has an elliptical shape of between 15 000 and 50 000 square metres, depending on the size and operational use of the bomb. Release height also has a considerable effect. The altitude at which the bomb opens after release is controlled by the programmable electronic fuze which provides a variety of opening delay times.

CB 130 cluster bomb with cutaway skin

The Cardoen bomblet is intended for use against tanks and armoured vehicles, troop concentrations etc. It is stated armour plate of more than 203 mm can be penetrated. Used against troop concentrations, shrapnel spreads over an area of up to 50 000 square metres. The complete cluster bomb is intended to withstand sustained forces of 6 g encountered by combat manoeuvres of a high speed attack aircraft. The CB 130 and CB 500 are fitted with lugs for the standard NATO 14 inch, Warsaw Pact 250 mm spaced suspensions and the single point bomb lug.



CHARACTERISTICS

	CB 500	CB 130
Type		
Length	2·64 m	2·05 m
Diameter	446 mm	253 mm
Fin span	650 mm (closed)	-
	1140 (open)	400 mm (open)
Weight	245 kg	60 kg

Fuze: Nose mounted, adjustable delay 3 - 18 s
Bomblet (for both versions)
Weight: 740 g
Length: 360 mm
Diameter: 48 mm
Tail diameter: 48 mm

STATUS
Production.

4488.303
CARDOEN GENERAL-PURPOSE BOMBS

Cardoen manufactures a standard range of general-purpose aircraft bombs suitable for use with bomber or fighter aircraft. Various sizes are produced, standard items being the 250 lb (113 kg) Mk 81, 500 lb (227 kg) Mk 82, and the 1000 lb (454 kg) Mk 83. All are constructed of forged seamless steel bodies with a tempered steel nose section and cruciform tail assembly for flight stabilisation. Standard explosive fillings are employed and mechanical time fuzes are fitted normally. Bombs are provided with NATO standard coupling eyebolts at 14-inch (35·6 cm) centres.

STATUS
Production.

CONTRACTOR
Cardoen Explosivos, Providencia 2237, Santiago, Chile.

Cardoen GP bombs are produced in three standard sizes: 250 lb, 500 lb and 1000 lb

CHINA (PEOPLE'S REPUBLIC)

4437.303
57 mm AIRCRAFT ROCKET

Among the range of aircraft armament indigenously produced in the People's Republic of China, the 57 mm aircraft rocket is employed on Chinese-built F6 fighter/ground attack aircraft for use against either aircraft targets or surface targets such as naval craft or battlefield strong points, tanks, personnel concentrations, fuel dumps etc. On the F6 aircraft the 57 mm rockets are carried in underwing pods, each of which contains eight rounds. These may be fired (electrically) separately or in salvo. The rocket is stabilised in flight by a set of folding tail-fins.

CHARACTERISTICS
Calibre: 57 mm
Length: 915 mm (overall)
Span: 230 mm
Weight: 3·992 kg (complete)
Warhead weight: 1·372 kg (HE)
Operating temperature range: +50 to -60° C

STATUS
Production.

AERO-AMMUNITION 30-1

The F6 fighter aircraft mentioned above has as its normal armament three 30 mm cannon and weapons of this calibre are found on other aircraft of the Republic's air forces. A range of ammunition is manufactured for use in 30 mm cannon against air and surface targets; standard types include: high explosive incendiary tracer (HEIT), high explosive incendiary (HEI), armour piercing explosive (APE), and practice. All types are supplied with cartridge cases of 70/30 brass.

CHARACTERISTICS

Type	HEIT	HEI	APE
Calibre	30 mm	30 mm	30 mm
Weight of round	840 g	840 g	828 g
Total length	266 mm	266 mm	266 mm
Projectile weight	418 g	418 g	407 g
MV	795 m/s	795 m/s	800 m/s
Pmax (kg/cm²)	3050	3050	3050
Penetration	—	—	10 mm*

*Penetration means the depth of penetration of the shell when encountering a uniform steel target at a distance of 50 to 75 m with a velocity of 360 m/s and an angular incidence of 30°.

STATUS
Production.

TBA 68 mm AIRCRAFT ROCKETS

Thomson Brandt Armements (TBA) produces a variety of 68 mm aircraft rockets to suit a number of operational requirements, and suitable for use with different classes of combat aircraft.

Two generations of rockets are currently available:

(1) The explosive warhead rocket, the effectiveness of which results from impact on the target, and which is designed for a direct hit. This generation includes conventional warhead types such as the anti-armour rocket with hollow charge and the anti-equipment and personnel rocket with a fragment sheaf.

(2) The multi-projectile warhead rocket, multi-dart, with an armour-piercing capability.

Both generations are detailed in the table (below) but the following paragraphs relate principally to second generation rockets.

The latter is an area weapon. It is fired in ripples with a stand off range from 2000 m to 4000 m. The effectiveness of the multi-dart warhead results from the ejection of a large number of sub-projectiles, long darts with an L/D ratio of 10:1. These armour-piercing darts, organised in series of tight sheaves, horizontally scatter over large areas and strike vehicles in the vicinity with a high velocity. Even when fired 'on a pass' this area weapon does not require any stabilised aiming: the sheaf scatters over a vertical area, 40 m wide and 15 m high. The warhead is fitted with an electronic fuze, the electro-mechanical pyrotechnic train of which is cut off. The timer is adjusted from 1 to 19 seconds (1 or 2 steps). The explosive warhead is fitted with a piezoelectric impact detector.

This universal armament, which can be adapted to any combat aircraft, is used with Matra 155 (Matra F4) and Matra F2 rocket launchers, (first generation rockets).

STATUS

Mass production. Since 1955 at least 3 million explosive charges have been made for first generation rockets. Second generation rocket development continued from 1977-1979, and qualification from 1982 to 1984.

CONTRACTOR

4834.303

MULTI-DART HELICOPTER ANTI-ARMOUR SYSTEM

Recent advances in fire control techniques have made it possible to develop a new weapon system for attack helicopters such as the Eurocopter HAP, AH-64, UH-60, Cobra, Augusta 129, and after modification, the Puma, Dauphin, Gazelle, BO 105 etc. The system employs 68 mm aircraft rockets with multi-dart warheads and is called the Multi-Dart rocket system by Thomson Brandt Armements (TBA).

In addition to the fire control unit, the system consists of: a specific rocket launcher and a multi-projectile munition. The munition is made of two parts: (a) a multi-projectile armour-piercing warhead using kinetic energy to acquire its piercing power, and (b) an improved F2 type 68 mm rocket motor.

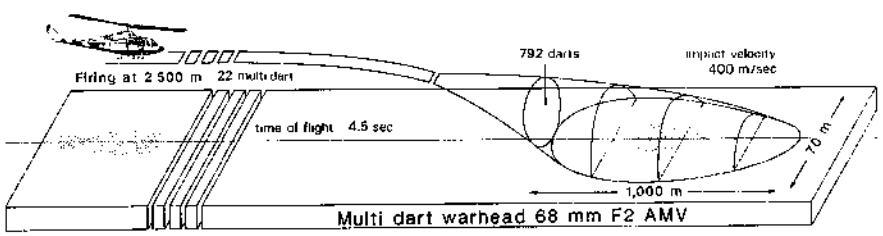

Diagram of Multi-Dart helicopter ground attack pattern

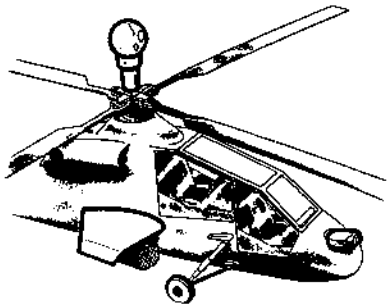
Each tube of the rocket launcher is fitted with an electronic remote control which sends an electromagnetic impulse to the warhead fuze. The transmitted signal defines the trajectory time of flight before the burst of the military payload: dart sub-projectiles (other versions can use flares and decoys).

OPERATION

The warhead is controlled by a remotely settable time fuze. At a preset time after the rocket motor has functioned, the head ejects a sheaf of armour-

piercing projectiles in the vicinity of the target. The programmed time of flight is initiated from the cockpit through a manual operator box or through the fire control system.



Considerable penetration is the result of the dart thinness (L/D ratio 10:1) and of the very high velocity provided by the new composite propellant 68 mm rocket motor. The darts have an impact velocity of 600 to 300 m/s:

AMV darts (anti-equipment and vehicle), diameter: 9 mm, weight 35 g, perforate 8 mm of steel plate

ABL darts (anti-light armour), diameter 13·5 mm, weight 190 g, perforate 10 mm of steel plate

The useful range varies from 2000 to 3000 m. This weapon is a current threat to armoured air defence vehicles and all armoured infantry fighting vehicles.

Munition characteristics are essentially the same as those given in the table in **4833.303**, above, apart from a reduction in maximum range of 2000 m for first generation rockets and 1000 m for second generation rockets when used in the helicopter application, and a slightly lower maximum impact velocity (600 m/s) in the latter role.

Impression of Multi-Dart RS helicopter anti-armour system

The new Multi-Dart 68 mm munition is fired in ripples, 12 to 18 shots, from new TBA rocket launchers (compatible with the first generation rockets, SNEB 68 mm, **4542.303**, below). Three versions of rocket launcher will be available, according to the carrying capacity of helicopters:

Type 68.12 L: Capacity 12 munitions
Type 68.22 L: Capacity 22 munitions
Type 68.36 L: Capacity 36 munitions

STATUS

Mass production. First generation rockets began development in 1977 and production commenced in 1979. Second generation development followed with mass production starting in 1981.

CONTRACTOR

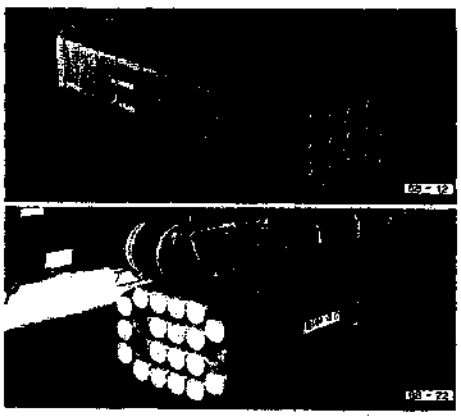
Thomson Brandt Armements, 52 avenue des Champs-Elysées, 75008 Paris, France.

4542.303

TBA 68 mm HELICOPTER ROCKET LAUNCHERS

Several sizes of launcher have been developed by Thomson Brandt Armements (TBA) for the use of 68 mm SNEB aircraft rockets from helicopters for ground attack roles. Similar construction methods are used for the three current sizes, which are capable of firing 12, 22 or 36 rockets. The tubes are grouped together to form a single unit which can be mounted on the helicopter by standard NATO 14-inch (356 mm) suspension lugs, or saddle suspensions. The principal features of the existing range are given in the following table.

CHARACTERISTICS



Type	68-12	68-22	68-36
Number of tubes	12	22	36
Length	120 cm	120 cm	140 cm
Width	31 cm	45 cm	60 cm
Height	26 cm	33 cm	40 cm
Weight empty	23 kg	50 kg	83 kg
Weight loaded	75-100 kg	145-190 kg	310-390 kg
Firing rate		300 rounds/minute	
Power supply		22-30 V DC/5A

Thomson Brandt Armements helicopter rocket launcher units

4835.303

TBA 100 mm AIRCRAFT ROCKETS

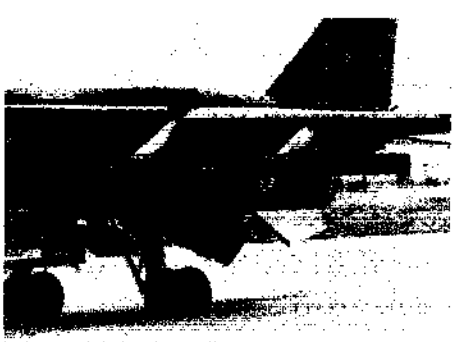
Thomson Brandt Armements (TBA) has a range of 100 mm aircraft rockets, similar to the company's 68 mm rockets (**4833.303**). Two generations of rockets are currently available:

(1) The explosive warhead rocket, the effectiveness of which results from impact on the target and which is designed for a direct hit: (ECC) the anti-armour rocket; (DEM) the demolition and anti-shelter rocket; and (EEG) the anti-equipment and personnel rocket.

(2) The multi-projectile warhead rocket, multi-dart, with an armour-piercing capability.

The latter is an area weapon. It is fired in ripples with a stand off range from 2000 m to 4000 m, at a very low altitude. The effectiveness of the multi-dart warhead results from the ejection of a high number of sub-projectiles, long darts with an L/D ratio of 10:1. These armour-piercing darts, organised in series of tight sheaves, horizontally scatter over large areas and strike all vehicles they encounter with a high velocity.

The 100 mm multi-dart warhead exists in three versions:



(a) Six darts AB 24 (anti-armour), armour-piercing power: 80 mm of steel plate

(b) 36 darts ABL (anti-light armour), armour-piercing power: 115 mm of steel plate

(c) 192 darts AMV (anti-equipment and vehicles), armour-piercing power: 8 mm of steel plate

Even when fired on a single pass this area weapon does not require any stabilised aiming; the sheaf scatters over a vertical area, 40 m wide and 15 m high.

This universal munition, which can be adapted to every combat aircraft, is used with TBA 100·4 or Matra C6 rocket launchers.

TBA 100 mm rocket launcher pods on Jaguar aircraft

BRANDT 100 mm ROCKET LAUNCHERS
In addition to supplying 100 mm rockets to the producers of a variety of rocket pods and launchers the Brandt Armements organisation also manufactures its own launcher pods. The Type 100-4 (F3) is intended for use with any of the Brandt 100 mm diameter aircraft rockets described in **4835.303**, above, and is available in both four- and six-tube versions. Both are suitable for mounting on all aircraft fitted with standard NATO 14-inch (356 mm) attachment points. The four-tube model has been selected by the French Air Force in which service it is known as the F3.
CHARACTERISTICS
Type 100-4 (F3)
Length: 290 cm
Width: 23 cm
Height: 24 cm
Weight: 70 kg (empty); 240 kg (loaded)
Rate of fire: 400 rounds/minute
Number of tubes: 4
STATUS
Production.

3867.303
HELICOPTER GUN MOUNTING 19A001
The 19A001 mounting is designed for use in SA 330 Puma helicopters to carry a 20 mm automatic gun Type 621 which is located in the right-hand fuselage door of the helicopter, enabling the machine to be used for attacking ground troops, armed reconnaissance, and similar air support actions. The Type 621 automatic gun is equipped with the left-hand flat feed mechanism, and a muzzle brake with two vent ports. The gun is supported in a monobloc cradle with air suspension assemblies. The ammunition supply consists of four boxes of 240 rounds and the gun is fitted with an SFOM optical sight. Firing is under the pilot's overriding authority and an ADS CPL8 control box is provided which enables firing in a free mode, or in eight-shot limited bursts at a rate of 740 rounds/minute. There is compensation for aerodynamic forces acting on the gun by means of an adjustable device which is electrically and mechanically controlled. There is electro-mechanical locking of the fork after azimuth setting.
CHARACTERISTICS
Calibre: 20 mm
Elevation: +5 to -40°, relative to aircraft floor
Azimuth: +45° from axis of aircraft R/H door port
Ammunition: 4 × 240 rounds
Weight of mounting with gun: 165 kg
Overall weight: 632 kg (with 960 rounds)
STATUS
Series production. Operational with the French Army.
CONTRACTOR
GIAT (Groupement Industriel des Armements Terrestres), 10 place Georges Clémenceau, 92211 Saint-Cloud, France.

M621 20 mm automatic gun mounted on helicopter

1271.303
30 mm AIRCRAFT GUN DEFA 552A
The 30 mm DEFA gun is the French development of the German Mauser revolver gun principle and is similar to, and virtually interchangeable with the British ADEN Mk 4. Over 10 000 units have been manufactured and the gun has been proved in combat in a number of theatres. Since 1971 a long-life version has been developed, called Canon Automatique de 30 mm, 550-F2A (DEFA 552A) which replaces the gun type 552 and with which it is directly interchangeable.

The principal characteristics of the DEFA 552 and the DEFA 552A are light weight, a rate of fire of 1200 rounds per minute, and provision for automatic recocking in the event of a stoppage. The gun uses 30 mm ammunition developed for the DEFA/ADEN weapons which is available in the usual variety of types: armour piercing, HE incendiary, etc. Belted ammunition may be fed to either side of the gun. Spent cases are ejected from the same side of the weapon as accepts the feed. Links are ejected on the opposite side. The ammunition is electrically ignited.

The DEFA 552 revolver gun incorporates safety devices to ensure that firing is impossible unless the cartridge is in the firing position and the control slide, which carries the round firing contact, is in the forward position. In operation the whole gun recoils about 12 mm. On the ground a special device is used to cock the gun by hand. A single pyrotechnic cartridge is provided for automatic recocking during firing if a stoppage should occur.

CHARACTERISTICS
Calibre: 30 mm
Gun weight: 81 kg
Rate of fire: 1300 rounds/minute
Chrome barrel life: 5000 rounds
STATUS
The DEFA 552 and DEFA 552A cannon are in service with the French Air Force, the Israeli Air Force and others throughout the world. Two 552s are standard equipment on all Mirage III and Mirage Vs, and other aircraft types fitted include the Jaguar, Etendard IV M, Fiat G91 and Super-Etendard.
CONTRACTOR
Groupement Industriel des Armements Terrestres (GIAT), 10 place Georges Clémenceau, 92211 Saint-Cloud, France.

1273.303
30 mm AIRCRAFT GUN DEFA 553
The DEFA 553 30 mm aircraft cannon is a direct development of the DEFA 552. Its performance is similar to the 552 but design modifications have been made to improve service life and facilitate installation. A new barrel in nitro-chrome steel is used with a muzzle device to reduce muzzle pressure. Other changes have been made to simplify installation and the DEFA 553 weapon will now accept ammunition feed from either side without modification.

Other features, including in-flight recocking, correspond to the DEFA 552 model, and the same ammunition is used.

The electric control for the DEFA 553 provides the following facilities.

'OFF' – firing of the gun completely inhibited.
'Continuous fire' – not normally used in action.
'0·5 s' – maximum continuous burst length 0·5 s.
'1 s' – maximum continuous burst length 1 s.

In twin installations a unit is needed for each gun and an additional control and junction box providing:

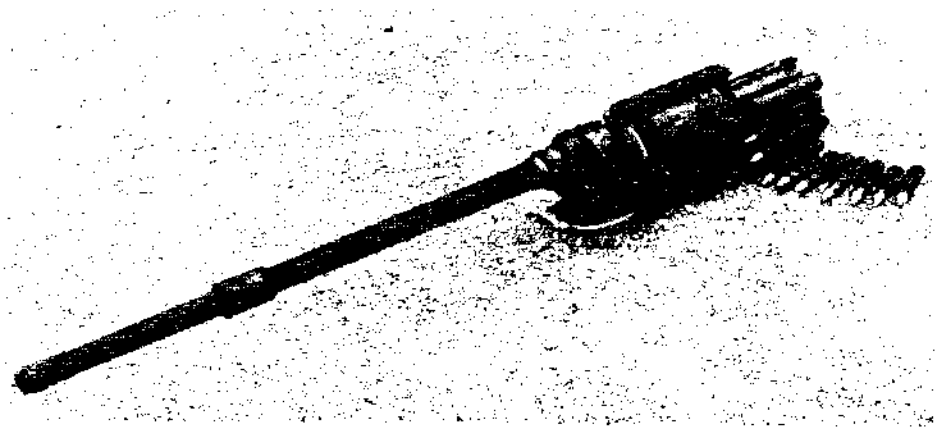
Position 1 – both guns inhibited.
Position 2 – continuous fire, both guns.

Position 3 – both guns in burst lengths (which may be different) set into each individual control unit.
Position 4 – gun camera switched on

CHARACTERISTICS
Calibre: 30 mm
Gun weight: 87 kg
Rate of fire: 1300 rounds/minute
Chrome barrel life: 5000 rounds

STATUS
The DEFA 553 cannon is in production and is fitted in Mirage F1, Jaguar, Alpha-Jet, Macchi 339K, Casa 101, and Pucara aircraft

CONTRACTOR
Groupement Industriel des Armements Terrestres (GIAT), 10 place Georges Clémenceau, 92211 Saint-Cloud, France.



5246.303
30 mm AIRCRAFT GUN DEFA 554

The new DEFA 554 lightweight aircraft gun is a further development of the DEFA 553 (**1273.303**) gun and has been designed for installation on high performance aircraft. It has already been selected for the Mirage 2000 fighter and each of these will have two fuselage mounted guns. The gun, which can also be pod mounted, weighs only 85 kg and has two rates of fire, 1800 rounds a minute for use in the air-to-air role and 1100 rounds a minute for the air-to-ground role. Muzzle velocity is about 820 m/s.

CHARACTERISTICS
Calibre: 30 mm
Gun weight: 80 kg (approx)
Rate of fire: 1800 rounds/minute

STATUS
Development.

30 mm aircraft gun DEFA 554

1275.303
AIRCRAFT GUN 20 mm M.621

The M.621 20 mm cannon is a versatile weapon developed in France by Manufacture Nationale d'Armes de Tulle, the national armaments factory. The weapon is particularly suitable for helicopter and light aircraft mounting because of its light weight and low recoil forces.

The M.621 utilises 20 mm ammunition which is interchangeable with the US M56 series used in the Vulcan cannon. It is electrically ignited and a full range of types is available: armour piercing, incendiary and fragmentation. Steel and brass cartridge case versions are manufactured. On firing, cases and links are ejected from the gun either downward or to the side according to installation.

Provision is made for left- or right-hand belt feed, and for special application, ammunition of different types can be fed to each side of the gun and selected at will by the gunner. The rate of fire is either 300 or 740 rounds per minute. Provisions can also be made for firing single shots.

Initial cocking of the gun is by cable, but provision is made for automatic recocking by pyrotechnic cartridge. This is available once only and is automatically triggered after a 0·3 s delay on firing. While firing, the whole gun mechanism including the barrel recoils, sliding on guide rails which are part of the mount cradle.

A variety of mountings and accessories are available to adapt the M.621 to different applications. One such is a gun pod which is under development and designed for installation on helicopters and light aircraft for attacking enemy ground forces, lightly armoured vehicles and helicopters. It contains 150 rounds of belted ammunition and has a rate of fire of 740 rounds per minute. Attachment is by standard NATO 14-inch (356 mm) pylons, overall length is 2810 mm and weight with ammunition is 140 kg. Other applications are a pintle mount for use in helicopters with shields for the gunner, chutes for spent cases and links, and a reflector sight mounted above the breech mechanism. In applications where minimum recoil force is essential a muzzle brake can be fitted in place of the flash eliminator. By this means, and using a shock absorbing mounting, the average recoil force can be reduced from 400 to 250 kg.

CHARACTERISTICS
Calibre: 20 mm
Gun weight: 47 kg
Muzzle velocity: 980 – 1030 m/s
Rate of fire: 740 or 340 rounds/minute
Accuracy: 80% rounds inside 2 mils (hard gun mount)
Length: 2207 mm
Round weight: 0·32 kg
Projectile weight: 0·1 kg
Range*: Over 1500 m
Average recoil force: 400 kg
*Gun stationary

STATUS
In production, and using specific mountings it has been fitted on Alouette III, Puma and Gazelle helicopters. A pod containing the M.621 gun and 140 rounds is also available for light aircraft and helicopters. The 20 mm M.621 is also used in ground applications.

CONTRACTOR
Groupement Industriel des Armements Terrestres (GIAT), 10 place Georges Clémenceau, 92211 Saint-Cloud, France.

3865.303
BM 400 MODULE BOMB

The BM 400 module bomb is designed as a low altitude air-to-ground area saturation weapon for the destruction of targets such as armoured vehicles, road or rail convoys, ammunition dumps, racars, missile launchers and similar high value equipments. This is achieved by successively ejecting three modules from the bomb body after its release, at preset times. Each module consists of a pre-fragmented warhead. The tail parachute, attached to each bomb module, slows it and ensures that its final descent onto the target is almost vertical.

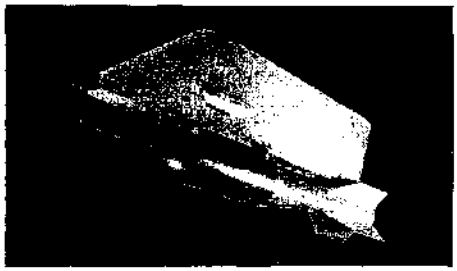
On impact with the ground, each anti-armour module ejects a horizontal sheet of high velocity calibrated fragments. Two fragment generators are available comprising respectively about:
(1) 800 main fragments, able to perforate 17 mm of steel at 50 metres from the explosion point (12 mm at 100 metres)
(2) 1500 main fragments, able to perforate 12 mm at 50 metres from the explosion point (7 mm at 100 metres)

An area of 600 metres long by 100 metres wide (or more depending on the perforation power and fragment density needed) can be covered using only two 400-kg modular bombs with suitable module spacing. Launching can be effected either by releasing the bomb(s) from an aircraft flying over the target area, or by the "toss bombing" method. The stand-off range of the bomb varies from 500 metres to more than 5 km. To increase this stand-off capability, a rocket booster is fixed at the rear part of the bomb. Ranges of 10 km have been achieved in this way.

Mirage 2000 wing stations carry six BM 400 module bombs for ground attack and a pair of Magic air-to-air missiles

CHARACTERISTICS
Length: 3·2 m
Diameter: 0·32 m
Weight: 390 kg

Weight of single module: 100 kg
Number of modules: 3
Attack altitude: 30 m
Launching speed: 350 - 600 knots



STATUS
Production.
CONTRACTOR
Thomson Brandt Armements, 52 avenue des Champs-Elysées, 75008 Paris, France.

3864.303
RETARDED 125 kg CLOSE SUPPORT BOMB

The 125 kg retarded close support bomb developed by Thomson Brandt Armements has two main elements: an impact fuze, and a retarder package. The company designed an impact fuze/retarder package for use with standard 125 kg fragmentation bombs to enhance their tactical performance and versatility. The 125 kg model derives from the fragmentation bomb type 81A thick wall ammunition, designed to scatter numerous fragments and manufactured by Thomson Brandt for the French Air Force.

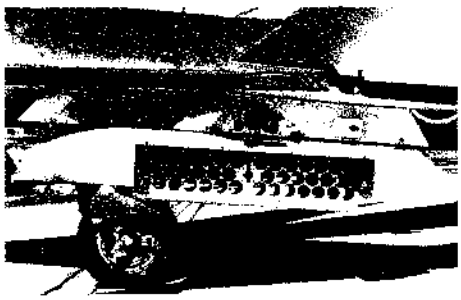
The complete package comprises two distinct parts, the fuze which is inserted into the bomb, and the retarder tail that is attached to the rear of the bomb body.

Retarder Unit. Specially designed by Thomson Brandt for the 125 kg bomb, the retarder tail unit appreciably improves the aerodynamic efficiency of the bomb. A near-vertical final trajectory is achieved by use of a parachute retarder which is locked into the bomb body only after appropriate safety measures have been completed. The parachute opens after a preset delay, which is selected on the ground before take-off, according to mission requirements.

Retarded 125 kg close support bomb under pod

Thomson Brandt Armements FP 78 fuze

CHARACTERISTICS
Length: 770 mm (outside bomb body)
Span: 310 mm (packed); 640 mm (deployed)
Weight: 12 kg
Parachute delay: 13 - 17 s (preset on ground)
FP 78 Fuze. This is a high sensitivity super-rapid impact type, which can also be used with standard 250 kg bombs. It ensures that the bomb will explode at optimum height by means of a rod which extends from the nose of the weapon. Arming of the fuze is achieved at a safe distance by means of a faired air-driven motor and an accelerometer-based locking device after removal of the mechanical safety actuated by a pylon sensor.
CHARACTERISTICS
Length: 450 mm (350 mm clear of bomb body)
Weight: 2·6 kg
Safety arming delay: 7 s for 125 kg bomb at 500 knots



STATUS
The complete fuze/retarder package is in production.
CONTRACTOR
Thomson Brandt Armements, 52 avenue des Champs-Elysées, 75008 Paris, France.

4486.303
ALKAN GROUND ATTACK CARTRIDGE LAUNCHERS

Alkan ground attack cartridge launchers are designed as simple, low-cost ground attack weapons for use on various categories of aircraft, ranging from light machines such as the SIAI-Marchetti SF260 to higher performance types like the Super Etendard and the Mirage. As an external pod, the launcher system is fitted on any pylon equipped with standard 14-inch (356 mm) spaced ejector hooks and it is also compatible with rocket launchers. In operation a ground attack is made at the aircraft's upper speed limit in horizontal flight and at very low altitude over the target to minimise exposure to defensive fire. A wide range of cartridges to suit roles such as illumination, anti-armour, anti-personnel, countermeasures etc are produced. The anti-tank grenades are hollow charge munitions which can be parachute-retarded to ensure that they drop onto the target nearly vertically. They have a penetration potential of 200 mm of armour. The anti-light vehicle cartridges have an effective range of about 15 metres.

Launchers also are produced in a variety of sizes and configurations: the 500 model with 20 74 mm cartridges weighs 74 kg fully loaded and is designed for light aircraft (eg SIAI-Marchetti SF260); the 530 model has a capacity of 40 cartridges of the same size, weighs 135 kg fully loaded and is already used with the Alpha-Jet, Mirage III, Super Etendard and others.

STATUS
In production and service.
CONTRACTOR
R Alkan et Cie, rue du 8 mai 1945, 94460 Valenton, France.

Model 430 ground attack cartridge launcher on an Alkan pylon of a Super Etendard (launcher open for loading)

4836.303
FEU 80 ELECTRIC MULTI-PURPOSE BOMB FUZE

Existing stocks of older free fall aircraft bombs are retained for use as conventional or retarded HE bombs, and to maximise their operational usefulness Thomson Brandt Armements (TBA) offers the FEU 80 fuze which was developed for new generation bombs but can be fitted to earlier munition stocks. Four versions are available:

FEU 80 BO: impact nose fuze
FEU 80 BC: impact tail fuze
FEU 80 PRLF: adjustable proximetric fuze
FEU 80 RA: radio altimeter fuze

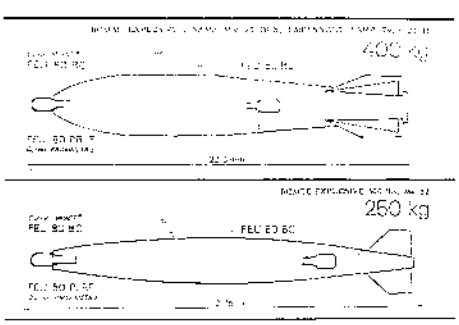
The FEU 80 fuze can fulfil by itself the missions previously requiring the use of two old generation fuzes (nose and tail). It fills all requirements and works in any climatic conditions.

All the functions, except those of the release systems are performed through electro-mechanical or electronic circuits ensuring safety, reliability, adaptability and effectiveness.

Safety, both when stored and when mounted, is ensured through the total absence of power in the arming mechanism and firing circuit; the presence of visual-check mechanical locks; and immunity to electro-magnetic radiation.

Reliability is guaranteed through: electronic circuits which can be checked automatically without destructive effects, being air tight and water-tight when mounted and on the ground (bombs as complete rounds can thus remain under the aircraft or placed on the ground out-of-doors); a calculated service-life of 20 years in a container; and the position of the firing and priming system inside the bomb. On account of this mechanical and electrical protection, operation is ensured after impact, irrespective of the hardness of the target.

Adaptability is ensured through the possibility of displaying the adjustable parameters without removing the fuze and modular design (straightforward adaptation of the fuze functions for use on new type bombs). The control circuits will permit in-flight adjustment of the arming-time, the priming delay and the explosion-height.



Effectiveness, using electrical power affords the possibility of priming the tail fuze with the firing order being generated remotely or on impact by the nose detector for greater effect in the event of an attack from above.

CHARACTERISTICS
Overall length: 122 mm
Diameter: 85 mm
Assembly thread diameter: 2 or 3 inches
Weight: 2·4 kg

STATUS
In series production. Entered service with French armed forces in 1984.
CONTRACTOR
Thomson Brandt Armements, 52 avenue des Champs Elysées, 75008 Paris, France.

FEU 80 multi-purpose bomb fuze

Typical FEU 80 bomb fuze fittings

3863.303
BAT 120 RETARDED BOMB

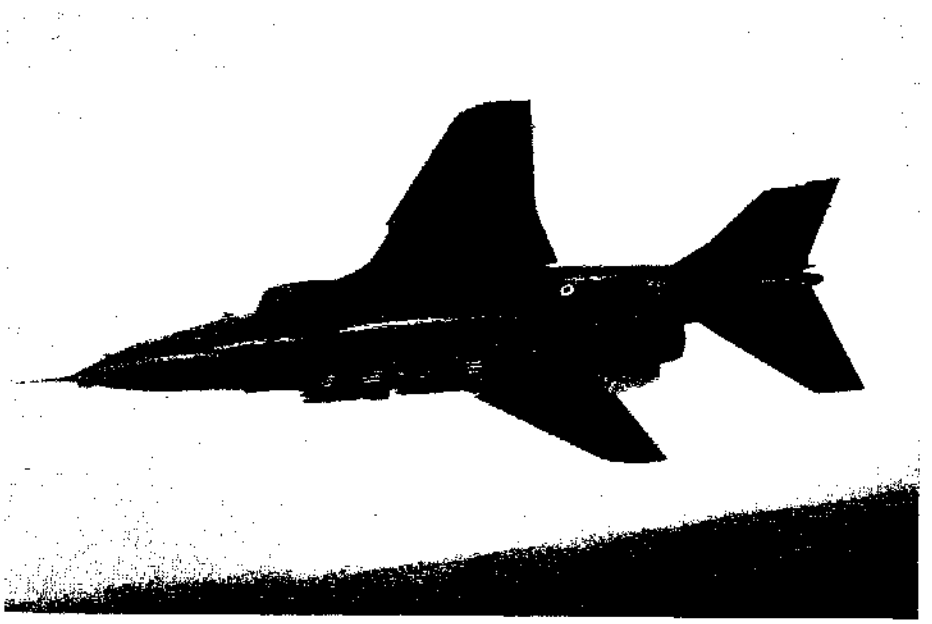
The Thomson Brandt BAT 120 is a 120 mm calibre parachute retarded bomb for close support (Bombe d'Appui Tactique) which is designed to engage various surface targets such as convoys of vehicles, parked aircraft and missile sites. With an incidence nearly vertical on impact with the ground, the BAT 120 bomb meets this requirement by scattering a horizontal sheet of calibrated fragments. Two different versions are available:

(1) AMV anti vehicle and equipment. This delivers more than 2600 main fragments regularly distributed and designed to perforate four millimetres of steel at a distance of 20 metres from detonation point
(2) ABL anti lightly armoured vehicle. This version ejects about 800 main fragments, each capable of penetrating eight millimetres of steel 20 metres from impact point.

In both cases, the explosion produces numerous secondary fragments which may be effective against many targets.

BAT 120 bombs are released in sticks, from the same Brandt adaptors as BAP 100 cratering bombs (**3152.303** below). For example, 72 BAT 120 bombs could be released using only four store stations on a single aircraft. An acourate intervalometer integrated in each adaptor ensures correct sequencing of bomb release.

BAT 120 tactical retarded bombs loaded on BAe Hawk aircraft



CHARACTERISTICS
Bomb length: 1·5 m
Weight: 34 kg
(This equates to about 125 kg for a 3-bomb load, with adaptor; 330 kg for a 9-bomb load, with adaptor; 740 kg for an 18-bomb load, with adaptor).
Release speed: 350 – 600 knots; 150 – 350 knots light aircraft versions.
Nominal release height: 80 m
STATUS
Series production.
CONTRACTOR
Thomson Brandt Armements, 52 avenue des Champs-Elysées, 75008 Paris, France.

3152.303
BAP 100 mm CRATERING BOMB

The Thomson Brandt Armements BAP 100 cratering bomb is specially designed to neutralise airfield runways and taxiways. It can be used against other hard targets such as highroads, concrete buildings and shelters.

A stick of bombs is released to provide a very high hit probability despite low level attitude aiming difficulties. In order to achieve one cut, it has been calculated and demonstrated that 12 to 18 bombs are needed depending on the aircraft sighting system and the size of the target. After a parachute braking phase, a rocket assisted acceleration phase ensures concrete penetration. The bomb explodes under the concrete slab thanks to an optimised delay. A long delay fuze bomb is also available.

Up to 18 bombs can be carried on a single pylon, using a specific multiple store carrier, which is for BAT 120 bombs (**3863.303**). A quick hooking system allows the loading of 18 bombs in less than ten minutes without any special training.

French Air Force Jaguar aircraft with 18 BAP 100 runway cratering bombs mounted on the under-fuselage attachment point

CHARACTERISTICS
Length of bomb: 1·8 m
Weight: 32·5 kg
HE weight: 3·5 kg
Release speed: 350 – 600 knots
Nominal release height: 65 m

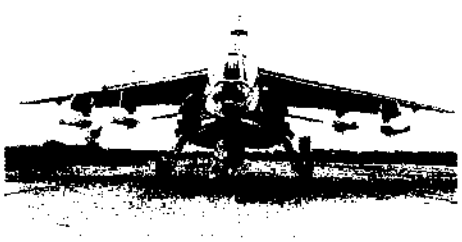
F-5 releases BAP 100 bombs

A similar version (37 kg), released at a nominal height of 80 metres against standard runways, is also available.

The main adaptors designed for the BAP 100/BAT 120 system are:

	Lug spacing	Maximum load	Total weight (kg)
14-3-M2	14 inches	9 bombs	320
14-10-3-M2	250 mm	9 bombs	320
30-6-M2	30 inches	18 bombs	710

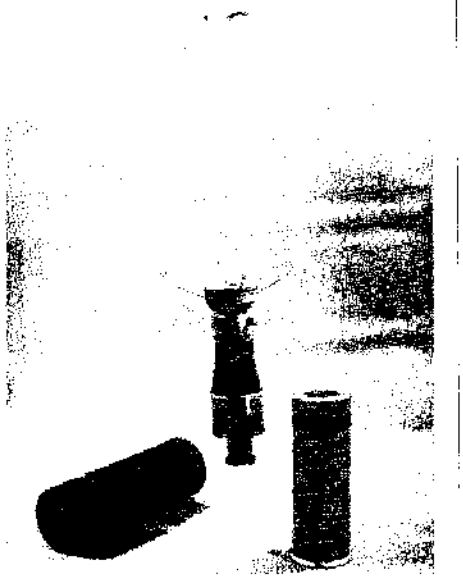
Two special adaptors (14-4-M2) are also used to carry and release 16 bombs on Alkan PM3 pylons (2 × 323 kg) for Mirage III and V aircraft.



STATUS
In series production and operated by five countries.

CONTRACTOR
Thomson Brandt Armements, 52 avenue des Champs-Elysées, 75008 Paris, France.

4597.303
THOMSON BRANDT 74 mm ANTI-ARMOUR GRENADE



Thomson Brandt produces a 74 mm cartridge that can be fired from all 74 mm diameter launchers (eg. Alkan types 501, 530 and 5120 associated with a multistore carrier CEM 1). It is an anti-armour munition, which can equip aircraft to attack armoured and ancillary vehicles, using a shaped charge grenade which has a significant secondary fragmentation effect. The grenade is retarded to increase the angle of attack thus effecting better target penetration.

CHARACTERISTICS
Calibre: 74 mm (cartridge); 70 mm (grenade)
Length: 214 mm (cartridge); 190 mm (grenade)
Weight: 2 kg (cartridge); 1·6 kg (grenade)
Release speed: 350 - 600 knots
Release height: 50 m
Main effect: >200 mm armour steel perforation
Secondary effect: lethal fragments up to more than 10 m

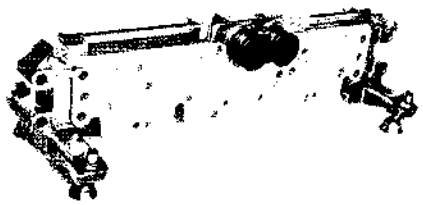
ALKAN STORE EJECTORS



Alkan pyrotechnic ejector release units (ERUs) meet the requirements of most kinds of stores whether fitted with the NATO 14 inch and 30 inch lug suspension system, with 250 mm-spaced lugs, or with some other suspension system.

The locking/unlocking of the hooks is obtained through toggle device with no overcentre system; the mechanism operation is therefore totally safe and independent of the hook-applied loads. The ejector's structure is generally made up of two half-shells, the one which positions and retains the mechanism, the other which serves as the cover and can be easily removed for inspection and maintenance. All components of the pyrotechnic subassembly are designed with a view to facilitating their maintenance and removal. The pistons can be retractable and telescopic (2 or 3 stages). These new generation ERUs can perform up to 50 firings between two cleanings.

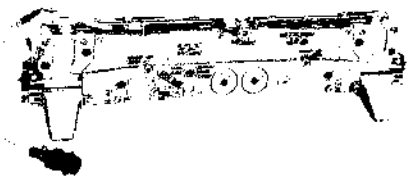
The type 165 and type 176/178 ERUs are designed conventionally, ie they are fitted with swaybraces and chocking screws. The 165 model has a very low height and is therefore particularly adapted for multiple store carriers and low pylons. The three-hook 176/178 models provide for both the 14 inch and the 250 mm lug suspension as well as the single lug store carriage.

The series of saddle system bomb racks includes a heavy duty unit, the type 155, and an automatic unit, the type 1005. The chocking system, eliminating the ejector arms, ensures significant aerodynamic reduction and excellent boresight retention.

A new generation of ERUs, the hook lifting series, is designed to equip modern combat aircraft with an improved store suspension system; the aerodynamic drag is greatly reduced by eliminating the chocking screws and having very small fixed swaybraces. The store is lifted up through its hooks by an appropriate mechanism ensuring the chocking with the necessary preload balanced between the fore and the aft hook on ground and in-flight. The new series of hooks lifting ejectors is mainly composed of the 1216 (for Mirage 2000) and its derivatives the 1218, the 1259 (meeting the USAF/USN joint requirements) and the heavy duty 1459 model. A light aircraft release unit also uses the same concept.

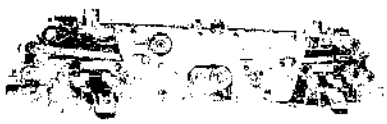
Alkan triple-hook ejector Type 176

ERU 1216
This very low height ejector release unit is used in the Alkan twin store carrier TSC 4035 and is being series produced to equip all the light duty pylons of Mirage 2000.
Ultimate load: 16 000 daN per hook; 12 000 daN per swaybrace
Weight: 10 kg
The derived model, type 1218, equips the TSC 4036, flight tested on the F-16 aircraft.



ERU 1259
This model complies with the US Air Force/US Navy specifications: automatic and independent hook-latching, practice bomb carrying capability, integrated safety handle, secondary release. Three integrated fuze arming units are mechanically connected to the unlatch mechanism. A store presence indicator is connected to the hook-lifting mechanism.
Ultimate load: 16 000 daN per hook; 15 000 daN per swaybrace
Weight: 9·57 kg
The 1259 ERU has been ground qualified and in-flight tested (carriage and firing) with the F-16 and F-16 XL (using a twin store carrier 4037).

ERU 1405
The 1405 ERU has been specially designed to equip the heavy duty centreline and inboard pylons of Mirage 2000, for which it is now manufactured in series.
Ultimate load: 18 000 daN per 14 inch hook; 32 000 daN per 30 inch hook; 15 000 daN per swaybrace
This ejector is fitted with semi-automatic, single point controlled articulated swaybraces.



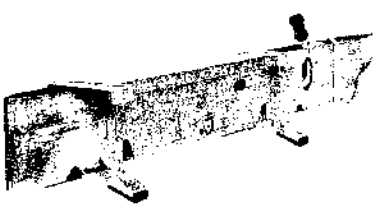
ERU 1459
This semi-automatic 14/30 inch heavy duty ERU is designed to be installed in the place of the MAU 12 or 40. Store chocking is ensured by the centrally controlled hook lifting system. The ERU 1459 has the same general features as the above-described 1259 model.
Ultimate load: 25 600 lb per 14 inch hook; 61 200 lb per 30 inch hook

ERU 1240
The ultra-light type 1240 ERU has been designed essentially for aircraft where pyrotechnic ejection is only required for emergency jettison. The store is chocked by two independent hook-lifting devices, a simple solution for lower load factors.
Weight: 4·99 kg

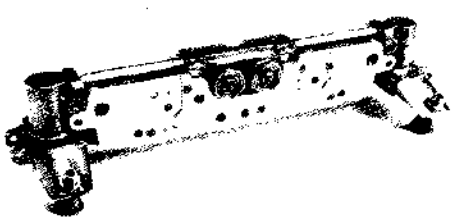
TYPE 6091 MAST
The Alkan type 6091 suspension mast has been designed to equip light planes and helicopters. It is mainly made up of an electromechanical release unit with an automatic hook latching mechanism and a lifting hook chocking system. For boresight harmonisation, the mast's support can be adjusted laterally (± 1 degree). After harmonisation, the weapon's boresight position is constant and repeatable, even after store removal and re installation.

Alkan Type 1259 ejector

Articulated swaybrace heavy duty ERU Type 1405 for Mirage 2000



Alkan Type 1459 ejector



Hook lifting ejector of the 1200 Series

Alkan Type 1216 hook lifting ejector

Alkan Type 6091 light aircraft mast

Low height light duty ERU Type 165

Carriage capacity: 500 lbs under 8591 MIL STD load factors
Weight: 10 kg
STATUS
Series production is in progress of the ERUs 1216, 1405 and the Type 6091 mast; series pre-production has begun of the 1259; and prototypes have been constructed of 1240 and 1459 equipment.
CONTRACTOR

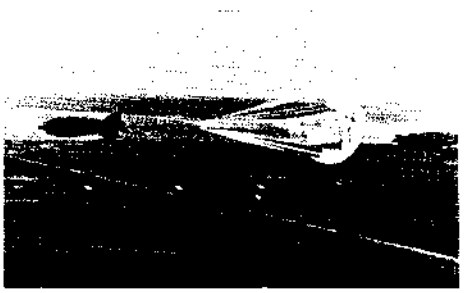
Alkan semi-automatic crutchless ERU Type 1005

3866.393
ALKAN TWIN-STORE CARRIERS
A new generation of twin-store carriers has been developed by Alkan, based on their small lightweight, semi-automatic ejector release units (ERUs). Their main feature is the small frontal area resulting from the ERU's reduced volume which gives optimum drag characteristics and carrying capacity/weight and dimensions ratio. They are designed for the carriage of any NATO-standard bombs and more particularly the laser-guided bombs which require special structure arrangements for their nose and tail guidance surfaces.
TSC 4010
The type 4010 twin store carrier can carry two 500 lb bombs fitted with either 14 inch or 250 mm spaced lugs. Specially designed for the BAe Hawk aircraft, with which it has been successfully flight tested, it is in series production and can be adapted to various training and light ground attack aircraft types.
TSC 4035
Fitted with 1216 ERUs, this model has a carrying capacity of up to two 500 lb bombs and is suitable for the Hunter aircraft and similar types. Pre-production has started.

Alkan TSC 4037 can carry up to 2 × Mk 81 bombs



Alkan TSC 4010

TSC 4036/7
These meet the requirements of the MSER-2 programme. Respectively equipped with type 1218 and type 1259 ERUs, with a carrying capacity of two 1000 lb bombs, aircraft types for which they are suited include: the A-4 Skyhawk, the F-16 (on which flight tests have been carried out, see photo), the F-111, Jaguar, Mirage 2000 and others. Pre-production has started.

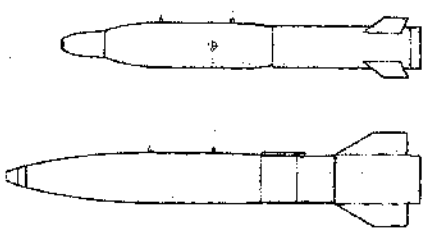
1514.393
MATRA TYPE 200 BOMB RETARDING SYSTEM
The Matra Type 200 bomb retarding system was approved for use by the French Air Force in 1964. It can be used with SAMP-made 250 and 400 kg GP bombs (**5214.303**). The equipment consists of a cruciform nylon parachute packed into a container within the tail of the bomb, together with the appropriate fuzing equipment according to the mission being flown and the characteristics of the retarding system. In typical operations the bomb is released at an altitude of about 30 m (100 ft) at a forward speed of between 400 and 600 knots. The bomb will then hit its target, exploding on impact, at a time when the attacking aircraft is about 480 m (1500 ft) ahead of the explosion. This ensures complete safety for the attacker. Provision can be made before loading the weapon on to the aircraft to adjust the fuze operation for different release conditions.

Comprehensive safety provisions are made in the Matra 200 system. The parachute is locked to the bomb body only after release has taken place, so that should the parachute deploy while the weapon is still being carried by the aircraft it will pull away before dangerous turning moments are built up by the drag of the 'chute'. Similarly the parachute does not open until it is well clear of the aircraft. Provision is also made for the parachute to rotate with respect to the bomb while it is in flight eliminating the possibility of parachute twist.

Nose and tail fuzes are fitted with the retarding mechanism. These normally operate in the 'instantaneous' mode unless safety requirements are not met, ie when parachute functioning, release altitude, and release speed are all correct. If safety requirements are not met then there is a danger that the attacking aircraft will be damaged by the bomb explosion, and the fuze is automatically set to operate after a delay of 15 s. Provision is made within the fuze to prevent inadvertent instantaneous explosion in the case of a ricochet when conditions required for normal operation have not been met and the system is operating within 15 s delay.
STATUS
In production and in service with the French and other Air Forces. By March 1983, 30 000 had been ordered, 95 per cent for export. In 1975 Matra introduced a new weapon, Durandal (**1999.303**), for this role.
CONTRACTOR
Matra SA, BP No 1, 37 avenue Louis Breguet, Velizy-Villacoublay Cedex 78146, France.

Type 200 retarded bomb

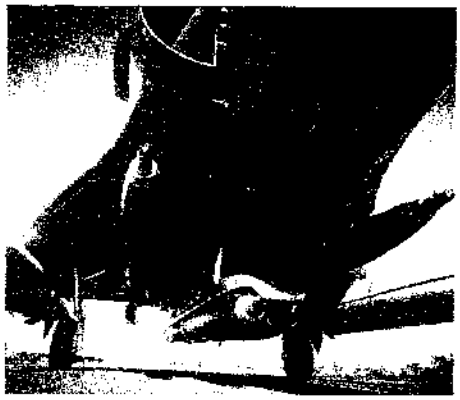


Release of Matra Type 200 retarded bombs by Mirage aircraft

4596.393
MATRA SFA BOMB RETARDING SYSTEM
The Matra 200 bomb retarding system (**1514.393**) has been in use since 1965 with a variety of 250 and 400 kg 'conventional' bombs of French and other manufacture. In order to extend the release envelope of such weapons to fit smaller bombs and also to permit air burst detonations, Matra has developed a new system, SFA, which consists of a new retarding and arming system.

SFA is designed to fit on SAMP 125 or 250 kg general purpose or reinforced splinter effect bombs and allows bombing from heights half those of earlier systems and over a much wider speed range (in particular low speeds). The SFA system permits bombing from a distance by delaying the retarding function.

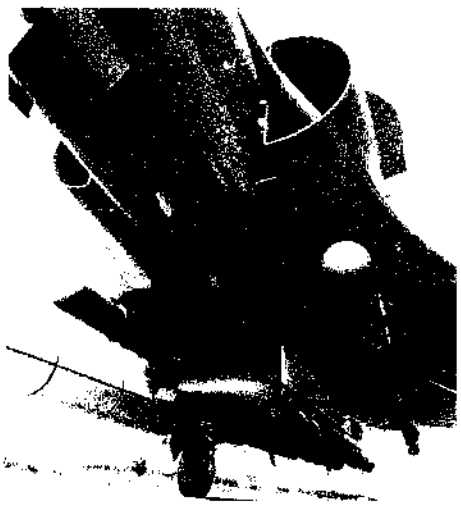
The system is delivered as a single rear-end unit to be connected onto the bomb frame as any



General arrangement drawing of Matra SFA retarding system fitting to SAMP 125 and 250 kg bombs

conventional tail unit would be. There is a choice of operating mode; a proximity fuze for initiating detonation above ground level, or an impact fuze for detonation on contact. Performance characteristics are adequate for release heights ranging from 20 to 30 metres, and permit diving bombing approaches. It is also possible to employ 'toss-bombing' stand-off attack techniques using the ability to vary the retardation delay from zero (ie at release) to 24 seconds.

Other adjustable parameters include: release speed, 350 – 650 knots; release height, down to 24 metres; and proximity or impact fuzing. Safety features ensure that detonation is inhibited if any of the following conditions are encountered: insufficient altitude, inadequate speed, parachute failure etc.



DEVELOPMENT
Development was undertaken by Matra as a private venture using company funding, and by early 1984 was virtually complete.
STATUS
The in flight qualification has been completed and production started.

Matra SA, BP No 1, 37 avenue Louis Bregeut, Velizy-Villacoublay Cedex 78146, France.

SFA 250 retarded bombs on Mirage 2000 aircraft

1999.303
DURANDAL PENETRATION BOMB
The Matra Durandal penetration bomb, developed in co-operation with Thomson-Brandt and SAMP, has been designed particularly for the disablement of airfields by low-level bombing attacks in which the objective is to render the runways unusable for a long period. Naturally it can also be employed against other targets of a similar nature. The technique of Durandal consists of an initial rapid retardation of the bomb after release until it adopts the optimum non-ricochet angle, followed by prompt acceleration to a very high impact velocity to ensure penetration of the runway. It is stated that concrete slabs up to 40 cm thick can be penetrated in this way. The ensuing explosion of the warhead from beneath the runway surface results in extensive damage over a wide area because of the heave effect, according to the makers.

Durandal system qualification has already been carried out for the Mirage III, Mirage 5, Mirage 2000 and Jaguar aircraft and adaptation and qualification testing under other aircraft are continuing. The Mirage III or 5 can carry between six and ten Durandal while the Jaguar can carry between six and eleven Durandal.
CHARACTERISTICS
Length: 250 cm
Max diameter: 22·3 cm
Max wingspan: 43 cm
Weight: 219 kg
Max carrying speed: Mach 1·8 at 10 000 m
Release conditions: Minimum launching altitude 75 m, launching speed 450 – 600 knots
Effectiveness: Destruction of 150 – 200 m² of concrete runway
STATUS
Series production began in 1977 and over 29 000 units have so far been ordered for use by 12 countries. The first operational Durandals were delivered in 1978. Operational on Mirage III, 5, Jaguar and other aircraft types. The USAF has now adopted the Durandal system.
CONTRACTOR
Matra SA, BP No 1, 37 avenue Louis Breguet, Velizy-Villacoublay Cedex 78146, France.

3150.303
BELOUGA DISPENSER WEAPONS (BLG 66)
The Belouga is a ground attack dispersion weapon of the 'cluster-bomb' type which satisfies the requirement for a low-drag air-to-ground weapon producing a regular and homogenous pattern of grenades which reach the ground almost vertically for maximum effect. It is suitable for attacking stationary or mobile area targets and can be released from low-flying high-speed aircraft.

Three types of grenade have been developed for the following attack missions:
(1) general purpose (fragmentation) for vehicle convoys, equipment, and fuel stores, parked aircraft etc
(2) anti-tank (armour-piercing) for tanks, AFVs, APCs etc
(3) area interdiction for use against airfields, harbour areas, shunting yards, highway junctions, etc.

After release the Belouga bomb is braked to enable the aircraft to clear the area before the grenades are ejected. The grenades are dispensed at a regular rate and these are also braked. The weapon is supplied as a complete round armed and ready for use, in a special packing, and a standard NATO 14-inch (356 mm) attachment is used. The pilot can select either of two pattern configurations prior to release.
CHARACTERISTICS
Overall length: 3300 mm
Diameter: 360 mm
Span: 550 mm
Number of grenades: 151
Grenade calibre: 66 mm
Grenade weight: 1·3 kg each
Total weight: 305 kg
Release conditions: 60 m minimum height, 550 knots max speed
Area coverage: 40 – 60 m wide, 120 or 240 m long

Belouga submunition dispensing weapons on Jaguar

STATUS
Mass production began in 1979, and by the beginning of 1985 at least 3100 units had been ordered for French and other air forces.

MATRA UNGUIDED AIRCRAFT ROCKET LAUNCHERS
The Matra company in France have specialised in the design and manufacture of unguided aircraft rocket launchers. All calibres, including the British two-inch rocket, are catered for and Matra launchers are in widespread use. They have been adopted by NATO and are manufactured under licence in a number of countries.

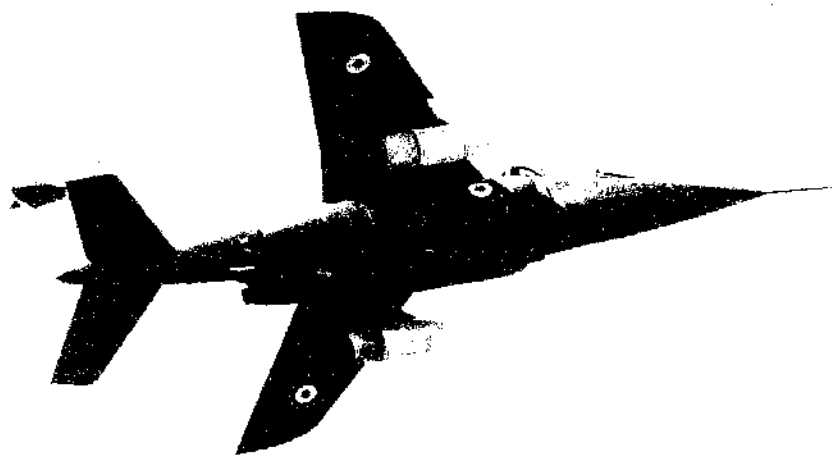
Although the range of the launchers is wide they all embody similar design principles. The construction is in the form of a faired tube which, when charged with rockets, forms an aerodynamically smooth pod for external carriage under the wings or fuselage of fighter aircraft at high and low altitudes. Provision is made to insulate the rocket propulsion motors from

thermal effects. Comprehensive safety provisions are built into the electrical rocket firing systems.

Recent developments include a series of expendable launchers which are used once only and then jettisoned. Further flexibility is provided by launchers combined with an external fuel tank.

Around the three calibres, 37 mm (less used today), 68 mm, and 100 mm and offering many variants for each of them, Matra produces a complete range:

(1) RL F2 6 (68 mm) training rockets
(2) RL F4 MA 18 (68 mm) rockets
(3) RL F1 36 (68 mm) rockets



The new 100 mm rocket, topped with a large warhead, permits effective firing at long range.

STATUS
Orders in January 1985 amounted to 5200 for France and 50 per cent export.

CONTRACTOR
Matra SA, BP No 1, 37 avenue Louis Breguet, Velizy-Villacoublay Cedex 78146, France.

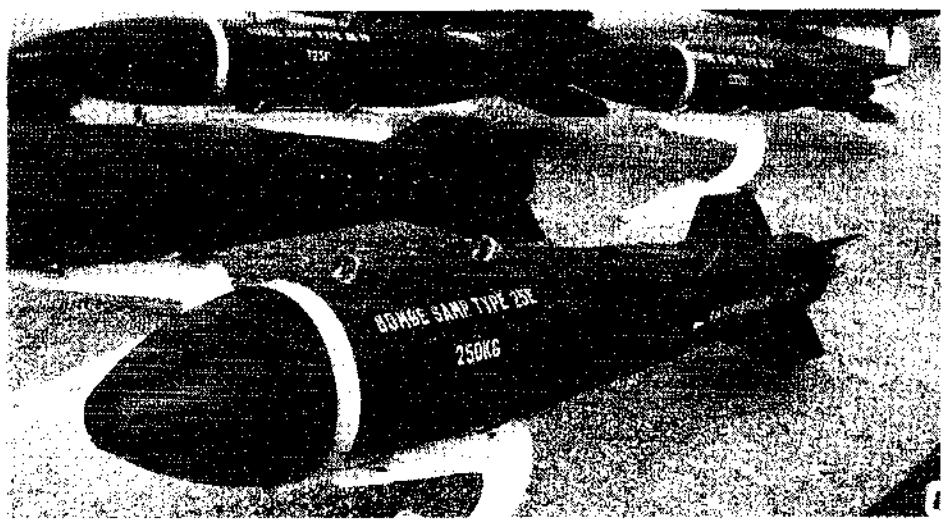
SAMP GENERAL-PURPOSE BOMBS

50 to 120 kg bombs. These are intended for use on light attack aircraft and are carried on underwing pylons, and in addition they can be carried on multiple ejector racks of fighter-bombers. They all have NATO suspension lugs and a standard two-inch well for the fuze.

250 to 500 kg bombs. These can be carried under any NATO bomb rack and can also be provided with a retarding device for low altitude bombing and an integrated arming control device.



1000 kg bomb. This can be carried by any aircraft with 30-inch (762 mm) suspension lugs and can also be provided with a retarding system or a guidance system, such as that developed by Matra.

CONTRACTOR
Société des Ateliers Mécaniques de Pont-sur-Sambre, 37 Grande Rue, 59138 Pont Sur Sambre, France.

HBS 202 HELICOPTER ARMAMENT SYSTEM

The helicopter armament system HBS 202 has been specifically designed for installation on the MBB helicopter BO 105. It is a rigid mounted system which is aimed by helicopter manoeuvring. It consists of a frame fixed underneath the fuselage between the skids, a cradle for gun installation, an electro-hydraulic cocking and triggering device and the control panel. The ammunition is stored in an in-board container with a flexible connecting chute to the gun. A reflex sight is employed.

The weapon itself is the Rheinmetall 20 mm automatic cannon Mk 20 Rh202 (**5600.103** in 1982-83 and earlier editions) which is particularly suited to these purposes because of its low recoil forces and its high reliability under extreme service conditions.

CHARACTERISTICS

Weapon
Type: Mk 20 Rh202
Calibre: 20 mm × 139 NATO
Rate of fire: 1000 rounds/minute
Muzzle velocity: HEI-T, TP-T 1050 m/s; API-T 1100 m/s; APDS-T 1150 m/s
Recoil force: 550 - 750 kgf
Tactical range: 2000 m
Type of fire: Single fire; or controlled burst
Cocking: Electro-hydraulic
Triggering: Electro-hydraulic
Ammo storage capacity: 525 rounds
Sight: Reflex

Helicopter armament system HBS 202 with Mk 20 Rh202 mounted below fuselage. Note flexible ammunition feed from inside aircraft

Weight
Gun mount: 96 kg (without gun and ammo)
Mk 20 Rh202: 75 kg (approx)
525 linked cartridges: 175 kg
Combat weight: 346 kg

27 mm MAUSER CANNON

Mauser in participation with Diehl and Dynamit Nobel (combat ammunition, propellant and primer cap) developed the Mauser 27 mm weapon system under contract with NAMMO (NATO MRCA Development and Production Management Organisation).

The main characteristics of this cannon are high muzzle velocity, high rate of fire from the first round, high degree of accuracy and reliability, favourable installation parameters such as low weight, small volume envelope, low reaction forces and for all types of ammunition identical exterior ballistics (permit mixed belts) and fuze response at extreme angle of impact (HE). The five types of ammunition are: AP, APHE, HE, TP and TP-F.

The MRCA Tornado aircraft is armed with two of these installed cannons and the German version of the Alpha-Jet with a single cannon in a pod. The new Swedish multi-role combat aircraft (JAS-39 Gripen) now under development will also be equipped with one internally installed cannon.

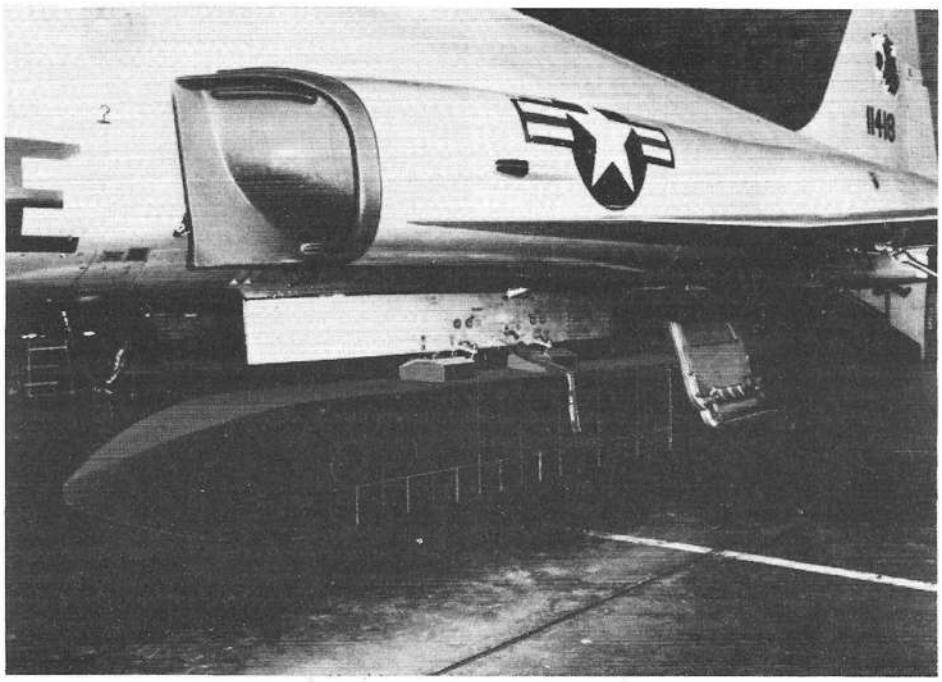
MODULAR DISPENSER SYSTEM (MDS)



The Modular Dispenser System is a captive dispenser weapon for use on tactical fighter aircraft. It fits on all standard bomb racks. The basic ejector models can be assembled in different configurations to suit aircraft type(s) and operational function(s). Various submunitions may be carried and dispensed with the MDS to suit it for use against runways, armoured fighting vehicles, soft targets, surface-to-air missile sites, and other battlefield objectives.

Operational features include low-level submunition delivery and automatic pattern control. The system may be re-used for numerous sorties.

CHARACTERISTICS
Overall length: 2·5 - 4·5 m (variable, depending upon aircraft type)
Width: 630 mm
Height: 340 - 660 mm (variable, depending upon aircraft type)
Total weight: 500 - 1750 kg
Submunition weight: 70 - 80% of total
Aircraft speed at submunition ejection: Mach 0·6 - 0·9
Altitude at ejection: Approx 50 m

STATUS
In development.

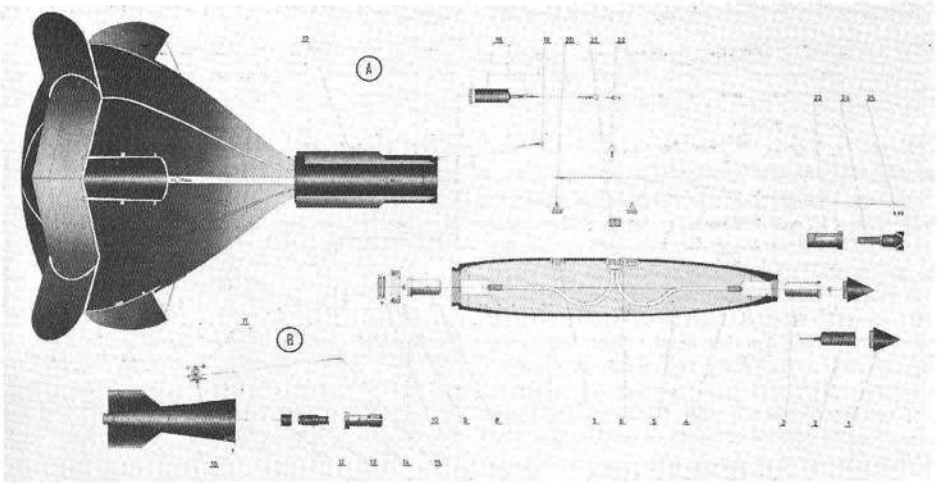
LU250 EG-FT BOMB

The LU250 EG-FT bomb is a general-purpose low-drag explosive bomb complying with American Mk 82 bomb specifications (MIL-B-82548). The bomb is designed to meet the requirements of the largest possible majority of bombing missions using both the blast and fragmentation effects along with the concussion effect produced in the ground and buildings.

The fuzes used for 'smooth' bombs with conical fins are generally mechanical. The bomb bodies are equipped to receive either mechanical or electrical fuzes. The first type is assembled using booster adaptors.

A BSU 49/B retarder is also fitted to use the LU250 EG-FT in low-altitude attacks. Two versions are offered:



(1) bomb body with conical fin
(2) bomb body with retarder.

The BSU 49/B inflatable retarder is a cruciform tail stabiliser that can be used in either the 'low-drag' configuration without inflating the retarder, or in the 'high-drag' configuration with the retarder deployed. The inflatable retarder is used in low-altitude bombing with a high drag to allow the bombing aircraft to escape the blast and fragmentation effects of the bomb. This high drag is achieved by opening a balloon-parachute, called ballute, enclosed in the container fin.

When the bomb is dropped, the spring which holds the arming wire stretched, unwinds. When completely unwound, it frees two pin safeties and opens the cover. The ballute assembly is then freed under the effect of the external springs on the cover and of the internal ejection spring, and is immediately inflated by the external airflow, which comes in through four symmetrical inlets. The cover remains integral with the ballute, thus avoiding any risk of projection to the rear which might strike the bombing aircraft.

CHARACTERISTICS

Type LU250 EG-FT	(conical fin)	(with retarder)
Length	2·154 m	2·162 m
Diameter	273 mm	273 mm
Fin span	380 mm	385 mm
Weight	240 kg	254 kg

LU 250 EG-FT bomb with retarder or conical fin, electrical or mechanical fuzes

*(**A**) LU250 EG-FT bomb with retarder (**B**) LU250 EG-FT bomb with conical fin (**1**) nose cap (**2**) nose electrical fuze (**3**) nose adaptor bushing (**4**) explosive charge (**5**) bomb body (**6**) NATO lug and arming wells for electrical fuzes (**7**) NATO suspension lug insert (**8**) tail adaptor bushing (**9**) rear blanking plate (**10**) sleeve coupling (**11**) wind vane (**12**) coupling regulator (**13**) fin mechanical fuze (**14**) priming relay (**15**) fin mechanical fuze arming wire (**16**) conical fin (**17**) retarder (**18**) electrical fuze (**19**) retarder opening control wire (**20**) NATO suspension lug (**21**) electrical circuit wells closure (**22**) fuze arming swivel hook (**23**) priming relay (**24**) nose mechanical fuze (**25**) nose mechanical fuze arming wire*

The retarder is a Goodyear Aerospace design which is also employed with US Mk 82 500 lb general-purpose bombs, and the American company also produces a larger version (BSU-50/B) for use with the 2000 lb Mk 84 bomb. Retarder characteristics are as follows.

CHARACTERISTICS

Retarder type	BSU-49/B	BSU-50/B
Diameter	222 mm	403 mm
Span	381 mm	940 mm
Length	660 mm	775 mm
Weight	25·4 kg	43·5 kg

STATUS

Production. In 1983 a licence arrangement covering marketing of the Luchaire-produced LU250 EG-FT bomb with BSU-49/B retarder and Borletti fuzes was revealed by an Italian consortium called Consor.

4428.303
TAL CLUSTER BOMBS

The TAL-1 cluster bomb is designed to achieve a high spin rate when dropped so that, when the fuze is activated after a preset time delay, sub-munition bomblets will be scattered evenly over a wide area in a circular pattern. The pattern size is governed by the point of fuze activation and can be a maximum of 53 000 m². 279 bomblets are carried, each with a weight of 500 grammes containing 160 grammes of high explosive and with a kill radius of eight metres.

TAL-1 is designed for external carriage by tactical ground support aircraft. It may be carried singly on a standard bomb rack pylon or in multiple mounting on tandem, TER, or MER type bomb rack. Safe carriage is ensured by a single arming wire which locks the time fuze and, after separation from the aircraft, a safety and arming mechanism allows a safe distance between the cluster and the aircraft. Each bomblet also has its own arming wire which is withdrawn by aerodynamic forces produced by the free air-stream when the cluster is activated.

TAL-2 cluster bomb, after pre-set delay, splits open and its spin scatters between 270 and 315 bomblets

CHARACTERISTICS

Weight: 250 kg
Length: 2159 mm without fuze, 2345 mm with fuze
Diameter: 406 mm
Fin span: 560 mm
Suspension: 356 mm (14-inch) twin lug
Payload: 279 × 500 g bomblets (TAL-1); 315 × 400 g bomblets (TAL-2)
Bomblet explosive: 160 g HE
Number of fragments: 1800

Between 270 and 315 bomblets are released when the bomb splits open, and these are armed by aerodynamic forces produced by the airstream and they explode on impact.

STATUS

First revealed in 1981 and believed to be operational. The TAL-2 model was revealed in 1983.

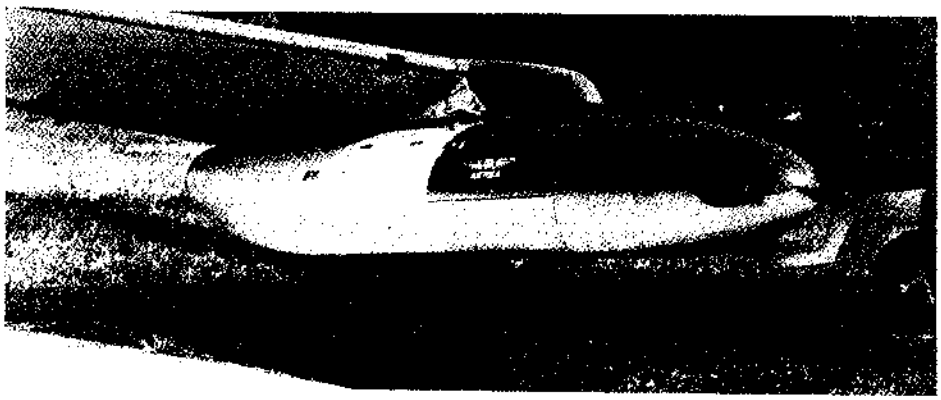
AEREA MULTI TASK POD

Aerea has developed a combination aircraft armament pod for use on fixed-wing aircraft and helicopters, which incorporates one ·50 inch calibre machine gun and six tubes for launching 2·75 inch rockets. The new unit is known as a multi task pod (MTP), and by proper selection of both the rocket warheads and round types, a variety of missions can be fulfilled with only a single pod.

The MTP can accept any ·50 inch machine gun that is suitable for airborne use, together with 250 rounds

Rear of Multi Task Pod showing ends of rocket launcher tubes and firing mechanism

Aerea Multi Task Pod contains ·50 inch machine gun and 250 rounds plus six 2·75 inch aircraft rockets



of ammunition. Other features include in-flight re-cocking, rocket intervalometer incorporated in pod, suitable for integrated store management system, lightweight, small cross section, standard NATO 14-inch hook spacing.

CHARACTERISTICS
Length: 1·8 m
Height: 410 mm
Width: 410 mm
Weight: 79 kg (empty); 175 kg (loaded, 250 rounds + 6 rockets)
Firing rate: 650 - 1000 rounds/minute
Temperature range: -20 to +50° C
STATUS
Production.

AEREA TWIN GUN POD 7·62

The Aerea twin gun pod P/N 781 586 is designed to carry two 7·62 mm FN machine guns with a total ammunition supply of 1000 rounds (500 rounds per gun). The pod may be carried as an external store on any aircraft pylon equipped with two standard NATO 14-inch (356 mm) lugs. Each gun is supported by a damping cradle to minimise recoil effects, and can be easily collimated using a double-axis front support. Cartridge cases and coupling links are normally ejected through special ducts, but an improved pod with retained cases and links can be provided. The normal bomb jettison feature may be used to jettison the pod in an emergency.

CHARACTERISTICS
Length: 1750 mm
Height: 290 mm
Width: 395 mm
Weight: 55 kg (empty, with guns); 84 kg (loaded)
Rate of fire: 650 - 1000 rounds/minute

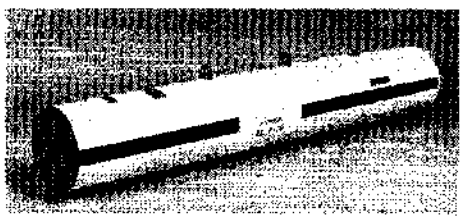
AEREA ROCKET PODS

The current Aerea production programme includes an extensive range of rocket pods for use on fixed-wing tactical aircraft, helicopters and training aircraft. Built in glass reinforced fibre plastics or light metal alloy, according to their purpose or the rocket calibre, all the launchers are of the non-expendable type. The firing tubes are of light alloy and can be replaced if necessary. All pods have a frangible protective nose fairing which protects the rockets during flight but permits the rockets to leave the launcher when fired, whether fired singly or in ripple or salvo.

The launcher pods are attached to the aircraft by standard NATO 14-inch (356 mm) lugs. The main characteristics of the various models are listed in the paragraphs below, which follow a table of the principal types (the manufacturer's identifications conform to the following code):

Prefix letters	Purpose	No of tubes	Calibre (mm)
HL	Helicopter launcher	eg 7	eg 80
AL	Aircraft launcher	eg 18	eg 68
SAL	Supersonic aircraft launcher	eg 12	eg 80



Current Aerea rocket pods:

HL-14-50: Helicopter launcher, 14 tubes for 50 mm rockets
HL-18-50: Helicopter launcher, 18 tubes for 50 mm rockets

Ground firing tests of Aerea SAL-12-80 supersonic aircraft rocket launcher pod for 81 mm SNORA rockets

HL-28-50: Helicopter launcher, 28 tubes for 50 mm rockets
AL-18-50: Aircraft launcher, 18 tubes for 50 mm rockets
AL-25-50: Aircraft launcher, 25 tubes for 50 mm rockets
AL-8-68: Aircraft launcher, 8 tubes for 68 mm rockets
AL-18-68: Aircraft launcher, 18 tubes for 68 mm rockets
AL-6-70: Aircraft launcher, 6 tubes for 2·75 inch rockets
AL-18-70: Aircraft launcher, 18 tubes for 2·75 inch rockets
HL-7-70: Helicopter launcher, 7 tubes for 2·75 inch rockets

Aerea HL-7-70 helicopter rocket launcher pod for 2·75 inch rockets

Aerea AL-18-50 aircraft rocket launcher pod

Aerea HL-28-50 helicopter rocket launcher pod

Aerea AL-6-80 aircraft rocket launcher pod

Aerea AL-18-70 aircraft launcher pod for 2·75 inch rockets

CHARACTERISTICS

Type	Rockets	Weight	Rate of fire	Length	Diameter
HL-14-50	14 × 2 inch SNIA-BPD	15 kg (empty); 76 kg (loaded)	10/s	1123 mm	270 mm
HL-18-50	18 × 2 inch SNIA-BPD	27 kg (empty); 96 kg (loaded)	10/s	1400 mm	305 mm

BRD-4-250 and BRD-4-450 BOMB AND ROCKET DISPENSERS

The BRD-4-250 bomb and rocket dispenser is used for training pilots, and this model can be loaded with four practice bombs mixed with 2 inch, 2·75 inch or 68 mm SNEB rockets. It is constructed of light alloy metal and its weight makes it suitable for use with light aircraft and helicopters as well as other tactical aircraft. A newer version, the BRD-4-450, can carry four practice bombs and four rockets of the same calibre as the BRD-4-250. Suspension is by means of standard NATO 14-inch (356 mm) lugs.

CHARACTERISTICS
Length: 2400 mm
Width: 432 mm
Weight: 73 kg (empty)
Payload: 4 × Mk 76 practice bombs, and/or Mk 106 bombs, 2 × 2 or 2·75 inch rockets or 68 mm SNEB rockets

STATUS
Production.

9BRD-4-250 bomb and rocket dispenser with typical load

4869.303
2-inch BPD AIRCRAFT ROCKETS

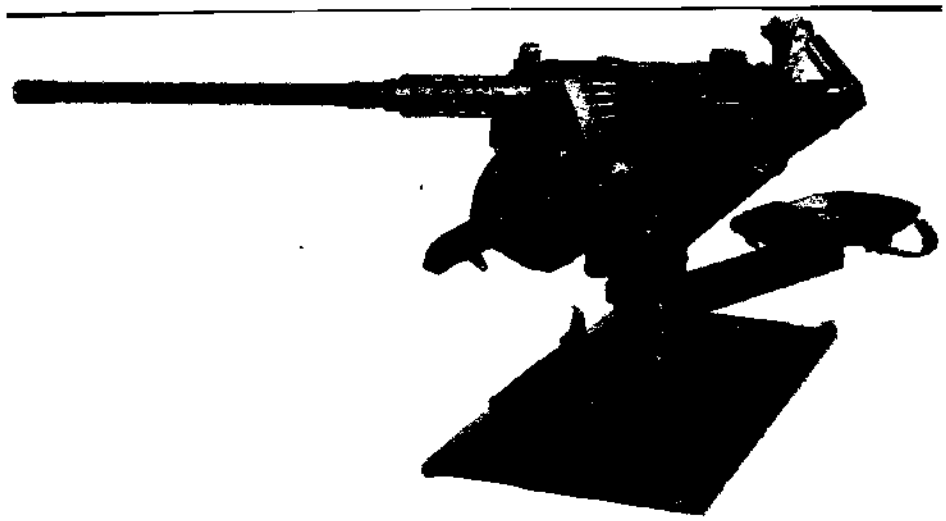
The 2-inch BPD air-to-ground rockets system has been developed to provide effective attack by fixed-wing aircraft and helicopters against a variety of battlefield targets. Systems consist of 2-inch BPD rockets and launchers of various sizes to suit different operational tasks. Two-inch ARF/8M3 and ACR/M4 rocket models are currently available for use.

Several types of warhead are available: HEI, PFF, AT-AP, SP (spotting), illuminating, practice (smoke, flash and inert) and all weigh 2·2 kg each. At present, 3·0 kg warheads with higher terminal effects are being developed.

The current range of launchers consists of six models: 14, 18 or 28 tubes for helicopters; 29 tubes for helicopters and light aircraft; and 18 and 25 tubes for aircraft.

CHARACTERISTICS
Rocket types: ARF/8M3 and ACR/M4
Calibre: 51 mm
Length: 1048 mm
Weight: 4·8 kg
Burn time: 1·1 s
Total impulse: 982 N.s
Max pressure: 11 771 K Pa
Burnout velocity: 515 m/s

Loaded weights
Helicopter: 14-tube, 82 kg; 18-tube, 13 kg; 28-tube, 74 kg
Helicopter/light aircraft: 24-tube, 184 kg
Aircraft: 18-tube, 16 kg; 25-tube, 167 kg



STATUS
In production.

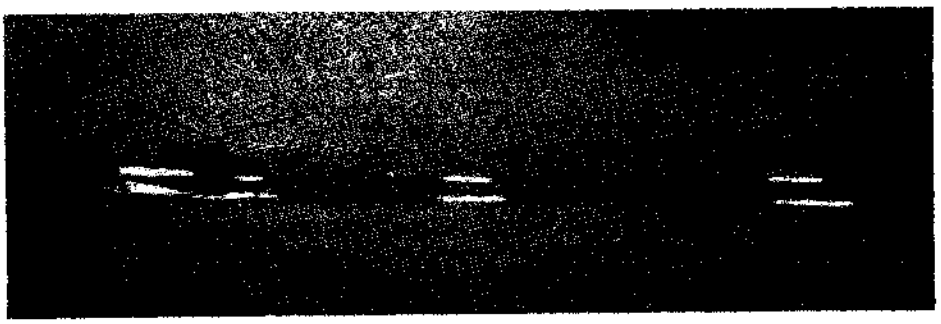
DOOR GUNNER POST

The Door Gunner Post (DGP) is a device used to mount 12·7 mm (0·5 inch) machine guns in helicopters and capable of rapid fitting or removal in either single or double installations. DGP can fire at up to 70° downwards with the gunner always seated. A wide variety of helicopters including the very smallest can be fitted and the system includes a rotating support which incorporates a damping cradle to minimise recoil effects; a gas shock absorber to balance the gun for better aiming; a gunner's seat with inertia belts; and a base fitting sliding on rails with a locking device. An ammunition box is mounted on the gun with other boxes being located within easy reach of the gunner. A flexible chute is provided for case ejection and a net box collects the ammunition links.

CHARACTERISTICS
Gun: FN Browning 0·5 inch or equivalent
Ammunition: 100 rounds on mounting with stowage for 400 – 1000 rounds off mounting
Weight (with gun): 70 kg

STATUS
Production.



Aerea Door Gunner Post installation for mounting in ground attack helicopters

4868.303
81 mm BPD AIRCRAFT ROCKETS

The 81 mm BPD air-to-ground rocket system can be installed on fixed and rotary wing aircraft for use against a variety of ground targets. Its component parts (81 mm rockets and a set of launchers) have been conceived as a single, rugged and reliable configuration providing high performance in the different operational missions.

The main characteristics of the equipment include: high precision due to rocket aerodynamics and propulsion; HE, PFF and AT-AP (anti-tank anti-personnel) warheads all weighing 7 kg and having the same aerodynamics configuration; ability to achieve

Agusta helicopter launches BPD 81 mm aircraft rockets

target saturation and long stand-off ranges with limited overall elevation of the launcher; availability of 6-, 7- and 12-tube launchers for helicopters and light subsonic aircraft, and 6- and 12-tube models for supersonic aircraft.

A system management unit is being developed to optimise rocket utilisation under any flight conditions and for any aircraft type. Also under development are submunition warheads which contain 11 AT-AP submunitions for a weight of 10 kg.

CHARACTERISTICS
Calibre: 81 mm
Length: 1·57 m
Weight: 15·9 kg
Burn time: 0·85 s
Total impulse: 9000 N.s
Burnout velocity: 630 m/s
Operating temperature range: –45 to +65°C

Loaded weights
Helicopter: 7-tube, 142 kg; 12-tube, 251 kg
Subsonic aircraft: 6-tube, 134 kg
Supersonic aircraft: 6-tube, 144 kg; 12-tube, 257 kg
STATUS
In production.

SOUTH AFRICA

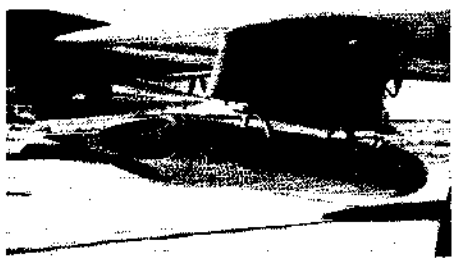
4540.303
SA AIRCRAFT BOMBS
Various types of free-fall bombs and special to purpose fuzes of indigenous design and manufacture, meeting NATO standards, are produced for use by aircraft of the South African forces. Current production includes the following:

Mk II Fragmentation Weapon System
Believed to be known also as 'Alpha' this is a 6 kg anti-personnel and anti soft-skinned vehicle aircraft bomblet. It was designed to produce a high-density uniform fragmentation pattern over a large ground area. It is normally used with Canberra aircraft, which release large numbers from sealed boxes containing 25 bomblets. Each bomblet is constructed of a thin-walled, approximately spherical, steel casing and a thick-walled inner steel casing containing an HE charge detonated by an SA222 inertial fuze having a 0·65 second delay. With most types of terrain except mud or water, good bounce characteristics ensure an air burst for maximum effects. Lethality decreases from 100 per cent within 1 metre radius of the detonation point to 30 per cent at a radius of 20 metres.

120 kg Aircraft Bomb
This is a conventional free-fall bomb consisting of a cast or forged body filled with RDX/TNT or TNT in the HE model, or filled with HE substitute in the practice model. The body can be fitted with a penetration nose cone and cup support, a charging tube (front and rear) for electronic fuzing, and an arming wire assembly for mechanical fuzing. The filling is either RDX/TNT 60/40 or TNT and the standard fuze is the SA771 mechanical nose fuze. The latter is a selective arming delay time point detonating instantaneous or delay action fuze with back-up from the SA772 tail fuze. This tail fuze is impact firing and also arming delay time selective, with either non-delay or various delayed firing options in the millisecond range.

A tail assembly weighing 8 kg completes the bomb. The empty bomb case weighs approximately 60 kg, or 107 kg assembled and filled.

250 kg Aircraft Bomb
This is of similar construction and configuration to the 120 kg bomb, but has an empty weight of about 116 kg, 219 kg assembled and filled, with a tail assembly weighing 9 kg.



460 kg Aircraft Bomb
This bomb is made as either the HE version with a filling of Torpex 4B for the cast steel body, or HE substitute for the practice version. Other components are a penetration nose and cup support, front and rear charging tubes for electronic fuzing, and an arming wire assembly for mechanical fuzing. The same fuzing arrangements as for the 250 kg bomb are available for the heavier weapon. Weights are: empty bomb, approximately 225 kg; bomb body assembled and filled, approximately 438 kg; tail assembly 28 kg.

The 120, 250 and 460 kg bombs are all fitted with NATO 500 suspension lugs for carriage on aircraft.
STATUS
In production and believed available for export to approved customers.

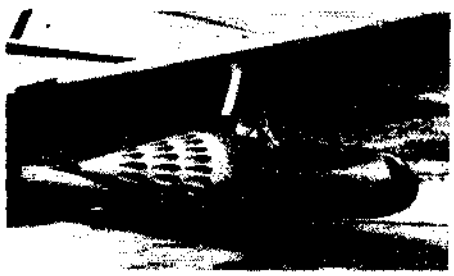
CASA TYPE 06.070 ROCKET LAUNCHER
This re-usable rocket launcher is designed to carry and launch six FFAR 2·75 inch 178 mm rockets, or six INTA S-11 rockets. It can be installed in any pylon type with standard NATO 14-inch (356 mm) suspension system. Basic and low-drag versions are produced.
OPERATION
Rocket firing is by means of an electronic intervalometer incorporated in the rocket launcher. Single rocket firing or ripple firing is selected by the pilot in the cockpit or by adjusting the mode selector incorporated in the launcher. Rate of fire is according to a firing interval of 30 ms (the intervalometer can be adjusted for a different firing rate upon request).



CHARACTERISTICS

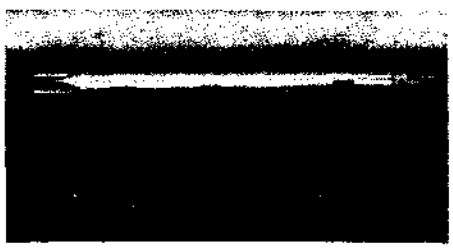
LANCO RC-06-100



This re-usable unit is designed to carry and fire six heavy 100 mm INTA S12 rockets. It can be fitted to any aircraft with 14- and 30-inch (356 and 762 mm) NATO attachments. The conversion from 14 to 30 inches is carried out by changing the position of the rear attachment.

OPERATION

Rocket firing is controlled by an electronic intervalometer incorporated in the launcher. Single rocket firing or continuous ripple firing can be selected by the pilot or set in on the ground if this unit is not available. The firing sequence can be controlled between 20 and 70 ms by adjusting the intervalometer without removing it from the rocket launcher.

CHARACTERISTICS
Length: 3·4 m approx
Weight (empty): 100 kg
Weight (loaded): 460 kg

Construcciones Aeronauticas SA, Rey Francisco 4, Madrid-8, Spain.

LANCO RC-06-100

1601.393
CASA 04.080 ROCKET RACK LAUNCHER

The CASA 04.080 rack launcher carries four 80 mm Oerlikon rockets and is designed for light aircraft and helicopters. It may be pylon mounted, either using the AH 039220 pylon or others with NATO attachments. The firing rate is controlled electrically and can be adjusted from 20 to 50 ms. The launcher is also available in the CASA 04057/080 version to carry and fire either four 57 mm (2·25 inch) rockets or four 80 mm Oerlikon rockets.

CONTRACTOR
Construcciones Aeronauticas SA, Rey Francisco 4, Madrid-8, Spain.

CASA 04.080 rocket rack launcher

1603.393
CASA AH 039220 UNIVERSAL PYLON

The universal pylon produced by CASA can be used to attach honeycomb or rack launchers, or machine-gun or bomb pods. The body has a main section attached to the aircraft by four screws, and a forward fairing mounted by one screw. The forward fairing contains accessible electrical ejector and firing circuits. A detachable yoke at the trailing end provides for long weapons which might otherwise meet the trailing edge of the aircraft wing. Ejector hooks are located at the standard NATO distance of 14 inches (356 mm).

CONTRACTOR
Construcciones Aeronauticas SA, Rey Francisco 4, Madrid-8, Spain.

5207.303
BRFA BOMB

The BRFA bomb has been designed specifically for attacking aircraft runways and can be carried by high performance aircraft such as the F-4 Phantom. Once released from the aircraft a parachute is deployed which retards the bomb and ensures that it is in the vertical position. A rocket motor is then ignited and propels the bomb to the target. The bomb penetrates the runway to a depth of some 600 mm before it explodes. Area of damage is quoted as 180 m.

CHARACTERISTICS
Length: 3·2 m
Diameter of bomb: 300 mm
Diameter over fins: 600 mm
Weight of bomb: 330 kg
Weight of explosive: 75 kg

CONTRACTOR
Explosivos Alaveses SA, Apartado 198 Vitoria, Spain.

5245.303
EXPAL BRP RETARDED BOMBS

The BRP range of low drag parachute retarded bombs have been designed specifically for fast low-level bombing by aircraft such as the F-4 Phantom. When the bomb is released, the arming wires activate the parachute system, braking the bomb while the aircraft pulls away. The bombs have safety devices which prevent explosion of the bomb in the event of any failure in any of its components, or if launching altitude does not guarantee a minimum safety distance. All EXPAL general-purpose low drag bombs (**5244.303**) can be transformed into BRP retarded bomb configuration by replacing the standard tail unit by the BRP tail and fitting a KAPPA nose fuze.

STATUS
In production. In service with the Spanish Air Force.

CONTRACTOR
Explosivos Alaveses SA, Apartado 198 Vitoria, Spain.

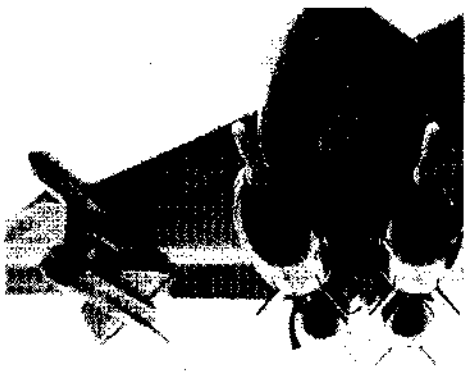
5216.303
FFV UNI-POD 0127
The FFV Uni-Pod 0127 has been designed for installation on jet trainers, light aircraft and helicopters. The pod is fitted with a single 0·5 inch (12·7 mm) Browning AN-M3 machine gun which has a rate of fire of up to 1250 rounds per minute. A total of 220 rounds of belted ammunition are carried and the spent cartridge cases and links are ejected or, as an option, may be collected in the pod. The machine gun can fire a variety of ammunition including ball, AP, API, APIT, and the API (HC); the latter will penetrate 13 to 19 mm armour plates at a range of 800 m at impact angles between 40 and 90°. A special damper on the upper part of the pod attenuates the recoil forces and the strain on the suspension lugs is less than 2000 N (204 kg).

FFV Uni-Pod 0127

The latest version of the pod is equipped with a remotely controlled gun charger which makes it possible to charge the gun, recharge it after a jam, make it safe, and count the rounds fired while airborne.
CHARACTERISTICS
Length: 1916 mm
Diameter: 360 mm
Suspension: 14-inch (356 mm) MIL-A-8591E
Weight loaded: 118 kg
Weight empty: 90 kg
Power supply: 28 V DC
STATUS
Certified for various aircraft and helicopters.
CONTRACTOR
FFV Maintenance, 581 82 Linköping, Sweden.

4430.303
FFV 30 mm ADEN GUN POD
The FFV 30 mm Aden gun pod has been designed for installation on jet aircraft for air-to-air and air-to-ground use. It is of the so called self-contained type and houses the 30 mm Aden gun, a magazine with 150 rounds and an option for 200 rounds, an electrical power unit, and a relay box. The gun is cocked pneumatically on the ground and a safety device prevents firing until the aircraft is airborne. The suspension system may be either 30- or 14-inch (762 or 356 mm) NATO standard lugs, MIL-A8591E, or Douglas T-shape lugs.
CHARACTERISTICS
Length: 3850 mm
Diameter: 500 mm
Weight loaded: 364 kg
Weight empty: 290 kg
Power supply: 28 V DC and 400 V AC, 400 Hz, 0·5 A 3-phase
STATUS
Produced in large numbers to arm the Saab-Scania AJ 37 Viggen and 105 aircraft.
CONTRACTOR
FFV Maintenance, 581 82 Linköping, Sweden.



FFV 30 mm Aden gun pod on AJ 37 Viggen

7514.393
VIRGO 120 kg FRAGMENTATION BOMB M/71
The M/71 120 kg fragmentation bomb has been developed for use against diverse targets such as landing craft, aircraft on the ground, anti-aircraft weapons, field artillery, light armoured, and unarmoured vehicles etc. Designed to disperse a large number of fragments of a predetermined size and weight at high striking velocity, the bomb is designed for one-point suspension in ejector release units.

To meet the demands of tactical requirements of being used at low altitudes the bomb is equipped with a built-in brake parachute which retards the bomb sufficiently to give the aircraft enough lead distance to be safe at the moment of burst. The bomb can be dropped from higher tactical altitudes with or without the brake parachute. As the bomb is designed for supersonic speeds it is equipped with protection against aerodynamic heating. A proximity fuze is fitted in the nose of the bomb, and this is based on the capacitance principle. The fuze system causes the bomb to detonate a few metres above the target or the ground vegetation.

The bomb body consists of three main external parts which are retained together by the central tube. The central unit features the lug and contains the electrical connector. The lug contains a sliding plunger which comprises a safety device blocking the arming of the proximity fuze. Another safety device to which the brake parachute is attached is installed in the rear part of the central tube. The front part of the tube houses the main components of the proximity fuze.

Virgo retarded bombs beneath Swedish Viggen attack aircraft. Note also Swedish-built Falcon air-to-air missile

The bomb tail, which is permanently attached to the bomb, is made of glass-fibre-reinforced plastic. It houses the brake parachute with its electronic release device.
CHARACTERISTICS
Bomb: M/71
Length with fuze and parachute fitted: 1895 mm
Diameter of body: 214 mm max
Fin span: 368 mm
Total weight of bomb (ready to drop): 121 kg max
Charge: RDX/TNT
Weight of charge: 30 kg
Position of lug from the front of the fuze: 1098 mm
Centre of gravity from the front of the fuze: 1094 mm
Proximity fuze
Length overall: 945 mm
Diameter: 64 mm max
Weight: 1·7 kg
Brake parachute
Length of container: 290 mm
Diameter of container: 89 mm
Weight of container: 1·2 kg
Diameter of open parachute: 530 mm
Release delay: 0·7 s
STATUS
Designed for A32 Lansen and adaptable for A35 Draken and AJ 37 Viggen attack aircraft. The Royal Swedish Air Force is the only known user.
CONTRACTOR
FFV Ordnance, 631 87 Eskilstuna, Sweden.

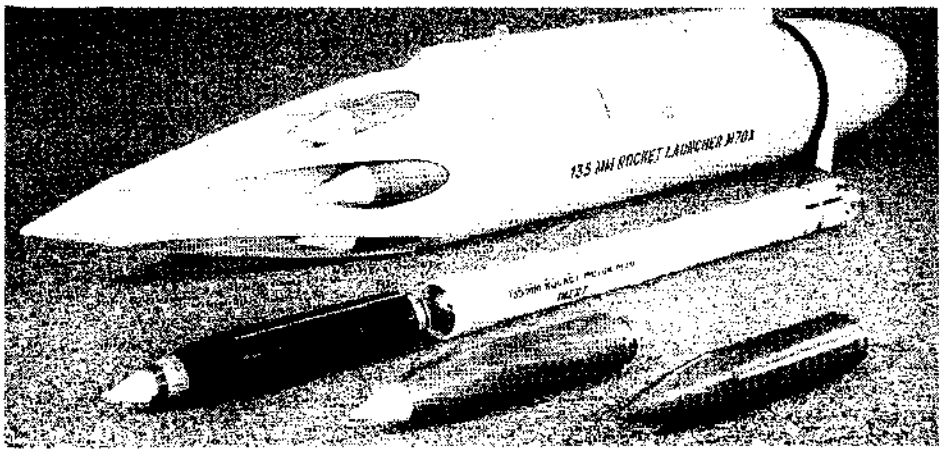
135 mm BOFORS AIR-TO-GROUND ROCKET SYSTEM M70
The 135 mm air-to-ground rocket system manufactured by AB Bofors is intended as part of a range of armament developed for the Saab AJ 37 Viggen. It consists of a launcher carrying six rockets and a pulse distributor of electronic type, which can be set for single or ripple firing. The launcher has a low-drag design. The rockets are protected against thermal heating during high and low altitude flight at supersonic speeds. Standard NATO-type suspension lugs can be provided so that the system is compatible with a wide range of tactical aircraft.

The rockets can be provided with either a general-purpose or an armour-piercing fragmentation warhead. A practice head is also available. Two fuzes can be used: a direct-action fuze with post-impact delay, or a highly sensitive direct-action fuze.

The rocket motors give high velocity and low dispersion, which gives a time of flight of approximately 3·5 s to 2000 m slant range in typical launching conditions.
CHARACTERISTICS
Total weight with six rockets: 400 kg
Weight (empty): 125 kg
Length: 3226 mm



Diameter: 486 mm
Pulse distributor for single or ripple firing
Firing interval in ripple firing: 0·1 s
135 mm rocket
Weight of rocket motor: 25 kg
Burning time: 2 s
Velocity at burn-out: 600 m/s
Weight
GP warhead with fuze: 21 kg
AP fragmentation warhead with fuze: 20 kg
GP warhead charge: 3·7 kg
AP fragmentation warhead charge: 5 kg
Practice head: 21 kg

STATUS

In service with the Swedish Air Force on the Viggen aircraft. Successful installations have also been made on the F-4 Phantom, A-7 Corsair, A-4 Skyhawk and Hunter.

CH-TABO BOMB DISPERSAL POD

The Swiss Federal Aircraft Factory at Emmen and the Federal Ammunition Factory at Houne have collaborated in the development of an aircraft armament pod to be used as a dispenser for bombs and/or submunitions for low-level attacks against lightly armoured vehicles, gun emplacements, radio/radar stations, and similar ground targets. Troops may also be attacked with the weapon.

The system comprises an aerodynamically shaped container which is attached to the carrier aircraft by normal weapons hard points. the bombs are spherical in shape and are equipped with a rigid cast aluminium tail assembly. The bomb case consists of an aluminium matrix containing 8000 cast steel balls. These are explosively dispersed after detonation by either mechanical detonators that are actuated when a telescopic probe touches the ground, or by elctronic fuzes set to operate at any chosen height above the surface. Using a proximity fuze to achieve an optimum height air burst, two CH-TABO container loads of bombs can penetrate 5 mm steel plate armour with a density of four fragments per square metre over an area of 200 × 50 m.

Swiss Hunter aircraft equipped with CH-TABO dispensers releases bomblets at low level

CH-TABO bomb dispenser with two ejected bombs

The bombs are carried inside the pod and ejected from the open rear end of the pod by dynamic pressure. After release they are aerodynamically braked. The container payload can be dispensed at any airspeed up to Mach 0·6 – 0·85. The container may also be employed for dropping other stores, such as medical or other supplies, communications equipment, life-saving items etc. The CH-TABO container is not jettisoned after dropping bombs or stores.

STATUS

Early production.

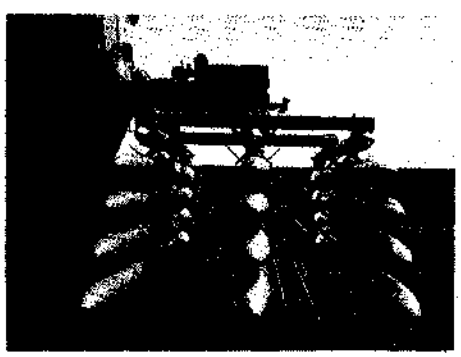
OERLIKON 81 mm AIRCRAFT ROCKET

The Oerlikon 81 mm SURA-D aircraft rocket is an upgraded version of the SURA-FL. This unguided solid fuel rocket with sliding fins is intended for air-to-ground use by fighter aircraft, and has proved effective when fired from helicopters and light reconnaissance aircraft. It can be used to engage point or area targets.

The fin assembly is a sliding fit on the rocket body and has a dual function; before firing the assembly acts as the front suspension, engaging with the front suspension lugs on the aircraft underwing rail. Lower rockets in the same cluster can also be engaged by means of the fin slots and by an additional integral suspension ring located forward of the main fin ring. The rockets are fired electrically, and on firing the sliding fin ring acts as a guide until it is met by the rear cone of the motor. It is then carried on with the rocket, stabilising it in flight.



Based on a standard propulsion element, the TWK 007, a variety of rocket types is produced by the use of differing fuze arrangements and warheads. These are summarised in tabular form.

CHARACTERISTICS

Calibre: 81 mm
Length: 1077 – 1212 mm (depending on type of shell)
Initial mass: 12·7 – 14·2 kg (depending on type of shell)
Max velocity at +18° C: Approx 530 – 595 m/s
Ignition voltage: 24 – 28 V
Propulsion unit mass: 8·4 kg
Mean thrust at +18° C: 7300 N
Burning time: 0·9 s

OERLIKON SNORA 81 mm ROCKET

The Oerlikon 81 mm SNORA rocket is an unguided solid fuel rocket with folding fins. It has a pure internal burning propulsive element. This rocket can be fired from multi-tube launchers both in subsonic air-to-ground engagements and ground-to-ground roles. Pods are used for supersonic air-to-ground missions. The design has been carried out with the needs of fighter aircraft, helicopter, tracked and wheeled vehicle installation in mind. The SNORA rocket is provided with the necessary safety devices for storage, transportation, handling, and firing. Correct functioning is ensured over a temperature range of -45 to +65°C. Based on a standard propulsion element, the TWK 006, a variety of types of rocket are produced by the use of differing fuze arrangements and warheads. These are summarised in the following paragraphs.

CHARACTERISTICS

Propulsion element type TWK 006
Weight: 8·7 kg
Mean thrust at +18° C: 11 000 N
Total impulse at +18° C: 910 kg/s
Action time at +18° C: 0·85 s
Length: 1033 mm

Rocket type RAK 022
Length: 1548 mm
Weight: 15·7 kg
V max from ground at +18° C: Approx 670 m/s
Range ground-to-ground at +18° C: Approx 10 km
Flight time over 10 km at +18° C: 50 s
Shell type UGK 028: Practice
Weight: 7 kg

Rocket type RAK 023
Length: 1416 mm
Weight: 13·2 kg
V max from ground at +18° C: Approx 820 m/s
Range ground-to-ground at +18° C: Approx 10 km
Flight time over 10 km at +18° C: Approx 50 s
Shell type SSK 031: Fragmentation explosive
Weight
Trotyl explosive: 1 kg
Shell ready to fire: 4·5 kg
Number of spherical fragments: 702
Fragment weight: 2 g
Nose fuze type RKX332: Mechanical impact
Length of fuze: 46 mm
Muzzle safety: Minimum 30 m
Armed after: Max 100 m
Weight
Explosive: 9·5 g
Fuze ready to fire: 320 g
Response angle: 15°
Response sensitivity on 2 mm aluminium: 100 m
Detonator safety
Rain safety

Rocket type RAK 024
Length: 1548 mm
V max from ground at +18° C: Approx 670 m/s
Range ground to ground at +18° C: Approx 10 km
Flight time over 12 km at +18°: Approx 50 s
Shell type SSK 029: Fragmentation explosive
Weight
Trotyl explosive: 1·7 kg
Shell ready to fire: 7 kg
Number of spherical fragments: 1215
Fragment weight: 2 g
Nose fuze type RKX 332: Mechanical impact

Rocket type RAK 025
Length: 1783 mm
Weight: 19·7 kg
V max from ground at +18° C: Approx 520 m/s
Range ground to ground at +18° C: Approx 10 km
Flight time over 12 km at +18° C: Approx 50 s
Shell type SSK 032: Fragmentation explosive
Weight
Explosive: 2·8 kg
Shell ready to fire: 11 kg
Number of spherical fragments: 2133
Fragment weight: 2 g
Nose fuze type RKX 332: Mechanical impact

Rocket type RAK 026/RAK 054
Length: 1510 mm
Weight: 13·2 kg
V max from ground at +18° C: Approx 820 m/s
Flight time over 2 km at +18° C: Approx 3·2 s
Warhead type PHK 030: Hollow charge
Weight
Explosive: Approx 1 kg
Warhead ready to fire: 4·5 kg
Warhead with fragmentation effect
Penetration in steel: Minimum 350 mm
Response angle: 15°
Ignition via contact cap
Base fuze type RBK 331: Electro-mechanical, with mechanical and electronic time element
Detonator safety : to 30 m
Armed after: 100 m
Rain safety
Ignition energy from propulsion element

A range of rocket launchers suitable for fitting to fighter aircraft and helicopters is produced by Oerlikon, and these are detailed in entry **4135.303** which follows.

STATUS

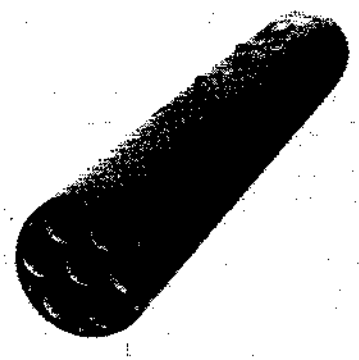
In production. SNORA rockets have been successfully tested on various aircraft types including the following: SF260 W, Hawk, MB326K, MB339, Venom, Hunter, Mirage, Skyhawk A-4.

CONTRACTOR

Machine Tools Works Oerlikon-Bührle Ltd, 8050 Zurich, Switzerland.

4135.303

OERLIKON ROCKET PODS



A range of rocket pods for firing Oerlikon SNORA aircraft rockets is produced for fitting in various fighter aircraft and helicopters. The main characteristics of these are listed in the following tables.

Rocket Launcher Type SAL-12-80 (RWK 020)

Suitable for use on all types of sub- and supersonic aircraft, the SAL-12-80 pod is of lightweight metal construction with a replaceable frangible nose fairing to close the 12 firing tubes during flight. It is fitted with a standard NATO and centre lugs suspension system.

CHARACTERISTICS

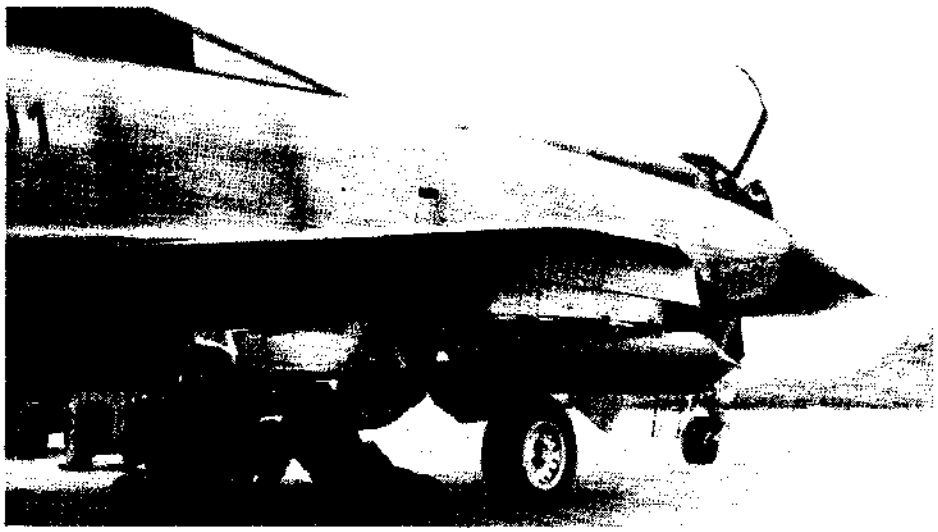
Calibre: 81 mm
Number of tubes: 12
Length: 2550 mm (approx)
Diameter: 396 mm (approx)
Weight: 69 kg (empty); 227 - 305 kg (with rockets, depending on type of shell)
Firing: Single, or salvoes of 2, 6, or 12 rockets
Rate of fire: 12 rounds/s

Type HL-7-80 helicopter rocket launcher

Type HL-7-80 rocket launcher installed on a helicopter

Rocket Launcher Type SAL-6-80 (RWK 021)

This is a six-tube launcher for use on supersonic aircraft.



CHARACTERISTICS
Calibre: 81 mm
Number of tubes: 6
Length: 2600 mm
Diameter: 296 mm
Weight: 48 kg (empty); 127 - 166 kg (with rockets, depending on type of shell)
Firing: Single, or salvoes of 2, 3, or 6 rockets
Rate of fire: 10 rounds/s

Rocket Launcher Type AL-6-80 (RWK 024)
This is a six-tube launcher for use on subsonic and light aircraft.
CHARACTERISTICS
Calibre: 81 mm
Number of tubes: 6
Length: 2214 mm
Diameter: 296 mm
Weight: 38 kg (empty); 117 - 132 kg (with rockets, depending on type of shell)
Firing: Single, or salvoes of 2, 3, or 6 rockets
Rate of fire: 10 rounds/s

Rocket Launcher Type HL-7-80 (RWK 022)
This launcher is designed for use on helicopters.
CHARACTERISTICS
Calibre: 81 mm
Number of tubes: 7
Length: 1800 mm

Type SAL-12-80 rocket launcher (RWK 020)

Type SAL-12-80 rocket launcher installed on a fighter aircraft

Type AL-6-80 rocket launcher for subsonic and light aircraft

Diameter: 296 mm
Weight: 33 kg (empty); 125 - 143 kg (with rockets, depending on type of shell)
Firing: Single, or salvoes of 2, 3, or 7 rockets
Rate of fire: 10 rounds/s

Type SAL-6-80 rocket launcher for supersonic aircraft

STATUS
In production.

1269.303
OERLIKON 30 mm GUN TYPE KCA
The aircraft gun type KCA is of 30 mm calibre and has been developed by Oerlikon, Switzerland. The weapon is a further example of the development of the Mauser revolver principle which has been almost universally adopted for single barrel aircraft cannon since the end of the Second World War.

The KCA differs, however, from almost all comparable guns in the present generation in using a new design of ammunition in which the ratio of propellant charge to projectile weight is over 2:1 whereas in most other guns, the ratio is likely to be 3:2. In addition, the KCA ammunition has a higher projectile weight than other 30 mm types.

As a result of these factors and lightweight design of the moving parts of the weapon, a firing rate of 1350 rounds per minute is obtained and a muzzle velocity of over 1030 m/s. The weapon is therefore well suited to ground attack as well as air-to-air engagements, and for the former role a long gun range is required to give the attacker a wide firing bracket.

The Oerlikon KCA has a four chamber revolver mechanism so that before firing the gun mechanism has to be cycled three times to charge all chambers. This can be done in the air by a pneumatic re-loading system.

Ammunition for the KCA is available in a range of types: TP, HEI, SAPHEI, and AP.
CHARACTERISTICS
Calibre: 30 mm
Length of barrel: 1976 mm
Length of gun overall: 2691 mm
Width of gun: 242·5 mm
Height of gun: 249·5 mm
Gun weight: 136 kg
Muzzle velocity: 1030 m/s
Rate of fire: 1350 rounds/minute
Accuracy: 50% rounds inside 2·5 mils
Round weight: 0·89 kg with steel cartridge
Projectile weight: 0·360 kg
Range: Over 2000 m gun stationary
STATUS
The Oerlikon KCA is in series production, and has been selected by the Swedish Air Force for installation under the Saab Viggen attack aircraft.
CONTRACTOR
Machine Tool Works Oerlikon-Bührle Ltd, 8050 Zurich, Switzerland.

Oerlikon Type 30 mm KCA cannon

4070.303
OERLIKON HELICOPTER ARMAMENT
To meet the growing need for armament on helicopters for both transport and combat duties, Oerlikon has developed and tested a number of cannon installations for the engagement of enemy helicopters and various ground targets. This work has been carried out in close collaboration with helicopter manufacturers such as Agusta, CASA and Westland. The most suitable cannons are the Oerlikon 20 mm KAA, KAD and the 25 mm KBA types. Details of each are given in the table.

CHARACTERISTICS

Type	**KAA**	**KAD**	**KBA**
Calibre	20 mm	20 mm	25 mm
Muzzle velocity	1040-1100 m/s	1040 m/s (approx)	1100-1360 m/s (approx)
Rate of fire (rounds/min)	1100	850(approx)	570
Total length	2690 mm	2744 mm (approx)	3105 mm
Mass of cannon	88 kg	68 kg	112 kg
Mass of cradle	45 kg	49 kg	33 kg
Firing system		Electro-mechanical	
Projectile mass	110-125 g	125-144 g	180 g*
Mass of comp round	322-337 g	306-337 g	500 g*
Length of comp round	203·5 mm	213 mm	223 mm

*25 mm APDS-T projectile mass 150 g, complete round mass 475 g.

The cannons with their cradle are rigidly fixed to the helicopter structure. Depending on the size of the aircraft, the configuration may consist of either a cannon on each side or of a single cannon on the fuselage centre-line or pintle-mounted in the cabin. Belted ammunition is fed to the cannons from containers inside the helicopter through specially designed chutes. Ammunition types available cover the range of TP, AP, APDS-T, SAPHEI and HEI, all of which can be supplied with or without tracer

STATUS

The fixed forward firing installation has been tested and proved on the Westland Lynx helicopter.

HISPANO OERLIKON 20 mm TACTICAL AIR ARMAMENT

Two types of 20 mm calibre aircraft cannon were manufactured by Hispano Suiza in Switzerland and by their UK company, British Manufacture and Research Co Ltd of Grantham, Lincolnshire. Both types, the 20 mm Mk 5 and 20 mm Mk 2* are similar and are derived from the original Hispano type 404 weapon. The Mk 5 model is lighter in weight than the Mk 2* and has a higher rate of fire. Although no longer part of the company's programme, this weapon remains in extensive service in many parts of the world.

A wide range of 20 mm ammunition types is available, including armour piercing, tracer, ball, and HE incendiary. Different types of fuze are also available. The round has a brass case and is percussion fired. Ammunition is normally supplied in 60-round belts or as individually packed rounds.

A wide variety of tools and accessories are available for 20 mm Mk 2* and Mk 5 guns.

CHARACTERISTICS

20 mm Mk 5 gun

Calibre: 20 mm

Gun weight with feed: 42 kg

Muzzle velocity: 850 m/s

Rate of fire: 580 – 640 rounds/minute

Length of gun: 2052 mm

Round weight: 1367 g

Projectile weight: 138 g

Range: 1600 m, to velocity 300 m/s, gun stationary

STATUS

Hispano 20 mm aircraft cannon are in service with over 30 air forces. Over 98 000 20 mm guns of all types have been made in the UK alone. It is now regarded as obsolete though many examples can be expected to remain in service for a considerable period to come.

UNION OF SOVIET SOCIALIST REPUBLICS

3181.303

SOVIET AIRCRAFT ARMAMENT NOTE

Unclassified information on Soviet aircraft armament tends to be limited in both quantity and precision but the increasing emphasis on this aspect which has been detected by observers of Soviet military activities calls for a summary of the known characteristics of Soviet equipment of this nature.

Bombs

The following types of free-fall bomb are known to have entered service with Soviet forces and those of some allied nations:

(1) HE – High explosive bombs are issued in 100, 250, 500, 750 and 1000 kg sizes
(2) Incendiary – Incendiary bombs are issued in 100, 250 and 1000 kg sizes
(3) AP – Armour piercing bombs are issued in 250 and 500 kg sizes
(4) Concrete dibbers are known to be used in both 250 and 500 kg sizes, the latter being designated the M62
(5) Cluster bombs have been in service for a number of years and the following varieties are known to exist: HE, incendiary, HEI, fragmentation, and anti-tank (shaped charge)
(6) Napalm bombs are available.

Categories (4) and (5) probably include one or more types of retarded bomb mechanism.

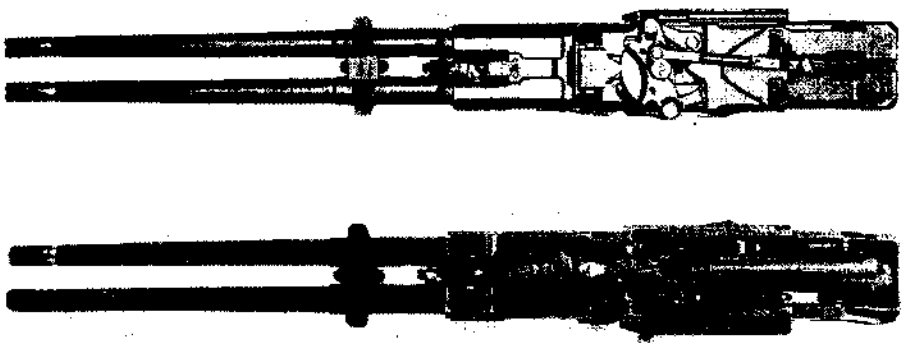
Unguided Rockets

Unguided rockets are employed in both air-to-air and air-to-ground roles and are carried by fixed-wing aircraft and helicopters. In the case of the heavier rockets, use is restricted to ground attack (or anti-ship) roles. The following types have been identified:

57 mm: The rocket itself is designated S-5 and is of 55 mm diameter for use with 57 mm launcher tubes. A variety of warheads is available including: chaff, anti-tank, HE, and fragmentation. Applications have been noted on such types as the Fitter and Fishbed fighter aircraft and the Hind helicopter. A range of launcher pods has been observed of 8, 16, 19 and 32 round capacities and designated: UV-8-57; UV-16-57; UV-19-57; UV-32-57.

Mi-24 Hind ground attack helicopter is armed with four UV-32-57 rocket launcher pods, rails for anti-tank guided missiles, and a four-barrel Gatling-type 12·7 mm machine gun in a remotely aimed chin turret

137 mm: This rocket is known as the M-100 and has a launch weight of 15·6 kg.



160 mm: No information is available on this rocket apart from its designation (S-16) and the fact that it can be launched from the Hind-A helicopter.

190 mm: Of 190 mm calibre, and designated TRS 190, this rocket has a launch weight of 46 kg and can be launched by the MiG-19.
212 mm: Little is known apart from the designation, ARS 212, launch weight of 116 kg and use with the MiG-19.
220 mm: No information is available, but some sources report the existence of a 210 mm rocket known as the S-21 which is used with the Hind-A.
240 mm: Known as the S-24 and associated with the MiG-17 and Mig-21 (one rocket per pylon) and the Hind helicopter.
325 mm: No details available.

Cannon and Machine Guns
The following types are known to be in service:
12·7 mm: UBK machine gun has been used in the MiG-15UTI trainer aircraft and more recently in the Mi-24 helicopter. The latter is probably the most important application of this calibre of machine gun in aircraft, beginning with the single chin mounting in the Hind. This was followed by a multi-barrelled, Gatling-type gun with four 12·7 mm barrels mounted in a turret that provided coverage of 70° left and right of the aircraft datum in azimuth, and elevation movement from −60 to +15°. The estimated range of this weapon is about 1500 m. It has been suggested that the four-barrel 12·7 mm gun may be succeeded on the Hind helicopter by the GSh-23 (see below) as used on the MiG-21.
23 mm: Two 23 mm single-barrel cannon have been identified, the NS-23KM (Nudelman-Suranov) and the NR-23 (Nudelman-Rikter). In many installations the two are probably interchangeable. The NS-23 is understood to be of earlier design and to have a lower rate of fire, ie 550 rounds/minute compared with about 850 rounds/minute for the NR-23. Widely used in fighter, bomber, and certain transport aircraft.
23 mm GSh-23: This is a twin-barrel 23 mm gun employed both as an internal weapon and in the GP-9 gun pack for belly mounting. In the latter case, as used on the Fishbed 'E', the pack has a capacity of 200 rounds. Cyclic rate of fire is about 3000 rounds/minute and effective range 3000 m. A version of this weapon has been noted that is designed for mounting within a pod for carriage on an aircraft underwing attachment point. This variant has been seen on some Yak-36 Forger carrier aircraft.
23 mm: A 23 mm six-barrelled cannon is known to be in use on some recent Soviet aircraft but the only known installation of this is on MiG-27 aircraft.
30 mm: The NR-30 cannon is used on the Su-7, Su-20, Yak-28, and MiG-19S, and has a rate of fire of 850 rounds/minute with normal, HE, and HEI ammunition. A capacity of 70 rounds is typical.
30 mm: The 2NR cannon is used in Fitter A and Fitter C aircraft.
37 mm: The N-37 (or NS-37) cannon has a cyclic rate of fire of 400 rounds/minute and is used in such aircraft as the MiG-15, MiG-17, MiG-19, Yak-25, and Yak-27R.

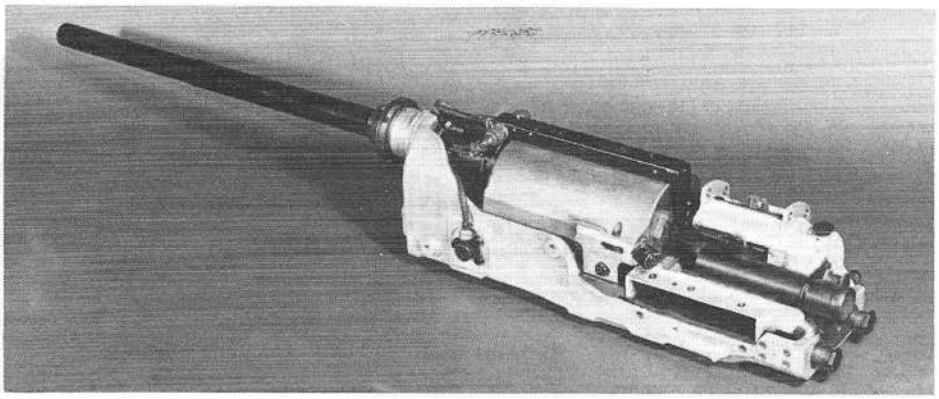
5185.303
30 mm ADEN CANNON
The 30 mm Aden cannon was developed shortly after the end of the Second World War by the ADE (now the Royal Armament Research and Development Establishment at Fort Halstead), and the Royal Small Arms Factory (RSAF) at Enfield Lock. The first production model was known as the Mk 1 and the current production cannon is the Mk 4. An improved Mk 5 version was also developed, known as the Straden, which had a higher rate of fire (see below).

The design of the weapon is simple with the whole assembly contained within the cradle unit; installation mounting points are at the rear and front barrel entry position of the cradle. Mounting of the cannon is possible at any angle on the longitudinal axis to suit the specific aircraft requirement, and both left- or right-hand feed versions are available. Cocking is pneumatic with provision for manual operation, and the ammunition, which is belt fed (disintegrating link), is electrically fired.



The Aden operates in the following manner. A cylinder (revolving drum) has five cartridge chambers, into which the cartridges are loaded in two stages, indexed by the movement of a gas operated slide. Firing takes place when a round is in line with the barrel, the whole mechanism being safely locked at the moment of firing; a round cannot be fired if the barrel/cylinder is not correctly locked in position, and with a round in line with the barrel. When a round is fired, the gas pressure passing through the barrel gas port acts via a piston onto a slide mechanism, which, travelling rearward within the cradle unit revolves the breech cylinder and feed sprockets, bringing a round into position for feeding into a chamber. The slide mechanism is then moved forward by the action of return springs, further indexing the cylinder and feeding into a chamber. The Aden cannon can be mounted internally in an aircraft, in a pod for installation under a pylon, or in a blister pod which is mounted under the fuselage of the aircraft.

TYPICAL INSTALLATIONS
Harrier with two cannon, each with 130 rounds of ammunition.
Hawk trainer with a blister pod with one 30 mm cannon.
HAL Gnat with two cannon, each with 115 rounds of ammunition.

HF-24 Marut with four Mk 4 guns, each with 120 rounds of ammunition.
Hunter with four cannon, each with 150 rounds of ammunition.
Jaguar (RAF) two cannon with 150 rounds of ammunition per cannon.

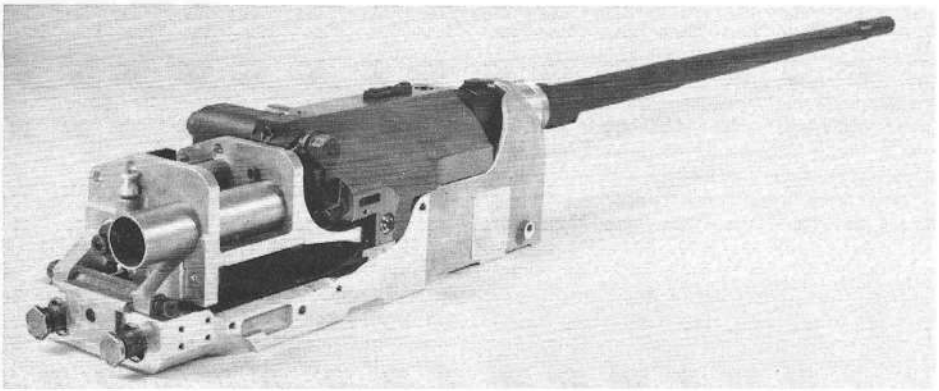
CHARACTERISTICS
Type: Aden Mk 4
Calibre: 30 mm
Gun length: 1590 mm
Total gun weight: 87 kg
Barrel length: 1080 mm
Barrel weight: 12·25 kg
Muzzle velocity: 790 m/s
Rate of fire: 1200/1400 rounds/minute
Recoil load: 31·4 kN
Cocking: Pneumatic
Firing: Electric (26 V DC)
Ammunition
Practice round (Mk 4*Z)
High explosive round (Mk 6*Z)
Armour piercing (Mk 1*Z)
Armour piercing incendiary (under development)
Typical system weight: 196 kg (gun + 200 rounds)

DEVELOPMENT
RSAF Enfield have now completed the development programme designed to increase the effectiveness of the Aden Mk 5 cannon by increasing its rate of fire from 1200/1400 rounds/minute to 1500/1700 rounds/minute combined with improved reliability. Guns modified to this standard are termed Aden Mk 5 (Straden) cannon. This work has now been absorbed into the 25 mm Aden programme (see **4870.303**, below).

30 mm Aden cannon

CONTRACTOR
Royal Small Arms Factory, Enfield Lock, Middlesex. Enquiries to Director of Sales, Ministry of Defence, Stuart House, 23-25 Soho Square, London W1V 5FJ, England.

4870.303
25 mm ADEN CANNON



The 30 mm Aden cannon (**5185.303**) was developed shortly after the Second World War at the RSAF, Enfield, and subsequently enjoyed a considerable reputation in a wide variety of aircraft and other applications, but it was realised that the scope for improvements to overall system performance was limited. It was therefore decided to modify the 30 mm Aden to fire the more powerful NATO 25 mm ammunition. The result is the 25 mm Aden cannon, which has been selected for RAF Harrier II (GR5).

The design criteria laid down during feasibility studies that led to the Aden 25 were:

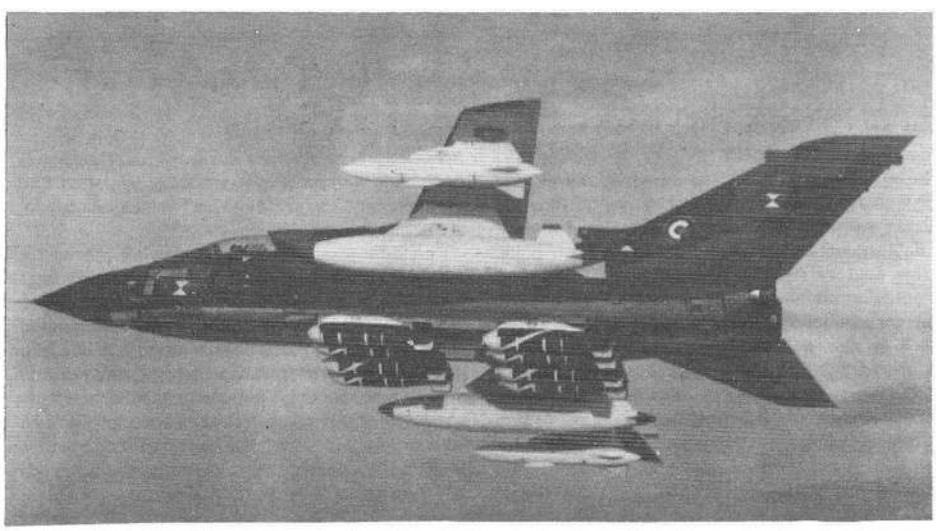
(1) The space envelope and mounting points of the gun (excluding the barrel) should be the same as those of the 30 mm Aden.
(2) It should have a rate of fire of 1650 - 1850 rounds/minute, so that in a two-gun configuration its performance would match that of the US GAU 12.
(3) Weight should not be more than ten per cent above that of the 30 mm Aden.
(4) Loads on the aircraft airframe should be similar to those for the 30 mm Aden.

The studies also revealed that the longer length and cartridge case diameter of the 25 mm round could be accommodated within the 30 mm cradle length; higher strength materials would enable the higher pressure of the 25 mm round to be restrained within the same dimensions as the 30 mm Aden gun; and the rate of fire of about 1800 rounds/minute could be achieved using the technology already developed for the STRADEN (stretched Aden) project of the early 1970s.

In conjunction with Royal Ordnance Small Arms Division, BAe are developing a pod to mount the gun and to accommodate the storage and feed for the larger 25 mm round. Other aspects, such as the suppression of blast and gas ingestion, involve RAE, Farnborough and A&AEE, Boscombe Down.

25 mm Aden aircraft cannon

CHARACTERISTICS
Calibre: 25 mm
Gun length: 2285 mm
Barrel length: 1700 mm
Operation: Gas, revolver
Mass: 92 kg (including barrel)
Max cross section: 246 × 240 mm
Rate of fire: 1650 - 1850 rounds/minute
Time to rate: 20 ms
Muzzle velocity: 1050 m/s
Ammunition: 25 mm NATO Stanag 4173
Electromagnetic hazard: None (percussion fired)
Power requirement for drive: Self-powered
Trunnion force: 26 kN (peak); 21 kN (average)



STATUS
The British MoD has selected the 25 mm Aden for the Harrier GR5 being jointly developed by BAe and McDonnell Douglas. The pilot model has completed a significant number of trial firings with good results and prototype guns have been built at RSAF Enfield for air firing (in Harrier GR3) and other trials in 1985. The pre-production and qualification phases are expected in early 1986. In RAF service the Harrier GR5 will employ twin Aden 25s carried in pods beneath the fuselage and just to the sides of the centre-line. Total weight of the twin Aden 25 pod with 200 rounds is 430 kg.

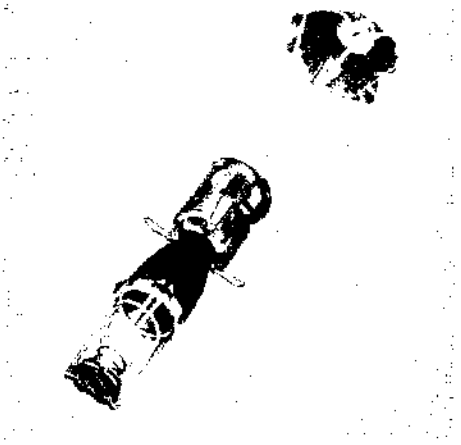
1277.303
CLUSTER BOMB No 1 Mks 1, 2, 3, and 4 (BL 755)

BL 755 has been developed to meet a requirement for a weapon that will yield a high kill probability against a range of small hard and soft targets encountered in the battlefield and immediate tactical area. Because of the efficiency of modern surface-to-air weapon systems it is operationally necessary for air-to-ground attacks, in support of ground forces, to be carried out at very low level. Any other form of attack necessitates prolonged exposure to the enemy ground defences and negates any element of surprise. This will result in unacceptable losses to the attacking aircraft.

To compensate for the aiming errors inherent in low-level attack, BL 755 covers the target area with a pattern of bomblets the dimensions of which are proportional to the aiming errors. The dual function bomblets are effective against armoured and soft-

Tornado GR1 with BL 755 anti-armour weapons

skinned vehicles, parked aircraft and personnel, and are distributed evenly within the pattern.



Before take-off, one of four time delays is set to ensure a safe weapon/aircraft separation distance. When the bomb is released, its primary striker is armed and, on completion of the selected timer interval, the striker operates and fires the primary cartridge. The gas pressure generated by this cartridge releases the two-part bomb body skins before activating the main gas cartridge to eject the bomblets. 147 bomblets are carried in seven bays with 21 bomblets in each bay of the bomb body. The bomblet ejection velocity is varied between the bays to ensure an even ground pattern. Each bomblet is armed after a short period of flight and, on impact, uses a shaped-charge effect to give a penetration of armour of at least 250 mm. In addition to its armour penetration capability, each bomblet casing explodes into over 2000 fragments which have an effective penetration against non-armoured vehicles and other targets.

BL 755 is compatible with current and future strike aircraft. It can be carried in a bomb bay or externally with twin 14-inch (356 mm) or single suspension. It can be delivered using a simple or sophisticated sighting system; it is immune from electronic countermeasures and incorporates a safety mechanism which provides protection for the aircraft during carriage and release and the deployment of bomblets.

CHARACTERISTICS

Weight: 277 kg

Weapon payload: 147 bomblets

Improved BL 755 bomblet

Length: 2451 mm

Diameter: 419 mm

Fin span: 566 mm

Suspension: Twin lug at 14-inch (356 mm) spacing or single lug

Main variations from Mk 1

Mk 2, shorter time delays

Mk 3, addition of 250 mm twin lug suspension

Mk 4, incorporates same time delays as Mk 2

IMPROVED BL 755

The interim RAF requirement to increase its anti-armour capability against MBTs with improved armour that are entering service is to be met by an Improved BL 755.

The Improved BL 755 system retains the shot-gun principle of compensating for aiming errors but takes advantage of the higher weapon aiming accuracy of modern aircraft by modifying the pattern of bomblets.

The submunition is retarded to increase angle of attack thus permitting later target acquisition and better target penetration whilst the warhead incorporates advances made in shaped charge technology and explosives since the introduction into service of the original BL 755.

Other BL 755 design features are unaltered so that full aircraft compatibility and flexibility of operation of the current weapon are retained.

STATUS

BL 755 has been in service with the Royal Air Force since the early 1970s and has been supplied to six primary NATO air forces and those of other nations. It is used on numerous aircraft types. In Swiss service the BL 755 is designated FI Bb 79. Improved BL 755 will enter RAF service shortly and is available for export to approved clients.

1267.393

BRITISH BOMB RETARDING SYSTEM

The British bomb retarding system was developed in the UK by Hunting Engineering Ltd. The retarder is incorporated in a special bomb-tail assembly which can be readily applied to a wide range of existing ballistic bombs.

The retarding tail with its associated fuze has been designed to overcome the problem of low altitude attack. If a conventional bomb is used from low altitudes it is likely that the separation of the attacking aircraft from the bursting of the bomb will be small enough to endanger the attacking aircraft. The purpose of the retarding tail is to decelerate or retard the bomb after release, and allow the aircraft to reach a safe separation distance before the bomb impacts and explodes. Conventional delayed action bombs, if used in this way, are liable to ricochet and to miss their targets.

Multiple release of retarded bombs from Phantom aircraft

The retarding tail utilises a combination of a ribbon parachute and air-brakes (retarder arms) formed from the structure of the tail. This technique has the advantages of providing very high drag after a closely predictable time delay, essential for accurate control of bomb stick spacing leading to improved probability of target destruction.

The basic structure of the retarder tail consists of a base ring made in forged steel in which are incorporated eight securing pads for attaching the tail to the bomb. The steel inner cone is welded to the base ring and at the aft end carries the one-piece fin casting in light alloy. This casting is riveted to the steel inner cone. The four retarder arms consist of spines carrying the outer skin sections. The spines pivot at the root of the fins and when extended form four airbrakes. When closed the skin sections form the tail cone enclosing the folded ribbon fabric.

The design incorporates various safety measures which ensure that at no time does the bomb constitute an unacceptable hazard to the aircraft during carriage or after release.

A timer mechanism which controls the operation of the unit is housed within the inner cone. As the bomb is released from the aircraft this timer is initiated by a lanyard. After a short interval to allow the bomb to fall clear of the aircraft the timer triggers the release of the retarder arms. These arms are forced into the airstream by a spring and then aerodynamic forces extend them to the fully open position. The energy released in this operation is absorbed by a tear-webbing shock absorbing device.

At the base of the tail, couplings are provided to connect with the tail fuze of the bomb, so that the arming of the latter is controlled by the action of the retarding tail mechanism.

While being carried aboard the aircraft, retarding tail bombs resemble conventional fixed fin types. The fins are provided to stabilise the bomb aerodynamically immediately after release. In the event of the bomb being jettisoned the retarding tail is not operated and neither is the fuze armed. Retarded bombs can be carried externally or internally in subsonic or supersonic aircraft.

CHARACTERISTICS

Bomb Retarder Tail Type 117

This tail is 1035 mm long and 584 mm span. It was developed initially for use with British 1000 lb HE medium capacity Mk 6 and 9-19 series bombs. Two types of tail, Mk 3 and Mk 4, are available. The Mk 3 with a tail fin span of 584 mm is suitable for external carriage while the Mk 4 with a tail fin span of 419 mm is suitable for both external and internal bomb carriage.

Bomb Retarder Tail Type 118

This tail is 970 mm long and 463 mm span. It was originally designed for use with the British 540 lb HE medium capacity bomb.

Adaptors are available to couple type 117 and 118 retarding tails to many other types of HE bombs, including the principal US types such as Mk 82 and 83, Mk 64, Mk 65, and Mk 117.

Both types of retarder are designed for a shelf life of at least five years without attention.

STATUS

The retarding system is in service with the Royal Air Force and is being supplied to air forces overseas.

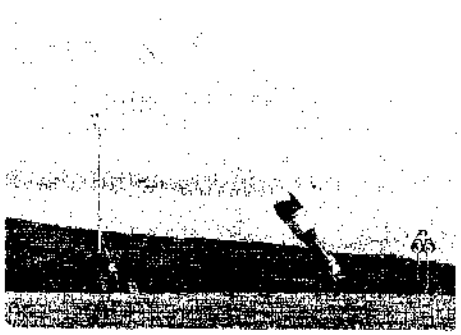
Hunting Engineering Ltd, Reddings Wood, Ampthill, Bedfordshire MK45 2HD, England.



5218.303

JP233 LOW ALTITUDE AIRFIELD ATTACK SYSTEM

The JP233 airfield attack weapon system has been developed for the Royal Air Force for use in counter air operations. The operational concept of the weapon is the suppression of an enemy's ability to mount aircraft sorties by damaging the aircraft operating surface of his airfields and then preventing its repair, to an extent that prevents take-off and landing for prolonged periods.

The weapon is designed for the high speed, low level, simultaneous delivery of two complementary weapons – a cratering weapon to attack and render unuseable, runways, taxiways and grass operating strip, and an area denial weapon to pose a continuing threat to vehicles and crew engaged in airfield repair. The JP233 weapon comprises a cratering weapon designated SG357 and an area denial weapon designated HB876. Each of the weapons consists of a dispenser loaded with submunitions, 30 for the SG357 and 215 for HB876. A Tornado carries two JP233 systems mounted in tandem on the port and starboard shoulder pylons with the forward positions occupied by the two HB876 dispensers and with two SG357 dispensers aft.

To ensure effective ground cover both types of

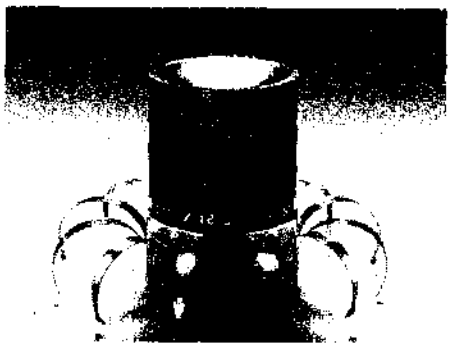
SG357 runway cratering submunition for JP233 airfield attack weapon

JP 233 full load release from Tornado GR1 aircraft

submunitions are dispensed simultaneously in a coordinated sequence. The SG357 submunitions disrupt the operating surfaces by causing craters, heave and fractures over a large area whilst the HB876 mines overlay the cratered area to delay runway repair operations for some considerable time. The submunitions also cause a considerable amount of consequential damage to secondary targets such as aircraft, vehicles or buildings adjacent to the area being attacked.

The system can be configured for carriage by a range of advanced aircraft including Tornado, F-111 and F-16 where multiple dispensers are employed on either fuselage or wing mountings.

Apart from denying the enemy the use of his airfields, JP233 can equally well be employed against other important targets such as railway marshalling yards, transport and tactical vehicle concentrations, road networks, supply support depots, areas to which the enemy requires freedom of access and use.



It is claimed that typically, JP233 is five times more effective per aircraft load than other systems.

STATUS

The JP233 Weapon System is in the production phase and will be introduced to the RAF inventory by the mid 1980s

CONTRACTOR

Hunting Engineering Ltd, Reddings Wood, Ampthill, Bedfordshire MK45 2HD, England.

1845.393

WESTLAND-FRAZER NASH HIGH STRENGTH MACE

The ejector release unit (ERU) is in the form of a beam with the operating mechanism, breech etc, sandwiched between a pair of sideplates, one a baseplate, and the other a closure plate. The sideplates terminate in two identical gas operated ejector ram assemblies which also carry the store retaining jaws and incorporate integral wedge systems conforming to the crutchless form of store retention.

The jaws are designed to suit the recommended STANAG saddle lugs which are mounted on the store at 14-inch (356 mm) centres. The jaws are connected to the locking wedges by spring loaded links so that when the jaws are engaged with the saddles the wedges are forced into the clearance between the abutments on the ram cases and the surface of the saddle lugs. This effectively 'locks' the store to the ERU preventing any sway or pitch. Spigots are incorporated in the base of both ram case forgings to control yaw and fore and aft movement of the store.

The jaws are linked by connecting rods to a central operating toggle which, when turned on its axis, withdraws or engages the jaws. The linkage forms a geometric lock comprising an 'over-centre' system which is maintained in both locked and unlocked positions by a compression spring coaxial with a rod suspended between a projection on the breech and one arm of the linkage. In the locked position this rod is at the limit of its travel and so maintains the over-centre attitude, thus preventing the toggle turning. The release is achieved by a gas operated plunger which drives the toggle round so that the line of action of the spring on its rod now swings above the toggle pivot, reversing the sense of the geometric lock and maintaining it in the unlocked position with the jaws retracted from the bomb lugs. The design of the mechanism is such that the weight of the store tends to intensify the geometric lock in the loaded position, and, when released, to contribute a positive force to open the mechanism and prevent any possible 'hang-up'.

High-strength 14-inch (356 mm) MACE ejector release units for the Tornado

The plunger which operates the mechanism is housed in the breech block which forms the central unit of the gas system. The plunger is held in position by a screw cap and a spring. In operation the gases enter the cylinder at the upper end, via internal porting leading from the combustion chambers, and forces the plunger down against the spring, tripping the geometric lock, and retracting the jaws. The combustion chambers are twin receptacles bored in the breech block and threaded to receive the cartridge holders. These are inter-connected internally so that they both feed the gas system to ensure that if only one cartridge fires from electrical initiation the other will ignite sympathetically.

Internal ports lead from the combustion chambers fore and aft to the gas tubes which conduct the gases, on firing, to the ejector ram assemblies via interchangeable throttles housed in the inlets to the ram cylinders. These throttles are 'plug-in' units drilled with a gas port of some pre-determined diameter to govern the amount of gas entering the ram. By interchanging throttles with different orifice diameters the thrust of the rams can be adjusted to suit a limiting aircraft reaction, or by installing throttles of differing bore sizes at the forward and aft rams a differential thrust can be obtained to vary the attitude of launching of the store. These throttles can also be supplied with ports drilled to exhaust the gas directly to atmosphere so that the rams are inoperative when a free-fall gravity drop is required.

STATUS

Following the Panavia 'Intent to Purchase' notification issued in March 1973, development testing continued through 1973 to qualification of units in early 1974. Design was in accordance with a Panavia specification to meet the requirements of the multi-role combat aircraft for which the unit will be produced. Subsequent design improvements include an increase in overall strength and the option of quickly converting the unit to conventional sway braces in order to carry stores with the standard bail lug.

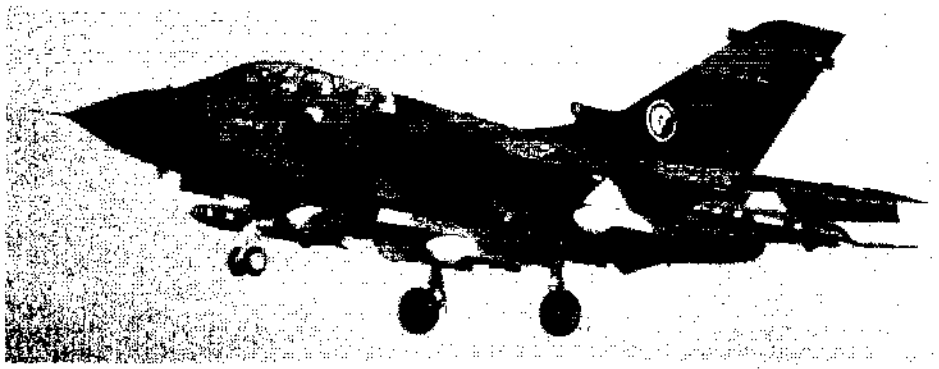
ML CARRIER BOMB LIGHT STORES No 200

The ML Aviation carrier bomb light stores No 200 (CBLS 200) is an aerodynamically faired carrier combining maximum strength and stiffness with minimum weight. It was developed from world-wide experience gained with the earlier ML CBLS 100, several hundred examples of which were supplied to many air forces before production ceased.



Standard carrier-to-aircraft suspension is via lug pockets for single suspension, NATO twin 14-inch (356 mm) and NATO twin 30-inch (762 mm) suspension. Lug pockets for twin 250 mm and other suspensions are also provided as required.

CBLS 200 is fitted with four ML ejector release units (ERUs) permitting the carriage and ejection, with standard ERU jaws, of four stores each up to 103 mm diameter and 750 mm long. Jaws for larger diameter stores are provided as required. Electrical and/or mechanical fuzing devices are fitted as and when called for by the particular types of stores to be carried. Stores up to an individual weight of 35 kg can be fitted at each ERU station. All stores are ejected vertically.

A comprehensive range of optional extra role change kits permits CBLS 200 to be converted rapidly from one type of light bomb to another with normal

ML carrier bomb light stores No 200 with rocket pannier

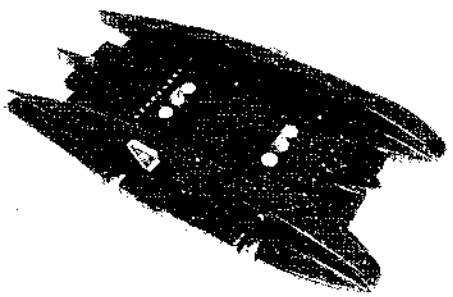
Four CBLS 200 on inner wing pylons and beneath fuselage of Tornado

first line servicing tools. A simple modification allows two five-inch flares to be carried to provide a night illuminating capability.

CBLS 200 incorporates a continuously re-cycling autoselector thus requiring only the simplest of electrical connections to the parent aircraft.

As an optional extra, rocket panniers to accept either four FFAR 2·75 inch or four SNEB 68 mm or four SNIA-VISCOSA 50 mm rockets can be provided to attach to the sides of CBLS 200 (two rockets in each side panel). In such cases, suitable electrical wiring systems, including a further continuously recycling autoselector, are added to the CBLS 200 itself.

CHARACTERISTICS
Overall length: 2464 mm
Diameter: 423 mm
Weight (less stores and rocket panniers): 53·5 kg
Weight with rocket panniers (less stores and rockets): 78 kg



STATUS
CBLS 200 is in production for air forces world-wide for use on a large number of aircraft types including Hawk, Alpha Jet, Jaguar and Tornado. It has also been adopted for aircraft currently in development.

CONTRACTOR
ML Aviation Co Ltd, White Waltham Aerodrome, Maidenhead, Berkshire SL6 3JG, England.

1264.393
ML AVIATION LIGHTWEIGHT LOW-DRAG TWIN STORE CARRIER

This carrier increases the capacity of a normal single external weapon station so that two stores can be carried. It is designed for use on wing or fuselage stations and incorporates two ML ejector release units, (ERUs) of the No 119 Series. These may be either ERU 119 Mk 1 providing for NATO twin 14-inch (356 mm) suspension or, alternatively, ERU 119 TH – a three hook variant combining within itself NATO twin 14-inch, twin 250 mm and single suspension. All the necessary fuzing services for a full range of modern conventional stores are incorporated in the carrier which can be supplied with electrical wiring for pilot or auto-selection according to requirements. Typical weapons used with this carrier are 250 kg HE bombs or rocket launchers.

The carrier consists basically of a main spar and baseplate machined from stretched light alloy plate. Raised lugs on the sides of the main spar form the attachment points for the two ERUs. Lightweight

ML Aviation lightweight low-drag twin store carrier

fairings are fitted over the main structure to minimise the aerodynamic drag of the carrier.

Twin lugs at the standard 14-inch (356 mm) centres are provided for mounting the carrier on any standard weapon pylon. If desired the carrier suspension can be offset from the centre line by 57 mm to either side, to adjust rolling moments or to increase store-to-aircraft clearance. Adaptors are available to use this carrier with single lug type store suspension or the 30-inch (762 mm) centres type.

CHARACTERISTICS
Carrier weight, including 2 × ERU 119: 37 kg
Length overall: 1638 mm
Width overall: 655 mm
Depth overall: 146 mm
Max store diameter: 420 mm
Max store weight: 550 kg
Max aircraft speed: Mach 0·95 loaded; supersonic empty

STATUS
The ML lightweight low-drag twin store carrier is in service with, or in production for, Alpha Jet, Harrier, Hawk, F-104 and Hunter aircraft. Flight trials with other aircraft types are also in progress.

CONTRACTOR
ML Aviation Co Ltd, White Waltham Aerodrome, Maidenhead, Berkshire SL6 3JG, England.

4484.393
ML AVIATION CARRIER BOMB TWIN STORE 30°

This carrier increases the capacity of a normal single external weapon station so that two 1000 lb class stores can be carried. It was designed primarily for the Harrier GR3 but is equally suitable for the wing and fuselage stations of most modern high performance aircraft and incorporates two ML ejector release units (ERUs) of the 119 Series (**7513.393**).

Arming connector assemblies are mounted on swivelling brackets which rotate from the vertical to horizontal position allowing free access for the operator to connect lanyards after stores are loaded to the carrier; each arming bracket assembly is then swivelled back to the vertical position for flight.

The ERUs are mounted 30° from the vertical to

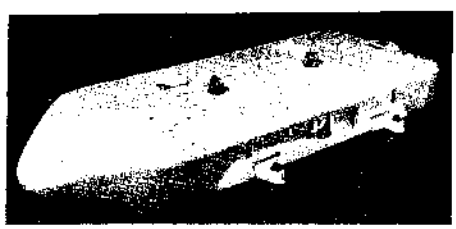
ML carrier bomb twin store 30°

provide increased horizontal distance between adjacent weapons thus reducing mutual aerodynamic interference and giving a subsequent reduction in release disturbance.

Each carrier has a Port/Stbd (Left/Right) selector switch to provide ground presetting if required and an auto selector which sequences the release pulses.

CHARACTERISTICS
Carrier weight: 48 kg (including 2 × ERU 119)
Length overall: 1498 mm
Width: 407 mm (less sway braces)
Depth: 194·5 mm

STATUS
Product on



CONTRACTOR
ML Aviation Co Ltd, White Waltham Aerodrome, Maidenhead, Berkshire SL6 3JG, England.

4485.393
ML AVIATION TWIN STORE INTEGRATED CARRIER

This carrier increases the capacity of a normal single external weapon station so that two 1000 lb class, or three lighter stores, can be carried.

The carrier introduces a new philosophy where the ejection system and operating linkage of a production ERU 126 (BRU 36A) (**4431.393**) is embodied in the structure of the carrier. This significantly reduces the carrier weight in relation to the strength provided. Logistic advantages accrue where the parent aircraft uses the ERU 126 (BRU 36A). Provision of electrics and store arming facilities for the central (third station) are built in as standard, however the third station is an optional extra.

Maintenance and ground handling functions are greatly facilitated by hinged side access panels which open to expose the complete ERU and arming connectors. These arming connectors can be rotated to the horizontal position, to allow connection of arming lanyards and cables after the weapon has been satisfactorily loaded to the ERU. The connector assembly is then rotated to the vertical position for flight.

ML twin store integrated carrier

The two shoulder stations are 22½ degrees from the vertical. This provides the optimum store body separation and minimum release disturbance for the AV8B pylon installation for which it was initially designed. The ISIC is, however, totally suited to all known high performance aircraft pylon installations embodying NATO standard suspension and is capable of adaptation to other suspension standards if required.

CHARACTERISTICS
Carrier weight: 45 kg (two-store configuration)
Length overall: 1422 mm
Width overall: 433 mm (less sway braces)

STATUS
Production.

CONTRACTOR
ML Aviation Co Ltd, White Waltham Aerodrome, Maidenhead, Berkshire SL6 3JG, England.

7513.393

ML EJECTOR RELEASE UNITS No 119 SERIES

The basic ML Aviation ejector release unit (ERU) No 119 accepts a very wide variety of stores with NATO twin 14-inch (356 mm) suspension. The two hooks are connected by a linkage forming a geometric lock via an over centre toggle mechanism thus ensuring complete integrity of carriage. All 119 Series ERUs are operated by two NATO standard cartridges housed in a central breech. The gas system incorporates provision for the control of the debris of cartridge combustion thus ensuring a considerable number of firings before the ERU requires servicing (up to 30 firings in 30 days).

When the cartridges are fired the gases so generated operate a release piston which positively opens both hooks simultaneously and, also, after passing through the throttles, extend the two ejector rams against the store, thus imparting ejection velocity to the store. By fitting differing throttle sizes ejection velocity against a given store can be increased or diminished within the total capacity of the ERU. Reaction loads against aircraft or carrier structure can also be adjusted as desired in the same way. By fitting differential throttles variable thrust can be obtained on the ejector rams thus enabling adverse release characteristics in pitch to be corrected so that a clean and stable release may be obtained. The ejector rams are housed in the two forged steel ejector ram barrels at the ends of the ERU which also incorporate the crutching arms (sway braces) and the holes for the mounting bolts.

The ERU is exceptionally light and is suitable for installation in aircraft pylons and in multi-store weapon carriers. It can be mounted between side-plates (as in a pylon) or side-mounted on a carrier beam or structure.

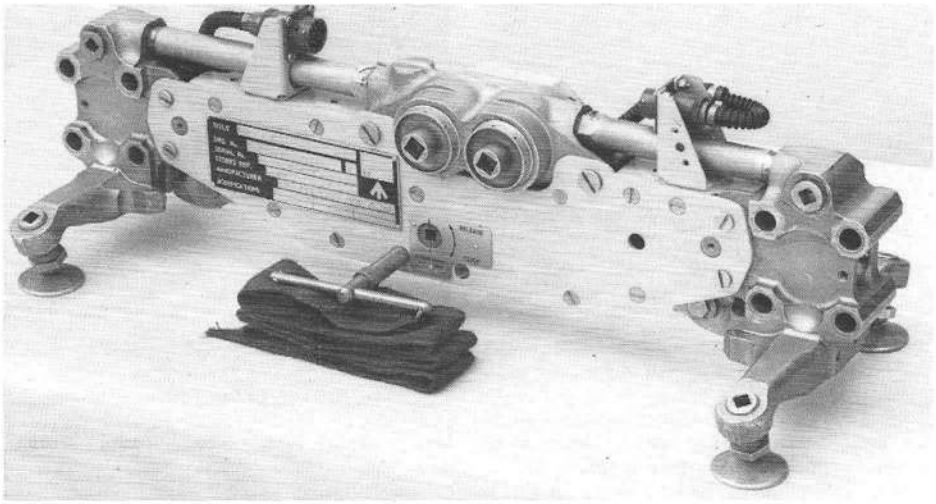
Several variants of ERU No 119 have been developed to meet the specific requirements of many customers throughout the world and the basic design permits such variations to be quickly and readily introduced. Among the latest designs is ERU 119TH incorporating a third suspension hook with the result that the particular variant will accept stores with either NATO twin 14-inch (356 mm) suspension, twin 250 mm suspension or single suspension.

CHARACTERISTICS

Overall length: 495 mm

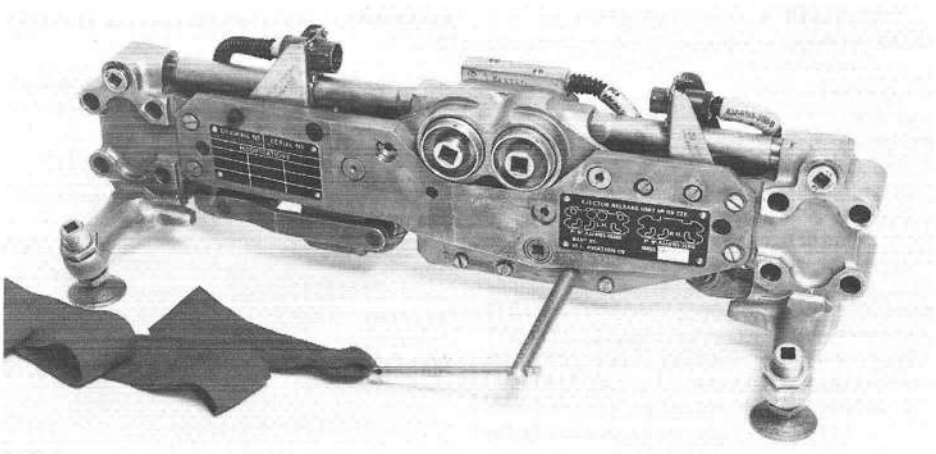
Overall height: 143 mm

Overall width: 44·5 mm – mounting width, sway braces etc protruding



Typical performance

Store weight 952 kg: Ejection velocity 2·4 m/s



Store weight 454 kg: Ejection velocity 3 m/s

Store weight 66 kg: Ejection velocity 8 m/s

Temperature range (without cartridge): -60 to +150° C

ML ejector release unit No 119

ML Aviation ejector release unit No 119TZE

Strength data

ERU 119: (Two-hook variants) depending on type selected

Ultimate hook load: Up to 13 608 kg

Ultimate crutch arm load: Up to 8618 kg

Ultimate yaw movement: Up to 2560 kg/m

Weight: 7·5 – 8·2 kg (with cartridge holders and throttles)

STATUS

Aircraft using the ERUs of the No 119 Series include Alpha Jet, Canberra, CF104, Casa 101, Draken, F104G, FST-2, Gnat, Harrier, Hawk, Hunter, Jaguar, Lightning, Phantom F4F, F4K, and F4M, Sea Harrier, Strikemaster aircraft, and Lynx, Sea King Commando and Sikorsky HH60 helicopters. ERU 119 is now in service with over 20 nations.

CONTRACTOR

ML Aviation Co Ltd, White Waltham Aerodrome, Maidenhead, Berkshire SL6 3JG, England.

1993.393

ML EJECTOR RELEASE UNIT No 120

This ERU is provided with two sets of suspension hooks to accommodate stores fitted with bomb lugs at either 14- or 30-inch (35·6 or 76·2 cm) centres. Therefore it can, if necessary, carry the larger stores or multi-weapon carriers. It is suitable for installation in a wing pylon or bomb bay. The positive lock and release mechanism for both pairs of hooks is mounted between two forged steel ejector ram barrels incorporating crutching arms and mounting holes.

The unit is operated by gas pressure from a central breech containing two cartridges. When fired the rapidly expanding gases are transmitted to an actuator piston which first unlocks the hook mechanism and thence, via a variable throttle system, to each of the ejector rams which thrust the store off. Readily interchangeable throttles enable the ram characteristics to be adapted to the role.

CHARACTERISTICS

Linear velocity: 15 ft/s on 1000 lb store (4·6 m/s on 454 kg store) with a reaction of 19 000 lb/ft (860 kg)

Temperature range: -60 to +150° C (without cartridge)

Strength data

Max reaction load at 120° C: 22 000 lb/ft (9980 kg)

Ultimate crutch arm load: 50 000 lb/ft (22 700 kg). Normal to 16·5 inches/diameter store (42 cm)

Ultimate hook load 14-inch (35·6 cm) centres: 47 000 lb/ft per hook (21 300 kg)

Ultimate hook load 30-inch (76·2 cm) centres: 58 000 lb/ft per hook (26 300 kg)

Weight: 67½ lb (30·6 kg)

STATUS

In service with, or in production for, Buccaneer and Jaguar aircraft.

ML Aviation Co Ltd, White Waltham Aerodrome, Maidenhead, Berkshire SL6 3JG, England.

4431.393

ML BOMB EJECTOR RACK BRU-36A/A AND EJECTOR RELEASE UNIT No 126

The ML BRU-36A/A has been developed for installation at all seven weapon pylon stations on the McDonnell-Douglas AV-8B development of the V/STOL Harrier. With minor modifications to meet RAF requirements, the BRU is given the British designation of Ejector Release Unit No 126 and will be installed on the British version of the AV-8B known as the Harrier GR Mk 5. The design is based on the proven principles of the ML ERU No 119 (**7513.393**) with a central geometric lock coupling two bomb hooks, but provides a greatly enhanced load carrying capability within stringent weight limits. It will accept a range of stores up to 1045 kg with NATO twin 14-inch (356 mm) suspension manually crutched at four points by fore and aft crutch arms (sway braces). Store loading is facilitated by the incorporation of a hook operating mechanism that enables each store lug to be latched automatically and independently during loading. The hooks are, however, automatically coupled during release and ejection. Variable store pitch control is effected by fore and aft self retracting ejector pistons each of which is controlled by the setting of a three-position throttle selected on the ground on-aircraft. An integral ground safety lock is incorporated to eliminate the

ML Aviation bomb rack unit BRU-36A/A, UK designation ERU No 126

need for separate safety pins and warning flags. Fuzing units are fitted to provide a store nose and/or tail mechanical arming facility.

A number of design features are included to minimise maintenance and turn round operating costs and allow the BRU to be operated for 180 days before it becomes necessary to remove it from the aircraft for routine maintenance. The most significant of these is the ability to remove all gas-affected moving components for cleaning at 50-shot or 30-day intervals with the BRU remaining fitted to the aircraft. Off-aircraft maintenance times are themselves reduced by the ability to remove and refit the gas system as a complete assembly for routine cleaning without dismantling or disturbance of the mechanical linkages. Likewise the complete electrical assembly including bomb-on-station microswitches can be removed and replaced without linkage disturbance and with no switch adjustment necessary after replacement.

CHARACTERISTICS

Length: 612 mm
Height: 160 mm (from store line)
Width: 215 mm (at crutch arms)
Weight: 12·9 kg
Cartridges: 2 CCU-44B or CERU No 201
Ultimate hook load: 21 795 kg
Ultimate crutch arm load: 16 044 kg
Ultimate yaw movement: 14 445 Nm
Carriage capability
Max store weight: 1045 kg
Max store diameter: 711 mm
Minimum store diameter: 229 mm
Operational temperature range: -40 to +70° C
Typical ejection velocity: 3·05 m/s for 500 kg store with up to 5670 kg reaction and BRU throttle settings of 100%/100%

STATUS

Qualification testing complete and in production for the AV-8B and Harrier GR Mk 5.

HUNTING HIVOLT CARRIER BOMB LIGHT STORES

The crutchless principle for carriage and release of stores is the basis of a new generation of light stores carriers produced by Hunting Hivolt. The basis is a free fall modular release unit, EMRU No 21, which is so designed that by combining units together three-store carriers, CBLS No 105, or other combinations can be built up. Provision is made for unit selection, fuzing, and store-on-station indication.

The units are designed for current and future flares, markers, and other light stores of up to 22·7 kg in weight, 914 mm in length, and diameter varying between 77 and 127 mm. They will carry and release, or jettison, stores at all heights up to 4570 metres, at speeds of 0 to 250 knots and function within the temperature range -40 to +90° C.

The EMRU is operated electrically by the same stored energy actuator (SEA) which is used on the EMRU No 22. Stores, for carriage on this unit, need a special lug which is simply attached to existing stores

Carrier bomb light stores No 105 Mk 3

by bands. Four hooks engage with this lug and a spring loaded wedge system provides automatic and progressive take-up of any tolerance in attachment of the store without inhibiting its release.

Loading of stores onto the carrier is quick and simple. The unit is cocked by means of a cocking lever at the rear of the unit; the store is raised against the unit and pressed against a small platform between the hooks which then close over the lug. A safety pin and manual release are provided for use on the ground.

CHARACTERISTICS

EMRU No 21 Mk 3
Length: 290 mm
Width: 168 mm
Depth: 105 mm
Weight: 4·2 kg
Operating voltage: 18 - 28·5 V DC continuous or pulsed (14 ms minimum)
Max store weight: 22·7 kg
Max store size: Length 914 mm, diameter 77 - 127 mm
Operating temperature range: -40 to +90° C

STATUS

In production for UK MoD and used on Lynx helicopters.

Hunting Hivolt Ltd, Riverbank Works, Old Shoreham Road, Shoreham-by-Sea, Sussex BN4 5FL, England.

1266.393
HUNTING HIVOLT WEAPON RELEASE EQUIPMENT EMRU No 20 Mks 1 to 5

The Hunting Hivolt electromagnetic release units (EMRU) No 20 were designed basically for free fall release and electro-mechanical operation. They are twin hook types with suspension centres at the NATO Standard of 14 inches (356 mm). The method of release is through an electrically operated spring stored energy unit, solenoid unit Type 1000.

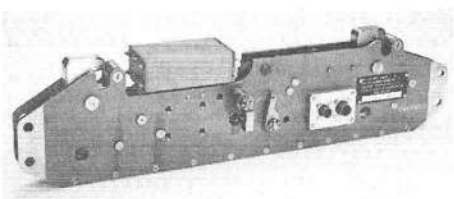
The system is intrinsically safe and reliable but for some applications an independent bomb release safety lock (BRSL) may be called for. The requirement is met by fitting a Hunting Hivolt actuator MAL 19. When these are fitted, a store-on-station switch is also used to indicate when a weapon is in place.

Two basic types of EMRU No 20 are manufactured; one type having a stainless steel body and the other, a lightweight version, with aluminium alloy body. All units are similar in appearance and have the same dimensions.

In operation, each suspension hook is independently latched thus meeting NATO requirements. When the unit is cocked the hooks are closed and held so by a linkage mechanism consisting of a system of jointed struts maintained by a sear in a near straight condition. The sear is released

CHARACTERISTICS

	EMRU	EMRU
Release unit designation	No 20 Mks 1, 2 & 5	No 20 Mks 3 & 4
Normal store weight	660 kg	295 kg
Ultimate load	22 700 kg	9 080 kg
Body material	Stainless steel	Aluminium alloy
Weight	8 kg (Mk 2)	5 kg (Mk 4)
Bomb release safety lock	MAL 19 (Mk 1 only)	MAL 19 (Mk 3 only)
Length	All types	545 mm
Width		71 mm (no BRSL)
Depth		138 mm (no BRSL)
Stores suspension centres		356 mm (14 inch)
Operating voltage range		18 - 28·5 V DC continuous or pulsed (14 ms minimum)
Operating temperature range		-60 to +150° C



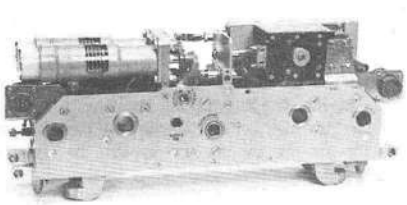
by the action of the solenoid, the strut system collapses and the hooks open. The possibility of a hang-up is eliminated by positive displacement of a strut joint when the sear is released.

STATUS

EMRU No 20 is in production. The Mk 1 and Mk 2 units are used on Nimrod aircraft, while the Mks 3 and 4 are in service on Wessex, Wasp, and Sea King naval helicopters. The Mk 5 is fitted to Lynx helicopters.

CONTRACTOR

Hunting Hivolt Ltd, Riverbank Works, Old Shoreham Road, Shoreham-by-Sea, Sussex BN4 5FL, England.



EMRU No 20 Mk I

1844.393
EMRU No 22

The EMRU No 22 is the first of the new generation of free-fall crutchless release units for the carriage and release of weapons and other stores from aircraft. The unit requires a new type of lug on the weapon and, by providing what is effectively self-adjusting four point suspension, the need for conventional crutches (sway braces) is eliminated. There is an overall weight saving in installation and the loading of stores is easier and quicker.

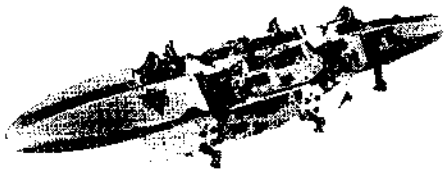
The EMRU is operated electrically by a well proven spring stored energy actuator (SEA). This is a hermetically sealed device consisting of a spring loaded plunger held, when cocked, in a compressed state by a rotary solenoid operated lock unaffected by mechanical forces and responding only to a specific

EMRU No 22

voltage. Duplication is provided to meet service requirements.

The EMRU No 22 consists of two dual (two tongued) pivoted hooks in a frame controlled by a simple linkage mechanism. The mechanism and SEA are hand-cocked by the use of a simple cocking tool, the weapon is raised to the unit and locked in place, again by simple hand tool. The mechanism is held mechanically in place by a release lever and a safety pin is provided to meet ground safety requirements. Spring loaded wedges in the base of the unit provide automatic and progressive take-up of any tolerance in the attachment of the store without inhibiting store release in any way.

A bomb release safety lock (BRSL) can be provided within the overall envelope of the unit, if required. This is the Hunting Hivolt actuator MAL 19. The complete equipment has been designed to meet the very difficult environment of naval helicopter operations.



CHARACTERISTICS
Length: 422 mm
Width: 81 mm
Depth: 167 mm
Total weight: 7·9 kg without BRSL; 8·19 kg with BRSL
Operating voltage range: 18 - 28·5 V DC continuous or pulsed (14 ms minimum)
Max store weight: Up to 450 kg
Ambient temperature range: -40 to +90° C

STATUS
In production for UK MoD and used on Lynx and Sea King helicopters.
CONTRACTOR

ML TRIPLE STORE CARRIER
This carrier is mechanically and electrically interchangeable with the American triple ejector rack (TER) currently used on many aircraft throughout the world.

The ML triple store carrier (TSC) is fitted with three ML ERU 119s thus giving improved ejection velocity, pitch control of stores at release, twin cartridge reliability, and increased bomb release speeds. An international range of stores can be carried and released: flares, rocket launchers, and bombs (including the Matra type retarded bombs for which reaction points are provided). Full fuzing is available for all stores and modern electrical systems are installed.

The MLTSC can either be supplied new or, if desired, be produced by conversion of customer's existing US TERs.
CHARACTERISTICS
Overall length: 1697 mm (66⅞ inches)
Overall height: 383·5 mm (15⅛ inches)
Weight (less stores): 68 kg (150 lb)
STATUS
In production for Phantom and other aircraft.

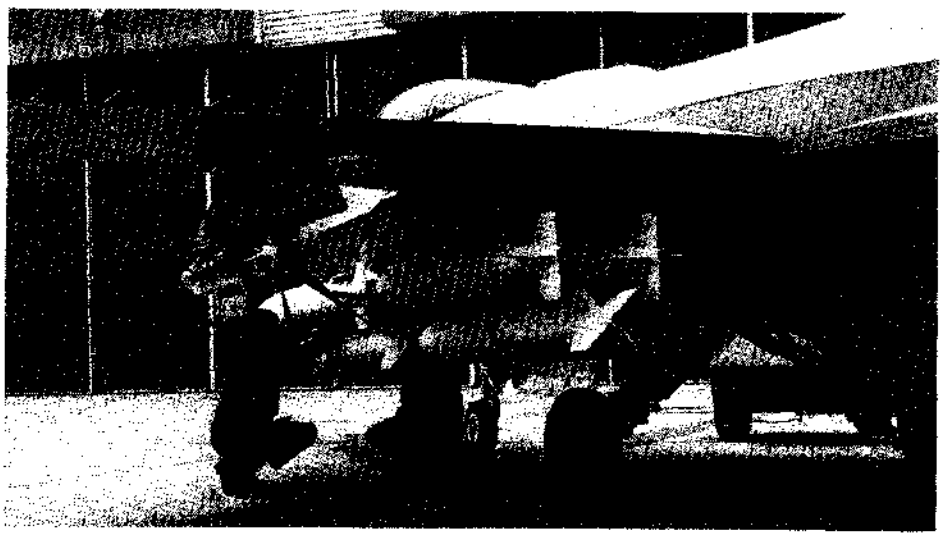
UNITED STATES OF AMERICA

5225.303
UNITED STATES AIRCRAFT ARMAMENT
The range of American aircraft armament is without doubt the most extensive of any nation in the world, and probably the most varied. It includes well over 200 types of bomb, among them conventional free-fall bombs of many weights and sizes, as well as 'cluster' bombs containing sub-munitions of all types. In the following paragraphs certain specific types have been described in greater detail, eg Mk 20 cluster bomb (**1998.303**), while in the Analysis section of this volume will be found a comprehensive table (**1850.314**) listing more than 300 types of air-deliverable munitions produced in the USA. Elsewhere in this book there are other entries dealing with related aspects such as the use of add-on guidance packages to convert conventional 'iron' or 'dumb' bombs into guided weapons, or 'smart' bombs (**1597.311**), HOBO (EO) and laser-guided smart bombs and Paveway laser-guided bombs (**1534.311**) in the Systems section.



The American inventory of air-deliverable weapons includes free-fall nuclear bombs which may be capable of both tactical and strategic use, and these also are listed in the table. Additional details of these and other payloads in the strategic context will be found in appropriate entries in the Systems section dealing with US strategic weapon systems.

Another type of aircraft-carried munitions dealt with in other parts of *Jane's Weapon Systems* are those used for anti-submarine warfare, eg mines and depth charges.

US airborne munitions have been widely supplied to foreign nations, and therefore can be found in the inventories of many countries; for this reason, and because of the long period over which such supplies may have been delivered, no attempt has been made to compile extensive lists of users.

4865.303
ISCB-1 AREA DENIAL CLUSTER WEAPON
The ISCB-1 is a newly introduced, air-delivered, area denial cluster weapon designed to fulfil such missions as runway attack, interruption of enemy traffic over bridges etc. The weapon achieves this by combining the technology of ISC Technology's Rockeye cluster bomb (**4599.303**) with computer techniques, resulting in an air-delivered fragmentation weapon featuring variable programmed detonation of individual area denial mines.

Designed, developed and manufactured within the ISC concern, the ISCB-1 consists of a Mk-7 dispenser, Mk 339 nose fuze, a tail cone assembly, and 150 electronically timed mines plus 65 dummy mines. The Mk-7 dispenser gives the same weapon/aircraft interface, aerodynamic compatibility, and ground dispersion patterns as the Rockeye. This yields immediate certification with at least 12 current aircraft types.

As with Rockeye, after launching from the aircraft the Mk 339 fuze initiates a linear shaped charge, the Mk-7 dispenser splits open and the mines are released. However, differing from the Rockeye, the ISCB-1 tail cone assembly houses a bomb panel which receives information to program the delay times of individual mines. The latter are programmed on the ground using an ISCT delay programmer or fuze set key to detonate on impact or in 10-second increments for up to 24 hours to deny enemy access to target areas covering 3000 and 5000 square metres. Programming can be carried out until the time of take-off.
STATUS
Production.

ROCKEYE II Mk 20 CLUSTER BOMB
The Rockeye Mk 20 cluster bomb is an unguided free fall weapon, delivered in the same manner as a conventional bomb, for use with all bomb rack configurations. Rockeye dispenses 247 dual-purpose armour-piercing shaped charge bomblets, which are distributed over a variable attack area. Since precise aiming is not required, the pilot need maintain delivery attitude for only a short duration prior to release of the bomb, thereby reducing the aircraft's vulnerability to ground defences and improving pilot safety.

The Mk 339 dispenser opening fuze provides pilot options for dispenser opening delay, provides safe separation from the aircraft prior to arming, and initiates a linear shaped charge which splits open the container. The bomblet fuze discriminates between soft and hard targets, detonates the bomblet, and provides additional safety for pilot and aircraft.

Rockeye is smaller and lighter but contains more

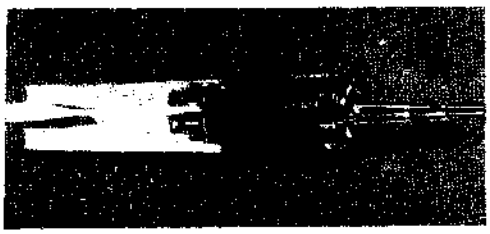
ROCKEYE II Mk 20 CLUSTER BOMB
The Rockeye Mk 20 cluster bomb is an unguided free fall weapon, delivered in the same manner as a conventional bomb, for use with all bomb rack configurations. Rockeye dispenses 247 dual-purpose armour-piercing shaped charge bomblets, which are distributed over a variable attack area. Since precise aiming is not required, the pilot need maintain delivery attitude for only a short duration prior to release of the bomb, thereby reducing the aircraft's vulnerability to ground defences and improving pilot safety.

The Mk 339 dispenser opening fuze provides pilot options for dispenser opening delay, provides safe separation from the aircraft prior to arming, and initiates a linear shaped charge which splits open the container. The bomblet fuze discriminates between soft and hard targets, detonates the bomblet, and provides additional safety for pilot and aircraft.

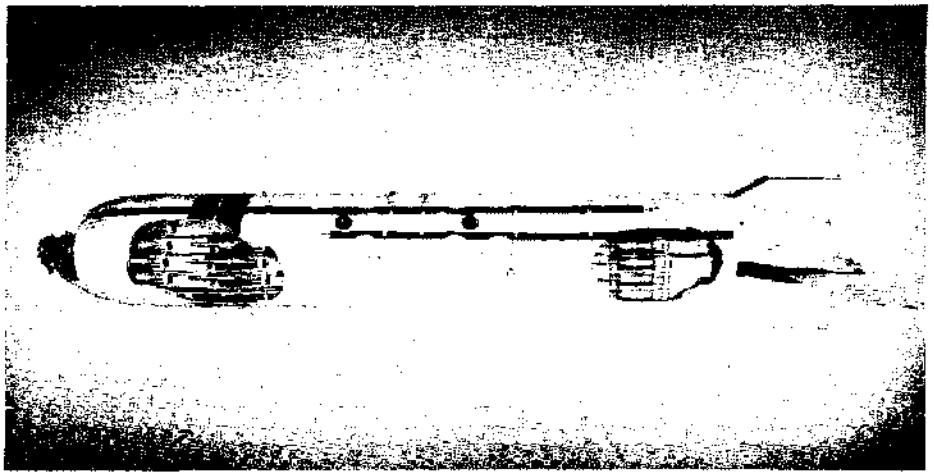
Rockeye is smaller and lighter but contains more

net explosives than similar cluster bombs, and its smaller size and weight permit as much as 800 lbs more fuel per mission according to the weapon's manufacturer, thus considerably increasing aircraft range and endurance.



No special storage facilities or handling equipment are required, and no periodic maintenance is necessary. The store is delivered ready to fly and service life exceeds 20 years it is claimed. Only visual inspection is needed before flight.

OPERATION



Delivery is literally the same as that for a conventional 500 lb bomb. The sizes and shapes of impact areas can be changed according to aircraft speed, altitude, dive angle and the dispenser opening delay time. In heavily defended target areas, Rockeye can be delivered at high speeds and at altitudes as low as 30 metres pitch up or 76 metres in level flight.

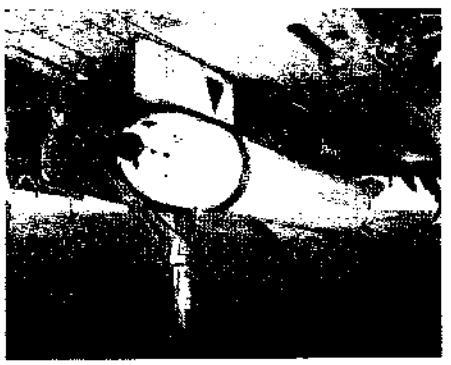
CHARACTERISTICS

Length: 2·33 m (without fuze cover); 2·4 m (with fuze cover)
Diameter: 335 mm
Fin span: 437 mm (closed)
Lug spacing: 355 mm
Centre of balance: 165 mm (fwd of aft lug)
Weight: 222 kg (assembled)
Explosive payload of bomb cluster: 45·3 kg

Single dual-purpose Rockeye II bomblet

Cutaway Rockeye II cluster bomb, showing internally stowed bomblets

Bomblet weight: 151·5 kg (total)
Release altitude: 76 m (minimum in level pitch); 30 m (minimum pitch up)
Typical bomblet impact pattern: 4800 m² (released from 152 m)



STATUS

Operational, entered service in early 1970s. In use by US forces and more than ten other countries throughout the world. Modern tactical aircraft that have carried Rockeye include: A-4, A-6, A-7, A-10, F-4, F-5, F-8, F-15, F-16, Mirage, Jaguar, and Hawk.

ISC is the main international contractor for Rockeye, and assumes total responsibility for the supply of all contracted goods and services.

Rockeye II Mk 20 cluster bomb loaded onto aircraft

1996.303

GAU-8/A 30 mm GUN SYSTEM

The GAU-8/A 30 mm gun system is designed to provide a cost-effective weapon to engage the full array of ground targets encountered in the close air support role. The system has an ammunition capacity of 1174 rounds and weighs 1723 kg when fully loaded. Aluminium cased ammunition with either armour piercing incendiary, HE incendiary, or target practice projectiles can be fired at either 2000 or 4000 shots per minute. Ammunition for the GAU-8 weapon is manufactured by the Aerojet Ordnance and Manufacturing Company of Downey, California and Honeywell Inc of Hopkins, Minnesota. The family consists of the following rounds: armour piercing incendiary (API), high explosive incendiary (HEI) and training practice (TP). The API round has a lightweight body which contains a sub-calibre high-density penetrator of depleted uranium. In addition to its penetration capability, depleted uranium is a naturally pyrophoric material which enhances incendiary effects. The HEI round employs a standard M505 fuze and explosive mixture with a body of naturally fragmenting material that is effective against lighter vehicle and material targets. The TP projectile simulates the exterior ballistics and provides a ballistic match to the HEI and is used for pilot training and gunnery practice. Development of the aluminium alloy case material instead of the conventional brass or steel resulted in a 272 kg reduction in weight of a fully loaded system. The GAU-8/A gun system is composed of three major sub-systems: gun, feed system, and drive system.

The gun is an externally-powered, Gatling-type mechanism. Each of the gun's seven barrels fires only once during each revolution of the barrel cluster. Barrels are attached to the gun rotor by quick release interrupted lugs. The gun rotor is journalled within a stationary housing and contains the seven gun bolts. The bolts slide fore and aft on tracks and provide the ram, lock, fire, unlock, and extracting functions. The stationary outer housing contains a cam which drives the bolts through their respective functions. The GAU-8/A uses a rotary-lock bolt which provides ample locking area and support for the high pressure, aluminium cased 30 mm ammunition. The gun design features a three-shaft transfer unit which transfers rounds coming from the feed system into the gun rotor.

General Electric GAU-8/A 30 mm gun system

A new reverse clearing technique is used to clear ammunition from the gun after each burst. An electro/hydraulic drive system controls the clearing function and assures consistent positioning of the first live round on the feed side of the gun. Live rounds which have cycled into the weapon but have not yet fired at trigger release are returned to the feed side of the gun in less than one second ready to fire at the next trigger application.

The GAU-8/A gun system is driven by hydraulic drives operating off the aircraft hydraulic system. Dual motors are employed operating from independent hydraulic systems. Only one motor is energised to fire the system at half rate. The hydraulic drive units include controls for the two firing rates and the reverse clearing function.

A linkless ammunition feed system is used to store and feed ammunition. Spent cartridge cases and any unfired rounds are returned to the storage drum after passing through the gun.

The major components are the cylindrical drum unit in which the ammunition is stored; the exit unit which removes rounds from the drum unit and inserts them into an endless conveyor belt; the conveyor system comprising the conveyor belt and the chuting through which it moves; the transfer unit which removes rounds from the gun end of the conveyor belt, feeds them into the gun, and re-inserts the spent cartridge cases into the belt for return to the storage drum; and the entrance unit which transfers cases from the conveyor system back into the drum unit. Each round and case is in smooth, continuous motion when the system is feeding and the gun is firing.

CHARACTERISTICS

Firing rate: 2100/4200 rounds/minute
Length: 6400 mm
Weight: 1723 kg
Ammunition capacity: 1174 rounds
Power requirements: 77 hp
Muzzle velocity: 1066 m/s
Barrel life: 20 000 rounds (minimum)
Time to rate: 0·55 s
Dispersion: 5 mil

STATUS

Operational testing at Nellis AFB has verified its ability to defeat medium tanks. Over eight million rounds have been fired. The General Electric Company has delivered more than 600 for the A-10 close air support aircraft.

GAU-12/U EQUALISER 25 mm AUTOMATIC GUN

General Electric's 25 mm five-barrel Gatling gun (GAU-12/U Equaliser) was designed making full use of the technology developed and proved on the GAU-8/A 30 mm gun programme. High rate of fire, combined with high muzzle velocity and excellent ballistics of the 25 mm round, make it a candidate for numerous applications in either air-to-air, air-to-ground, or ground-to-air roles.

The outstanding terminal ballistics are attributable to the standard 25 mm round of ammunition. This round produces a muzzle velocity of 1097 metres per second which, when combined with the rate of fire of up to 4200 rounds/minute, makes the GAU-12/U Equaliser extremely effective for a variety of combat missions.

The lightweight (125 kg) externally powered weapon features reverse clearing, a 20 000-round maintenance cycle, and an MRBF that exceeds 15 000 rounds. Although providing much more effective firepower than the 20 mm Vulcan, the GAU-12/U Equaliser is similar in size and power requirements to the 20 mm.

General Electric GAU-12/U Equaliser 25 mm automatic gun and ammunition

The standard 25 mm round family includes TP, HEI and APDS rounds with steel cases and percussion primers. In addition, a full-bore API round has been developed for use in high performance aircraft.

CHARACTERISTICS

Type: 5-barrel Gatling, 25 mm
Length: 2134 mm
Max diameter: 279 mm
Weight: 122 kg
Power to drive: 10·4 kW
Ammunition: Standard 25 mm (TP, HEI, APDS)
Muzzle velocity: 1097 m/s HEI
Dispersion: 6 mil (80% of rounds fired)
Rate of fire: Variable up to 4200 rounds/minute
Time to rate: 0·4 s
Drive type: Externally powered
Feed system: Linkless or linked
Clearing: Gun reversal
Recoil force
Peak max: 9000 lb (40 kN)
Peak recurrent: 8000 lb (36 kN)
Average at 3600 rounds/minute: 4000 lb (18 kN)

STATUS

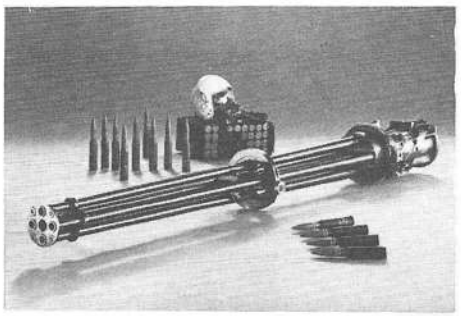
In production and in US Marine Corps service.

CONTRACTOR

General Electric Company, Armament and Electrical Systems Department, Lakeside Avenue, Burlington, Vermont 05402, USA.

3891.303

GAU-13/A 30 mm LIGHTWEIGHT GUN



The GAU-13/A 30 mm lightweight aircraft gun is a four-barrel, Gatling design, which although based on the General Electric GAU-8/A seven-barrel gun (**1996.303**), incorporates a number of innovations to improve serviceability and reduce overall weight while retaining comparable ballistic performance. With a firing rate of 2400 rounds/minute, the GAU-13/A employs the same reverse clearing operation as the GAU-8/A. The gun is suitable for internal or external mounting on an aircraft, and GE has developed a special pod to house the GAU-13/A.

GPU-5/A

The GPU-5/A is a compact external store incorporating the GAU-13/A 30 mm four-barrel gun to provide a significant anti-armour and ground attack capability for attack or fighter aircraft. The pod can be used with a wide variety of aircraft types such as the F-4, F-5, A-7, F-15, F-16, F-20, A-4, A-10 and F-18. The main components are the GAU-13/A gun, a helical ammunition feed system which surrounds the gun, a self-contained pneumatic drive, and a supporting structural assembly. The ammunition feed has space for 353 rounds, enough air capacity to fire two full complements of ammunition, and the only power required from the aircraft is 7·5 A of 28 V DC or 115 V AC, 400 Hz, 300 W. The support structure can be configured for use as either a standard 30-inch (762 mm) rack fitting or as an adaptor for direct mounting on specific aircraft. A novel boresighting procedure in effect boresights the receiver aircraft rack thereby eliminating the need to boresight the gun each time it is re-attached to the aircraft.

GPU-5/A lightweight 30 mm gun pod on centre-line station of USAF F-5

New four-barrel GAU-13/A Gatling 30 mm lightweight gun with GAU-8/A range of ammunition

CHARACTERISTICS

Gun: GAU-13/A (4-barrel)
Calibre: 30 mm
Length: 2794 mm
Max diameter: 304 mm
Ammunition: GAU-8/A TP, HEI, API
Rate of fire: Up to 3000 rounds/minute
MV: 1037 m/s TP/HEI; 987 m/s API
Gun life: 250 000 rounds
Pod: GPU-5/A
Length: 4320 mm
Diameter: 610 mm
Weight: 862 kg (loaded); 621 kg (empty)
Ammunition capacity: 353 rounds

STATUS

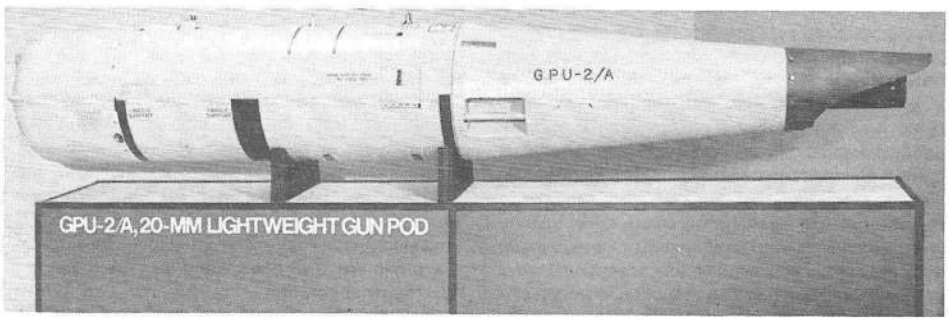
In production and in USAF service.

GPU-5/A has been successfully flight-tested against ground targets on the Northrop F-5 and F-20, the Vought A-7, and the McDonnell Douglas F-4E and F-15.

CONTRACTOR

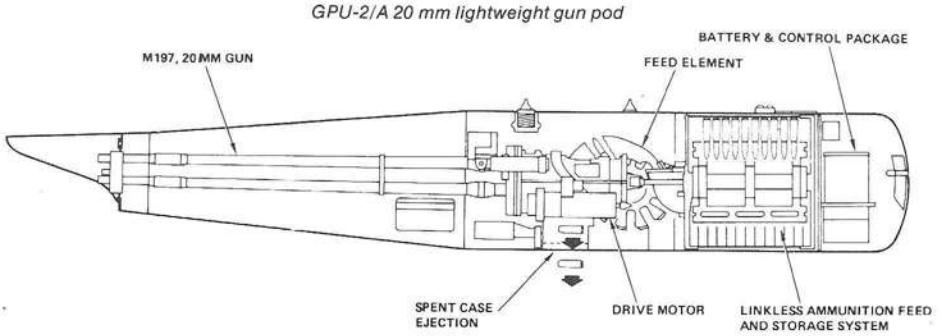
General Electric Company, Armament and Electrical Systems Department, Lakeside Avenue, Burlington, Vermont 05402, USA.

1678.303



GPU-2/A 20 mm LIGHTWEIGHT GUN POD

The GPU-2/A 20 mm pod is a lightweight self-contained gun system requiring only a trigger signal from the aircraft. This pod can be mounted on a wide variety of existing helicopters and fixed-wing aircraft by using standard suspension racks. The total system weight when loaded with 300 rounds is less than 600 lb (272 kg).



General Electric Company has designed and produced a quantity of GPU-2/A pods for the USN. These systems use the three-barrel M197, 20 mm gun which has been in military inventory since 1969. The firing rate for the GPU-2/A is selected at either 750 or 1500 shots per minute. Rounds are fed to the gun through a linkless ammunition storage and feed system. This system maintains positive round control throughout all storage and feed operations.

The design concept of this system has been proven by combat experience with the SUU-11/A mini-gun pods. Power for the system is provided by a 32 V DC rechargeable nickel-cadmium battery located in the aft section. This battery will fire up to three ammunition complements without a recharge. If the aircraft has sufficient power available, provision is made to trickle charge during operation of the aircraft.

The pod can be loaded with ammunition while suspended from the aircraft. The storage drum is

GPU-2/A 20 mm lightweight gun pod

GPU-2/A 20 mm lightweight gun pod mechanical arrangement diagram

made accessible by simply removing the aft fairing. A belt of ammunition is attached to a loader mechanism which strips the links and feeds rounds into the storage drum in the proper attitude.

The first maintenance required for the GPU-2/A is at 15 000 rounds. At this time the front track bolts on the gun rotor are re-torqued. Barrel life is 15 000 rounds; however, the barrels can be changed within two minutes while the pod is still suspended from the aircraft. No special tools are required for maintenance.

CHARACTERISTICS
Weight: Approx 270 kg
Length: 304 cm
Diameter: 48 cm
Ammunition capacity: 300 rounds
Rate(s) of fire: 750 or 1500 rounds/minute
Gun: 20 mm M197

CONTRACTOR
General Electric Company, Armament and Electrical Systems Department, Lakeside Avenue, Burlington, Vermont 05402, USA.

4434.303
GPU-5/A LIGHTWEIGHT 30 mm GUN POD

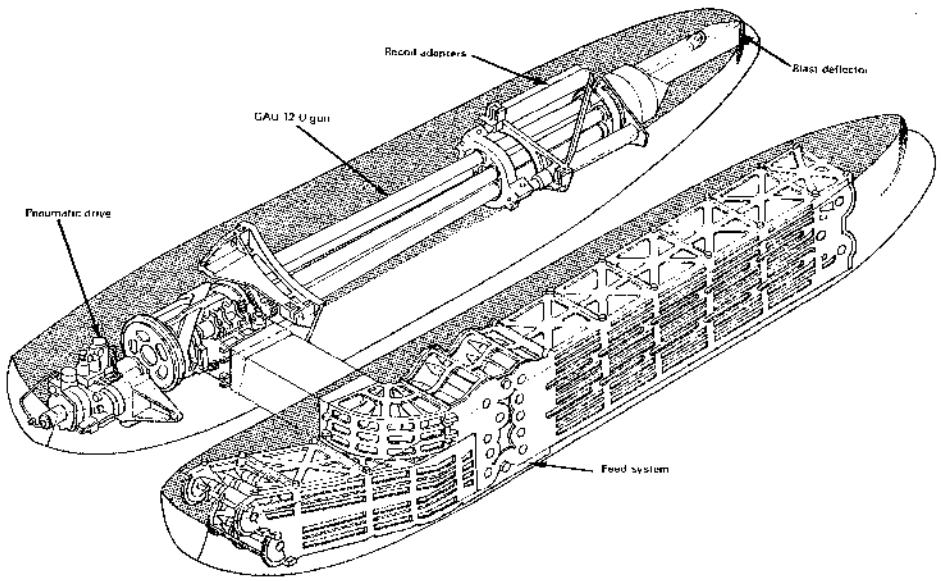
The GPU-5/A is a lightweight 30 mm gun pod with a high rate of fire developed to destroy heavy armour and a wide variety of mobile and fixed targets at extended ranges. It is adaptable to many fighter and attack aircraft, weighs about 862 kg when loaded, and is completely self-contained.

The system comprises the newly developed GAU-13/A 30 mm four-barrel Gatling gun (**3891.303**), a helical closed loop ammunition feed system, a self-contained pneumatic drive with microprocessor controls, and a strongback and structural assembly. The linkless ammunition feed system holds 353 rounds in two helical layers of ammunition carriers surrounding the gun and extensive use is made of fibre reinforced plastics to save further weight. The pneumatic drive uses a reversible turbine capable of generating 60 hp at 9000 rpm and sufficient air is stored for two outfits of ammunition to be fired in one-second bursts.

The primary structural component is the strongback which is a one-piece aluminium housing used to mount the pod to the aircraft with the recoil adaptors mounted inside it and connected by linkage to the gun. The skin of the pod is made of aircraft-type structural aluminium honeycomb and the entire pod is designed to be capable of withstanding supersonic flight speeds.

CHARACTERISTICS
Gun: GAU-13/U 4-barrel Gatling
Calibre: 30 mm
Rate of fire: 2400 rounds/minute
Ammunition capacity: 353 rounds
Length: 4·3 m
Height: Approx 610 mm
Weight (loaded): 862 kg
Weight (empty): 621 kg
Power requirements: 115 V, 400 Hz, 300 W, 3-phase or 28 V DC, 210 W

STATUS
In production and in service with USAF. Can be installed on wing or centre body stations of a variety of tactical aircraft including the A-4, A-7, AV-8B, F-4, F-5, F-15, F-16, F-18, A-10, and OV-10. The F-20 and other applications are being investigated.



CONTRACTOR
General Electric Company, Armament and Electrical Systems Department, Lakeside Avenue, Burlington, Vermont 05402, USA.

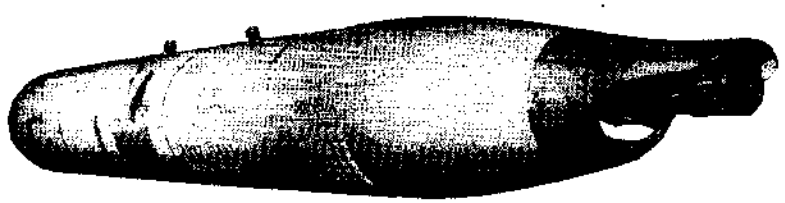
4433.303
AV-8 HARRIER 25 mm ARMAMENT SYSTEM

The AV-8 armament system is a lightweight 25 mm gun system with a high rate of fire designed to provide an effective air-to-air and air-to-ground attack capability. It was developed for the USN and uses the GAU-12/U gun.

The GAU-12/U gun is a five-barrel Gatling type which is similar in overall dimensions to the M61A1 Vulcan gun (**5547.103** in 1982-83 and earlier editions) and fires the US standard family of ammunition which includes practice, HE incendiary, armour piercing incendiary and armour piercing discarding sabot ammunition and is also compatible with European-made 25 mm ammunition. A full-bore armour piercing incendiary round has been developed as a part of the AV-8 armament contract.

The system consists of two pod-like structures bolted to the bottom of the left and right of the aircraft. The pod on the left contains the GAU-12/U gun, blast deflector and drive mechanism. That on the right contains a compact 300-round linear linkless feed system. A cross-over fairing connects the two pods and contains the ammunition chuting and drive shaft. The pneumatic drive employs a rotary drive motor turning at 9000 rpm and developing 35 hp. The production version uses bleed-air from the aircraft engine. Gun recoil forces are transferred directly to the left forward aircraft mounting points.

Internal arrangement of AV-8 Harrier armament system



CHARACTERISTICS
Gun: GAU-12/U
Calibre: 25 mm
Muzzle velocity: 1097 m/s (depending on ammunition used)
Rate of fire: 3600 rounds/minute
Ammunition capacity: 300 rounds
Weight
Gun: 125 kg
System (loaded): 558·4 kg
System (empty): 408·6 kg
Power requirements: 28 V DC 15 A max

STATUS
In production for the USN.

CONTRACTOR
General Electric Company, Armament and Electrical Systems Department, Lakeside Avenue, Burlington, Vermont 05402, USA.

1287.303
VULCAN GUN PODS SUU 16/A AND SUU 23/A

These gun pods are of identical size and weight and both incorporate six-barrel Vulcan 20 mm cannon and ammunition. Designed for installation on standard external store pylons, these pods provide a ready means of greatly increasing the cannon fire power of subsonic and supersonic fighter and ground attack aircraft. The pod mounted Vulcan gun is particularly well suited to the engagement of ground targets from ranges of 700 m or more. The pods are of aerodynamic shape and attachment to the aircraft is by bomb lugs at standard 760 mm (30-inch) centres.

SUU 23/A Vulcan 20 mm gun pod

Both pods are of similar internal layout, a cylindrical ammunition drum containing 1200 rounds occupying the rear portion of the pod. A linkless feed system couples this to the gun.

The pods differ in the type of Vulcan gun fitted but their performance and hitting power are identical. In the earlier SUU 16/A design the cannon is the standard M61A1 mechanically driven by a ram air turbine. This turbine is mounted on a hinged skin panel of the pod and is lowered into the airstream prior to firing. The use of a ram air turbine restricts the rate of fire at aircraft speeds below 350 knots (650 km/h). A further consequence of the turbine is that pod drag is somewhat greater than for the SUU 23/A pod in which a self-powered GAU-4 model Vulcan is used. For initial rotation of the GAU-4 gun in the SUU 23/A pod an electric inertia starter is provided.

In operation Vulcan gun pods are aimed using a gunsight or fire control system. During firing spent cartridge cases are ejected overboard and not retained. The gun is cleared automatically after the firing button has been released so that 'cook-off' is eliminated. During the clearing process a small number of live rounds are ejected.

A number of accessories are available to simplify loading, maintenance, and testing of the pods.

CHARACTERISTICS

	SUU 16/A	SUU 23/A
Length	5·05 m	
Diameter	560 mm	
Weight with 1200 rounds	780 kg	785 kg
Weight empty	484 kg	489 kg
Boresight adjustment		
elevation	±1°	±1°
Azimuth	·0·5°	±1°
Accuracy	80% shots inside 8 mil	
Rate of fire	6000 rounds/minute	
Ammunition	20 mm M 50 series	
Power input from aircraft		
at 208 V 400 Hz 3 phase	7 A	10 A
at 28 V DC	—	3 A

STATUS

Both SUU 16/A and 23/A pods are in service with US forces. They are compatible with a wide range of tactical aircraft including F-100, F-105, F-4, A-4D, and F-111. The SUU 23/A pod is in service on Royal Air Force McDonnell Douglas Phantoms.

CONTRACTOR

General Electric Company, Armament and Electrical Systems Department, Lakeside Avenue, Burlington, Vermont 05402, USA.

1270.303

GENERAL ELECTRIC VULCAN 20 mm AIRCRAFT GUN AND LINKLESS FEED SYSTEM

The General Electric M61A1 Vulcan aircraft cannon is of 20 mm calibre and employs the multi-barrel principle first used by Dr Gatling. The Vulcan is the standard USAF aircraft gun and is increasingly being used by the USN.

The gun has a rotary action and in the M61A1 is externally powered from the aircraft hydraulic or electric supply. A self-powered version, the GAU 4 is similar in all respects except that barrel rotation and operation of the action is derived from gun gas bled from four of the six barrels.

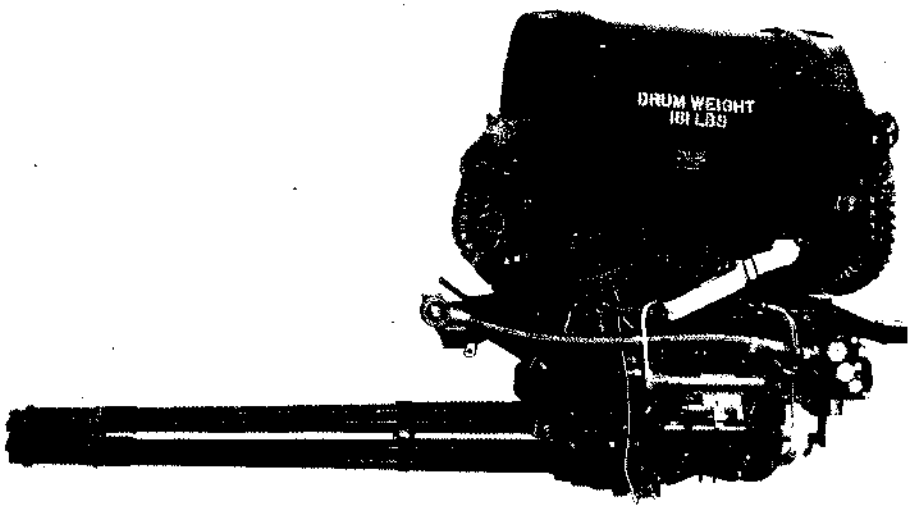
The outstanding features of the Vulcan are its high rate of fire, normally 6000 rounds per minute, the high muzzle velocity of about 1036 m/s and its exceptional reliability in comparison with more conventional weapons.

Ammunition linked into belts has been used with Vulcan guns but feed reliability was poor at the high rates of fire characteristic of the weapon. There are also problems of link disposal. For these reasons in the majority of applications Vulcan cannon are associated with a linkless feed system. There are considerable variations in the detailed layout of gun and feed systems in service as each is tailored to the particular requirements of the aircraft installation. The essential elements are the M61A1 or GAU 4 gun, the linkless feed ammunition chutes which contain the ammunition conveyor, the cylindrical ammunition canister, and the drive power coupling between the gun and the ammunition drum.

The Vulcan gun has six rifled barrels and is externally powered. All barrels are rigidly clamped together and attached to the forward end of the breech rotor which rotates in a stationary housing. The rotor revolves anti-clockwise looking in the direction of fire. Cam followers operate the bolt for each barrel successively chambering, firing, and extracting the rounds as the gun rotates. The linear actions needed for these operations are imparted to the followers by an elliptical slot machined in the rotor housing.

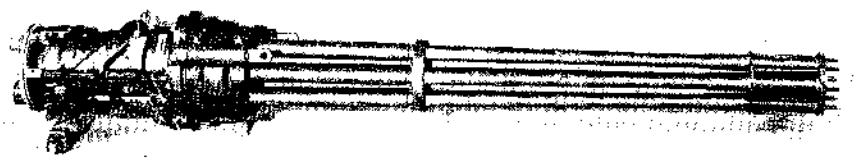
The multi-barrel design gives long weapon life by reducing heat dissipation and barrel erosion. A variety of barrel muzzle clamps are available to give different shot dispersion patterns. When the minimum dispersion clamp is in use 80 per cent of shots are within an eight mil cone.

Standard M50 series electrically primed ammunition is used which is available in a variety of types: incendiary, armour piercing with and without tracer etc.



In the self-powered variant, the GAU 4, gun gas is bled from four of the six barrels to operate the mechanism by means of a gas piston and drive which is mounted between the barrels ahead of the gun action. The GAU 4 develops sufficient power to operate the feed system. The gun is initiated by an electrically operated inertia starter.

Linkless Feed System



The linkless feed ammunition drum may be tailored to meet specific ammunition capacity requirements or to fit a specific envelope. Linking the drum to the gun is a single or twin ammunition conveyor belt contained in flexible chuting. With a single conveyor belt the spent cases are ejected overboard, but in many installations a return conveyor for spent cartridge cases is provided.

The ammunition drum carries the rounds stored between radial partitions. A central rotor in the form of a helical archimedean screw then moves the rounds from the drum into the conveyor in a multi-stage operation.

Many accessories are available for loading and maintaining Vulcan cannon and their feed systems.

Linkless ammunition feed system and 20 mm M61A1 Vulcan gun for F-4E aircraft

20 mm M61A1 Vulcan gun

CHARACTERISTICS

The self-powered GAU 4 variant of the basic M61A1 Vulcan cannon has virtually identical performance and characteristics, except that it is approximately 5 kg heavier.

Calibre: 20 mm
Weight: 120 kg
Length: 1875 mm
Recoil travel: +6 mm
Average recoil force: 1810 kg
Max rate of fire: 6600 rounds/minute
Time to max rate: 0·3 s
Stopping time: 0·5 s
Ammunition: M53, M55AZ, M56A3 etc
Muzzle velocity: 1036 m/s
Round weight: 0·25 kg
Projectile weight: 0·1 kg

20 mm Linkless Feed System

The exact specification for the 20 mm linkless feed depends upon aircraft design considerations. The data below relate to the installation on the LTV A-7D aircraft which is typical:

Ammunition capacity: 1020 rounds
Firing rate: 6000 or 4000 rounds/minute
Ammunition weight: 1·14 kg
Feed system weight (less ammunition): 190 kg
Drive system: Shaft coupling to gun hydraulic motor
System type: Double ended cases retained in drum
Total ammunition chuting length: 4·57 m

STATUS

The M61A1 and GAU 4 20 mm Vulcan guns with their associated linkless feed systems are in service with the USAF, the Royal Air Force, and with other air forces operating F-104 and F-4 aircraft. The weapon and its associated feed are in service on A-7, F-104, F-111, F-105, F-14, F-15, F-16, F-18 and other aircraft. Podded installations are also available and are in service

CONTRACTOR

General Electric Company, Armament and Electrical Systems Department, Lakeside Avenue, Burlington, Vermont 05402, USA.

1118.303

M35 ARMAMENT SUB-SYSTEM

The XM35 is a fixed mounted armament sub-system located under the left weapon sponson on an AH-1G helicopter. The system carries one 20 mm automatic gun XM195, a Vulcan type with six barrels. This is a modified M61A1 gun with blast deflectors on the end of 102·6 cm barrels. The 20 mm ammunition is link-fed to the right side of the gun from ammunition containers mounted on the left and right sides of the helicopter outside the aircraft. The weight of the system with ammunition is 530 kg; without ammunition 245 kg. The system carries approximately 950 rounds of ammunition with a firing rate of 750 - 100 rounds/minute. The 30 mm cannon has a maximum effective range of 3500 m. The sight used is an XM73 reflex type.

DEVELOPMENT

The XM35 system was developed by the US Army Weapons Command and the General Electric Company. A production contract was awarded to the General Electric Company in 1968.

STATUS

US forces.

CONTRACTOR

General Electric Company, Armament and Electrical Systems Department, Lakeside Avenue, Burlington, Vermont 05402, USA

1182.303
Mk 4 MOD 0 GUN POD

The Mk 4 Mod 0 pod is a self-contained and self-powered 20 mm gun system. The pod contains a twin-barrelled 20 mm Mk 11 Mod 5 gun. The container is a low-drag cylindrical shape with detachable nose and tail cones, designed for supersonic flight in fighter and attack type jet and propeller aircraft. Belted ammunition is carried forward from the rotary magazine through dual feed chutes. Expended cases and links are ejected downward from the bottom of the pod at a velocity of 23 m. A salient feature of the gun pod is the instantaneous full rate-of-fire. The pod is equipped with mounting provisions for both 30- and 14-inch (762 and 356 mm) suspension systems and is normally attached to the aircraft on a standard ejector rack such as the Aero 7A, Aero 27, MAU 9A/A etc.

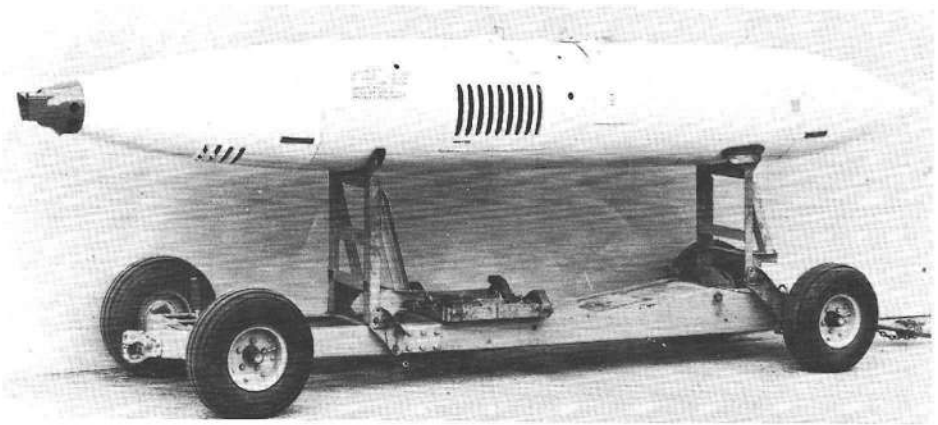
CHARACTERISTICS

Primary kill mechanism: Blast fragments, or penetration (depending on whether HEI or API ammunition is used)
Weapon type: Anti-material and anti-personnel
Payload fuzing: Contact
Range: 950 m
Firing rate: 700 or 4200 rounds/minute
Delivery: Strafe
Weight
Total, loaded: 630 kg
Total, empty: 357 kg
Payload (750 rounds): 269 kg

OPERATION

The Mk 4 gun pod is aimed with either a fixed sight or a fire control system. It is fired by pressing the control stick trigger. Gun reaction time is instantaneous. Delivery is normally made in a shallow dive of 5 to 30°. Slant range for a 'point' target should be 900 m or less. Area targets may be profitably attacked from a longer range because accuracy is not of primary importance. Normally delivery speed is 400 knots but may be at any speed within the performance limits of the aircraft.

STATUS



The Mk 4 gun pod has been flown and fired from the following aircraft: A-4 (1, 2, and 3 pods), F-4 (1 and 3 pods), A-7 (1 and 2 pods), A-6 (1, 2, 3, and 4 pods), OV-10A (1 pod), F-100 (1 and 2 pods), H-34 (1 pod).

The first production pod was delivered in August 1965, and by that time more than $12 million had been expended on development at Hughes and about one million rounds of 20 mm TP ammunition had been fired. The first USN production contract was for 347 pods and this was closely followed in June 1965 by another for a further 482 pods. The last deliveries were made in October 1967 but Hughes continued active in-service development and support under later USN contracts.

Active service on USN and USMC A-4, F-4, and OV-10 aircraft took place in SE Asia, and a number of pods were transferred to the Israeli Air Force with which service they were used on A-4 aircraft.

CONTRACTOR

Hughes Helicopters Inc, Culver City, California 90230, USA. (Subsidiary of McDonnell Douglas)

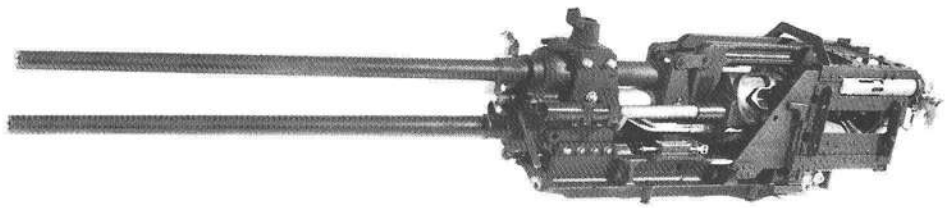
Hughes Mk 4 gun pod

1183.303
Mk 11 MOD 5 GUN

This weapon is intended for aircraft air-to-ground, air-to-air and ground vehicle installation. Each installation consists of a 20 mm Mk 11 Mod 5 gun mechanism and a Mk 2 Mod 1 loader. The gun mechanism consists of the following major components: receiver assembly, breech assembly, revolver cylinder assembly, and one Mk 19 Mod 3 and Mk 20 Mod 3 barrel.

The Mk 11 Mod 5 gun is a twin-barrel, air-cooled, belt-fed, combination gun-gas and recoil-operated automatic weapon firing electrically primed ammunition from an eight-chamber revolver cylinder. The gun is fed by two belts of Mk 6 links which enter the mechanism on opposite sides of the loader. Belts are simultaneously advanced by a single sprocket within the loader which is driven by the revolver cylinder shaft. The mechanism simultaneously rams two cartridges, fires two cartridges, and ejects two cases which are relinked and ejected from the gun at approximately 30 m/s.

CHARACTERISTICS



Gun length: 199 cm (with loader); 179 cm (without loader)
Gun weight
Gun mechanism: 65·3 kg
Barrels: 23·1 kg
Loader: 20·4 kg
Rate of fire: 4200 or 700 rounds/minute (other rates available)
Time to rate: Instantaneous (0·003 s)
Chamber pressure: 4·077 kg/cm²
System of operation: Recoil gun-gas boosted
System of locking: Fixed breech revolver principle
System of feeding: Self-feeding through gun-driven sprockets
Method of loading: Gun-gas powered dual rammers
Location of feed opening: Left and right side of loader, 2 belts (top and bottom feed optional)
Location of ejection opening: Rear of loader, 2 openings
Method of charging: Integral, air operated valve
Method of cooling: Air
Recoil distance: 28·5 mm
Distance between barrels: 104·7 mm
Number of chambers in revolver: 8
Belt velocity, average: 1·5 m/s (each belt)
Ignition system: 120 V, 400 Hz
Barrel length: 143·5 cm
Actual length: 143·5 cm
Effective length: 161·3 cm (including revolver)
Barrel removal: Quick disconnect lever, 60° interrupted threads
Rifling
Barrel: None (smoothbore system)
Revolver: 8 rifled, replaceable inserts
Number of grooves: 9
Twist: 26°, right hand
Recoil
Average: 1134 kg
Peak: Recoil 3628 kg; counter-recoil 2268 kg
Ammunition: 20 mm Mk 100 series; 20 mm Mk 50 series

STATUS

Developed for USN as part of the Mk 4 gun pod programme (see **1182.303**, above). Although demonstrated successfully as an internally fitted aircraft gun in the F-8, the Mk 1 gun has only seen active service in the podded application. Details of these roles with the USN, USMC, and Israeli Air Force are noted in the Mk 4 pod entry.

CONTRACTOR

Hughes Helicopters Inc, Culver City, California 90230, USA. (Subsidiary of McDonnell Douglas)

Mk 11 Mod 5 20 mm gun

1119.303
M156 ARMAMENT MOUNT

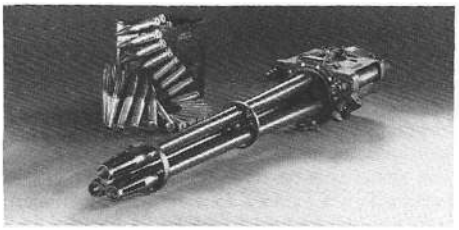
The M156 multipurpose armament mount consists of two separate mountings, one fitted to each side of the UH-1 helicopter. Each mount is capable of carrying and firing the M158A1 and M200A1 2·75-inch rocket launchers or carrying external stores suspended from standard 14-inch (356 mm) bomb racks, MA-4A. External stores must not exceed 245 kg per mount. A product improvement proposal to enable the M156 to carry a fully loaded 19-tube rocket launcher using the later heavy warhead rocket has been evaluated.

Both mounts are fixed in elevation and traverse, and sighting is by means of an XM60 reflex fixed sight. Total empty weight is 37 kg.

STATUS

US forces.

4432.303
XM188E1 30 mm THREE-BARREL AIRCRAFT GUN



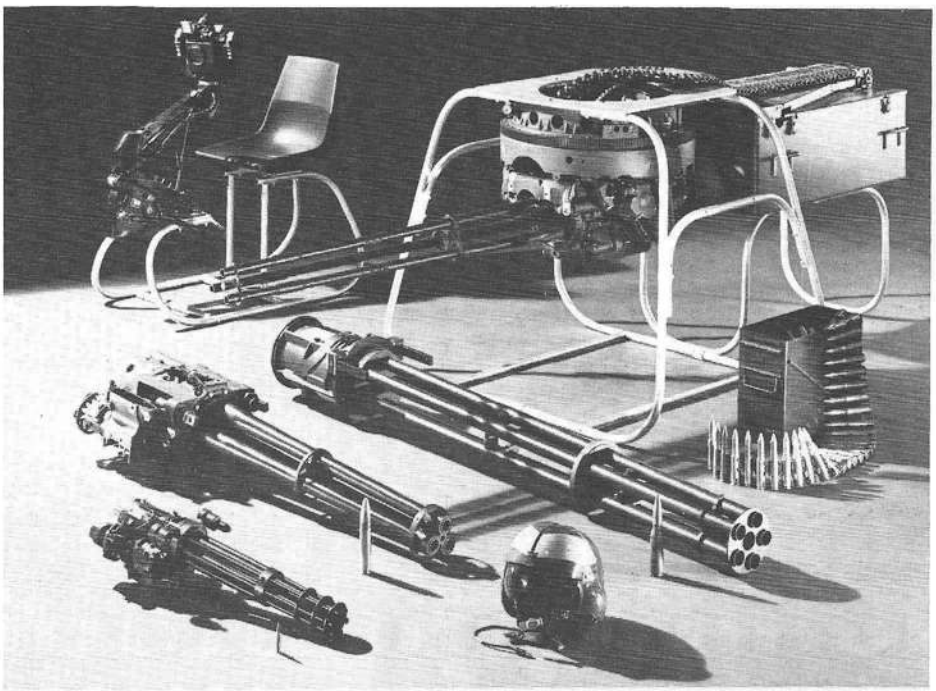
The XM188E1 is a lightweight 30 mm three-barrel variant of the basic General Electric 20 mm M61A1 Vulcan design (**5547.103** in 1982-83 and earlier editions) and succeeds the earlier XM188 (**1285.303** in 1981-82 and earlier editions). It is designed to fire the XM-788/789/799 ADEN/DEFA ammunition at rates of fire variable up to 2000 rounds/minute. Its low recoil force attenuation system and lightweight design make it suitable for air-to-air and air-to-ground applications on small fixed-wing aircraft and helicopters as well as for surface-to-surface and surface-to-air applications on small naval craft. The gun is completely interchangeable with the 20 mm M197 weapon (**2856.103** in 1982-83 and earlier editions) with no modifications to the vehicle. Its variable rate of fire allows the optimum rate to be selected to avoid resonance effects of the vehicle.

CHARACTERISTICS

Type: Externally powered 3-barrel Gatling
Calibre: 30 mm
Muzzle velocity: 792 m/s
Rate of fire: Variable up to 2000 rounds/minute

Recoil force: From 696 kg max at 730 rounds/minute to 1814 kg max at 2000 rounds/minute
Length: 1440 mm
Max diameter: 234 mm
Weight: 50 kg
STATUS
Prototype weapons were built and tested by the US Army, but no production plans have been revealed to date.

CONTRACTOR
General Electric Company, Armament and Electrical Systems Department, Lakeside Avenue, Burlington, Vermont 05402, USA.



XM188E1 30 mm three-barrel aircraft gun

4435.303
UNIVERSAL TURRET FOR HELICOPTER GUNSHIPS

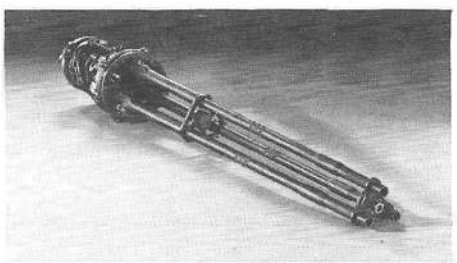
This is essentially the same turret as that now in production for the US Army's AH-1J and AH-1T helicopters but in production for the AH-1S Cobra helicopter. It is a fourth-generation system incorporating numerous improvements over the initial production version.

The basic components consist of the turret, linked feed system, and three electronics boxes containing the turret, gun, and logic controls. The turret aim is controlled by the pilot or co-pilot through helmet sights or by the co-pilot through a dedicated pantograph sight or a companion missile sub-system sighting station such as the TOW sight unit. The turret is electrically driven by two servo motors which receive position commands from the sighting system and give quick response and safe reliable operation.

The turret can operate the 7·62 mm Minigun, the 20 mm M197 Vulcan, the 30 mm XM188E1, and the 30 mm XM230E2 Chain Gun and all can be interchanged without using special tools in less than 30 minutes. 750 rounds of 20 mm ammunition or 500 rounds of 30 mm ammunition can be carried. The prime armament to date has been the M197 Vulcan 20 mm gun and the following characteristics apply to this installation.

General Electric universal turret for helicopters, with selection of various guns which can be fitted, and gunner's station in background

CHARACTERISTICS
Gun: M197
Calibre: 20 mm
Rate of fire: 750 or 1500 rounds/minute
Ammunition capacity: 750 rounds
Elevation
Limits: +21 to -50°
Slewing rate: 60°/s
Training
Limits: ±110°
Slewing rate: Over 80°/s
Pointing accuracy: <3 mil in each axis
STATUS
In production for the US Army AH-1S Cobra helicopter.
CONTRACTOR
General Electric Company, Armament and Electrical Systems Department, Lakeside Avenue, Burlington, Vermont 05402, USA.



1286.303
M197 20 mm THREE-BARREL AIRCRAFT GUN

The M197 aircraft gun is a three-barrel, fully automatic gun. It is a lightweight derivation of the 20 mm Vulcan M61A1 six-barrelled weapon. The M197 utilises many of the M61A1 components and has a rate of fire variable to 3000 shots per minute.

Like other guns in the Vulcan series the M197 needs external power – about 3 hp – for its operation.

The M197 fires standard US 20 mm ammunition of the M.50 series. Ammunition can be fed to the gun as a standard linked belt or by a linkless feed system.

CHARACTERISTICS
Calibre: 20 mm
Rate of fire: 400 – 3000 rounds/minute
Muzzle velocity: 1036 m/s
Number of barrels: 3
Weight: 66 kg
Length: 1892 mm
Average recoil force: 68 kg (at 1500 rounds/minute)
STATUS
In production since October 1969 and in service on the USMC, Iranian Sea Cobra attack helicopter AH-1J, and the OV-10A aircraft. The M197 forms part of the GE flexible weapon system and is used in the GE lightweight gun pod.
CONTRACTOR
General Electric Company, Armament and Electrical Systems Department, Lakeside Avenue, Burlington, Vermont 05402, USA.

20 mm M197 aircraft gun

1112.303
M21 MAMEE HELICOPTER ARMAMENT SYSTEM

The M21 aircraft armament system is made up of two 7·62 mm M134 machine guns (miniguns) and two M158 pods with seven 2·75 inch folding fin rockets each. MAMEE comprises a pair of novel ammunition storage and feed containers which provide a capacity of 3000 rounds of 7·62 mm ammunition in each of the two 11-inch (30 cm) diameter cylindrical containers. The system can fire six pairs of rockets in one second or 4000 rounds of 7·62 mm ammunition a minute. The rocket pods are aimed by manoeuvring the aircraft to which they are fixed. The machine guns, however, traverse 12° inboard to 70° outboard and +15 to -90° in elevation and depression. When the guns traverse inboard to 12° they operate a limit switch that stops the firing on the inboard pointing gun. The gun on the opposite side then increases its rate of fire from 2400 to 4000 rounds/minute, compensating for the non-firing gun. This allows a heavy volume of fire to be placed on the target.

A complete M21/MAMEE installation consists of the following major components:

(1) two 2·75 inch rocket launchers (M158A1)
(2) two 7·62 mm six-barrelled machine guns (M134)
(3) two MAMEE ammunition storage and feed systems
(4) one pilot's rocket launcher reflex sight and intervalometer
(5) one gunner's sighting station for machine guns
(6) one gunner's control panel for guns
(7) control box assembly for 7·62 mm guns
(8) two gun mount assemblies
(9) two rocket rack assemblies.

STATUS
American and Italian Forces. Over 600 M21 systems and about 1000 MAMEE installations have been produced.
CONTRACTOR
Emerson Electric Company, Government & Defense Group, 8100 West Florissant Ave, St Louis , Missouri 63136, USA.

1116.303
M28 ARMAMENT SYSTEM

The M28A1 armament sub-system is an electrically controlled, hydraulically operated, dual weapon that provides wide angle coverage and rapid fire for the AH-1G Hueycobra. The M28A1 consists of a power operated chin turret, mounting the 7·62 mm machine gun M134 on the right and the 40 mm grenade launcher M129 on the left. Ammunition is stored in the ammunition bay and moved to the turret through fixed and flexible chuting. Fire control equipment is located at the gunner/co-pilot station and allows the gunner to train the weapons in azimuth and elevation. Provisions are made for the pilot to fire the weapons in the stow position. The system provides the AH-1G

Hueycobra with area and point fire for attack on personnel and lightly armoured and unarmoured material targets during escort and armed reconnaissance missions.

CHARACTERISTICS

Max effective range: 1500 m (7·62 mm gun); 1500 m (40 mm grenade launcher)
Elevation/depression: +12 to +17·5/–50°
Muzzle velocity: 838 m/s (MG); 240 m/s (grenade launcher)
Rate of fire: 2000 or 4000 SPM (MG); 420 SPM (grenades)
Traverse: 114° l or r of aircraft datum
Weight: 203 kg (empty); 407 kg (loaded)
Ammunition
Capacity: 4000 (M134), 300 (M129) rounds
Type: Linked 7·62 and 40 mm
Sighting: M73 pilot's reflex with lighted reticle and manual range adjustment; gunner's flexible reflex sight with automatic airspeed compensation

STATUS

US Forces.

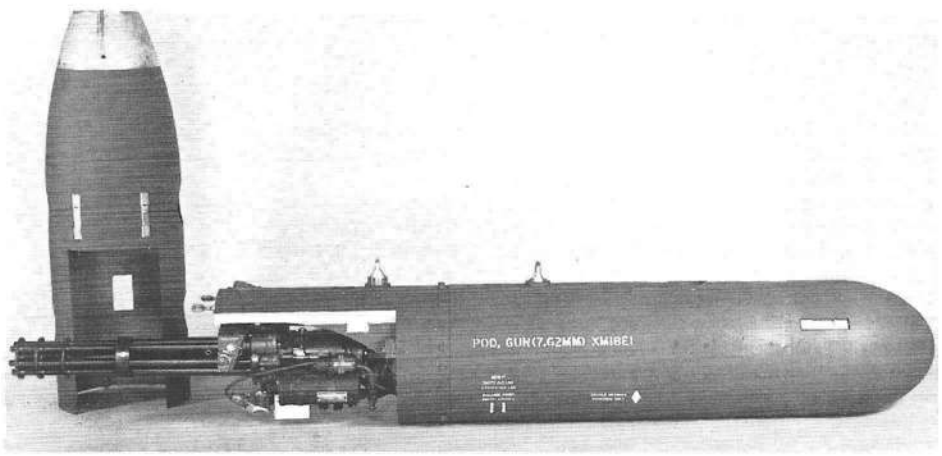
XM28E1 ARMAMENT SUB-SYSTEM

The armament sub-system XM28E1 is similar to the M28 (**1116.303**) except for minor changes in the drive motor, which is a motor with two distinct speeds as opposed to a motor which produces two speeds through use of a control resistor.

STATUS

US forces.

1836.303
XM30 AIRCRAFT ARMAMENT SUB-SYSTEM



The XM30 sub-system is a two-gun installation of XM/140 30 mm guns, one on each side of the UH-1B helicopter. Ammunition is stored inside the aircraft. The sub-system weighs approximately 1800 lb (816 kg) when fully loaded. It is capable of firing at a combined rate of approximately 850 rounds per minute. The guns are remotely controlled and may be fired by the co-pilot. The pilot can also fire the guns when they are in the fixed forward (stow) position.

1268.303
MINIGUN POD TYPE SUU 11B/A

The General Electric M134/GAU 2B/A Minigun is a 7·62 mm calibre development of the 20 mm M61 series of 'Vulcan' cannons. It has outstanding firepower and the SUU 11B/A pod provides a convenient means of giving its power to any tactical aircraft. The pod is light in weight and small in size and is equipped with standard bomb lugs for attachment to the weapon pylon. The pod can be carried on a wide range of fixed-and-rotary wing aircraft up to a maximum speed of Mach 1·2.

The gun is mounted in the forward half of the pod and fires through the stainless steel nosecap. The centre section of the pod contains the linkless ammunition feed system. A drum magazine is employed containing 1500 rounds of standard NATO 7·62 mm ammunition Type M59, M80, or M60. In the rear of the pod is the electrical control package. The linkless feed system is essentially the same as the larger scale one already developed for the Vulcan. In the Minigun pods the feed is single-ended and spent cartridge cases are ejected overboard through a port on the bottom of the pod. The ammunition is conveniently loaded from standard belted ammunition using a hand operated de-linking loader.

Provision for gun harmonisation is built into the gun mounting. A screw adjustment provides movement of the gun line through approximately ±¾°. Shot dispersion can be varied to suit operating conditions and target characteristics. At minimum dispersion 80 per cent of shots are within a 6·5 mil included angle.

SUU 11B/A Minigun pod

CHARACTERISTICS

Designation: USAF Minigun pod SUU 11B/A; US Army Minigun pod M18A1
Gun: 7·62 Minigun M134/GAU 2/A
Feed: Linkless type MAU 7
Drive: SUU 11B/A electric. AC or DC: 28 V at 15 A or 208 V AC 400 Hz 3-phase 2 A per phase.
XM 18 E1 electric, 28 V DC 15 A only
Length: 2159 mm
Diameter: 305 mm
Weight: 147 kg (loaded); 111 kg (empty)
Ammunition capacity: 1500 rounds
Rate of fire: SUU 11B/A 3000 or 6000 rounds/minute; M18A1 2000 or 4000 rounds/minute
Average recoil force: 136 kg at 6000 rounds/minute

STATUS

In service with US and other forces.

HUGHES LIGHTWEIGHT ROCKET LAUNCHER XM260

Hughes Aircraft Company, under US Army contract, has developed a lightweight launcher for the 2·75 inch rocket system to be used on Army attack helicopters. It will be fitted to both the AH-1 Cobra, and the AH-64 Apache attack helicopter. The lightweight rocket launcher (LRL) is produced in two models, with capacities of seven and 19 rounds respectively and both are lighter than their predecessors. With a combat ordnance load of four 19-tube launchers, the LRLs provide a gross weight saving of about 120 kg per aircraft. This reduction is effected by the inclusion of the stores management, fuzing and fire control system, thus allowing an increase in fuel load. Fuze-timing selection is possible from the cockpit and the LRL is capable of launching 2·75 inch rockets powered by either the standard Mk 40 or its replacement higher thrust, Navy-developed, Mk 66 motor.

CHARACTERISTICS

Type: M260	7-tube	19-tube
Length	1651 mm	1651 mm
Diameter	254 mm	406 mm
Weight (empty)	15·5 kg	35·9 kg
Rocket capacity	7	19
Suspension	NATO 14 inch	NATO 14 inch
Firing interval	0·06 s	0·06 s

DEVELOPMENT

Development was carried out by Hughes Aircraft's Missile Systems Group for the US Army Missile Command, Redstone Arsenal, Alabama.

STATUS

The initial production contract awarded in late 1979 called for delivery of 1500 M-260 (7-tube) and 1200 M-261 (19-tube) models. Production was completed six months ahead of schedule in October 1981. A second production contract for nearly 4000 M-261 and 600 M-260 models was placed in May 1983, with deliveries to be completed in 1986.

CONTRACTOR

Hughes Aircraft Company, Missile Systems Group, Canoga Park, California 91304, USA.

US Army AH-64 Apache attack helicopter fires a pair of 2·75 in rockets from launchers on outboard wing pylons

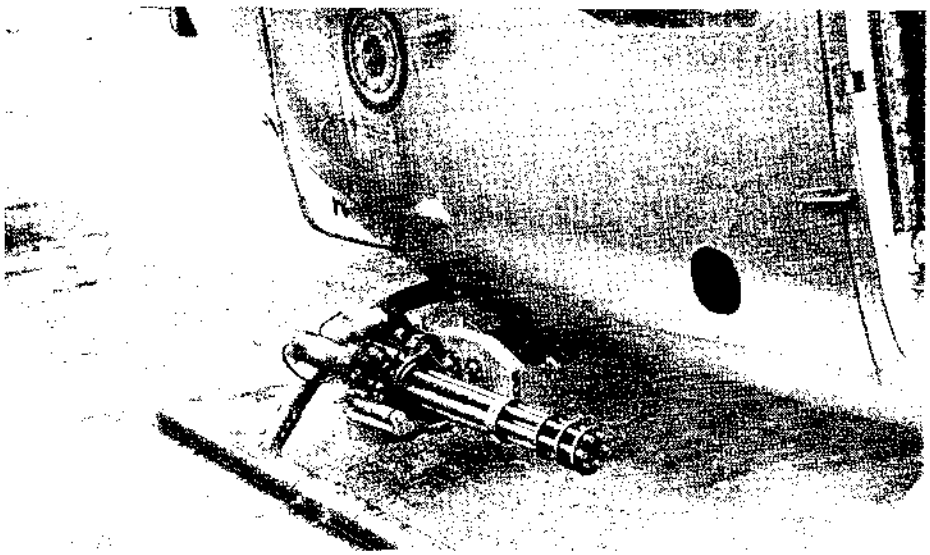
1592.303
EMERSON FLEXIBLE TURRET SYSTEM (FTS)

Designed specifically as a 'strap-on' system for light observation and reconnaissance helicopters, Emerson's lightweight, flexible FTS (previously named MINI-TAT) has been extensively evaluated by the US Army Weapons Command, Project MASSTER, and the Canadian Defense Forces. It is claimed to be the only 'off-the-shelf' proven flexible armament system that will fit several light helicopters without structural modification. Customers include the Iranian Army Aviation (for Agusta 206B helicopters – see accompanying illustration), the Canadian Defense Forces (for CH-136s), and the French Army (for the SA-341 Gazelle).



Offering a field of fire of 360° azimuth, +10° elevation, and -70° depression, the FTS is easily adaptable to a variety of helicopters and can be rapidly installed in the field. System weight is 62·6 kg exclusive of weapon and ammunition.

After initial adaptor kit installation, the FTS can be re-installed or removed in 30 minutes. In most configurations the FTS is mounted to the existing helicopter skid mounts. Versatility is one of its most attractive features. The system is compatible with a wide variety of helicopters including the military Uni- series, the international AB-205, AB-206, British Westland Lynx, Scout, and Wessex V, West German BO105, Japanese OH-6J, Canadian CH-136, French SA-341 Gazelle.

Electrically powered, the FTS can be slewed at rates of 80°/s in azimuth, elevation, and depression. Design of the FTS provides for easy access to the system for simplified maintenance. Additionally, in the event of the loss of aircraft power, the FTS can be quickly jettisoned.

CONTRACTOR

Emerson Electric Company, Government & Defense Group, 8100 West Florissant Ave, St Louis, Missouri 63136, USA.

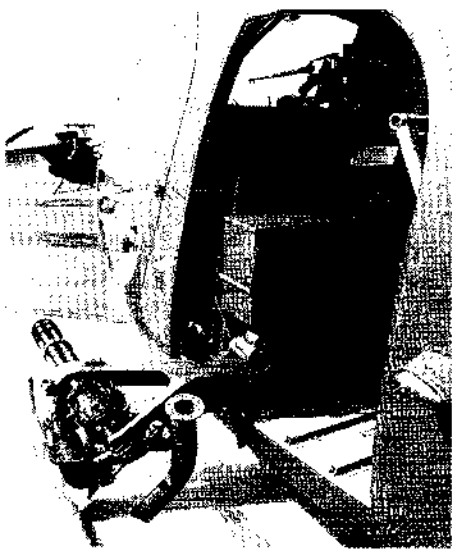
XM27E1 7·62 mm ARMAMENT SUB-SYSTEM HELICOPTER



The XM27E1 was developed by Hughes under contract from the US Army Weapons Command for use with the OH-6A/OH-58A Scout helicopters. The basic concept was an outgrowth of the Hughes XM7 system which was proposed as a part of the original US Army Scout helicopter competition. The XM7, with similar characteristics, mounted two 7·62 mm M60 machine guns. The XM27E1 system, on the other hand, mounted a GFE General Electric M134 7·62 mm Minigun which was modified by Hughes to incorporate a dual speed drive assembly consisting of an electric motor, speed control unit, and a gear reduction assembly.

The XM27E1 is a compact, self-contained unit which is positioned on the left floor of the rear compartment. The unit can be mounted or demounted in less than ten minutes by two men and attachment is accomplished through use of three quick-release pins. The gun is flexible in elevation only (+10°, -24°) and fired at a 'two-step trigger' selectable rate of 2000 or 4000 rounds/minute. System capacity is 2000 rounds of belted 7·62 mm NATO ammunition. The Hughes-developed XM70E1 reflex sight was provided with the system for fire control purposes. This sight is an optical beam splitter type which is mechanically linked to the system.

CHARACTERISTICS

Armament sub-system
Weight (without ammunition): 48·5 kg (107 lb)
Weight (with ammunition): 106·6 kg (235 lb)
Effective range: 1100 m
Ammunition capacity: 2000 rounds
Elevation limits: +10°, -20°
Elevation rate: 30°/s
Operating voltage: 22 - 30 V DC

Automatic gun M134 (Minigun)
Calibre: 7·62 mm
Rate of fire: 2000/4000 rounds/minute
Weight: 30·4 kg (67 lb)
Muzzle velocity: 869 m/s
Cooling: Air
Feed: Gun-driven de-linking feeder Mau 56/A

Hughes XM27E1 7·62 mm armament sub-system

Links: M-13
Power: Electric, dual-speed drive motor

Helicopter reflex sight XM70E1
Type: Collimated, illuminated reticle
Weight: 2·2 kg (4·8 lb)
Width (extended/stowed): 254/356 mm (10/14 in)
Height: 228 mm (9 in)
Range: Adjustable, 250 - 1500 m
Drive: Mechanically coupled to gun
Lamp power requirements: 0·68 A (each filament)

Range compensating for 7·62 or 40 mm ammunition

STATUS

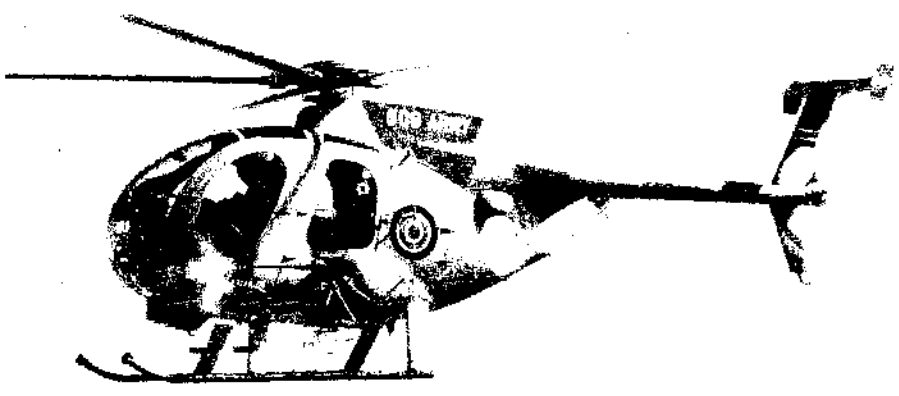
In April 1966, an initial contract was awarded to Hughes by the US Army Weapons Command, Rock Island Arsenal, Rock Island, Illinois for the development and subsequent production of 268 XM27E1 kits plus spares. Further contracts for the production of 606 additional kits plus spares were awarded in 1967 and 1968. Total value of all contracts was over $27 million.

Over 10 000 000 rounds were fired from XM27E1 kits mounted on OH-6A helicopters during the Viet-Nam conflict. To our knowledge, the XM27E1 was never utilised on the OH-58A in combat, although it was checked out and cleared for use in US testing. The XM27E1 earned a reputation as one of the Army's most reliable helicopter weapon systems. This same weapon system, under Hughes Helicopters Inc's designation of HGS-5, is now in limited production for sales world-wide for use on the Hughes 500 series light attack helicopter.

CONTRACTOR

Hughes Helicopters Inc, Culver City, California 90230, USA. (Subsidiary of McDonnell Douglas)

4436.303



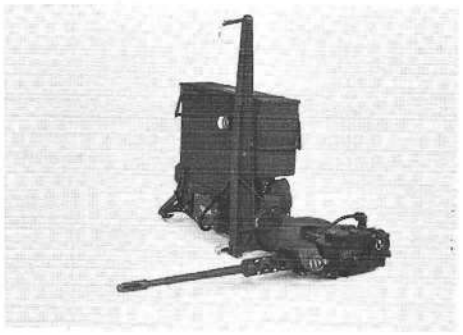
HGS-55 7·62 mm ARMAMENT SUB-SYSTEM

Capitalising on the XM27E1 technology (**1115.303**), Hughes Helicopters Inc has developed and built a light combat helicopter armament sub-system designated the HGS-55 which mounts the Hughes 7·62 mm EX-34 Chain Gun weapon. As adapted to Hughes 500 series helicopters, the reliable EX-34 provides accurate point target suppressive firepower at ranges out to 900 metres. In highly manoeuvrable helicopters, the EX-34 is extremely effective against non-armoured soft targets such as general material and transportation systems.

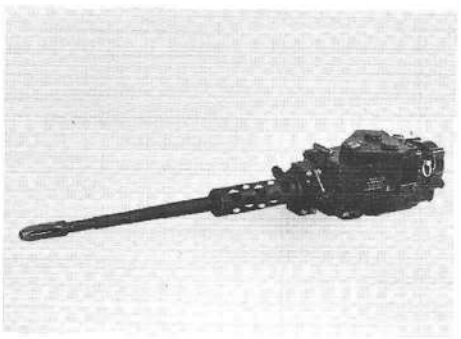
In the HGS-55 system, the EX-34 fires 570 shots a minute of NATO standard 7·62 mm ammunition. Over 500 000 rounds have been fired through a series of EX-34 prototypes and all firings confirm the exceptional reliability of this weapon. The contractor claims the potential for combat availability several orders of magnitude better than any comparable weapon of this calibre.

CHARACTERISTICS

Configuration: HGS-55



Hughes 500MD helicopter equipped with HGS-55 armament sub-system



Gun: EX-34
Calibre: 7·62 mm
Rate of fire: 550 rounds/minute
Muzzle velocity: 856 m/s
Ammunition: 2000 rounds NATO standard
Weight (with ammunition): 98·9 kg
Weight (without ammunition): 40·8 kg
Power supplies: 26·5 V DC at 0·22 kW

STATUS

Following extensive tests in 1978-79 by the British Royal Small Arms Factory, a number of these guns were purchased by the British Army. Subsequently the EX-34 was adopted by the UK MoD for use on the MCV-80 vehicle and future AFVs. The Royal Small Arms Factory has begun series production of the EX-34 under licence, with deliveries commencing in 1985. The Canadian Forces are also evaluating the EX-34 for various applications. An experimental version capable of 1000 rounds/minute is under development, and in addition to the HGS-55 model featured in this entry there are other versions for fixed wing aircraft and land-based applications.

Hughes Helicopters Inc, Culver City, California 90230, USA. (Subsidiary of McDonnell Douglas)

1108.303
M5 AIRCRAFT ARMAMENT SYSTEM

The M5 is used on the UH-1B/M helicopters. It consists of a flexible remote controlled, servo-power driven gun turret mounted in the nose of the UH-1B/M. The turret incorporates one M75 40 mm grenade launcher. Linked ammunition is stored in a rotary ammunition drum in the cargo hook hole, pulled through a flexible chute by an ammunition booster, and fed to the grenade launcher. The system also has a box feed system in addition to the rotary ammunition drum. A master armament control panel is located in the instrument console and is accessible to both the pilot and co-pilot gunner. A flexible hand control sight assembly mounts above the co-pilot's seat from which the co-pilot can sight and fire the system. The sub-system can also be fired in the stow position by either the pilot or co-pilot by means of a trigger switch on both cyclic stick grips. In this mode, the turret is flexible in elevation. An MWO has been applied to the sub-system to give the sight lead angle compensation. A dual-range reticle has been applied for more accuracy at long range.

CHARACTERISTICS

Effective range: 1500 m
Elevation/depression: +15°, -35°
Muzzle velocity: 240 m/s
Rate of fire: 230 rounds/minute
Traverse: 60° right and left
Ammunition
Type: Linked 40 mm
Capacity: 150 rounds; 300 rounds
Sighting: Reflex type: gunner/co-pilot operated in elevation and deflection

Weights	**Box fed**	**Drum fed**
Empty	106 kg	101 kg
Loaded	152 kg	208 kg

STATUS

US forces.

1109.303
XM8 40 mm ARMAMENT SUB-SYSTEM HELICOPTER

The XM8 was developed by Hughes Helicopters Inc under contract from the US Army Weapons Command for potential use with the OH-6A/OH-58A Scout helicopters. The present concept is based on a prototype effort performed by this contractor in support of the original US Army Scout helicopter competition eventually won by Hughes. This prototype system mounted on an M75 high velocity grenade launcher and its characteristics were very similar to the XM8 system mounting an M129 grenade launcher later sponsored by the Army.

The XM8 is a compact, self-contained unit which is positioned on the left floor of the aft compartment. The unit can be mounted or demounted in less than ten minutes by two men and attachment is accomplished through the use of three quick-release pins. The XM8 uses the same mounting points and is interchangeable with the XM27E1 helicopter armament sub-system (**1115.303**). The XM8 utilises a simple integrated feed system with a compact, quickly detachable ammunition container. Linked ammunition is spiral wound in this container to provide reliable, positive control of each round. Ammunition boost is not required.

The XM8 mounts an M129 grenade launcher which fires 40 mm rounds with a muzzle velocity of 240 m/s (790 ft/s). System capacity is 150 rounds of belted M384 ammunition. The gun is flexible in elevation only and fires at a rate of 400 rounds per minute. The XM8 incorporates a proven hydrospring recoil system which reduces peak recoil loads of the M129 by over 60 per cent. The Hughes-developed XM70E1 reflex sight is provided with the system for fire control purposes. This sight is an optical beam splitter type which is mechanically linked to the system and is used interchangeably with the XM27E1 armament sub-system.

Hughes XM8 40 mm armament sub-system

CHARACTERISTICS

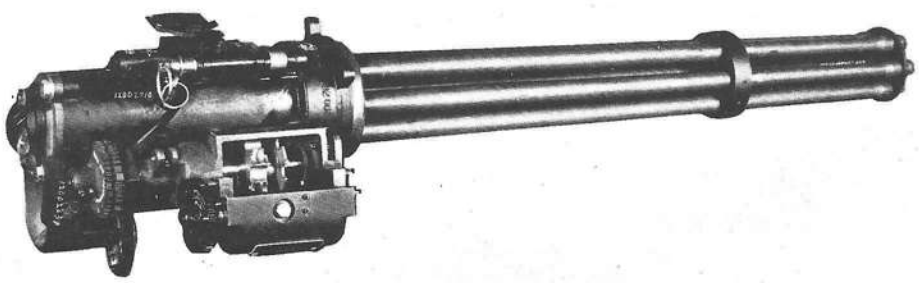
Armament sub-system
Weight (without ammunition): 54·4 kg (120 lb)
Weight (with ammunition): 107·9 kg (238 lb)
Ammunition capacity: 150 rounds
Elevation limits: +10°, -24°
Elevation rate: 25°/s
Operating voltage: 22-30 V DC
High velocity grenade launcher 40 mm M129
Rate of fire: 400 rounds/minute
Weight: 20·4 kg (45 lb)
Muzzle velocity: 240 m/s (790 ft/s)
Range: 2200 m
Method of operation: Electric motor
Links: M16, M16A1
Ammunition: M384 (HE), M430 (HEDP)

DEVELOPMENT

In June 1967, a contract was awarded to Hughes by the US Army Weapons Command, Rock Island, Illinois for the development and testing of eight XM8 helicopter armament sub-systems. This programme included a firing test fixture, two development models, two service test models and four prototype systems. Extensive flight tests were conducted on the OH-6A helicopter at Fort Irwin, California, and Apalachicola, Florida, and all hardware was subsequently delivered to the Army.

STATUS

Inactive.



CONTRACTOR

Hughes Helicopters Inc, Culver City, California 90230, USA.

1284.303
XM214 5·56 mm AUTOMATIC GUN

The General Electric Company has designed and developed a 5·56 mm automatic gun. The gun design is based on the proven principles of the operational M61A1, 20 mm Vulcan gun, and the GAU-2B/A, 7·62 mm Minigun. Selectable firing rates are available within the range of 400 to 6000 rounds per minute, permitting optimum engagement of a variety of targets. As few as three rounds to as many as 1500 rounds can be fired in single bursts. The weapon is a multi-barrelled machine gun externally powered and suitable for aircraft, helicopter, or ground vehicle installation. The 5·56 mm M193 (M196 Tracer) round weight is approximately half that of the 7·62 mm round and is the same as is used on the M16 rifle.

A single, rugged main spring is used for actuation of the firing pins. Elimination of the springs from the individual bolts allows the bolts and entire gun to be simpler, smaller, and lighter. A de-linking feeder provides a declutching action which, when the trigger is released, immediately stops the feeding of rounds. The gun continues to fire for a fraction of a second, firing out remaining rounds. This operation automatically clears and 'safes' the gun at the end of each burst. A combination access handle and safing

XM214 5·56 mm automatic gun

lever separates the main spring from the six gun bolts and provides a positive visual verification of the safe position.

A side-stripping feeder strips and disposes the ammunition links and feeds rounds to the gun. This feeder permits rapid installation of flexible ammunition belts or ammunition cans. The gun's access cover, bolts, and feeder can be removed and installed without tools or timing procedures. Reliability and maintainability of the 5·56 mm gun are expected to be equal to or better than that of the 7·62 mm Minigun.

The power input needed by the gun varies between 0·75 and 3·2 hp according to rate of fire selected. Electric or hydraulic motor drives are available for this purpose. A self-powered propellant gas-driven variant of the Minigun has also been developed. For the electric drive a range of nickel-cadmium batteries is available giving a duration of fire up to 80 000 rounds at 1000 rounds per minute.

CHARACTERISTICS

Calibre: 5·56 mm
Muzzle velocity: 990 m/s
Rate of fire: Up to 10 000 rounds/minute
Dispersion: 80% shots within 4 mils
Length: 686 mm
Weight (gun and drive): 15 kg
Recoil force, average: 110 kg (at 10 000 rounds/minute)

STATUS

Prototype weapons have been assembled and tested.

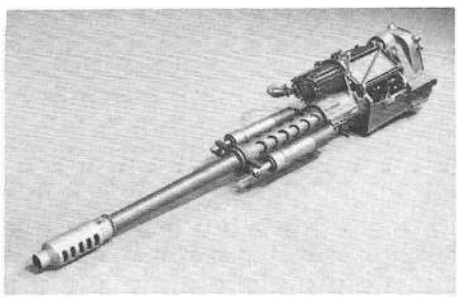
CONTRACTOR

Aircraft Equipment Division, General Electric, Burlington, Vermont 05402, USA.

1846.303
M230 30 mm CHAIN GUN WEAPON

Developed by Hughes Helicopters Inc, the 30 mm M230 chain gun is a single-barrel, externally powered weapon which incorporates a rotating bolt mechanism driven by a simple and reliable chain drive. The entire gun weighs 123 lb (55·9 kg) and will achieve firing rates from single round to 625 rounds per minute. The chain drive principle permits a simplified gun cycle which operates safely from an open bolt without requirement for chargers, declutching feeders, or other special devices. Since the M230 is motor driven, it provides inherent high belt pull, thereby eliminating the need for a powered booster. Long bolt-lock time insures an essentially gasless action and the resultant long dwell following firing provides for hangfire safe weapons.

As all the moving parts are totally keyed together, each and every motion within the chain gun is precisely timed and fully controlled. Further, 100 per cent positive round control within the M230's ballistically independent system eliminates those malfunctions due to conventional ammunition problems. These factors, coupled with the smooth power flow from its drive motor, ensure the highest reliability at all rates of fire.



DEVELOPMENT

Hughes Helicopters Inc initiated development of a 30 mm chain gun weapon in December 1972 and after an accelerated engineering and fabrication effort, the weapon was first fired in April 1973 and burst fired in May of that year. A 2500-round feasibility trial sponsored by the US Army was successfully completed in September 1973 and by December 1973, 4000 rounds had been fired. Subsequent models of XM230s were built and tested and a quarter of a million rounds of XM552/XM639 ammunition were fired through these several chain guns. Early in 1976, the DoD directed that the XM230 be rechambered to fire ADEN/DEFA type ammunition for purposes of NATO interoperability. To ensure interoperability, Hughes Helicopters Inc was given the responsibility for development of a family of US 30 mm rounds: M788 (TP), M789 (HEDP) and M799 (HE). The modified XM230 – designated the M230 – was first fired in March 1978. While the basic M230 gun can fire either linked or linkless ammunition through the use of a lightweight interchangeable transfer unit, the AH-64 will employ a linear linkless conveyor system.

Hughes AH-64 Apache attack helicopter armed with 30 mm Hughes M230 chain gun/cannon and 16 Hellfire missiles

Another member of the Chain Gun family, the M242, is in production for the US Army as the primary weapon for installation in the M2 and M3 Bradley fighting vehicles and the Light Armoured Vehicle (LAV-25) for the US Marine Corps. Additionally, the US Navy has adapted the M242 to Mk 88 deck mounts for use aboard fast patrol boats. This weapon (**5237.103** in 1982-83 and earlier editions) fires both European and US 25 mm ammunition.

Hughes M230 cannon

CHARACTERISTICS

Calibre: 30 mm
Combat ammunition: ADEN/DEFA/M789/M799
Practice ammunition: M788
Weight of receiver: 28·6 kg
Weight of barrel: 15·9 kg
Weight of recoil adaptor: 5·5 kg
Weight of linked or linkless transfer unit: 5·9 kg
Total gun system weight: 55·9 kg
Length: 1638 mm
Width: 254 mm
Height: 292 mm
Barrel life: To 10 000 rounds
Rate of fire: 625 ± 25 rounds/minute
Time to fire: 0·2 s
Time to stop: 0·1 s
Clearing method: Open bolt
Effective impulse (with muzzle brake): 20·42 kg
Power required: 6·5 hp
Reliability predicted: 15 000 MRBF

STATUS

In production.

1110.303
M16 ARMAMENT SUB-SYSTEM

Armament sub-system M16 contains two 7·62 mm M60CAL machine rocket launchers mounted on a UH-1B/C helicopter. Each set of guns is flexible in both elevation and azimuth. Capacity for the machine guns is 6000 rounds which is link-fed to the left side of each gun. The machine guns shoot 2000 to 2600 rounds/minute with a maximum effective range of 1000 m. Elevation of the guns is from +11 to -63° while traverse ranges from 12° inboard to 70° outboard. Machine gun firing cuts off electrically or mechanically when guns on a given side of helicopter are in danger of firing into the aircraft.

The rocket launchers M158 have an effective range of 3000 m. The pilot aims through a manual reflex sight for both machine guns and rockets. The co-pilot uses a flexible reflex sight for machine guns only. Machine guns cut off while rockets fire.

STATUS

US forces.

1113.303
M23 ARMAMENT SUB-SYSTEM

The M23 armament sub-system consists of two M60D 7·62 mm machine guns and two mounts, one on each side of the aircraft in the doorways. The pintle post assembly is attached to a base tube assembly which is attached to hard points on the helicopter fuselage. The machine gun, which is a belt fed, gas operated, air-cooled automatic weapon, is attached to a pivot cradle on top of the pintle post. The base can be employed at either the right or left side, and the pedestal is designed for right or left installation. The machine gun installs on either right or left pintle mounts without adaptation, and is a modified machine gun, M60, with aircraft ring type sights, spade grips and an improved feed system. A rapid reloading capability is provided by a 550-round ammunition box attached to the weapon by a flexible chute. A canvas bag attaches to the right side of the receiver to catch links and ejected cartridges. Free traverse and elevation is allowed within fixed stop limits to prevent self-inflicted damage to the helicopter. The sub-system utilises all standard 7·62 mm ammunition.

CHARACTERISTICS

Max effective range: 1100 m
Elevation forward: +3·5°, Aft +6·5° depression -80°
Muzzle velocity: 838 m/s
Rate of fire: 550 rounds/minute
Traverse: 2 - 178° in azimuth
Ammunition
Capacity: 550 rounds per gun
Type: Linked 7·62 mm
Weight: 78 kg (empty); 95 kg (loaded)

STATUS

US forces.

1114.303
M24 ARMAMENT SUB-SYSTEM

The armament sub-system M24 is similar to armament sub-system M23 except that it is mounted on the CH-47A helicopter and carries 200-round ammunition boxes. One machine gun mounts in the left forward escape hatch, the other across the right forward door.

STATUS

US forces.

5220.303
M41 ARMAMENT SYSTEM
The M41 armament system consists of a pintle mount, a 7·62 mm M60D machine gun, link and brass retainer, ammunition box and a gunner's safety harness, and the complete system is mounted on the rear ramp of the Boeing CH-47 helicopter used by the United States Army. The M60D is provided with positive mechanical stops to limit the elevation and traverse of the weapon.
CHARACTERISTICS
Ammunition capacity: 200 rounds
Weight without ammunition: 19 kg
Maximum effective range: 1100 m
Muzzle velocity: 838 m/s
Rate of fire: 550 rounds/minute
Elevation: +12·5 to +68°
Traverse: 47° left and right
Sight: Aircraft ring and post type
STATUS
In service with the United States Army

5221.303
XM94 ARMAMENT SUB-SYSTEM
Each sub-system provides two identical pintle installations which can be interchangeably mounted on either the right or left doorway compartment of a helicopter. These weapons can be utilised as a flexible pintle installation, or fixed in a forward attitude and remotely fired by the pilot. The grenade launcher used in the XM94 sub-system is the M75.
CHARACTERISTICS
Ammunition capacity: 800 rounds
Weight without ammunition: 540 kg
Effective range: 1500 m
Muzzle velocity: 240 m/s
Rate of fire: 400 rounds/minute
Elevation: +3·5 to −60°
Traverse: From fixed forwards to 135° aft

5222.303
XM59 ARMAMENT SUB-SYSTEM
The XM59 sub-system is an exterior mount sub-system for mounting one 7·62 mm M60D and one 0·50 XM213 (modified AN-M2) machine gun, in each side door of the UH-1D or UH-1H helicopter. The XM59 is basically an M23 system adapted for use with the 0·50 machine gun. The 0·50 kit pintle post assembly is attached to the M23 sub-system base tube assembly. A link receptacle and an expended brass deflector are provided to eliminate any hazard to the aircraft as expended cases and links are ejected from the weapon. Mechanical stops are provided to prevent any self-inflicted damage to the aircraft.
CHARACTERISTICS
Ammunition capacity: 100 rounds of 0·50 ammunition; 550 rounds of 7·62 mm ammunition
Weight: 126 kg with ammunition, 98 kg without ammunition
Range: 0·50 weapons 3000 m; 7·62 mm weapons 1100 m
Muzzle velocity: 0·50 – 857 m/s; 7·62 mm – 838 m/s
Elevation: +6·5 to −80°
Traverse: 2 – 178° in azimuth

YUGOSLAVIA

5223.303
YUGOSLAV AIRCRAFT ARMAMENT
Listed below is a resumé of aircraft armament used by the Yugoslav Air Force. It should be noted that the Soviet designations for bombs are very similar to those of Yugoslavia, for example Soviet HE general-purpose bombs are the FAB-100, FAB-250 and FAB-500 etc. Soviet incendiary bombs are the ZAB-100 etc. Soviet HC anti-tank bomblets are the PTAB-5 etc and the Soviet chemical bombs are the VAP and ZAP series.

BOMBS:
1·5 kg PTAB-1·5 HC anti-tank bomblets
2·5 kg PTAB-2·5 HC anti-tank bomblets
2·5 kg RAB-2·5 fragmentation bombs
3·5 kg RAP-3·5 fragmentation bombs
16 kg RAP-16 fragmentation bombs (normally used in clusters of eight)
45 kg ZAB-45 incendiary bomb
50 kg SAB-50 parachute flare
50 kg FOTAB-50 photo-flash
120 kg RAB fragmentation cluster bombs
250 kg FAB-250 HE general-purpose bombs
500 kg FAB-500 HE general-purpose bombs
DPT-150 cluster bomb unit with 54 PTAB 1·5 kg or 44 RAB 2·5 kg or 34 RAP 3·5 kg
150 litre PLAB-150L napalm

ROCKETS:
57 mm VRZ-57 high explosive (or anti-tank) in pods of 12 (pod is Lanser L57)
127 mm VRZ-127 high explosive (or anti-tank)

GROUND RADAR

BRAZIL

Note: Indigenous radar development in Brazil began in 1970, at the instigation of the PEA (Divisão de Eletrônica (Electronics Division) of the IPD - Instituto de Pesquisa e Desenvolvimento (Research and Development Institute)) a branch of the Brazilian Ministry of Aeronautics, the Centro Técnico Aerospacial - CTA (Aerospace Technical Centre). Following preliminary studies and programmes related to the acquisition of basic microwave expertise, and the formation of a nucleus of qualified personnel, two programmes were initiated. As reference to the brief descriptions which follow show, both these Brazilian radar initiatives employ S-band equipments, but future developments can be expected to embrace the other radar bands eventually to include certain more specifically military applications.

4132.153
S-BAND METEOROLOGICAL RADAR

This radar operates in the 2700 MHz frequency band and has preset ranges of 25, 50, 100, 200 and 400 km. The configuration of the equipment can be seen from the adjacent photograph, from which it will be noted that the large circular reflector can be steered in azimuth and elevation on its tower-mounted pedestal. This presumably allows the radar to be employed for both radiosonde tracking or weather/precipitation surveillance purposes.

Digital techniques are employed in signal processing with presentation as raw radar video. Other facilities include azimuth and range integration, iso-echo and iso-contour presentation with height density levels, colour TV screen display, and remote facsimile presentation. The normal display arrangements provide for sectorial coverage, PPI and RHI displays, and the antenna can be adjusted in elevation from the operating console.

STATUS

The PEA-built prototype has been fully tested and approved, and transferred to private industry for commercial production. Companies involved include Tecnasa for system integration and electronics, Motoradio for the microwave elements, and Jamy for tower, pedestal and antenna. Thirty-two of these radars were due to be procured, initially as part of the Brazilian Ministry of Aeronautics' Plano de Desenvolvimento do Sistema de Proteção ao Vôo (Flight Protection System Development Plan).

Antenna assembly of the Brazilian S-band met radar (Ronaldo S Olive)

Brazilian met radar console (Ronaldo S Olive)

CONTRACTOR

IPD/PEA - Divisão de Eletrônica, 12200 São José dos Campos, SP, Brazil.

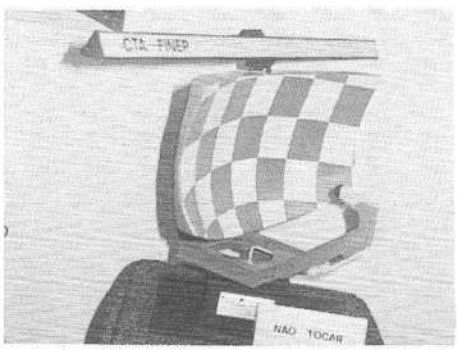
4133.153
ASR-BR1 AIRPORT SURVEILLANCE RADAR

This S-band airfield surveillance radar is the result of PEA's 'Meta 2' project, and the equipment is being procured in quantity for the Brazilian ATC system although it is equally suitable for military tactical applications.

The ASR-BR1 has a conventional transmitter with a magnetron modulator and delay line pulse generation. Apart from the magnetron and a thyratron switching tube, the transmitter is an all solid-state system providing adjustment of the PRF within ±10 per cent of its normal value. All transmitter components have automatic protection circuits against malfunctions. Receiver characteristics include: low noise figure due to a parametric input amplifier; self-radiation protection; synthesiser local oscillator with automatic frequency control; IF preamplifier with time-variable gain. The last feature equalises the returns from identical targets at different ranges, as well as protecting the IF amplifier against saturation caused by excessively strong re-run echoes from short range targets.

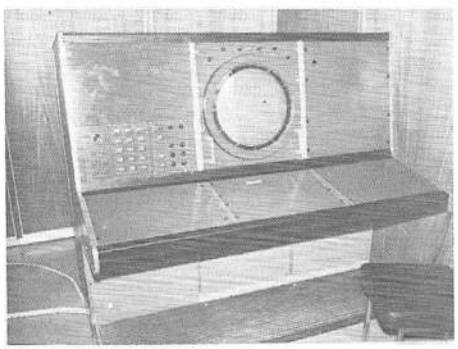
Signal processing is based on the use of a digital MTI which rejects fixed echoes, and the PRF can be varied to eliminate blind speeds. A conventional PPI CRT display is provided, and there is a video map facility which generates synthetic video representing the local geography of the airfield including such features as towers, tall buildings, mountains, etc.

CHARACTERISTICS



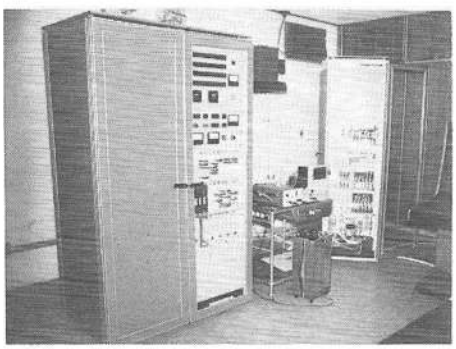
Frequency: 2700 - 2900 MHz
Peak power: 450 kW (typical)
Pulse width: 0·75 μs
PRF: 1000/s (variable ±10%)
Antenna beamwidth: 1·5° azimuth; Cos^2 5·5 - 40° elevation
Antenna gain: 32 dB (max)
Sidelobe attenuation: 25 dB
Rotation rate: 15 rpm
Receiver noise: 2 dB (at parametric amplifier input)
IF: 30 MHz
Max range: 110 km (2 m^2 target)
Detection probability: 0·9
False alarm probability: 10^{-5}
Sub-clutter visibility: 25 dB
First blind speed: 3500 km/h

STATUS



Twenty-four sets have been ordered for the Brazilian ATC network, and the first two installations are at the Porto Alagre (Rio Grande do Sul State) Airport and the São Pedro da Amdeia (Rio de Janeiro State) Naval Air Force Base.

CONTRACTOR



IPD/PEA - Divisão de Eletrônica, 12200 São José dos Campos, SP, Brazil.

CANADA

5678.153
CMR-3 COASTAL SURVEILLANCE RADAR

The CMR-3 Coastal surveillance radar is derived from the AN/SPS-503 naval radar (**5677.253**), and is designed for long range surveillance under severe weather and ECM conditions. The system operates in the E/F frequency band for optimum performance and uses a driven transmitter with pulse-to-pulse frequency agility over a wide bandwidth. The antenna is a tower-mounted, high gain, narrow-beam unit and the system is able to operate unattended in remote sites.

The transmitter uses a TWT amplifier fed by a frequency synthesiser and the low-noise, high dynamic range receiver employs pulse compression. This combination of frequency agility and pulse compression is designed to give excellent clutter and jamming suppression. The digital signal processing unit contains independent MTI (optional) and non-MTI channels. Each channel has its own CFAR circuits, and PRF discrimination is applied to both channels. Adaptive velocity compensation can be supplied with the MTI channel.

The tactical display used with the CMR-3 is a development of a marine collision avoidance system. It is capable of simultaneously tracking of up to 20 targets out to a range of 64 nautical miles.

Although the CMR-3 system is configured primarily for the surface surveillance role, it is also available in a combined air/surface search radar version. A version of the antenna with a cosec² beam shape would be used in this instance, and a digital MTI processing system can be added. Since the equipment is designed with dual, independent MTI and non-MTI channels, air and surface search can be carried out simultaneously.

CONTRACTOR

Canadian Marconi Company, 415 Legget Drive, PO Box 13330, Kanata, Ontario K2K 2B2, Canada.

CHINA (PEOPLE'S REPUBLIC)

2019.153
CHINESE MILITARY RADAR

After the end of the Second World War very little emerged until recently regarding Chinese military and civil activities in the radar field. However during the past two years the Chinese authorities have released some details of the country's operational systems. These details are very limited and certainly do not cover anything like the full range of systems in operation as little or no information has been provided on defence equipment development.

As with many other military systems, China has been largely dependent in the past on Soviet radar equipment. This equipment was readily available, although almost certainly obsolescent, and there is undoubtedly still a great deal of operational Soviet radar in China. However it is apparent from the details now emerging that China has been developing its indigenous radar with a substantial programme. For example it is known that China has constructed a missile early warning system (**2052.181**), a mobile 3-D tactical radar (**4817.153**) and a number of fire control systems, and with respect to these and other radar developments some code names have emerged from US sources. Cross Legs is the name given to a surveillance radar working in the 1250 MHz band with PRFs of 300 and 600 Hz, suggesting a maximum range capability of something under 500 km. Another name is Thick Skin which is applied to a height-finder 6500 MHz (H-band in the US military frequency band scale).

Information recently obtained from Chinese sources is given in the various entries following this foreword although details of a number of systems are insufficient to provide a meaningful entry. These include the Type 440 two-dimensional surveillance system and its companion height-finder Type 843A, the Type 797 airport terminal control radar operating in S-band with an effective range of 150 km, the Type 681 secondary radar and the Type 701 meteorological system.

In addition a number of reporting code names, with brief descriptions of the systems to which they refer, are given as follows:

Chop Rest

This is stated to be of Chinese origin and is an early warning radar. In general configuration it is similar to the Soviet Spoon Rest (**2889.153**) VHF equipment, with an array of multiple Yagi antennas, but having a distinctly larger number of elements. Operating frequencies are 162 to 169 MHz and 175 to 189 MHz. Range performance should reach about 250 km.

Cross Legs

Cross Legs is another early warning radar claimed to be deployed throughout China, often in company with height-finder radar(s), which indicates CGI/air-defence reporting centre installations. The antenna is an elliptical paraboloid with horn feed, supported on a four-legged base.

Cross Slot

Primarily employed for coastal defence, Cross Slot is also an early warning radar, located at fixed sites and often with height-finder radar(s). Operating frequency is in the E/F-band and the probable range is about 80 km. In addition to installations in China, Cross Slot has been reported in North Korea and Viet-Nam.

Gin Sling

Fan Song type radars (**2866.153**, **2867.153**, **2868.153**) for surface-to-air missile guidance used by the Chinese armed forces are known by the designation Gin Sling.

Moon Cone

Reported to have been developed in China, Moon Cone is an early warning radar consisting of multiple stacked dipole arrays, located one above the other on a vertical mast. The arrays diminish in area from bottom to top, there being three in a typical installation. VHF operation is almost certain and ranges of 250 km or more should be obtained.

Moon Face

Similar to Moon Cone, but having only one stacked dipole array.

Moon Mat

Similar to Moon Cone, but having only one stacked dipole array.

Moon Plate

Stacked dipole VHF array on trailer mounting.

Slot Rest

Reported to have been developed in China for early warning and target acquisition, Slot Rest is similar to the Soviet Spoon Rest (**2889.153**) radars. Operation is in the A-band (VHF). It is truck-mounted and has been observed in Viet-Nam as well as China.

Team Work

Team Work is a fire control radar deployed at anti-aircraft artillery sites in China and possibly elsewhere. It was first seen in Viet-Nam in 1972. Operating frequencies are believed to be in E-band.

4817.153
SW CHINA MOBILE TACTICAL 3-D RADAR

The South-west China Research Institute of Radar Technology has revealed brief details of a mobile, or transportable, 3-D tactical air surveillance radar that is now being offered for export. From artists' impressions issued by the Institute it can be gathered that the system broadly follows the Soviet pattern for equipment of this type, with the antenna, transmitter(s), receiver(s), turning gear and support structure, displays and operating facilities, etc being configured as a series of individual trailer or container loads, for assembly on site into the complete system.

The 3-D radar is shown as comprising a large double curvature scanner located on the rear of a cab that presumably contains the main transmitter/receiver electronic units, which is mounted on turning gear that forms the basis of a towed chassis. Stacked feed horns are located at the opposite end of the cabin to illuminate the scanner to generate a multi-lobe radar beam pattern. Connected to this unit by cables are a number of containers or shelters that are assumed to house the operating crew and other electronic equipment.

No detailed specifications have been released by the manufacturer, but features that have been disclosed include the following:

(1) an all solid-state multi-channel receiving system is used
(2) automatic 3-D tracking is provided
(3) comprehensive ECCM facilities include very low far-field side-lobe levels, PRF stagger, fast frequency jump, an adaptive threshold, digital cancellation, CFAR, frequency diversity operation, and multi-beam disconnection.

STATUS

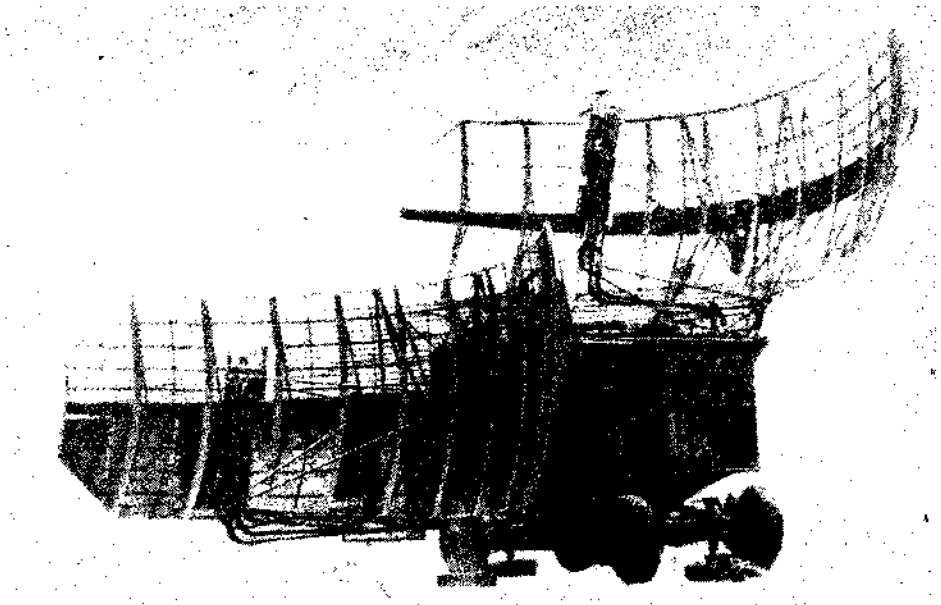
Unconfirmed, but prototypes are presumed to have been built and tested.

CONTRACTOR

South-west China Research Institute of Radar Technology, PO Box 501, Duyun, Guizhou Province, People's Republic of China.

4812.153
JLP-40 SURVEILLANCE RADAR

The JLP-40 is a tactical air defence radar designed for use with height-finder radar(s) for GCI or similar applications. It is similar in design to the Soviet Bar Lock radar (**2861.153**) from which it may well have been derived, and features the same arrangement of two large scanners attached to front and rear sides of a rotating cabin that houses the transmitter/receivers.



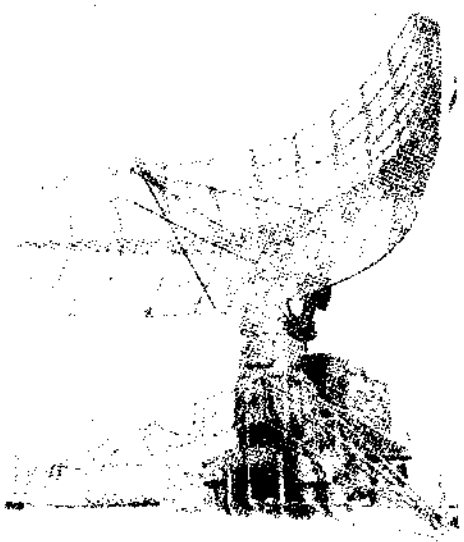
Operation is in the S- and L-bands, each parabolic scanner being illuminated by stacked horn feeds to generate families of multiple beams. There are five S-band transmitter/receivers and these are thought to operate with the lower of the two antennas, while the L-band feeds illuminate the upper scanner. An IFF interrogator is incorporated in the system also. Three PPI displays are provided, and one azimuth/range display, plus between two to four additional PPIs. MTI facilities are provided in the L-band transmitter/receiver chains.

The whole system is transportable, though hardly 'mobile' despite the use of wheeled trailers for much of the equipment, and clearly preparing such a large and complex system for operation must occupy several hours from the time of arrival at a surveyed site.

CHARACTERISTICS

Operating frequencies: L- and S-bands
Range: 270 km
Height: 20 000 m
Azimuth coverage: 360°
Elevation coverage: 0·5 – 30°
Accuracy: 500 m (range); ± 0·5° (bearing)

STATUS
Production.
CONTRACTOR
China Electronics Import & Export Corp, 49 Fuxing Road, Beijing, People's Republic of China.



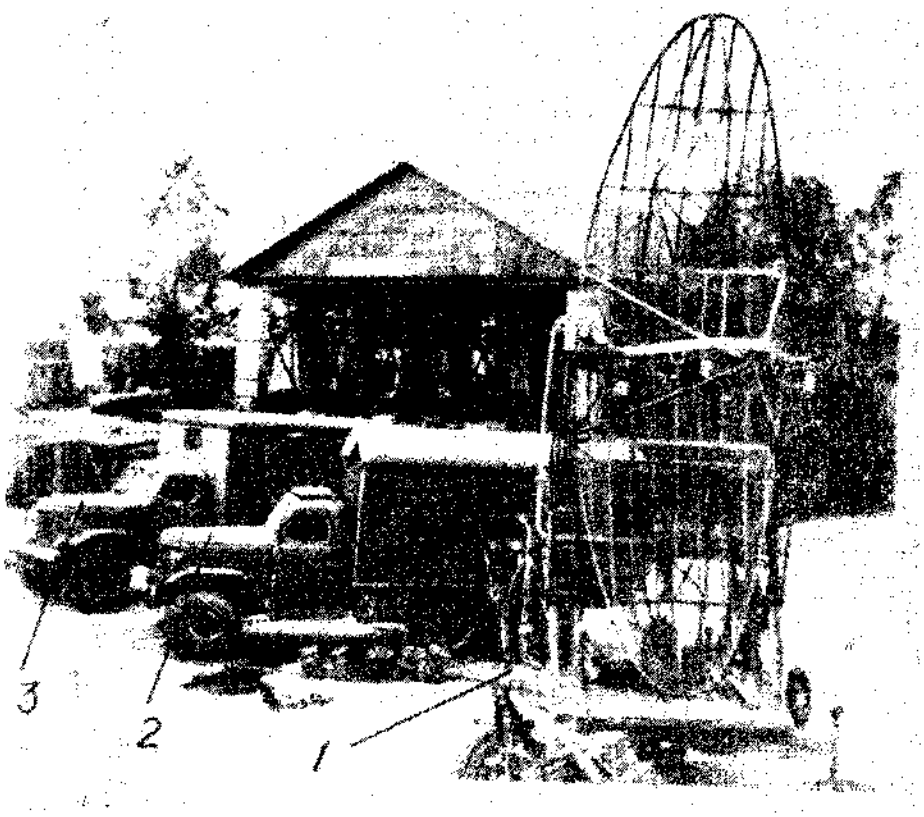
JLP-40 surveillance radar

4811.153
TYPE 581 AIR WARNING RADAR

The Type 581 is a medium and low altitude air warning radar for tactical applications. It is a transportable system with the 9·7 metre span scanner mounted on turning gear that is carried on a wheeled trailer, which is stabilised for operational use by large folding legs with screw-jacks at their ends.

The operating frequency is in the L-band, giving a detection range of up to 190 km against a fighter aircraft target. There are two units in a Type 581 mobile convoy, one consisting of the scanner and turning gear (and probably the diesel-electric generator unit also), and an electronics vehicle which includes the transmitter/receiver and operators' cabin.

CHARACTERISTICS
Frequency: L-band
Peak power: 500 W
Pulse width: 4 ms/2 ms
PRF: 300 Hz/600 Hz
Noise figure: 3 dB
Antenna: 9·7 × 3 m
Polarisation: Linear
Gain: 34 dB
Range: 190 km (fighter target)
Accuracy: 1 km (range); 4° (bearing)
MTI: 20 dB (clutter visibility); 34 dB (cancellation ratio)
Displays: PPI (12-inch); A/R (7-inch)
STATUS
Production.
CONTRACTOR
China Electronics Import & Export Corp, 49 Fuxing Road, Beijing, People's Republic of China.



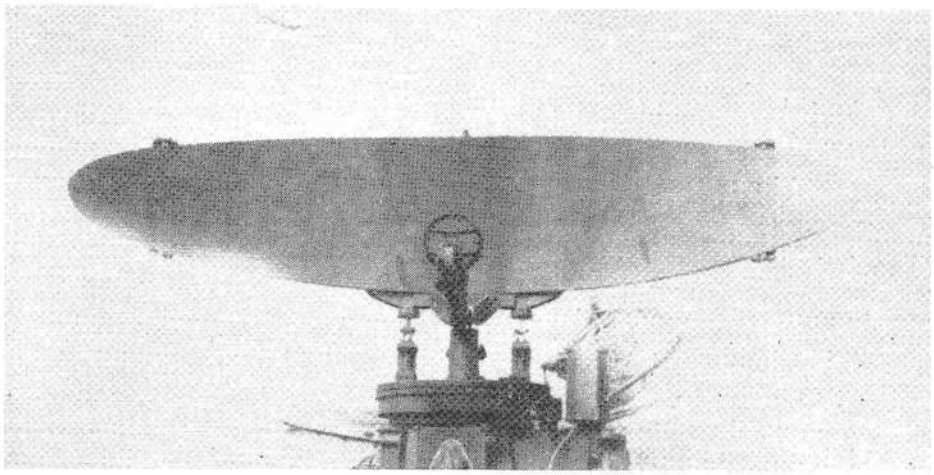
Type 581 air warning radar

4813.153
JLG-43 HEIGHTFINDING RADAR

The JLG-43 is a nodding heightfinder which follows the pattern of the well-known Soviet 'Cake' series of equipments. It is a mobile system inasmuch as it is readily transportable by military road vehicles, and the complete system can probably be carried in a two-truck load.

Operating frequencies are in the S-band and a 2 MW transmitter provides for coverage out to a range of 200 km and gives a height coverage of up to 25 000 metres.

CHARACTERISTICS
Frequency: S-band
Pulse width: 3 μs
Peak power: 2 MW
Range: 200 km
Height: 25 000 m
Elevation coverage: 0 – 30°
Accuracy: 300 m (height); 2° (azimuth)
STATUS
Production.
CONTRACTOR
China Electronics Import & Export Corp, 49 Fuxing Road, Beijing, People's Republic of China.



JLG-43 heightfinding radar

4814.153
TYPE 404A COAST SURVEILLANCE RADAR

The Type 404A is an X-band surveillance radar for use by coastal defence forces. There are two receiver channels operating in frequency diversity and comprehensive signal processing facilities are provided. The elliptical antenna is equipped with a remotely adjustable circular polarising device to reject rain and other clutter. Display arrangements include a PPI, and A- and B-scope presentations.

CHARACTERISTICS
Frequency: X-band
Range: To radar horizon
Antenna gain: 39 dB
Accuracy: 100 m (range); 0·35° (bearing)
Resolution: Better than 200 m (range); 0·8° (bearing)
STATUS
Production.
CONTRACTOR
China Electronics Import & Export Corp, 49 Fuxing Road, Beijing, People's Republic of China.

Type 404A coast surveillance radar

5761.153
COAST TRACKING RADAR

This is a mobile X-band coastal radar used for surface vessel tracking and the accurate control of coastal weapon systems. Tracking range on a 7500 m target is given as 60 nautical miles (96 km) with an accuracy of 30 m in range and 1·5 mil in azimuth. The rotating antenna is mounted on a flat-bed truck which also carries the operations cabin containing the necessary processing equipment and displays.

CHARACTERISTICS
Frequency: X-band
Antenna beamwidth: 1 × 2°
Peak power: 200 kW
Pulse width: 0·2 μs
Accuracy: 30 m (range); 1·5 mil (azimuth)
Resolution: 60 m (range); 20 mil (azimuth)
STATUS
In production and service.
CONTRACTOR
China Electronics Import & Export Corp, 49 Fuxing Road, Beijing, People's Republic of China.

4810.153
EAGLE COASTAL RADAR

Under the name of 'Eagle' the Chinese authorities are offering for export a Ku-band mobile radar designed for use by coastal artillery units, presumably for target detection and location as well as for fire correction by means of splash-spotting techniques, although this is not categorically stated.

The general arrangement consists of a small (1- to 2-ton) four-wheeled van with a modestly sized mesh antenna unit with its turning gear mounted on the roof of the cab. The latter houses the transmitter/receiver and display equipment in addition to providing working space for the operating crew. Power for the radar is derived from a small portable engine-driven electrical generator that can be located a short distance from the vehicle which is equipped with corner jacks for stability on site.

CHARACTERISTICS
Frequency: Ku-band
Range: 50 km (1000 - 3000 t ship target); 27 km (75 t craft)
Accuracy: 0·09° (bearing); 15 m (range)
Weight: 300 kg (radar only)
STATUS
Production. Available for export.
CONTRACTOR
China Electronics Import & Export Corp, 49 Fuxing Road, Beijing, People's Republic of China.

Eagle coastal radar

4809.153
CHEETAH ARTILLERY RADAR

Cheetah is the name given by the Chinese authorities to a Ku-band mobile radar that is stated to be for battlefield use by artillery formations for surveillance and gun fire correction purposes. The complete unit, except for a small engine-driven portable electrical generator that is apparently located a short distance from the radar unit, is carried on a six-wheeled military truck.

The complete system is probably a Chinese version of the Soviet SNAR-2 radar known to NATO as Pork Trough (**4328.153**), except that in Soviet Army service the equipment is carried on a tracked vehicle.

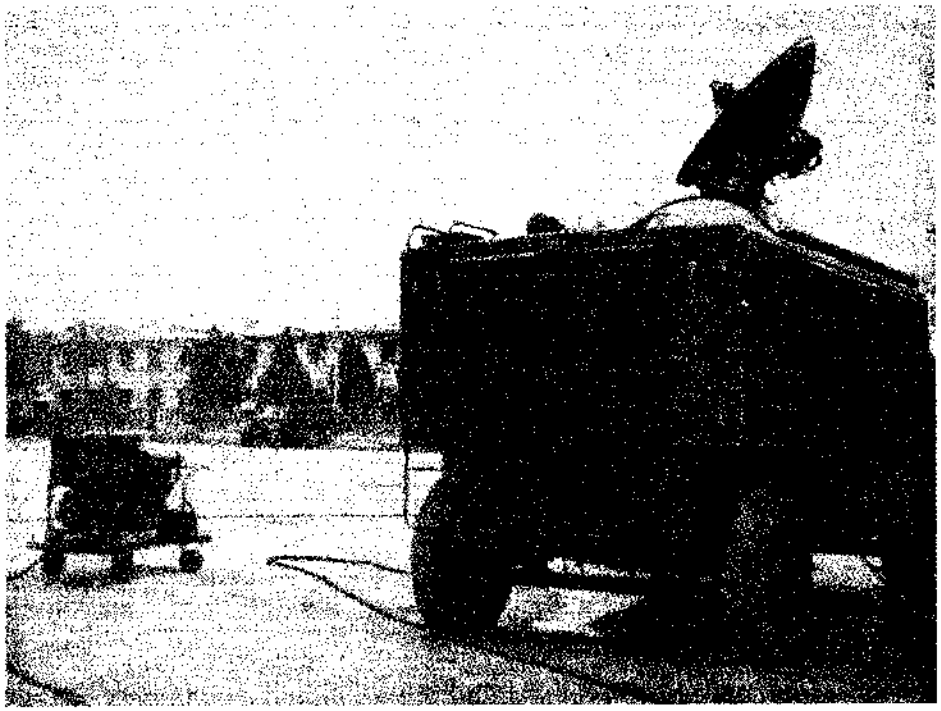
The Cheetah system is mounted on a flat-bed truck in a cab that contains the electronic equipment and also serves as the operators' cabin. A low-profile rotating antenna is mounted on the roof of the cab with part of the turning gear probably protruding below into the working space. The operational function of the Cheetah radar is battlefield surveillance for targets such as tanks and armoured concentrations, and for correction of artillery gun fire.

Although performance details are sparse, there are

Cheetah artillery radar

claims of some relevance, as indicated in the table below, and references to a two-colour display which shows moving targets in a different colour to the main picture, anti-jamming facilities, and MTI.

CHARACTERISTICS
Frequency: Ku-band
Detection range: 300 m – 16 km (tank target)
Elevation coverage: ± 10°
Accuracy: 5 m (range); 1 mil (azimuth)



STATUS
Production. Available for export.
CONTRACTOR
China Electronics Import & Export Corp, 49 Fuxing Road, Beijing, People's Republic of China.

4815.153
MW-5 FIRE CONTROL RADAR

The MW-5 is a mobile artillery fire control radar operating on X- and S-band frequencies. It is similar to the Soviet Fire Can radar (**2671.153**) and may well be either a copy or a derivative of that equipment. All the main elements of the equipment are housed in or on a four-wheeled trailer that consists of a container which also serves a cabin for the operating crew.

A circular dish antenna for target search and tracking is mounted on the roof of the cabin. The S-band is employed for target detection and acquisition, possibly with designation by a different long-range search/air warning radar associated with the military unit, and X-band will be used for target tracking. The conical scan technique is probably employed for the latter function. Good ECCM characteristics are claimed for the MW-5 by its manufacturer.

CHARACTERISTICS
Frequencies: S-band (search); X-band (tracking)
Detection range: 55 km (bomber)
Max tracking range: 35 km
Tracking accuracy: 20 m (range); 1·6 mil (azimuth); 1·8 mil (elevation)
STATUS
Production.
CONTRACTOR
China Electronics Import & Export Corp, 49 Fuxing Road, Beijing, People's Republic of China.

MW-5 fire control radar

4816.153
TYPE 311-A FIRE CONTROL RADAR

The Type 311-A fire control radar is for use with anti-aircraft guns and is normally employed with batteries of either 37 mm or 57 mm calibres. It operates on X-band frequencies and is capable of both search and target tracking functions and is generally used with a computer and an optical rangefinder.

The Type 311-A consists of an operations trailer with the main electronic and mechanical elements of the radar, and a towing vehicle in which the operators are carried together with a power generating set, tools and spare parts. The complete system can be set up or dismantled to move within about 15 minutes and the weight of the radar trailer is less than four tons. The towing vehicle with equipment weighs under eight tons.

Detection range on a fighter-size aircraft target in the search mode is at least 30 km, with a maximum tracking range of 25 km. Minimum reliable tracking range is about 500 metres. The radar can be switched to any one of three pre-programmed operating frequencies by the operator, and target position data in the tracking mode can be fed to the computer in either rectangular or spherical co-ordinates. In the search mode, the radar beam is oscillated in the vertical plane at a rate of 4 Hz to broaden the effective beam. A target within this beam that subsequently deviates in either elevation or azimuth by 20 mils or more from the radar boresight axis can then be tracked automatically.

CHARACTERISTICS
Operating frequencies: X-band, 3 switchable
Peak power: 200 KW (0·3 μs pulse); 180 KW (0·9 μs pulse)
Pulse width: 0·3 μs (narrow); 0·9 μs (broad)
PRF: 2500 Hz (narrow pulse); 833 Hz (broad pulse)
Antenna gain: At least 35 dB
Horizontal beamwidth: 2·6°
Vertical beamwidth: 2·4°
Sidelobe: –18 dB (max)
Receiver sensitivity: –92 dB/mW (CW)
Max range: 30 km (detection); 25 km (tracking)
STATUS
Production.
CONTRACTOR
Chuanbei Electronics Company, People's Republic of China.

4804.153
TYPE 701 WIND FINDING RADAR

The Type 701 is a wind finding radar for tracking meteorological radio sondes to obtain wind velocities, temperatures, pressures, and relative humidities at different levels of the atmosphere. It can be employed in either a fixed role or mounted on a four-wheeled trailer for mobile applications. An engine-driven generator is provided for use without main electrical supplies. A rectangular array of multiple Yagi antenna elements is mounted on the roof of the mobile version, the array being steerable in azimuth and elevation.

CHARACTERISTICS
Frequency range: 400 MHz + 3 MHz
Receiver sensitivity: < 5μV
Max detection range: 150 – 200 km
Max height: 20 – 30 km
Transmitter power: 20 kw (peak)
Weight: approx 2 tons (trailer version)
STATUS
Production.
CONTRACTOR
China Electronics Import & Export Corp, 49 Fuxing Road, Beijing, People's Republic of China.

Type 701 wind finding radar

5759.153
TYPE 711 METEOROLOGICAL RADAR

The Type 711 meteorological radar is a mobile or fixed weather radar system operating in X-band and used for general detection of dense cloud and precipitation. It employs a 1·5 m diameter horizontally polarised dish antenna, having a beam width of 1·5 degrees, which is mounted on a flat-bed truck in the mobile version. The vehicle also carries a small operating cabin which houses the necessary processing and display equipment. Resolution range is given as 200 miles with an azimuth and elevation error of 1·5 degrees.

CHARACTERISTICS
Frequency: 9370 ± 30 MHz
Peak power: 75 kW
PRF: 400 Hz
Pulse width: 1 μs
Antenna diameter: 1·5 m
STATUS
In production.
CONTRACTOR
China Electronics Import and Export Corp, 49 Fuxing Road, Beijing, People's Republic of China.

5760.153
TYPE 713 METEOROLOGICAL RADAR

The Type 713 is a fixed high-power meteorological radar operating in C-band and designed specifically for the detection of precipitation and warning of storms. The antenna diameter is 3·7 m and maximum range is given as 400 km. The dish antenna is pedestal mounted and a separate control cabin contains the processing and display equipment.

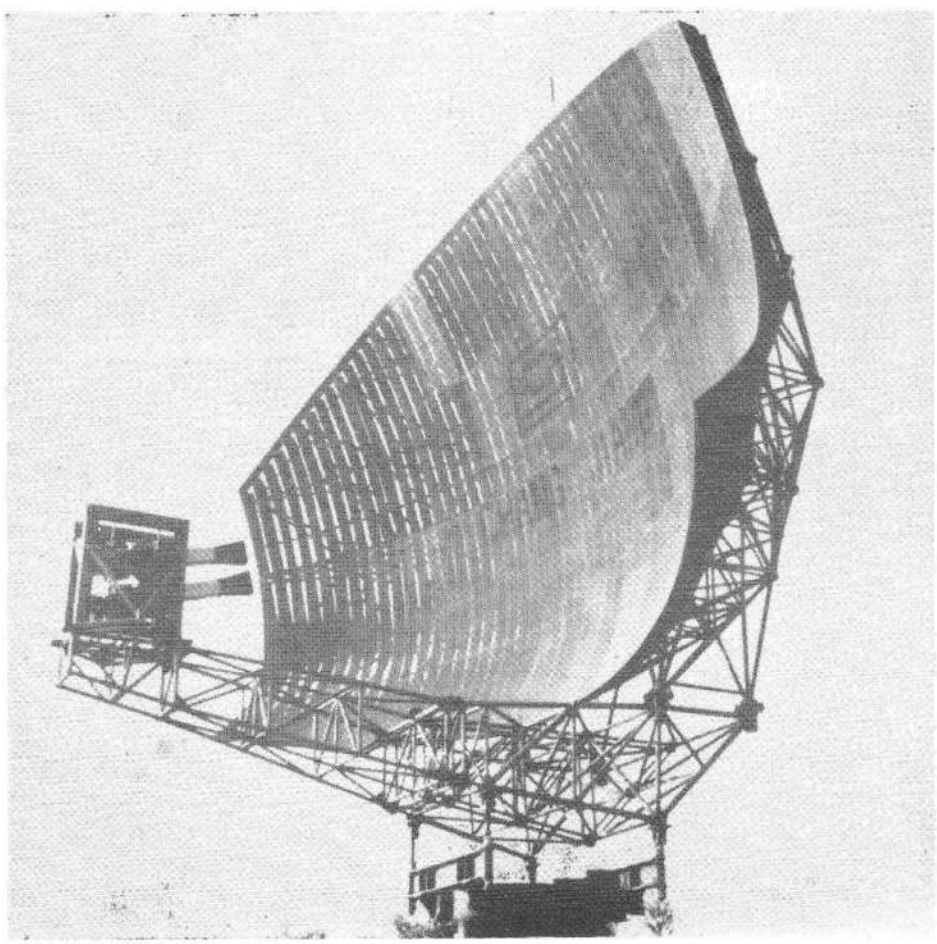
CHARACTERISTICS
Frequency: 5350 - 5450 MHz
Peak power: 250 kW
Pulse width: 2 μs
PRF: 200 pps
Antenna diameter: 3·7 m
Beamwidth: 1·2°
STATUS
In production.
CONTRACTOR
China Electronics Import & Export Corp, 49 Fuxing Road, Beijing, People's Republic of China.

4803.153
TYPE 714 METEOROLOGICAL RADAR

The Type 714 meteorological radar is a modern S-band equipment for the detection and location of precipitation and related cloud formations, and provides a variety of display facilities in addition to digital readout and recording facilities.

The design incorporates solid-state components with the exceptions of magnetron, thyratron and CRTs, and the circuitry provides for automatic noise monitoring, automatic power monitoring, IF and video normalisation facilities. The antenna is a high precision dish reflector, housed within a protective radome and illuminated by a front-feed horn. A desktop display gives four operational modes: PPI, slant range/height indicator (RHI), horizontal range/height indicator (DHI), and also drives a photographic display which can record selected or random pictures of the displayed data in accordance with automatic programming.

CHARACTERISTICS
Frequency: S-band
Peak power: 1 MW
Antenna diameter: 4 m
Noise factor: Better than 3 dB
Receiver dynamic range: 70 dB
Operating range: 600 km
Operating height: 24 km
STATUS
In production.
CONTRACTOR
China Electronics Import & Export Corp, 49 Fuxing Road, Beijing, People's Republic of China.



Type 714 meteorological radar

4806.153
TYPE 796 AIR ROUTE SURVEILLANCE RADAR

The Type 796 long range air route surveillance radar is a modern high-power solid-state L-band equipment that uses a large double curvature antenna and dual beam operation to provide good coverage at low and high altitudes for surveillance of air traffic over wide areas. It is claimed to have very good anti-clutter performance and low cover by virtue of an advanced DMTI technique and the adoption of a dual beam with a large vertical dimension to give a vertical pattern that provides a sharp cut-off at the horizon. Circular polarisation is employed to reduce precipitation clutter, and target detection is improved by means of frequency diversity operation.

Except for magnetrons, thyratrons and CRTs, circuitry is all solid-state, and for reliability of operation the electronics are duplicated.

CHARACTERISTICS
Frequency: L-band
Frequency separation: Over 80 MHz
Transmitter pulse power: At least 2·2 MW
PRF: 360 Hz (mean)
Receiver noise: 2·5 dB
Antenna: 15·5 m wide (8·7 m²)
Polarisation: Linear/circular
Gain: At least 35 dB (low beam); at least 33·6 dB (high beam)
Sidelobe level: ⩽-25 dB
Beamwidth (3 dB): 1·1°
Rotation rate: 6 rpm

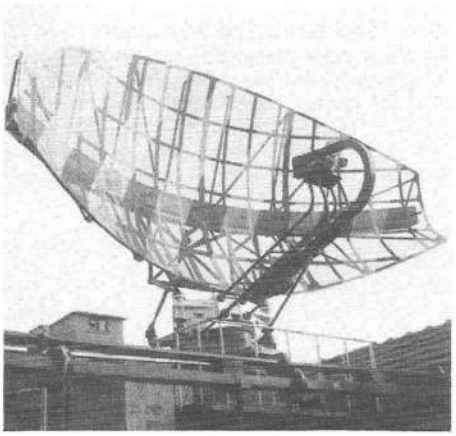
Type 796 air route surveillance radar

4805.153
TYPE 793 TERMINAL AREA RADAR

The Type 793 radar system is an integrated air surveillance and approach radar for the control of air traffic in terminal areas. S- and X-band radars are combined in a single system using a large elliptical paraboloid antenna illuminated by multiple horn feeds carried on a boom extending from under the lower edge of the scanner.



The surveillance function is performed by the S-band radar. This incorporates variable circular polarisation, a low-noise parametric amplifier, and DMTI facilities. It is a solid-state equipment apart from the transmitter and CRTs and ICs are used extensively. Facilities included in the X-band approach section of the Type 793 include adjustable circular polarisation, log IF amplifier, DMTI, digital techniques in range and angular measurements, and single-tube dual B-scope data presentation is provided.

CHARACTERISTICS	Search	Approach
Frequency	S-band	X-band
Range (max)	100 km	35 km
Range (medium rain)	80 km	15 km
Azimuth cover	360°	20°
Elevation cover	40° cosec	−1 to +9°
Max altitude	10 000 m	
Range accuracy	± 2%	± 2%
Azimuth accuracy	± 1·5°	± 0·5°
Elevation accuracy		± 0·35°

It has been stated that both fixed and mobile versions of this equipment have been produced.

STATUS
Production.

CONTRACTOR

Type 793 terminal area radar

4807.153
TYPE 791-A PRECISION APPROACH RADAR

The Type 791-A precision approach radar (PAR) is a typical military mobile radar equipment. It is mounted on a six-wheeled truck, although the manufacturers state that both mobile and fixed installations are available.

This Chinese-manufactured system closely resembles the Soviet RSP-7 PAR, known to NATO as Two Spot (**3295.153**), and it could well be a licence-made version although there are slight differences. For example, in the Soviet version the PAR antenna heads are located between the driver's cab and the radar cab, whereas in the Chinese model the antennas are at the rear end of the whole assembly.

However, this could be nothing more significant than the fact that the equipment was designed as a cabin-housed equipment meant to be carried on a flat-bed truck, and capable of being loaded either way round. There are similar slight differences in the scanner outlines.

Operation is in the X-band and dual transmitter/receivers are provided to ensure continuity of service; for the same reason the display indicators are also duplicated.

The two scanners, for search and azimuth guidance and for elevation guidance, are collocated on a mounting at the rear of the vehicle. There is an operators' cab in front of this which also contains communications facilities. Circular polarisation is provided to combat weather clutter and the receiver includes a logarithmic IF amplifier.

CHARACTERISTICS
Frequency: X-band
Range: 35 km (15 km in rain)
Coverage: 1 – 8° (elevation); 20° (azimuth)
Accuracy: 0·35° (elevation); 0·5° (azimuth)
Range accuracy: approx 60 m
Resolution: 200 m (range); 1·2° (angular)

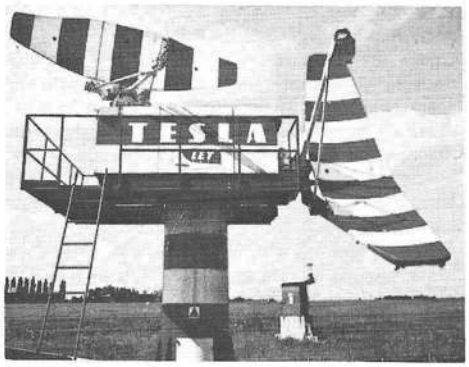
RL-42 SURVEILLANCE RADAR

The RL-42 operates at 10 cm wavelength and is designed to control traffic inside controlled airspace and in the terminal area. The range of surveillance is 120 km and its specifications meet CMEA standards for Group V 2 airport radars and also those given in ICAO Annex 10. It is the successor to the older OR-1, OR-2 and RL-41 models. Information on characteristics and features is sparse but includes operation in the diversity mode on two frequencies with auxiliary antenna lobe, digital MTI, digital target detector and plot extraction.

CONTRACTOR
Tesla, Pardubice, Czechoslovakia.



RL-42 surveillance radar

4332.153
RP-4G PRECISION APPROACH RADAR

The RP-4G system is for use on medium and large airports for conventional landings and also for V/STOL and STOL traffic. It is a normal type of PAR radar and is used for aircraft guidance and the final approach from 30 km away to touchdown. Information provided to the controller includes the flight altitude inside the approach sector, deviation from the glide path and cloud pattern and cloudbase in the vicinity of the approach sector. The equipment can be integrated into an automated air traffic control system without any modification.

STATUS
Probably in operation in civil and military airfields.
CONTRACTOR
Tesla, Pardubice, Czechoslovakia.

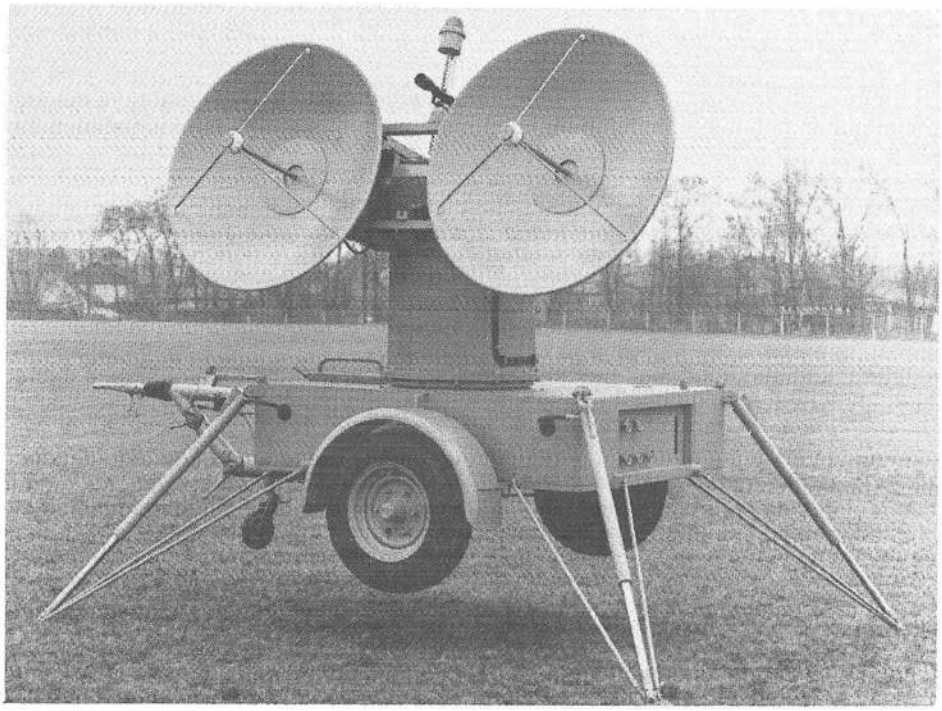
TERMA RADAR AND BALLISTIC INSTRUMENTATION

Terma has been in the field of ballistic instrumentation and the necessary supporting radars since 1961. The company manufactures ballistic instrumentation for internal and external measurements. The instruments are invaluable tools for ballistic research and development projects, and for product quality assurance tests.



Splash Spotting Radar

The splash spotting radar is intended for use on test ranges where firing is made over water and accurately determines the impact co-ordinates of shots. It has two modes, a spotting mode for measurement of slant range and bearing from the weapon to the point of impact, and a surveillance mode to scan the shooting area. It provides digital read-out of range and bearing on an LED display, and a hard copy print-out of measurement results.

The antenna is a 7 ft (2·1 m) slotted waveguide mounted on a gearbox. The gear is driven by a DC servo motor which enables the antenna to either rotate continuously or to scan in preselected areas. The receiver/transmitter and servo-amplifier are mounted inside the antenna supporting structure. The display unit consists of a CRT display, data handling and display controller and the interface and control assembly.

Doppler Radar

The DR 582 doppler radar is the system name consisting of a number of antenna units and a data unit operating with a suitable computer system. They are designed to supply measurement data of rockets, missiles, mortars and other projectiles ranging from the smallest to the largest calibre. They range from small muzzle velocity radars to large scientific systems and supply external ballistic data such as velocity, acceleration, drag coefficient and altitude/distance functions. Two different CW transmitter/receivers are available, one operating in S-band and one in X-band, with power outputs of 20 W at 2·63 MHz and 300 mW at 10·525 MHz respectively. The systems supply continuing on-line analysis. In-depth analysis of the radar data is provided by a specific combination of software and hardware, including fast Fourier transform techniques.

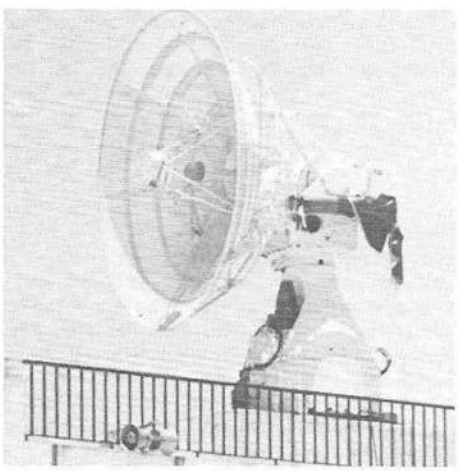
ADOUR II INSTRUMENTATION TRACKING RADAR

Adour II instrumentation radar is an improved version of the previous Adour, and is a G-band tracking system using the conical scanning principle. It is intended for acquisition and automatic tracking and is specifically designed for making measurements in:

(1) Flight test centres, for the calibration and evaluation of prototype aircraft, of airborne equipment such as altimeters and autopilots, and of ground equipment such as surveillance radar.
(2) Rocket and missile test centres and launching centres for measurements relating to missile, sounding rockets, and satellite launchers.

In addition, the radar is used at such centres for windfinding and similar measurements.



STATUS
Adour is installed on Australian, Brazilian, French, Swiss and other undisclosed test ranges. It is still in production for both French and export needs.

CONTRACTOR
Thomson-CSF, Division Systèmes, Défense et Contrôle, 40 rue Grange Dame Rose, BP34, 92360 Meudon-la-Foret, France.

Note: Adour is a member of an extensive range of French instrumentation tracking radars, other members of this family being:

Artois (**2063.153**)
Atlas (**1943.153**)
Bearn (**2065.153**)
Savoie (**1944.153**)

Details of these radars will be found on this and succeeding pages of this section of *Jane's Weapon Systems*. More detailed information on Adour is given in previous editions and details of the earlier Aquitaine tracking radar, will be found under entry number **2062.153** in the 1974-75 and previous editions of *Jane's Weapon Systems*.

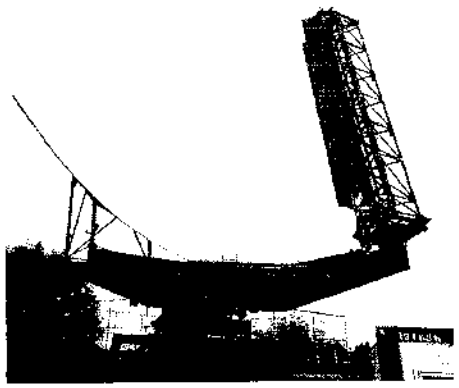
2060.153
ANTARES HEIGHTFINDING RADAR

Under the code name ANTARES (for antenna tracking altitude, azimuth, and range by electronic scan) Thomson-CSF has developed a heightfinding radar operating in E/F-band that can be used for air defence and civil air traffic control purposes. This system is designed mainly to measure the altitude of targets tracked by a 2-D search radar which is associated with it, with a very high accuracy and a high data renewal rate. ANTARES is an automated system, and all its input or output data are controlled or generated by an automatic digital processing unit. This feature, together with the utilisation of electronic scanning in elevation, enables the system to satisfy a practically unlimited number of altitude requests.



The ANTARES system consists of a heightfinding radar and a processing unit. Principal units of the radar are an antenna under a radome, a servo system for slaving the rotation of the antenna to that of the associated plan radar antenna, transmitter, receiver, and one angular error measuring receiver. More detailed information is given under this entry number in previous editions of *Jane's Weapon Systems*.

STATUS

No longer in production.

CONTRACTOR

Thomson-CSF, Division Systèmes, Défense et Contrôle, 40 rue Grange Dame Rose, BP34, 92360 Meudon-la-Foret, France.

2063.153
ARTOIS INSTRUMENTATION TRACKING RADAR

Artois is an electronic-scan multi-target tracking radar designed to perform highly accurate differential trajectory measurements.

The principal features of this radar are electronic scanning in a cone having a vertex angle of 10° minimum, instantaneous deflection from pulse-to-pulse, and multi-target tracking with controlled variable interlace.

More detailed information is given under this entry number in previous editions of *Jane's Weapon Systems*.

STATUS

No longer in production. One installed at Centre d'Essais des Lances on the French Atlantic coast for ballistic and tactical missile trials and training.

Thomson-CSF, Division Systèmes, Défense et Contrôle, 40 rue Grange Dame Rose, BP34, 92360 Meudon-la-Foret, France.

2065.153
BÉARN INSTRUMENTATION TRACKING RADAR

Béarn is a high-precision G-band automatic tracking radar designed for the trajectory of high-speed missiles at long range.

Facilities offered by the radar include manual or automatic acquisition of a target dynamically or statically designated by the rendezvous method; automatic tracking of radar echoes or transponder signals up to 4000 km; elevation, azimuth, and range co-ordinate read-out as numerical data in real time; automatic changeover to memory tracking in case of signal loss; polarisation switching without interruption of tracking; synchronisation of a chain of radars interrogating the same transponder; and, for shipborne installations, autonomous and automatic stabilisation of the pointing axis.

More detailed information is given under this entry number in previous editions of *Jane's Weapon Systems*.

STATUS

In operational use in France and a number of other countries.

CONTRACTOR

Thomson-CSF, Division Systèmes, Défense et Contrôle, 40 rue Grange Dame Rose, BP34, 92360 Meudon-la-Foret, France.

1943.153
ATLAS INSTRUMENTATION TRACKING RADAR

Atlas is a very high precision tracking radar designed for trajectography and satellite tracking. A monopulse G-band radar, Atlas automatically tracks radar echoes or transponder signals at distances up to about 4000 km. The equipment comprises an antenna turret with which are associated the RF and IF receiver circuits, a 1 MW peak transmitter codable and tunable from 5450 to 5825 MHz, an operating console, an interconnection cabinet, and a mains supply cabinet. The rangefinding unit, in the console, is fitted with a synchronising device that allows the radar to be used in series with other tracking radars of the same or different types.

The Atlas radar is available in fixed or transportable form. Operational optional facilities include TV monitoring, TV tracking and IR tracking.

CHARACTERISTICS

LOUXOR AIR DEFENCE RADAR

Louxor is an experimental prototype electronically scanned radar for short-range air defence applications. It was built as a research and development instrument in the definition and design of a production equipment suitable for use in such systems as Systèmes d'Armes sol-air à Courte Portée (SACP) planned for future close-in air defence applications.

Gun and surface-to-air missile systems will be directed and both fixed and mobile versions are likely to be developed.

The experimental prototype is mounted on a wheeled truck, and the rectangular planar array antenna can be folded flat for transport, erection being by hydraulic jacks. Operating frequency is in the G/H band and the antenna consists of 2500 radiating elements containing dipole phase-shifters under the control of a microprocessor computer. Front illumination of the array is employed, with multiple horns for monopulse operation. This arrangement provides search over a sector of −5 to +45° in elevation and +45° in azimuth without physical movement of the array. An operational system might have several arrays in a back-to-back configuration to provide all-round or sectorial cover greater than 90°. Alternatively, a single array could be directed in azimuth to provide cover over a 90° sector centred on any required bearing.

Transmitter power has not been disclosed, but the detection range against a nominal 1 m² target is quoted as 23 km, and the Louxor system has a target capacity of 32 targets of which any three can be automatically tracked with outputs for the direction of three guns or other weapons simultaneously. Digital signal processing is employed using microprocessors, and a digital MTI facility is incorporated. Tracking and search operations can be conducted simultaneously. Tracking accuracy is 1 mrad at 12 km.

STATUS
Prototype.

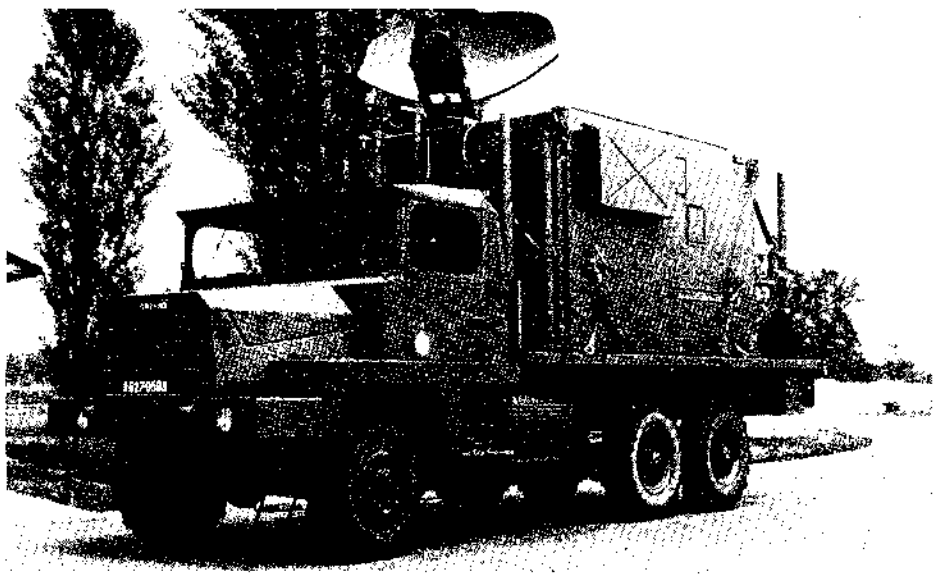
RAMSA LOW-ALTITUDE SURVEILLANCE RADAR TRS 2140



In mid-1977 a new mobile short-range, low-altitude surveillance radar was introduced under the name Ramsa, with the manufacturer's designation TRS 2140. The radar is of the pulse-doppler type and is installed in a cabin. Operational roles are associated with its use in an air defence system for warning and target designation for gun or missile air defence batteries.

Few details are available for publication other than those main characteristics listed below. An extending tower mounting for the antenna head is an alternative option for the Ramsa system.

CHARACTERISTICS
Frequency: D-band (former L-band)
Peak power: 150 W
Average power: 20 W
PRF: Dual with matching pulse-lengths (optional 3)
Antenna rotation rate: 60 rpm
Detection range: 15 km (fighter aircraft target); 20 km as an option
Associated IFF

STATUS
In production for an unspecified customer.

CONTRACTOR
Thomson-CSF, Division Systèmes, Défense et Contrôle, 40 rue Grange Dame Rose, BP34, 92360 Meudon-la-Foret, France.

1944.153
SAVOIE INSTRUMENTATION TRACKING RADAR

Savoie is a multi-tracking radar, intended for automatic tracking at long ranges. The equipment is designed to be shipborne or ground based.

CHARACTERISTICS
Type: Monopulse tracking radar
Antenna
Diameter: 8 m
Gain: 28 dB
Beamwidth (3 dB): 6°
Polarisation: Linear
Turret
Weight: 12 t
Azimuth rotation: +110°
Elevation rotation: 0 – 90°
Speed: 0·25 rad/s
Acceleration: 0·5 rad/s²
Accuracy of analysis axis: 5×10^{-4} rad
Transmitter
Peak power: 150 kW
Mean power: 22 kW
Pulse duration: 500 μs (pulse compression ratio 100)
Receiver
Pulse compression: Receiver controlled by computer
Noise figure: 2·5 dB

STATUS
One installed on the trials research ship *Henri Poincaré*. Several improvements have been introduced recently, mainly in the data processing capability.

CONTRACTOR
Thomson-CSF, Division Systèmes, Défense et Contrôle, 40 rue Grange Dame Rose, BP34, 92360 Meudon-la-Foret, France.

Savoie tracking radar antenna

3099.153
D-BAND EARLY WARNING RADAR
TRS 2052/TRS 2053/TRS 2056

The TRS 2052 is a D-band early warning radar which has been developed as a successor to the TRS 2050 (**2100.153** in 1976 and earlier editions). Externally, and in other general characteristics, the later radar is very similar to the TRS 2050. The double-curvature antenna is of the same dimensions (9 × 13 m) and independent high- and low-cover beams are radiated. Cosecant beam shaping in elevation extends to over 40° and sharp ground cut-off of the high-cover lobe produces a strong contrast between air target echoes and ground returns. High-grade circular polarisation ensures rejection of weather returns.

An IFF antenna of the sum/difference type is mounted on the primary radar reflector, as is the side-lobe suppression antenna.

Further development of this successful equipment has led to two more models, the TRS 2053 and TRS 2056. The TRS 2052 air-defence long-range surveillance radar, the medium-range and SRE radars TRS 2053 and TRS 2056, use different antennas with the same electronics. A fully equipped cabin transportable by air, rail and road, houses a transmitter/receiver unit which comprises mainly: two high-stability transmitter/receivers of the 2 MW 2 kW class, equipped with long-life magnetrons, tunable by single-knob control, operating in dual diversity; an associated IF interrogator; two reception and processing units comprising a logarithmic receiver and a digital linear MTI filtering assembly.

Optionally, an SLS reception box to get rid of sidelobes can be included.

In this fashion, a set suitable for both fixed and mobile installations is available to associate with different antennas to constitute the TRS 2052, TRS 2053 and TRS 2056 stations.

With a large antenna (13 × 9 m) featuring high gain and dual coverage, a highly jam-resistant air-defence master station, the TRS 2052, is obtained. This has a detection range capability in excess of 350 km for modern fighter aircraft. With a smaller antenna (9 × 5 m), it becomes the TRS 2053, designed for equipping military airfields as recovery station or as gap-filler radar in an air defence network. These radars are widely distributed around the world. The third one of this family, the TRS 2056, developed for the French Air Force as a movable recovery station, uses an 8·5 × 3·5 m antenna which can be dismounted without special tools. It is known also as Centaure.

Simultaneous use of operationally variable frequency, frequency diversity, constant-false-alarm-rate receivers, of high-performance, compatible MTI, and of sidelobe suppression, endows the radar with excellent anti-jamming capabilities.

All three sets are compatible with fully automatic operational use, and feature built-in test equipment.

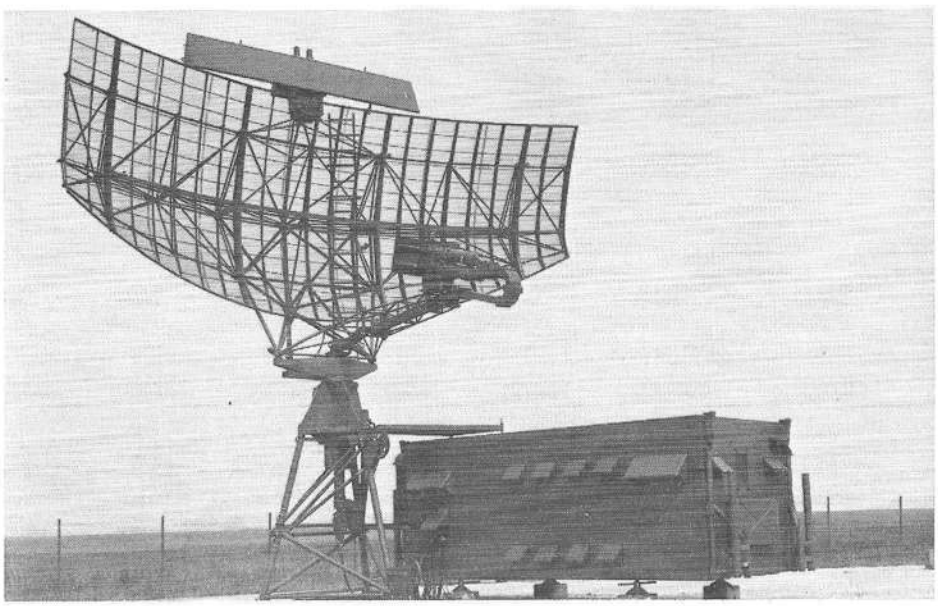
CHARACTERISTICS

Type: TRS 2052
Operating frequency range: 100 MHz in D-band
Antenna
Reflector dimensions: 13 × 9 m
Gain (low cover): 36 dB ± 0·5 dB
Gain (high cover): 35·5 dB ± 0·5 dB
Beamwidth in azimuth (3 dB): 1·2°
Cosecant: >40°
Polarisation: Circular, fixed
Rotation speed: 6 rpm
Transmitter
Frequency-tunable magnetron
Peak power: ⩾2·2 MW
Pulse duration: 3 μs
PRF: 350 Hz (3-period staggered)
Receiver
Noise figure of RF amplifier: 3 dB
Noise figure at input to reception chain: 4 dB
Intermediate frequency: 30 MHz
Sub-clutter visibility: ⩾25 dB
Digital post-detection integration
Power supply: 3-phase, 220/380 V, 50 Hz
Consumption: 40 kVA (55 kVA for diversity operation)
Performance
Detection range for fluctuating 2 m² target: >180 nm (330 km)
Detection in altitude: >60 000 ft (18 300 m)

DEVELOPMENT

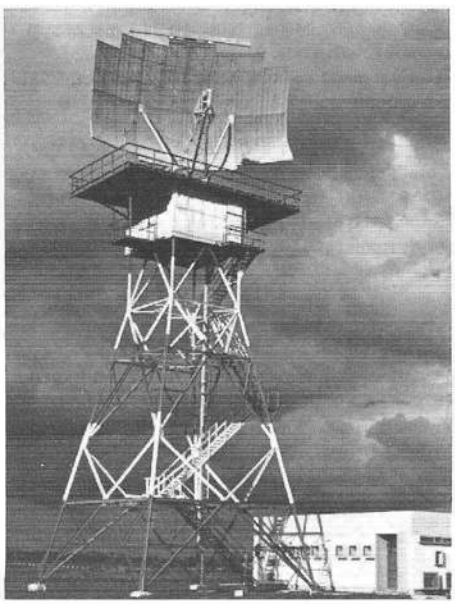
The TRS 2052 was developed in the mid-1970s as a successor to the TRS 2050 air defence early warning radar and the other derivatives followed shortly thereafter. The TRS 2053 and TRS 2056, developed for the French Air Force under the name Centaure, use the same transmitter/receiver as the TRS 2052 but have different antennas (see photographs).

STATUS



Numerous radars of this family have been supplied in France and to overseas customers. The TRS 2056, developed for the French Air Force as the Centaure, has been supplied in some quantity, and the TRS 2052 is known to be employed in the DACTA civil/military ATC and surveillance system supplied by Thomson-CSF to Brazil. The TRS 2053, also, is known to have been installed in France and other countries but details are lacking.

CONTRACTOR



Thomson-CSF, Division Systèmes, Défense et Contrôle, 40 rue Grange Dame Rose, BP34, 92360 Meudon-la-Foret, France.

TRS 2052 D-band early warning radar

TRS 2053 air surveillance and approach radar

TRS 2056 (Centaure) D-band early warning radar

3683.153
TRS 2054 LONG-RANGE SURVEILLANCE RADAR FAMILY

The TRS 2054 is a coherent, klystron-powered, long-range surveillance radar operating in the D-band of the radar spectrum. It has been evolved for air traffic surveillance roles and similar applications, and is thought to have been based upon experience gained with the TRS 2052 series of radars (**3099.153**). It embodies the latest concepts in steerable pattern null, coherent double-pulse operation and auto-regulating signal processing. This dual-channel 23 cm radar is claimed to be able to detect small aircraft at ranges of up to 200 nautical miles (370 km), and superior clutter see-through capabilities permit detection down to low levels. An integral plot extractor enables the radar to be connected to a data processing system.

The dual beam antenna uses offset feeds for reduced masking of the energy radiated by the reflector, thereby reducing sidelobes, and there is an elongated lower edge to the reflector to intercept radiation from the primary sources so that back lobes are reduced. The feeds are designed to ensure that the reflector edges are only illuminated by low-energy radiation, thus reducing spillover to a level comparable to the background level. A cosecant-squared radiation pattern, boosted at high elevation angles is employed, providing good contrast between short range targets and ground clutter. There is a sharp roll-off at low elevation angles, which also improves the signal-to-clutter contrast, and this is obtained by employing a reflector with a larger-than-usual vertical dimension. Compact stacking of the main and auxiliary feeds, gives good focusing for the high beam and reduced boresight separation between the two beams, while still maintaining a target-to-clutter enhancement of 16 to 18 dB. Programmable range/azimuth gated beam mixing (steerable pattern null) further improves clutter rejection.

The transmitter uses a TH 2068 klystron which is

stated to have a saturation gain of over 50 dB. It is a pulse-driven tube with five cavities giving a peak output of 5 MW, although in the present application it is deliberately under-driven to increase its service life. It is operated at 3·5 MW peak power and 4·7 kW mean power. The transmitter is crystal-controlled. At each pulse repetition interval, the transmitter generates a coherent pulse train consisting of a long duration pulse followed immediately by a short pulse. This provides a means of obtaining simultaneously in a single radar the benefits of both long- and short-pulse operation. The latter gives a precise radar cell and so improves both target resolution and signal-to-clutter contrast, these characteristics being especially valuable at short and medium ranges. At greater ranges, the longer pulse results in an increased useful detection range.

Signal processing and remoting is provided by a TPL 800 processor with enhanced capability thanks to the coherent signals received. Video processing includes log/FTC/anti-log conversion to suppress slow-moving clutter patches. In the UHF spectrum, STC is controlled through digital programming with a matrix of 64 × 64 cells. The receiver input stage is a low-noise solid-state, wide-band amplifier, and the linear amplifier which drives the MTI processor prevents clutter spectrum spreading. IF gain is automatically controlled by a dynamic clutter memory having a capacity of 128 × 128 azimuth/range cells (3° × 2 or 1 nautical miles), and ten-bit phase-coding of in-phase and quadrature channels eliminates MTI blind speeds. The MTI filter can be either a three-pulse filter or a three-stage recursive filter with programmable negative feedback. Video diversity summing is performed digitally.

Other members of the family use the same inherent transmitter/receiver and the antenna of the TRS 2053.

STATUS

In production and service in France and a number of other countries.

long-range surveillance radar

3272.153

TRS 2230/TRS 2215 3-D RADARS

This family of E/F-band air-defence three-dimensional radars, employing electronic phase scanning in elevation, is directly derived from the very high precision heightfinding radar SATRAPE which has equipped the French Air Force (see **2060.153** ANTARES).

The TRS 2230 is the fixed or relocatable version in this family. The TRS 2215 and TRS 2215D are the mobile versions, transportable by road, rail or aircraft (Transall, C-130, or equivalent), and can be deployed in less than one hour. Both radars employ the same space scanning techniques, the same transmitter, the same reception and processing circuits, and the same antenna components. They use two types of antenna; either a cylindro-parabolic reflector (TRS 2215 only) or a planar phased-array reflector (TRS 2215D and 2230D). This commonality, which has particular relevance to maintenance, logistics and training, allows in addition a high flexibility of deployment of the facilities in a system incorporating both versions (eg backing up of a fixed-station antenna by a mobile-station antenna).

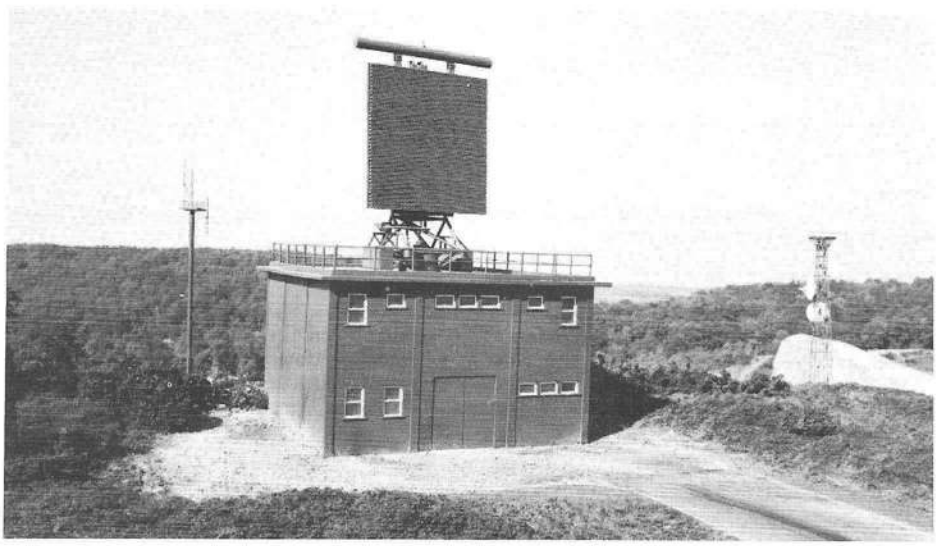
In the antenna with a cylindro-parabolic reflector, azimuth scanning is obtained by rotating the antenna continuously about a vertical axis. The primary feed is a linear array of elementary feeds, radiating circularly polarised waves, coupled with two waveguides through directive couplers. In the planar array antenna the two-waveguide feeder is linked to a set of horizontal rows of elementary feeds radiating circularly polarised waves. The two waveguides allow monopulse operation to perform the heightfinding function. Digital electronic phase-shift networks inserted between the elementary feeds and the corresponding directive couplers control the pointing of the beams.

The transmitter is an amplifying chain transmitter using a high-efficiency crossed-field amplifier as its final tube. It permits the use of the pulse-compression technique and that of pulse-to-pulse frequency agility. It is characterised by high efficiency (greater than 70 per cent) and a modular modulator allows repair operations, if required, to be carried out without shutting down the station.

The receiving section groups the receivers, the MTI unit, the extractor, the plot processing and altitude computing equipment, the control device for the tilting of the antenna according to the mode of operation imposed, and the monitoring desk.

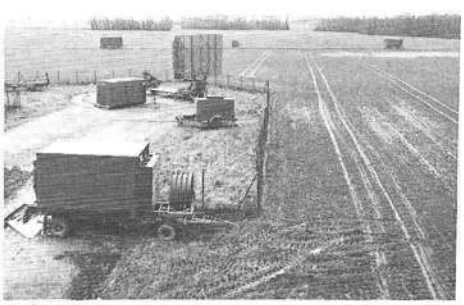
The receiver circuits comprise the anti-jamming chains and three angle error chains. The MTI device processes the signals received from any one of the three lower beams by programming. The extractor performs the extraction of primary and secondary plots and allows them to be associated together. It is followed by a plot processing system which computes altitude, and filters plots so as to transmit only useful data. The device generates the data in a digital form permitting the transmission of plots to a remote centre. The monitoring desk groups the monitor controls of the station's operation.

CHARACTERISTICS



Detection range (fluctuating 2 m² target): 510 km
Ceiling: >30 500 m
Elevation coverage: -3 to +30°; programmed operating multimode
Altitude accuracy:
TRS 2230: ±300 m at 300 km
TRS 2215: ±450 m at 200 km
Data renewal rate: 10 s
Antenna: TRS 2215
Gain: 40 dB
Beamwidths (3 dB): Azimuth 1·5°; elevation 1·9 - 4°
Polarisation: Circular, fixed
Rotation speed: 6 rpm
Transmission
Peak power: 700 kW
Average power: 10 kW
PRF (average): 380 Hz
Reception: CFAR
MTI improvement factor: 40 dB

STATUS



In production for French and other forces. The TRS 2215D is a later development which was shown for the first time at the 1983 Paris Air Show. An electronic scanning radar, the TRS 22XX which belongs to the same family, has been developed, and offered for the NATO E/F-band update programme.

3197.153
OEIL VERT RADAR

The Oeil Vert radar is a D-band equipment used in the AMX-30 SA self-propelled 30 mm twin gun anti-aircraft system (**2138.131** in 1982-83 and earlier editions) for surveillance and target detection. It is a pulse doppler system and is mounted on the turret of the AMX-30 carrier vehicle, the indicator and control units being inside and the transmitter/receiver, signal processor, antenna erection mechanism, and junction box being housed in a protective container attached to the rear of the turret.

Two surveillance modes are provided: (a) distant, with a range of 15 km intended for normal use, and (b) close-in, with a range of 6·5 km which is available at the operator's discretion to suit operating conditions. Each mode has several range gates. MTI and track-while-scan facilities are provided and good sub-clutter visibility also is claimed.

CHARACTERISTICS
Type: Pulse doppler
Frequency: 1710 - 1750 MHz
Power: 120 W (peak)
Max range: 15 km and 20 km as an option
Azimuth accuracy: ±2° (approx)
MTI radial speed range: 30 - 160 m/s (slow targets); 160 - 300 m/s (fast targets)
Tracking range: 13 km to almost 0 km

STATUS
In production. Used in the AMX-30 SA tracked AA gun system (**2138.131** in 1982-83 and earlier editions) and the Dragon AA tank project (**3679.131**). The Oeil Vert Plus system has been supplied to the Egyptian armed forces.

Oeil Vert scanner erected and ready for use

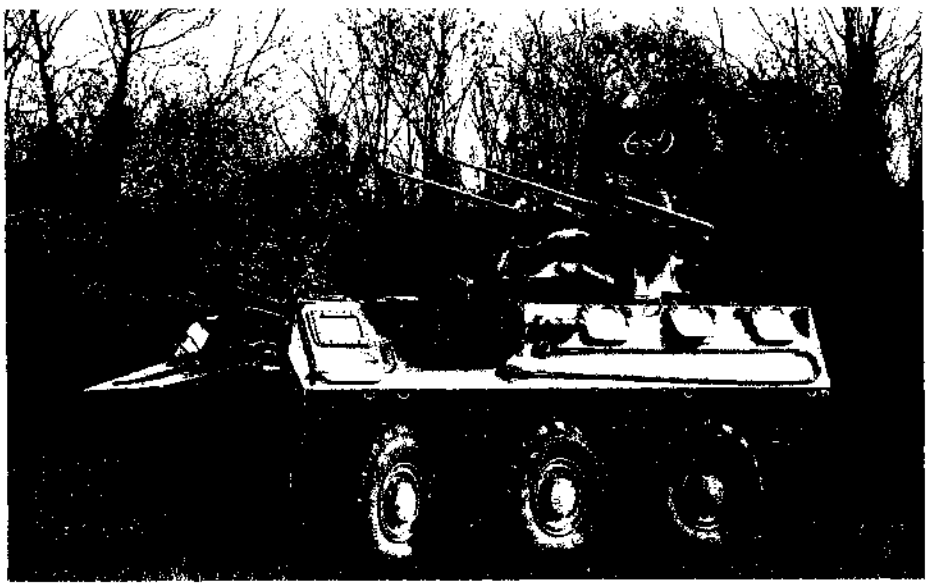
5601.153
RA 20S FIRE CONTROL RADAR



RA 20S is a coherent pulse doppler radar used for the detection and tracking of fixed and rotary wing aircraft flying at low and very low altitudes and is the successor to the RA 20 system described under **3717.153** in previous editions of *Jane's Weapon Systems*. It has been specially developed for integration in anti-aircraft defence systems fitted with 20, 23 or 25 mm twin-gun turrets or carriages, such as the TA20 turret designed by ESD. It can be used as the 'leader' of an anti-aircraft defence unit and operated to serve four vehicles or carriages with automatically slewed weapons.

The radar is discreet, lightweight and small, employing a solid-state transmitter, track-while-scan techniques and incorporating a built-in test system. It can be easily operated after a simple training course.

The RA 20S is IFF compatible and consists of two main sub-assemblies:

(1) an antenna unit comprising a retractable antenna, transmitter/receiver and processing circuits
(2) a control console fitted with the controls and a display module.

CHARACTERISTICS
Acquisition envelope
Azimuth: 360°
Elevation: -5 to +45°
Range: 1 - 12 km
Tracking type: TWS
Number of tracks: 2 (with possible extension)
Range: (to combat aircraft) 12 km; (to tactical helicopter) 12 km
Weight
Antenna unit: 60 kg
Console: 25 kg

TA20/RA 20S fire control radar mounted on an anti-aircraft defence vehicle

STATUS
In full production and more than 50 systems have been delivered to several defence forces.

CONTRACTOR
Electronique Serge Dassault, 55 quai Carnot, 92214 St Cloud, France.

5602.153
RODEO 2 FIRE CONTROL RADAR

RODEO 2 (radar d'observation et de designation d'objectifs) is a coherent pulse doppler radar used for the detection, tracking and identification of aircraft flying at low and very low altitudes and is particularly suitable for use against hovering helicopters on watch or at firing position. Identification of the latter is possible from an analysis of its blade flash and comparison with the signature of rotor blades held in a library bank. The basic concept of this equipment is very similar to that of the RA 20S (**5601.153**).

RODEO 2 can be used as the 'leader' of an anti-aircraft defence unit and operated to serve four defence vehicles, fitted with guns or missiles, the weapons of which are automatically slewed. It is IFF compatible and uses frequency agility against electronic countermeasures.

The system consists of two main sub-assemblies:

(1) an antenna unit comprising an antenna (in a radome), a transmitter/receiver, and data extraction and processing circuits
(2) a control console fitted with the controls and display module.

The equipment is a discreet, lightweight and small radar employing a solid-state transmitter, track-while-scan techniques and incorporating a built-in test system.

CHARACTERISTICS
Acquisition envelope
Azimuth: 360°
Elevation: -5 to +35°
Beamwidth: 6·5°
Range: 1 - 10·5 km
Tracking
Type: TWS
Number of tracks: 2 (with possible extension)
Range: On aircraft or moving helicopter >10 km; hovering helicopter at firing position >7 km; helicopter on watch (rotor motion) >5 km
Output: 120 W
Weight
Antenna unit: 60 kg
Console: 25 kg

STATUS
RODEO 2 is a prototype equipment which belongs to the RA 20S series of fire control radars (**5601.153**). It is a candidate for the French Army vehicle-mounted fire control radar for the SATCP MISTRAL missile.

CONTRACTOR
Electronique Serge Dassault, 55 quai Carnot, 92214 St Cloud, France.

3276.153
WEATHER RADAR TRS 2730

This radar makes conventional meteorological measurements; detects precipitation (rain, hail and snow) within a radius of 400 km; and manually tracks meteorological balloons (automatic tracking available as an optional feature).

The station comprises:

(1) a parabolic antenna, 3·05 m in diameter, mounted on a turret which provides mobility in both elevation and azimuth
(2) a servo cabinet
(3) a transmitter/receiver cabinet
(4) switchable display (PPI/RHI) on colour TV screen.

CHARACTERISTICS

Transmission frequency: Tunable, 5·6 - 5·8 GHz
Peak power: 250 kW
Pulse duration: 2 μs
Noise figure: 7·5 dB
Video: High degree of automation, allowing the set to be manned by one operator. Optional features include: picture transmission by synchronous line coupler or facsimile coupler; short range remoting.

STATUS

In production.

CONTRACTOR

Thomson-CSF, Division Systèmes, Défense et Contrôle, 40 rue Grange Dame Rose, BP34, 92360 Meudon-la-Foret, France.

TRS 2730 weather radar

2120.153
PERCEVAL/SPARTIATE RECOVERY RADAR TRS 2300

Perceval is a highly mobile helicopter and aircraft recovery radar station developed for the French forces. Its functions include early warning (secondary radar), approach and recovery (primary radar), and landing. All these functions can be carried out simultaneously.

The station comprises a lightweight trailer supporting the radar transmitter/receiver unit, MTI unit, the IFF interrogator and the antennas, a cabin housing two displays, associated means of telecommunication, and a trailer carrying a power generating set.

The antenna system comprises an azimuth antenna which can rotate continuously and an elevation antenna which scans in the vertical plane. The IFF antenna is integrated with the primary radar antenna.

The transmitter and the receiver operate in I/J-band and are transistorised and miniaturised.

The designation Perceval is that given to the export version of a system developed for the air elements of the French Army, to which service it is known as SPARTIATE (système polyvalent d'atterrissage, recueil, télécommunications, identification de l'Armée de Terre).

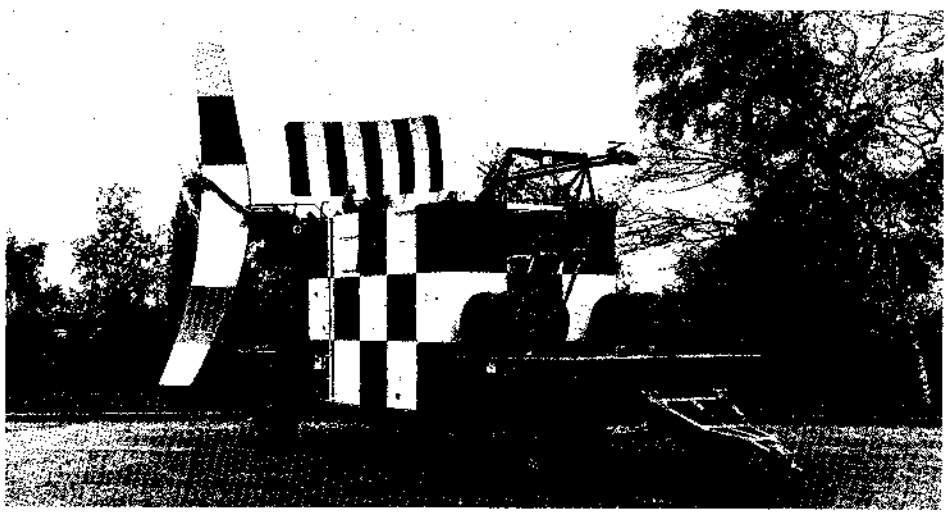
Additional details will be found under this entry number (**2120.153**) in earlier editions of *Jane's Weapon Systems*. No longer in production.

CONTRACTOR

Thomson-CSF, Division Systèmes, Défense et Contrôle, 40 rue Grange Dame Rose, BP34, 92360 Meudon-la-Foret, France.

TRS 2300 Perceval/SPARTIATE recovery radar

3492.153
PRECISION APPROACH RADAR TRS 2310



This J-band equipment replaces the TH.D 1012 (**2133.153** in 1978 and earlier editions), a PAR which is used all over the world. Specific improvements are:

(1) the equipment's total mobility
(2) performance in the presence of heavy rainfall greatly improved by the use of velocity filters in the processing chain
(3) possibility of controlling several approaches simultaneously by optimisation of antenna radiation patterns.

The equipment can be delivered for static installation with the same constituent elements. Approach control room equipment also is available in a static and in mobile versions, with a remoting capability of up to 3000 m. The PAR TRS 2310 meets ICAO recommendations. Fully solid-state design ensures very high reliability and ease of maintenance. The operation detection range is 20 nautical miles for Mirage aircraft with 90 per cent detection probability.

CHARACTERISTICS

Frequency band: 9000-9200 MHz
Antennas: Mounted on orientable turret allowing angular displacement of 200 or 270° (at least 2 QFUs)
Beamwidths (3 dB): 0·6° (elevation antenna); 1·1° (azimuth antenna)
Gain (high-resolution plane): 39·5 dB (elevation antenna); 38·5 dB (azimuth antenna)
Attenuation of first sidelobes: < -25 dB
Polarisation: Circular
Transmitter: High-gain TWT stage fed by high-stability pilot
Average power: 100 W (bad-weather mode); 50 W (clear-weather mode)

TRS 2310 precision approach radar

PRF: 3 PRF values in mode 2; 2 PRF values in mode 1
Receiver: Digital doppler processing
Noise figure: 3·5 dB

PERFORMANCE

Operating modes: Bad and clear weather
Ranges: 10 and 20 nm
Scanning ranges: Elevation from -1 to +9°; azimuth 20°
Data rate: 1 azimuth and elevation picture every half second
Improvement factor: 40 dB (fixed echoes); 30 dB (heavy rain echoes)
Precision: According to ICAO standards

STATUS

In production for several countries.

CONTRACTOR

Thomson-CSF, Division Systèmes, Défense et Contrôle, 40 rue Grange Dame Rose, BP34, 92360 Meudon-la-Foret, France.

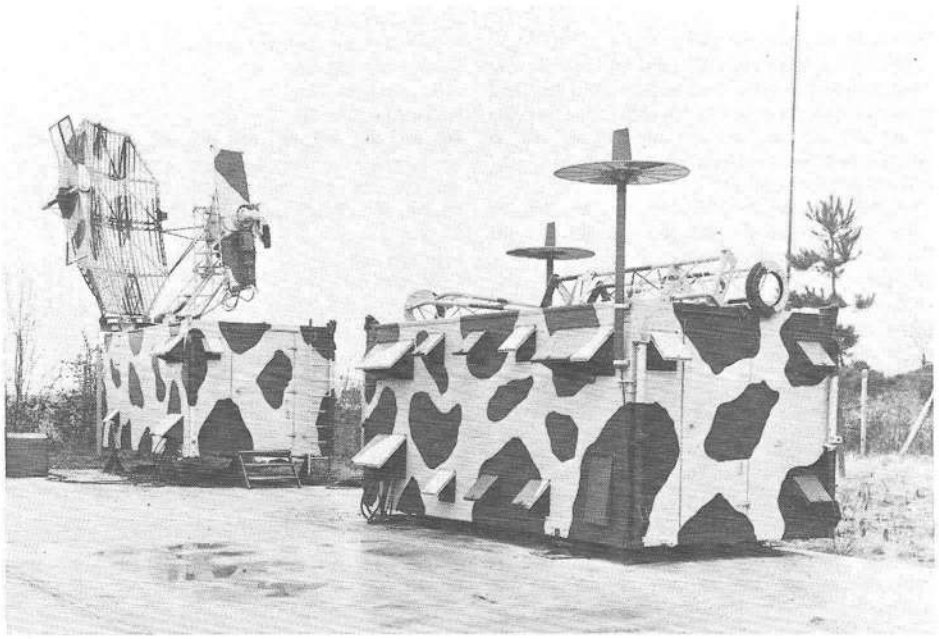
2119.153
PICADOR MOBILE 3-D RADAR

Picador TRS 2200 is a mobile air defence radar station operating in E/F-band. This station combines in a single system the radar functions of 3-D surveillance, heightfinding, and low-altitude surveillance. Designed to be transportable and capable of being deployed rapidly, it can be used for surveillance and interception control either as an autonomous station or as a gapfiller integrated into a large air defence system.

The complete station comprises an equipment cabin, an operations cabin, and power generators.

Equipment Cabin

On the reinforced roof of this cabin is fixed the antenna system which comprises a single reflector and three primary feeds. One of these is for 3-D search and heightfinding coverage and is an electro-mechanical rapid scan feed; a second is for low-



altitude plan coverage; and the third is for IFF coverage (with a supplementary omnidirectional antenna for the ISLS function).

STATUS

No longer in production. More detailed information is given under this entry number in previous editions of *Jane's Weapon Systems*.

Thomson-CSF, Division Systèmes, Défense et Contrôle, 40 rue Grange Dame Rose, BP34, 92360 Meudon-la-Foret, France.

Picador mobile air defence radar station, with operations cabin

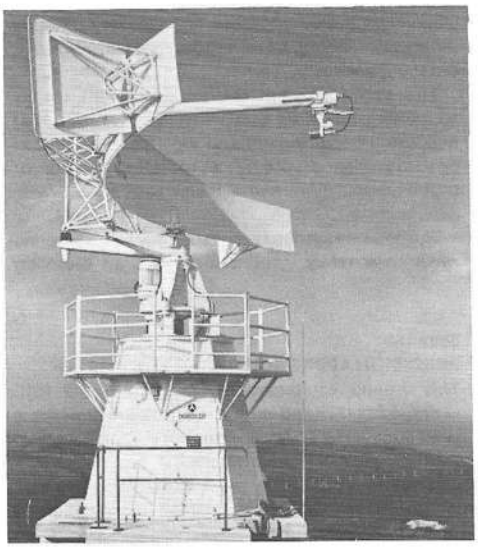
3100.153
COASTAL SURFACE SURVEILLANCE RADAR TRS 3405

This equipment is an I-band radar specially intended for the surveillance of maritime traffic in straits, harbour approaches, access channels, and harbours.

It is designed to provide high performance in range, resolution, accuracy, and protection against the various detection impairments encountered in sea surface surveillance, namely sea and rain clutter, and propagation loss in rain and heavy fog. High resolution is achieved by the use of an antenna with a narrow azimuth beamwidth, and a very short transmission pulse, which results in a very small radar cell. The use of frequency diversity allows decorrelation of sea clutter peaks, reducing the false alarm rate and improving the detection of small ships or buoys.

The radar operates in the I-band (former X-band). To achieve a high gain and avoid unwanted rain echoes which would result from the illumination of clouds at high altitude, the antenna elevation beamwidth is also narrow, and radiation polarisation can be switched from linear to circular. Detection at very close range is ensured by an elevation pattern of the inverted cosecant-squared type down to an angle of -25°.

Round-the-clock operating requirements demand two transmitter/receivers for each radar station. In this equipment, they are connected to the antenna through a passive diplexer rather than through a switching device, which enables both units to be operated simultaneously on a frequency diversity basis. As this mode of simultaneous operation is necessary only in heavy weather, the operating cost is not increased significantly. In addition, each reception channel is fitted with an automatic false-alarm regulation control slaved to the mean level of sea clutter.



This equipment is fully compatible with extractors and data remoting.

CHARACTERISTICS

Antenna
Gain: 44 dB
Resolution: 0·24°
Low sidelobes: 25 dB
Inverted cosecant: Squared pattern in elevation down to -25°
Linear and circular polarisation
Rotation rate: 5 or 10 rpm
Transmitter/receiver
Frequency: I-band (formerly X-band)
Peak power: 200 kW
High resolution pulse: 0·05 μs
PRF: 1080-570 Hz
Advanced anti-clutter and anti-jamming processing.

STATUS

In production.

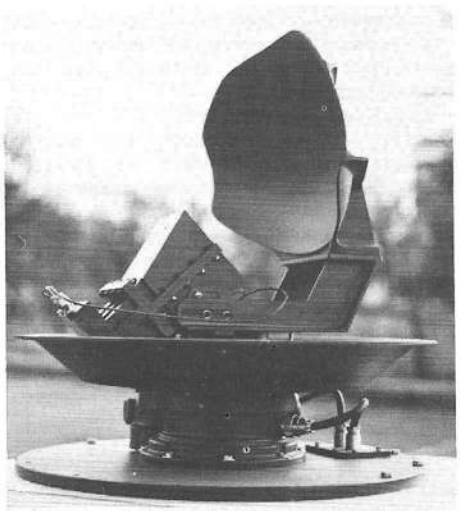
4224.153
TRS 2600 AND 2601 RADARS

The TRS 2600 and 2601 are acquisition radars for very short range weapon systems. They combine the functions of surveillance and target designation and are intended to pinpoint targets flying at low and very low altitudes. When associated with gun and missile systems, these radars are designed to ensure close defence of the battlefield, key points and operational moving units.

Both radars have been designed with regard to current and forseeable evolution in the air threat constituted by aircraft, missiles, pop-up/pop-down/hovering helicopters and RPVs etc, moving in a severe ECM and clutter environment. The TRS 2600 and 2601 are virtually identical, except for the method of taking into account the helicopter threat, and are IFF compatible.

CHARACTERISTICS



Frequency: Upper S-band
Rotation rate: 40 rpm
Operation: Burst operation/frequency agility
Range: Aircraft >12 km; hovering helicopter >6 km
Accuracy: 0·6° rms on hovering helicopter (TRS 2600); 1° rms on aircraft (TRS 2600/2601)
Tracking capacity: 6 simultaneous tracks

STATUS

Prototype.

TRS 2600/2601 radars

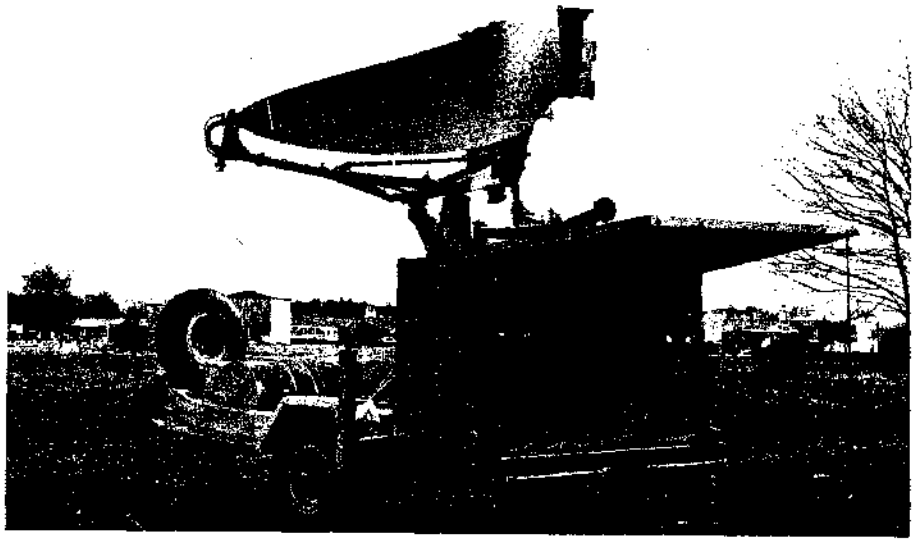
3273.153
MOBILE COASTAL SURFACE SURVEILLANCE RADAR TRS 3410

This mobile, cabin-installed station utilises the I-band transmitter/receiver of the TRS 3405 radar (**3100.153**) operating in frequency diversity for decorrelation of sea clutter peaks, coupled with a 4·4 m antenna located on a trailer. Installed at 40 to 50 m above sea level, this station detects small boats up to 25 km away, whereas for larger ships with superstructures at a height of 10 m or more, the detection range reaches 40 km.

The TRS 3410 radar is fitted with a track-while-scan (TWS) device which refines and maintains the data from a surface track, starting from a target designation made by the operator. These data are processed through a computer for the control of various types of anti-ship missiles whose batteries

can be located next to the radar station or remotely sited. The compounding of its own accuracy and of the data refinement by the TWS device gives an overall target parameters accuracy which is sufficient for the control of coastal artillery fire against surface targets.

CHARACTERISTICS



Antenna: 4·4 m parabolic reflector
Gain: 39·5 dB
Azimuth beamwidth (3 dB): 0·55°
Elevation beamwidth (3 dB): 4°
Polarisation: Circular
Rotation rate: 11 rpm
Transmitter/receiver
Frequency: I-band
Peak power: 200 kW
High resolution pulse: 0·05 μs
PRF: 1080-570 Hz
Advanced anti-clutter and anti-jamming processing

STATUS

In production.

CONTRACTOR

Thomson-CSF, Division Systèmes, Défense et Contrôle, 40 rue Grange Dame Rose, BP34, 92360 Meudon-la-Foret, France.

Thomson-CSF TRS 3410 mobile coast defence radar includes tracking of the co-operating helicopter to provide over-the-horizon target data

2141.153
RASIT 3190B GROUND SURVEILLANCE RADAR

Rasit 3190B is a long range (30 km) ground surveillance radar, for the detection, acquisition, localisation, and recognition of moving targets, either on or near the ground in all weathers. The Rasit 3190B is available in three versions: man-portable and broken down into four 30 kg sections, shelter-mounted and vehicle-mounted.

The equipment is a pulse doppler radar. It operates in I/J-band and uses a coherent receiver and multiple range gates and filters designed for a high probability of detection.

Echoes detected over the surveyed zone are displayed on a B-scope daylight display, connected to an electronic memory.

For each target acquired, the polar and UTM co-ordinates are displayed on the B-scope and the doppler tone is transmitted to the operator either by loudspeaker or by earphone. The operator is thus able to recognise pedestrians, wheeled and tracked vehicles, aircraft, and helicopters.

An automatic system can be arranged to trigger an acoustic alarm as soon as a target enters the surveyed zone. The operator can select the width of the surveyed zone from 30 to 120° and can choose the length surveyed by operating in either of two modes:

(a) Normal: overall radar range of 20 km
(b) Magnifier: any zone 2·5 km long within the total range.

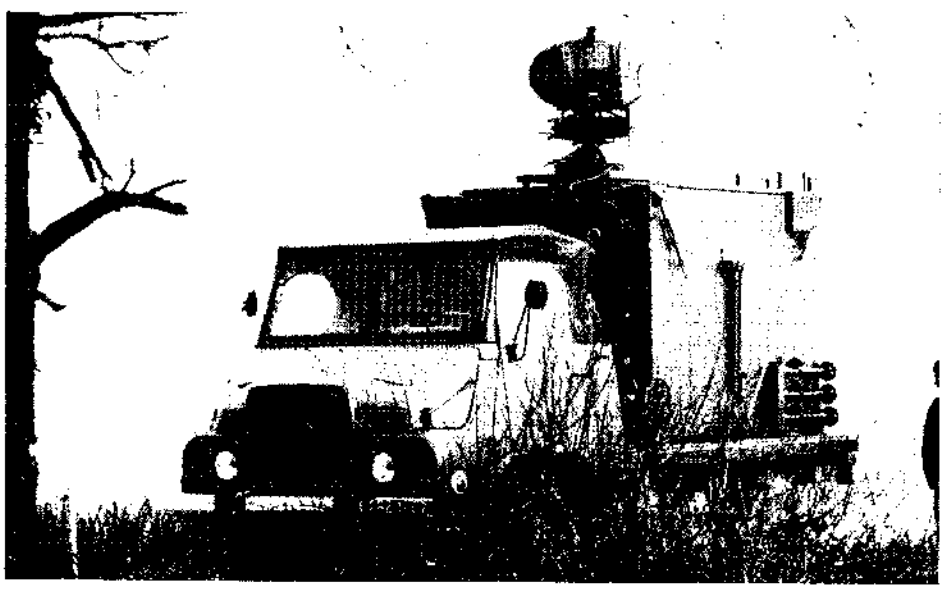
The equipment can be operated by a single inexperienced operator in a variety of conditions. Typical operating times are ten seconds to survey a zone 100° wide and 20 km long, and 30 seconds to acquire a target.

The antenna beam can automatically sweep a sector or can be stopped and then oriented towards a target. The antenna is equipped with a polariser making the radar insensitive to atmospheric perturbations. The radar also has very effective ECCM capabilities.

The RF unit can be mounted on a tripod with the control cabinet 50 m away. Alternatively it can be mounted on any of a variety of military vehicles, such as the APC Steyr, the APC Mowag, the Alvis-British Leyland Spartan, the Panhard M3 or the APC VAB, with the control cabinet inside the vehicle.

In addition to built-in tests, a tactical test bench can be supplied for third and fourth echelon maintenance. A tactical simulator designed for an efficient and comprehensive training of one or several operators is available.

CHARACTERISTICS



Operating frequency: I-band (200 MHz range)
Peak power: 2 kW
Polarisation: Linear or circular
Range (90% probability of detection)
Pedestrian: 18 km
Vehicle: >30 km
Helicopter: 15-25 km
Low-flying aircraft: 28 km
Range reduction: (4 mm/h rain) <10%
Accuracy: Azimuth ±10 mrd, range ±10 m
Sub-clutter visibility: More than 43 dB
Display: B-type daylight oscilloscope, numerical display of polar and UTM co-ordinates, doppler tone, automatic acoustic alarm
Power drain: 150 W (28 V)
Temperature range: -40 to +55° C
Reliability: Field tested MTBF >900 h
Overall weight: 90 kg
Number of loads: 4
Weight of the heaviest load: 28 kg
Distance between radar head and operator unit: 80 m max
Provision for target data transmission
Built-in tests
Options: Remote slave TV monitor; plotting table; compatible with Siclamen IFF (**3173.153**).

STATUS

In production in France. More than 450 equipments have been delivered to 20 armies. Licensed production is under consideration by other countries.

CONTRACTOR

LMT Radio Professionelle, 46-47 quai Alphonse Le Gallo, 92103 Boulogne-Billancourt, France.

Shelter mounted version of Rasit DDMT-1-A battlefield surveillance radar

3173.153
SICLAMEN IFF SYSTEM

The Siclamen system has been designed to meet all identification requirements for land vehicles operating in a combat zone, in the same manner as military aviation IFF. Because of the similarity of vehicles, the depth of combat areas and the range of anti-tank missiles, LMT Radio Professionelle has developed the BIFF (battlefield identification friend or foe) system known as Siclamen (Systeme d'Identification Compatible bande L'Ami ou Enemi) L-band IFF system. When installed on land vehicles, this system has a range of 30 km. It discriminates between two targets having a range difference of 100 metres and whose azimuths differ by 2 to 8 degrees, depending on the mode of use.

A Siclamen station consists of an interrogator, a control console and a directional antenna, and interrogates BIFF transponders associated with omni-directional antennas installed on friendly vehicles. The interrogating stations are associated with a primary sensor which may be any field or on-board radar, or even a laser rangefinder or television system, although Siclamen can operate completely autonomously if required. The frequencies used are the same as for IFF, ie 1030 MHz for transmission and 1090 MHz for replies. Information is exchanged by encoded pulse trains.

One use of Siclamen is with the Rasit radar (**2141.153**). The latter can operate in:

(a) Mode 1 - surveillance of a sector (apperance of echoes on the display)

Siclamen IFF equipment

(b) Mode 2 - antenna scan interrupt and manual aiming of the antenna at an echo of interest to the operator who can then place a range gate on this echo which generates a doppler sound corresponding to the type of moving object observed (pedestrian, tank, helicopter, etc) in the Rasit loudspeaker.

In mode 1, BIFF interrogations are transmitted continuously. In the case of any friendly vehicle echo, the amber light on the control console comes on when the antenna is pointed at the echo, with a flashing indication next to the echo on the display. It is then possible to check if this friendly vehicle corresponds to a given code entered via a keyboard. If affirmative, a green decoding light comes on and the amber indicator becomes continuous. In mode 2, the Siclamen system indicates on the console, in clear language form, the code of the friendly vehicle at which the radar operator is aiming the antenna. This is known as active decoding. Range of the vehicle is also displayed at the same time as the code.

CHARACTERISTICS
Frequency: 1030 MHz interrogation; 1090 MHz reply
Transmitted power: 10 W peak
Receiver sensitivity: -75 dBm
No of modes: 1 for BIFF
No of codes: 4096
Passive decoder: 1 for BIFF
Range readout: In tens of metres to 30 km
Range resolution: 100 m for two vehicles fitted with BIFF
STATUS
In production and in service with the French Army and other armies.
CONTRACTOR
LMT Radio Professionelle, 46-47 quai Alphonse Le Gallo, 92103 Boulogne-Billancourt, France

5782.153
IFF INTERROGATOR NRSI-3

The NRSI-3 IFF interrogator is the latest in a series of these equipments designed and manufactured by LMT Radio Professionelle. Types of installation are:

(a) a single interrogator with local control, with or without a permanent monitoring system
(b) a dual interrogator with local control installed in a 19 inch (483 mm) rack and consisting of two identical transmitter/receivers, a permanent monitoring system and an automatic switch-over system.

The system is fully solid-state with an optional programmable output power and optional monopulses receiver. Modes of operation are 1, 2, 3/A, B, C, D and compatibility with mode 4. Interlacing facilities are incorporated among the six modes with the possibility of alternating two groups at each antenna revolution. A remote control unit can

IFF interrogator NRSI-3

be fitted which allows all the front panel controls of the dual transmitter/receiver version to be remoted via a 2-wire line, as well as transmission of orders from the decoder.

The permanent monitoring system permanently checks the performance characteristics of the transmitter and receiver. For a dual system operating in the automatic mode, it controls operation on the stand-by unit in the event of the failure of the unit in service. The parameters checked are output power, threshold level, encoding, multiplexing, ISLS switching, SWR and remote control. A naval version of the NRSI-3 is also available.

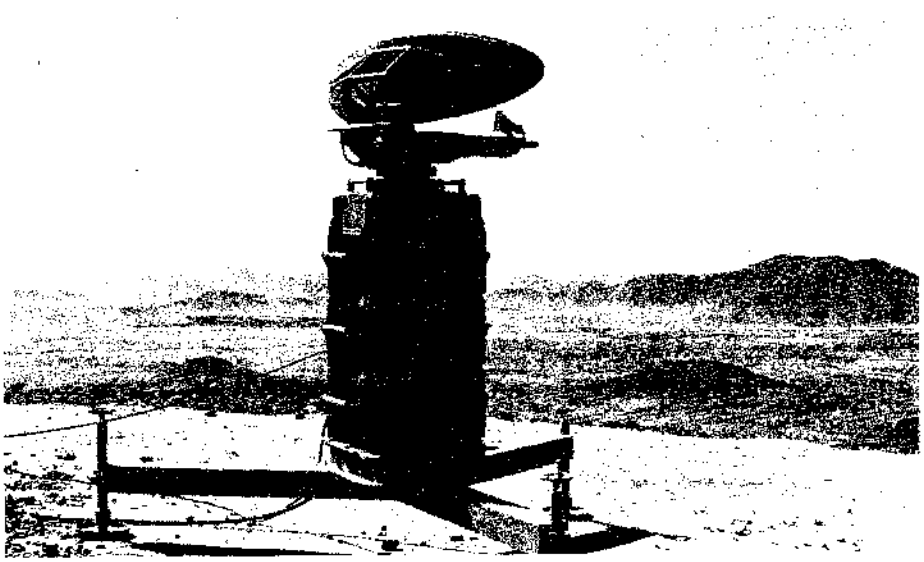
CHARACTERISTICS
Frequency: Transmit 1030 ±0·2 MHz; receive 1090 ±3 MHz
Peak power: 2 kW
Modes: 1, 2, 3/A, B, C, D and compatible with mode 4
Transmission delay: Adjustable from 28 μs to 926 μs with respect to the synchronisation signal
STATUS
In the pre-production phase.
CONTRACTOR
LMT Radio Professionelle, 46-47 quai Alphonse Le Gallo, 92103 Boulogne-Billancourt, France.

5769.153
IFF INTERROGATOR ANTENNA 3937A

The Type 3937A antenna is a lightweight unit designed for the transmission and reception of IFF signals. It is able to transmit 3 kW pulses with a 1 per cent duty cycle. The antenna has a double radiation pattern, for side-lobe suppression, which is necessary to prevent the identification of transponders outside the priority direction of the main lobe. It consists essentially of a radiation plane supplied, via a distributor, either on phase conjunction for a directional, or sum, pattern, or on phase opposition for a non-directional, or difference, pattern. Part of the signal difference is directed towards a rear dipole to provide additional cover to complete the rear lobe of the difference pattern. The antenna mounting attachment is designed for assembly to a variety of radar antenna structures.

CHARACTERISTICS
Frequency: 1030 MHz transmit; 1090 MHz receive
Power: 3 kW peak for duty cycle of 1%
Horizontal beamwidth (3 dB): 10° for sum channel; 30° for difference channel
Vertical beamwidth (3 dB): 40°
Dimensions: 2 m wide × 360 mm high × 355 mm deep
Weight: 20 kg
CONTRACTOR
LMT Radio Professionelle, 46-47 quai Alphonse Le Gallo, 92103 Boulogne-Billancourt, France.

3287.153
STENTOR BATTLEFIELD RADAR



Stentor is a doppler radar used for ground surveillance of critical areas, such as battlefields and frontiers. It is claimed to have the longest range for ground surface surveillance radars, making possible surveillance of remoter areas and, compared to medium-range radars, giving a significant increase in warning time to aid the interception of hostile units. At shorter ranges the benefits of a powerful signal are evident for high detection probability against very small or intermittent targets, or for minimising the absorption effects of adverse weather conditions. The Stentor ranges are: 30 to 40 km for pedestrian targets; 50 to 60 km for targets such as a Jeep, tank, truck; and 20 to 60 km for boats (depending on sea conditions) and helicopters (a major threat when flying low at low speeds since they are not detectable by classical air defence or low flying aircraft detection radars).

It is a transportable system comprising the radar head and an operator's console which can be remotely sited several hundred metres from the radar head. The radar head can be located on a tower, or on a naturally elevated site, to increase the surveyed area and, thus, distant detection.

The operating frequency is in the X-band (US I-band), tunable over 200 MHz with pulse transmission, ground clutter cancellation being by coherent detection and doppler filtering; rain cancellation circuits provide for all-weather operation. Moving targets are displayed on a daylight CRT with a digital memory. The surveyed sector can be instantaneously adjusted in aperture and in azimuth.

A tactical data communication system which enables a command post to simultaneously receive and process the data issued from one to ten Stentor radar stations is also optionally available, as are operator training simulators and third echelon bench test units.

Stentor is simple to operate (even by a single inexperienced operator) and to maintain, with high mobility, fast deployment and effective ECCM capability.

Stentor deployed in typical surroundings

CHARACTERISTICS
Frequency: I/J-band, tunable
Peak power: 60 kW
Polarisation: Vertical or circular
Antenna span: 1·6 m
Range: 0-60 km, according to target
Accuracy: 20 m (range); 4·4 mrad (0·25°) (azimuth)
Weight: 370 kg (radar head and operator's unit)
Power: 1·5 kVA, 220 V, 50/60 Hz
MTBF: >1000 h
STATUS
In production and operational with various armies
CONTRACTOR

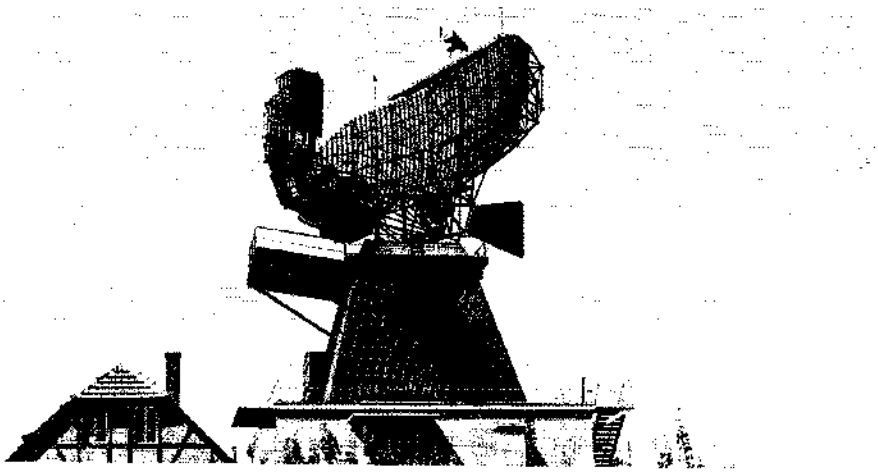
2155.153
THREE-DIMENSIONAL RADAR TRS 2201

The TRS 2201 is a long-range three-dimensional E/F-band air defence radar. A modern technology version of the ARES radar used in NATO's NADGE network, it ranks among the most powerful radars of its type in the world.



Major features of this radar are its high-power (20 MW peak) transmitter, its elaborate antenna structure, and its range of ECCM facilities that enable it to function satisfactorily in an ECM environment. The equipment is solid-state to the maximum extent possible, is of modular construction, and has built-in test facilities. More detailed information is given under this entry number in previous editions of *Jane's Weapon Systems*.

PERFORMANCE

Range capability of the TRS 2201 is more than 250 nautical miles (460 km) on fighter aircraft, there being no practical altitude limitation. Height measurement accuracy is ±1500 ft (457 m) up to 150 nautical miles (280 km). The data renewal rate is six per minute.

STATUS

More than 30 sets have been constructed but the equipment is no longer in production. Besides France several countries have been equipped with TRS 2201 stations and the equipment was selected by NATO as the main feature of its radar coverage (NADGE plan – see **1181.181**).

TRS 2201 long-range 3-D air surveillance radar

3271.153
VOLEX IV 3-D SURVEILLANCE RADAR TRS 2206

Volex is a fixed, E/F-band, 3-D surveillance radar providing continuously and simultaneously the azimuth, range, and altitude of any target within its cover volume; it may be used either as a 3-D air defence station or as a heightfinder.

The equipment consists, in the main, of an antenna system and dual transmitter/receivers. The antenna system comprises two antennas mounted side-by-side on a common turntable. Both are equipped with a Robinson elevation rapid-scan primary feed. The electronics are cabin-mounted and include two transmitter/receivers operating at a single-knob-controlled variable frequency, and equipped with constant-false-alarm-rate anti-jamming receivers. These solid-state equipments are fully interchangeable. Other features are sidelobe blanking and new-generation technology processing and data extraction facilities which result in high precision and resistance to ECM.

The Volex IV radar is intended to feed an automatic exploitation system housed in the same cabin as the transmitter/receiver. Heightfinding accuracy is ±460 m at a range of 240 km.

The earlier Volex III radar (**2160.153**) was described in previous editions of *Jane's Weapon Systems*, and certain successful features of this design are retained in the Volex IV which is also more fully described in previous editions.

Volex IV 3-D radar TRS 2206 in its fixed site configuration

STATUS

No longer in production.

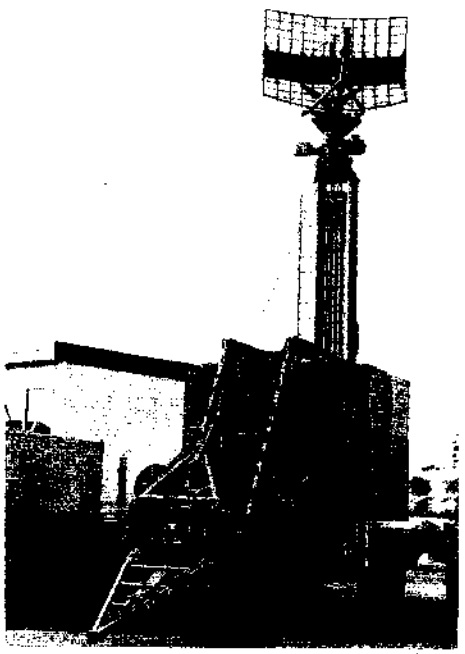
2156.153
TIGER RADAR TRS 2100 SERIES



Under the code name TIGER (terrifically insensitive to ground effect radar), Thomson-CSF has developed a family of lightweight high-performance radars, the first being the TRS 2100 for the detection of low-flying aircraft. A special version is produced for the French Air Force, designated Aladin. High performance in severe clutter is achieved by the simultaneous use of MTI circuits based on doppler frequency filtering and of pulse compression to limit the volume in which clutter echoes can mix with useful echoes. The radar can be used either as an autonomous detection centre, with local exploitation of radar data, or as a gap-filler station linked to an air defence network. Specific operational functions listed by the manufacturer include: control of tactical operations; low-altitude gap-filler; coastal and maritime surveillance; alert and target designation for SAM batteries; surveillance radar equipment role; and similar mobile or air-transportable applications.

The use of E/F-band makes it possible to have an antenna with a high gain and high angular resolution but with a relatively small reflector (5 × 2·3 m). The reflector profile is C-shaped with a double curvature and the vertical pattern has a steep slope at low elevations and is super-cosecanted at high elevations. An IFF sub-system is incorporated (IFF antenna integral with primary radar antenna) and a BITE facility monitors the main parameters and locates any faulty functions.

The transmitter uses a coherent amplifier chain. The transmission frequency is obtained from a highly stabilised crystal oscillator, and for frequency agility purposes transmission is carried out at different frequencies distributed at random over 200 MHz. The output power is provided by three successive amplifier stages (one transistor stage, one TWT stage, and one CFA stage). The phase stability of this chain is such as to ensure good clutter rejection

Tiger mobile radar

TRS 2106 mobile radar

performance. Pulse compression is achieved by incorporating crystal dispersive networks, the propagation time of which varies with the frequency in the transmit and receive circuits.

The receiver is preceded by a wide-band, low noise RF amplifier. Rejection of fixed echoes is obtained by a digital linear MTI. A constant-false-alarm-rate chain operates with the MTI processing chain.

The radar head can be linked by either a single coaxial cable or microwave link to a remotely sited operations unit. Utilisation can be manual, semi-automatic or fully automatic.

Other members of the TIGER family are the C-band TRS 2105 and TRS 2106 which are intended respectively for the detection of low-flying aircraft and alert and co-ordination to SAM and AA weapons.

OPERATION

The radar is transportable by helicopter or by conventional truck or cargo aircraft. The transmitter/receiver and antenna are mounted on a trailer. The antenna can also be mounted on a mast (14 or 54 m).

CHARACTERISTICS

Tiger S

Operational performance: On 2 m² (fluctuating target) with Pd=80%

Detection range: 120 km

Altitude detection: >6000 m

Elevation pattern: Cosecanted up to 45°

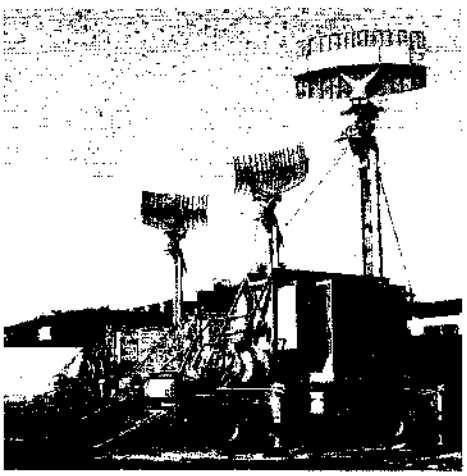
Sub-clutter visibility: >40 dB

First blind speed: >1500 knots

Antenna characteristics

Size: 5 × 2·3 m. IFF antenna integrated with primary radar antenna

Gain: 34 dB



Polarisation: Circular, fixed

Rotation speed: 12 rpm

Transmitter/receiver characteristics

Frequency range: 550 MHz.in E/F-band

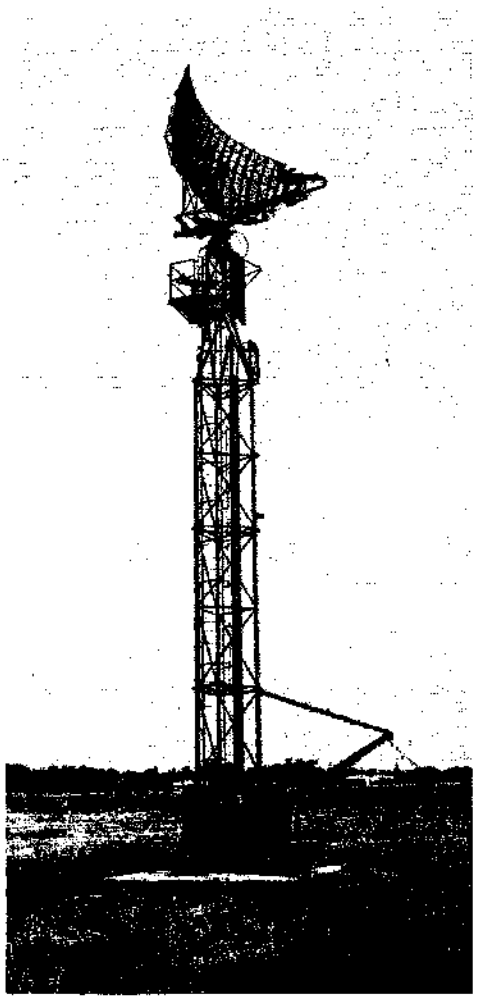
Mean power: 800 W

TRS 2105 mobile radar

Overall receiver noise figure: <3·5 dB

Frequency-agile using synthesiser; dual-PRF operating mode; linear 3-memory DMTI filter; CFAR; post-detection integration circuits.

Tiger G	**TRS 2105**	**TRS 2106**
Detection range	65 - 100 km	35 - 70 km
Data renewal rate	6 - 12 s	1·5 - 5 s
Frequency band	5·00 MHz in G-band	



High capacity automatic data processing, automatic initialisation of tracking.

STATUS

In production for French Air Force (Aladin) and a number of other governments including Egypt and Zaire.

SIEMENS MILITARY RADARS

Siemens-Albis Fire Control Radar

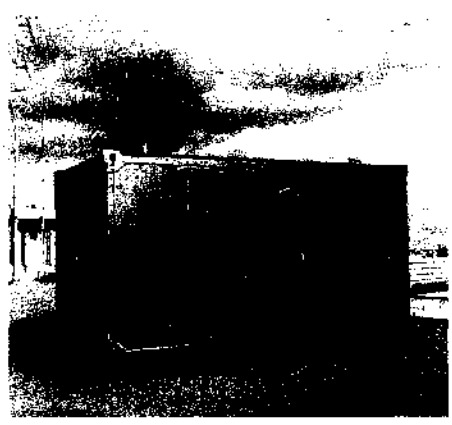
This J-band tracking radar was developed by Siemens-Albis Ltd for use in the Oerlikon-Contraves Type B2 version of the 35 mm AA Gepard tank (**2370.131** in 1977 and earlier editions). A monopulse pulse-doppler equipment, it has an operating range of 15 km and permanent echo rejection of better than 23 dB. In this application it is used in conjunction with the MPDR 12.

MPDR 12

The MPDR 12 is the acquisition radar of the Gepard AA tank Mk3. It is an E-band pulse-doppler radar with high sub-clutter visibility and high data rate (60 rpm). The system is integrated with the MSR 400 interrogator for IFF.

MPDR 16

This is the search radar used in the Roland mobile surface-to-air missile system (**2218.131**) and is a pulse doppler equipment operating in the D-band. The minimum and maximum target acquisition ranges are 1·5 and 16·5 km respectively. The 2 × 1 m antenna rotates at a rate of 60 rpm and is of cosec²-type. An integrated IFF facility is provided, using an MSR 400 interrogator.



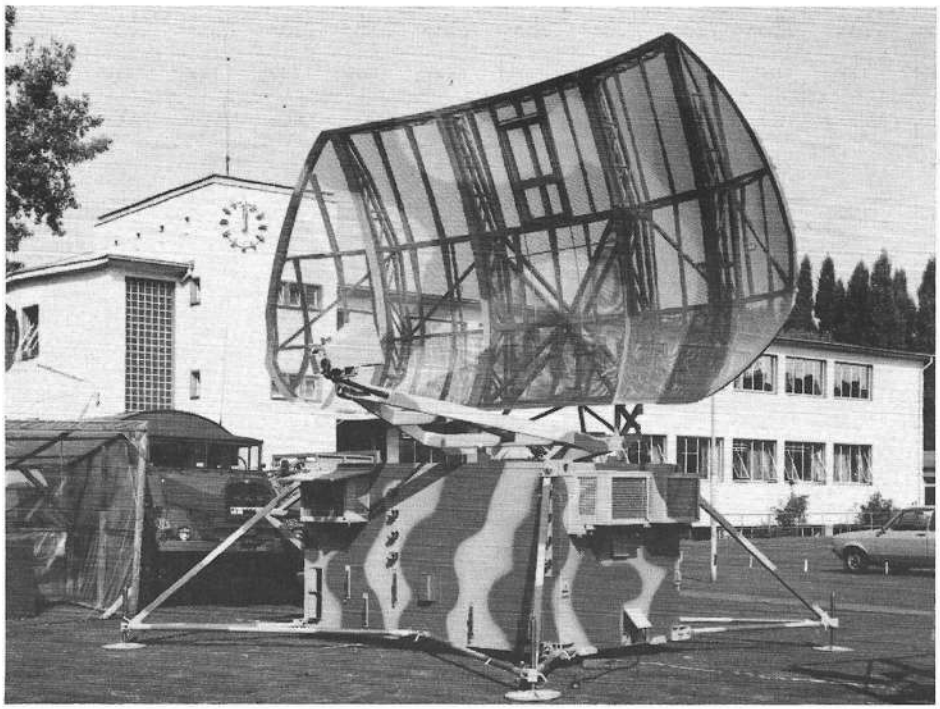
The doppler processor eliminates ground clutter. The extractor generates radar plots and feeds the computer of the associated tracking radar with azimuth, range and IFF response.

DR 621/641 (former MPDR 18X/MPDR 30X)

These I-band pulse doppler search radars are multiple application radars for the detection of low and very low flying aircraft and helicopters. Due to their construction, the systems can be installed in shelters, vehicles, tanks (eg Wildcat) and ships. The systems can be used as acquisition and target designation radars (DR 621) in automatic weapon systems, and as radar sensors (DR 641), in site defence systems. They can also be expanded to form command and control centres by adding data processing equipment and display.

MPDR 30

The MPDR 30 is a short-range D-band air surveillance radar with a range of some 30 km and operating in a pulse-doppler mode for use in mobile air defence networks. The West German Air Force employs these radars, in the TMLD system to provide a low level surveillance capability in support of the national air defence system. The radar is mounted on a five-ton truck chassis, the antenna being supported by a folding extensible mast which gives an effective increase in operating height of up to 15 m. The associated displays, electronics, and control facilities are housed within other vehicles which combine with the radar truck to form a mobile radar belt.



Siemens DR 621 radar in shelter-housed configuration

B2 version of 35 mm Flakpanzer Gepard showing Siemens-Albis fire control radar and MPDR 12 acquisition radar

Siemens DR 151/DR 161 on a truck

Siemens DR 172 (antenna shelter)

DR 151 (former MPDR 45E)
The DR 151 is an improved version of the MPDR 30 radar, in which the range is extended to 45 km. Other improvements include signal processing, ECCM, mechanical design etc. The system is mounted on one truck together with an 18 m extensible mast. The DR 153 is another version of this radar.

DR 161 (former MPDR 60)
The DR 161 is equivalent to the DR 151, but with range capability extended to 60 km.

DR 172 (former MPDR 90E)
Using a larger scanner and a higher sensitivity receiver in addition to a number of other modifications (eg frequency diversity) the range of the DR 151 can be extended to 90 km (instrumented range to 140 km). This radar can be stowed in two transportable shelters and is particularly suitable for airspace surveillance for airfields and in the SILLACS system (**4275.181**).

MPDR 3002 S
This is a medium-range E-band radar for air surveillance, used by the West German Army. It is equipped with a folding antenna mast mounted on a Marder tank chassis. Range is approximately 30 km.

DII 211 (former MSR 400)
The DII 211 is an IFF-interrogator for use in mobile short- and medium-range radar systems. The equipment employs passive decoding and can be equipped for active decoding. It is compatible with Mk X SIF and Mk XII techniques. Known applications include the Gepard AA tank mentioned above. The DII 211 is compatible with all low level radars of the MPDR series, MPDR 30/1, MPDR 16 (Roland), MPDR 3002 S, DR 151 and DR 161.

DII 111/DII 511 (former MSR 200/MSR 2000)
The DII 111 and DII 511 are parts of a new lightweight IFF-equipment family. They employ modern, fully solid-state technology.

The DII 111 is a compact mobile IFF-interrogator for use in short- and medium-range radar systems. The interrogator employs passive decoding (including civil and military emergency decoding as options) in compliance with STANAG 5017, ie it is compatible with Mk X-A and, if applicable, with Mk XII techniques. Applications thus far are in Wildcat (with radar MPDR 18/30X) and in the mobile radar system Reporter (produced by Hollandse Signaalapparaten BV).

The IFF/SSR-interrogator DII 511 is suitable for all applications in civil and military air traffic control systems. The DII 511 is a more powerful IFF-interrogator for use with larger, long-range radar and weapon systems (ground- or ship-borne).

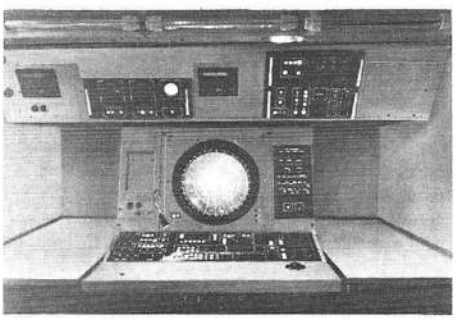
Siemens AG, Postfach 70074, 8000 Munich, Federal Republic of Germany.

5762.193
SIEMENS ARTILLERY SURVEILLANCE RADAR

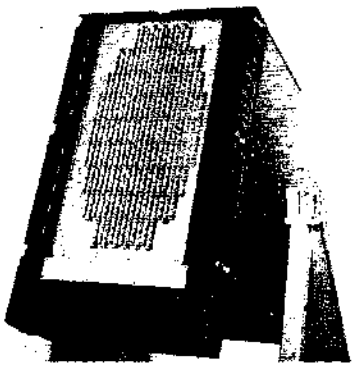
Siemens has signed a co-operation agreement with General Electric of the USA to make a joint bid for the development of a mobile artillery surveillance radar to replace the Green Archer system currently in operational use with the Federal German Army. The equipment is designed to detect, track and locate the source of artillery shells so that the necessary action can be taken.

The proposed system employs the latest technologies, has a C-band, fully phased array antenna and is designed to have a high location rate and accuracy as well as mobility. The radar will detect, track and identify enemy and own shells and from the data obtained it will compute the source and impact of enemy shells and the impact point of own shells. It employs a pencil beam following the horizon to detect the shells, and separate radiators to track them. The complete system is mounted on a 7-ton truck.



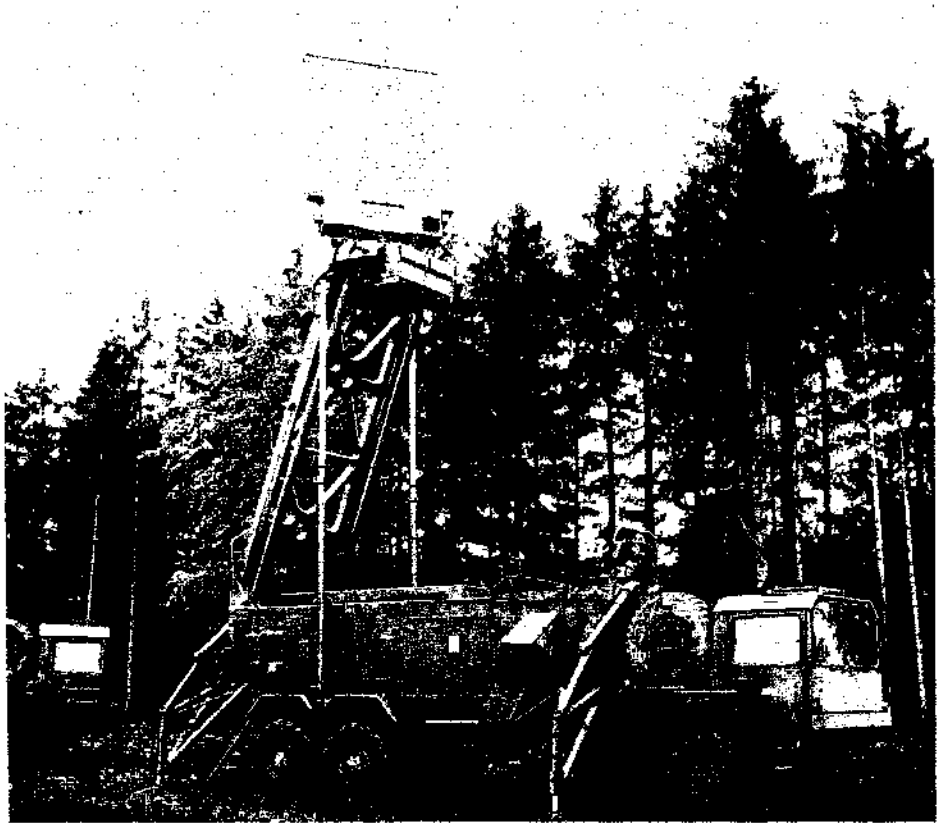
STATUS
The Siemens/General Electric team is carrying out a definition study on the proposed system.

CONTRACTOR
Siemens AG, ZVW 142, Hofmannstrasse 51, 800 Munich 70, Federal Republic of Germany.



3016.153
TRMS RADAR

The designation TRMS refers to the Telefunken radar, mobile search, a 5 cm wavelength system being manufactured by AEG-Telefunken under contract to the West German Ministry of Defence. The objective underlying the TRMS project was to develop a radar system providing the capacity for detecting and identifying targets independently of interference factors and rapidly changing air situations. TRMS is characterised by combined surveillance and heightfinding capabilities. Combining the surveillance and heightfinding characteristics renders the system especially suitable for coverage of low-flying aircraft and for use in topographically difficult terrain. The radar is capable of automatic tracking and identification in a rigorous environment with natural and intentional interference factors. The system reliably accomplishes practically continuous coverage of all aircraft movements. Moreover, if used as a coastal radar it detects sea targets also in the presence of strong sea clutter. Maximum range is stated to be 110 nautical miles (200 km) for a 3 m^2 target, with altitude coverage up to 20 000 m (65 000 ft).



The TRMS incorporates facilities for digital data processing to the extent that it is appropriate to carry out data processing at the radar site. These facilities include special filtering processes which condense and reduce the incoming data volume to such an extent that the entire situation in the air and, if applicable, at sea can be transmitted to the operations

TRMS operator's position and displays

TRMS antenna unit in transit configuration

TRMS unit demonstrating its antenna elevation

centre via one single telephone line. The production of tracks represents an essential filtering process which serves to exclude undesirable and insignificant target information from further processing and transmission.

The TRMS is also suitable for employment as an autonomous centre, being highly mobile, usable in widely spaced locations, ready for operation within the shortest time, and capable of operating rapidly under camouflage and cover. The IFF and SLS antennas are integrated into the array forming one unit.

TRMS is designed to be highly mobile and to allow its antenna to be raised above medium height vegetation. The antenna unit, the shelters with all the electronic equipment as well as the vehicles are designed for heavy-duty military use. Two trucks of the new Bundeswehr vehicle generation with cross-country capability serve as the carriers. One truck accommodates the sensor (radar assembly with antenna, transmitter, receiver, and signal processor), the other truck carries the operations equipment (target extractor, PR/IFF correlator, data and communications buffer, display unit and control panels). Both groups of equipment may be taken off the trucks. Up to a distance of 300 m they are connected by cable: over longer distances wide-band radio links may be installed.

A phased-array antenna is used for the TRMS which rotates mechanically in azimuth while simultaneously providing for step-scanning in elevation with a highly focused beam of circular or elliptic cross-section. The angular width of the beam varies according to the angle of elevation. To achieve a sufficiently high data rate, the pulse repetition frequency, the scanning rate and the beamwidth are adjusted to the search volume. Another feature contributing toward achieving the required data rate is the step-scanning in elevation with moving target indication. In other words, a step-scan MTI is used which, with a few hits, achieves a high improvement factor. Consequently, despite the consecutive 3-D scanning, it was possible with relatively little effort to find a solution which allows normal data rates to be achieved but is not liable to undesirable saturation phenomena.

The principal measure taken against interference of any kind is the selection of a small resolution cell, achieved by means of strong beam focusing and pulse compression. Furthermore, an MTI operating with optional single or double cancellation is available. Also provided is the frequency de-correlation of clutter echoes in the case of sea clutter, and circular polarisation in the case of weather clutter. Mutual interference of two TRMS installations is statistically very unlikely since this would require a common azimuth and elevation angle as well as identical frequency and polarisation. When the antenna was designed importance was attached to obtaining only very small sidelobes in the azimuth and elevation. As regards interference, the first countermeasure is again a high resolution characteristic in conjunction with frequency agility and high average transmitter power. Various operating modes of different data rates allow for further adjustments with regard to electronic threats. This variety of measures enables the TRMS to eliminate both natural interference and clutter and ECM to a large extent.

The operator's position is designed for one to three radar operators. From here the entire system including the offset sensor assembly is controlled. The functioning of the equipment is monitored at the indicator panel of the automatic self-test feature and through the performance monitor. This allows the operators to be easily and directly informed as to the state and efficiency of the equipment. For supervision within the area of coverage of the TRMS installation, a synthetic video display is available at which the ECM situation and the countermeasures selected in each case may be observed.

Targets are displayed on a computer-controlled 16-inch (406 mm) radar indicator in either analogue or digital form. The following information may be shown simultaneously on the analogue display: PR video, IFF video, PR and IFF jamming markers and five concentric range rings. The synthetic display comprises various geometric target and marking symbols. As a maximum the following functions may be displayed simultaneously: six height layers distinguished by symbol shape, target track with maximum five history position dots, IFF and code designation by five-digit labels (alpha-numeric), and target identity by symbol shape. The synthetic display may be supplemented by an analogue video background. A rolling ball is used for various purposes as, for example, the control of a measuring marker or the de-centring of the radar display up to the coverage limit.

In order to comply with the different requirements of different users, great importance was attached to making the TRMS flexible and expansible. This has been achieved on the one hand by the modular structure of the system, on the other hand by the provision of a freely programmable digital control system and adaptable software on the evaluation side. It is thus possible not only to program the antenna for different beamwidths at freely selectable angles of radiation, but also the synchronising pulse generator in respect of frequency and polarisation, pulse repetition and staggering times, pulse lengths and STC pattern. The digital MTI can be switched from single to double cancellation. For naval applications a special addition to the digital target extractor allows for automatic detection of sea targets as a result of the reduction of undesirable echoes due to sea clutter.

STATUS

Evaluation and field testing of TRMS prototype by the German Procurement Agency (BWB) was finished successfully in 1980, but orders have not yet been received. AEG is promoting the equipment in the overseas market but no orders have been notified.

WIMERA TRACKING RADAR

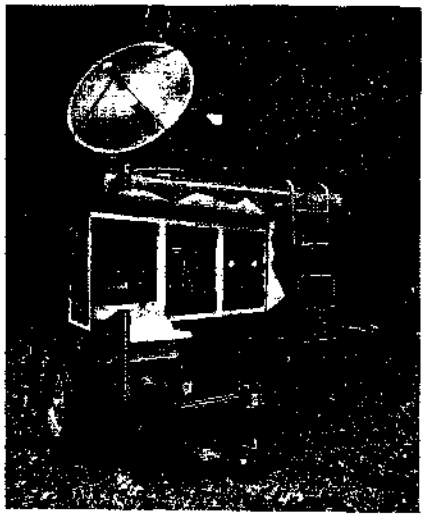
The Wimera tracking radar is a mobile balloon tracking radar currently in use with various armed forces. Wimera's wide operational scope necessitated modular construction and high mobility. It provides all the meteorological data necessary to compile complete weather reports, eg for field artillery, air forces and tactical staffs. The Wimera equipment has three components: radar, radiosonde system and computer.

All modules are housed in a compact shelter which enables operation in any terrain independent of the weather. The system requires only one operator. After a change of location, the Wimera can be fully operational again in only 15 minutes, and only two men are required to set up and level the radar units.

Target acquisition incorporates pre-selection facilities for various functions:

(1) optical target assignment
(2) spiral scanning
(3) sector scanning
(4) manual target assignment.

After the target has been acquired, the Wimera system self-switches to automatic target tracking. The radar data are indicated in digital form and printed out. Together with the data received from the radiosonde, (eg temperature, air pressure, humidity), a complete weather report can be transmitted by wire or radio.



A drone tracking version integrates two Wimera units into one system in order to guarantee exact control and recording of drone flight paths.

CHARACTERISTICS

Frequency: fixed, 9375 MHz
Peak power: 140 kW
Pulse length: 0·1/1 μs selectable
PRF: 1000/2000 Hz
IF: 60 MHz

Antenna diameter: 1200 mm
Antenna gain: 38·5 dB
Beamwidth: 1·8°
Polarisation: Linear
Range: 120 km
Acquisition range: ⩾40 m minimum
Tracking accuracy: ±10 m (range); ±1·5 mils (angle)
Scan frequency: 30 Hz

STATUS
In production.

5613.153
METEOR 300 WEATHER RADAR SYSTEM
Meteor 300 is a weather radar system suitable for both military and civil applications, as an analysis radar or a fully automated balloon tracking system for measurement of wind.

The analysis mode, provided by Meteor 300A, detects and evaluates precipitation areas in the atmosphere and also measures and presents their extent, position, height, intensity, direction of movement, speed and distance up to 400 km. The balloon tracking mode, provided by Meteor 300W, tracks and calculates elevation, azimuth and slant range. This data is then processed by a computer to obtain a profile of the upper wind structure in terms of speed and direction.

Meteor 300 systems are available for X-, C- or S-bands. The assemblies are designed with modular components for ease of servicing. No radome is required for the antenna. As an option, antennas may be equipped with different sized parabolic reflectors for diverse applications.

The systems are available in a mobile configuration (mounted on a vehicle or trailer), transportable version (installed in a shelter) or as a fixed installation. The equipment can also be modified to a fully computer-controlled digital windfinding system, including computer-stabilised antenna for pitch, roll and yaw, for shipborne applications.

INTERNATIONAL

1528.153
RATAC BATTLEFIELD RADAR
RATAC (*radar de tir pour l'artillerie de campagne*) is a lightweight (eight cabinets of 35 kg, or less, each) battlefield radar providing for detection, acquisition, identification, location, and tracking of surface targets such as troops, tanks, vehicles, low-flying helicopters and light aircraft. Other operational functions include artillery direction, surveillance of own forces, and helicopter control. It is comprised of six units and is designed for vehicle mounting. Pulse-doppler and monopulse techniques are employed and the operating frequency is in the 5 cm wavelength region. A highly effective fixed target cancellation system is said to make it possible to locate very slow moving targets with a small radar cross-section, such as a single man. Detection ranges are reported to be better than 15 km against vehicles and 8 km against troops, with an accuracy of 10 and 20 m in surveillance. Good all-weather performance is claimed.

The system incorporates its own computer, and target data can be presented in terms of either polar or grid co-ordinates. An optional plotting board unit permits target positions and movements to be recorded. A loudspeaker is provided to aid target identification by listening to the doppler characteristics of targets. Automatic target tracking facilities are included, and there are provisions for the transmission of data to own artillery. Operation with vehicle installed IFF is a possible option.

DEVELOPMENT
Development of RATAC was undertaken by LCT (Laboratoire Central de Télécommunications) under the direction of the French military authority, in 1966. A subsequent agreement between the French and West German governments provided for joint procurement and production for the armies of both countries. Tests were later carried out by the US Army at Fort Sill.

STATUS
RATAC is in service in France, West Germany, the USA and several other countries. Production in the USA was undertaken by ITT-Gilfillan under the nomenclature AN/TPS-58.

EL/M-2121 BATTLEFIELD SURVEILLANCE RADAR
The EL/M-2121 intelligence battlefield surveillance radar has been developed by Elta as an all-weather, mobile, very long range ground surveillance radar capable of detecting, locating and classifying targets moving on or near the ground in any type of weather or time of day/night.

One of the principal uses of the EL/M-2121 is for reconnaissance troops at ground observation posts to provide continuous surveillance and real-time information on activities of enemy forces deep behind the front line. The two operators can choose operational modes as follows:

(a) general continuous search - 360° PPI scan for location and designation of targets
(b) sector scan - angular sector scan to expand selected area
(c) zoom – B-scan display allows greater expansion and finer resolution of target range and azimuth
(d) identification mode - spectrum analysis of target doppler signal.

The complete system can be used as a transportable equipment with the radar and control equipment in a military centre, or divided with a fixed control centre operating a remote radar head. The antenna normally rotates continuously through 360° but can also carry out sector scans, or be pointed at designated targets.

The equipment is of modular construction and employs quadrature (I/Q) digital processing. A strong ECCM capability has been incorporated. It is microprocessor controlled and provides the operator

with an eight-colour TV multi-mode display on a 19-inch screen. Built-in expansion options include the ability to be interfaced with other computers to process signals and data.

CHARACTERISTICS

Detection ranges

Pedestrian: 20 km (0·1 m² target)
Small vehicle: 40 km (1 m² target)
Medium size truck: 70 km (10 m² target)
Large truck: 120 km (100 m² target)
Accuracy: Range 15 m; azimuth 0·1°
Resolution: Range 15 m; azimuth 0·3°

STATUS

In production.

EL/M-2215 AND -2216 SURVEILLANCE RADARS

The Elta EL/M-2215 is a general-purpose surveillance radar, evolved from the successful EL/M-2205 search radar (**1958.153**), and many of the engineering features of the latter radar have been retained in its successor. Improvements made possible by advances in the state-of-the-art have been incorporated, such as more elaborate signal processing facilities and increased transmitter output power. The transmitter/receiver is a redesigned and repackaged version of the former EL/M-2205. Modular design allows the second-generation EL/M-2215 to be configured in either single or dual transmitter/receiver versions, the latter offering a further choice between a dual-channel arrangement for redundancy or dual-channel with diversity operation. Other features include high resolution; a dual high/low-beam antenna; high clutter suppression; quadrature (I/Q) digital MTI; and fast frequency tuning.

The EL/M-2215 employs the AT-103 single beam antenna (as used in the EL/M-2205) or the AT-104 dual high/low-beam antenna. It may also be used with the AT-102 antenna to form the EL/M-2216 coastal radar for surface and low air cover search applications.

CHARACTERISTICS

Transmitter

Frequency: 3·1 – 3·3 GHz (2·7 – 2·9 GHz optional)
Output power: 425 kW peak
Pulse width: 0·95 μs (selectable 0·95 or 0·4 μs for EL/M-2216)
PRF: Fixed 1 of 4, or 4 staggered 900 – 1050 pps (1340 – 1560 pps for EL/M-2216 short pulse)

EL/M-2220 MOBILE SURVEILLANCE RADAR

Another variant of the EL/M-2215 (**3708.153**) is the EL/M-2220, a 2-D mobile air search and surveillance radar designed for tactical aircraft control, AA defence, or as a gap-filler. It features high clutter suppression, quadrature digital MTI, redundancy or dual-channel with diversity and improved signal processing.

Three versions of the system are available:

(a) EL/M-2220F for mobile fast deployment, comprising a S-280 shelter containing an EL/M-2215 transceiver, a 16-inch operator display console, and a small lightweight radar and I-F antenna mounted on top of the shelter. The EL/M-2220F can be deployed within 30 minutes
(b) EL/M-2220S for mobile air surveillance comprising an S-280 shelter containing an EL/M-2215 transceiver and a 16-inch display console, with an AT-103 large antenna on a towable platform

EL/M-2220 mobile air surveillance radar

(c) EL/M-2220D for long-range mobile surveillance which consists of two shelters, one containing two EL/M-2215 transceivers (dual-channel), the other housing two consoles; plus an AT-103 antenna on a towable platform.

CHARACTERISTICS

Frequency: 3·1 - 3·3 GHz (2·7 - 2·9 GHz optional)
Output power: 425 kW, peak
Pulse width: 0·95/1·4 μs
PRF: 1000/750 Hz, 4 staggered or random variable

Operation	EL/M-2220D	EL/M-2220S	EL/M-2220F
Detection range	80 nm	60 nm	30 nm

3646.153
EL/M-2106 POINT DEFENCE ALERT RADAR

The Elta EL/M-2106 point defence alert radar is designed to provide an early warning capability for anti-aircraft emplacements and forward installations. The EL/M-2106 is a portable battlefield radar that can also be used in such applications as target acquisition for surface-to-air missile systems and AA guns, as well as gap-filling roles.

The operating frequency is in the D-band (former L-band) of the spectrum, and typical detection range performance is about 16 km for fixed-wing aircraft and 10 km for helicopters (2 m² targets). Aural and visual warning of aircraft approach is given to the operator, and conventional scanning through 360° is normally provided, but a programmed sector scan with sweep-to-sweep memory is also available. The radar may also be remotely controlled from distances up to 100 metres.

The system is comprised of a transmitter, receiver, antenna assembly and display unit, and the entire installation breaks down into easily carried man-portable units. It can be set up in less than ten minutes and can be operated by one man with only minimal training.

The EL/M-2106H version is able to detect helicopters in movement or hovering. A processing channel analyses the signal reflected from the rotor blades while the helicopter is hovering and can differentiate between fixed-wing aircraft and helicopters in flight.

The EL/M-2106H is also designed to be fully operational in a moving vehicle such as an armoured car. A special mast mounted on the vehicle enables different deployment heights according to the geographical and tactical environment. The antenna is a cut-down version measuring 120 × 50 cm and weighing 19 kg.

EL/M-2106H radar mounted in an armoured car

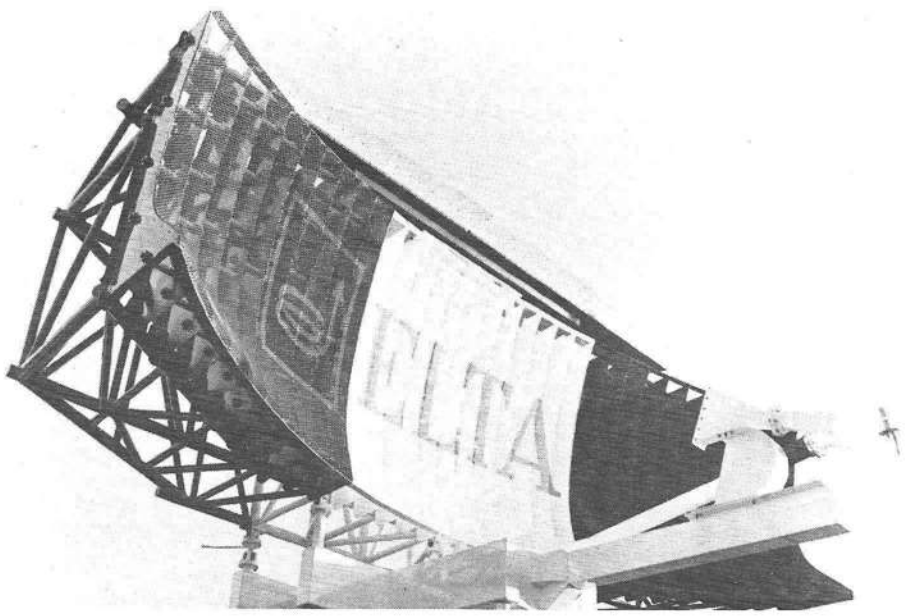
CHARACTERISTICS
(EL/M-2106H)

Transmitter/receiver frequency: D-band
Peak power: 150 W
Average power: 10 W
Pulsewidth: 6·6 or 13·3 μs
PRF: 8 or 16 kHz
Range gates: 10
MTI improvement factor: 50 dB
Dimensions: 40 × 26 × 33 cm
Weight: 26 kg
Antenna dimensions: 200 × 80 cm
Weight: 55 kg (including stand and pedestal)
Gain: 23 dB
Horizontal beamwidth: 5° (8° for EL/M-2106H)
Vertical beamwidth: 17°
Display: Synthetic with sweep memory. For each range gate, concentric circle of 36 LEDs. Indication of antenna position
Azimuth presentation: LED at 10° intervals
Range presentation: LED range circles spaced at 1 or 2 km intervals, giving max range of 10 or 20 km, selectable

STATUS

Production. A licenced version, known as Sentry, is being produced by the Astronics Division of Lear Siegler, USA (**5777.153**).

CONTRACTOR



Elta Electronics Industries Ltd (a subsidiary of Israel Aircraft Industries Ltd), Ashdod, Israel.

ELTA SURFACE RADARS

Elta Electronics Ltd produces a range of surface radars for ATC, search and acquisition, and similar applications, with fixed and land-mobile systems for surveillance roles, coastal protection etc.

The base model for most of this equipment, which is built on a modular design concept, is the EL/M-2205, and unless otherwise stated the following text relates to this model. (The current range is now based on the EL/M-2215 (**3708.153**) a modernised and improved version of the EL/M-2205.) Other models are the surface and low air cover search radar, EL/M-2206 and the coastal surveillance radar EL/M-2216XH which both employ the AT-102 antenna in place of the AT-103 used in the EL/M-2205, the EL/M-2220 mobile air surveillance radar (**4606.153**), and the naval version EL/M-2207 (**3264.253**) and EL/M-2208. All versions are constructed to conform to the MIL-E-16400 specification and are provided with BITE. Conventional PPI displays or synthetic (raster-type) displays are available for use with all models. Integrated IFF is available as an option and is used in military models. A high performance, compact, and lightweight E/F-band transceiver forms the basic building block, and two of these units may be operated together in dual diversity. Receiver models available include: linear with switchable STC, FTC, IAGC, Log-FTC-Antilog, CFAR. There is single-knob tuning of the transmitter frequency between 3·1 and 3·3 GHz, and a stable synthesiser enabling the whole equipment to cover this band in less than 20 seconds, in the EL/M-2206 version.

More details of the characteristics of this radar are given in previous editions of *Jane's Weapon Systems*.

Elta EL/M-2205 search radar scanner AT-103 with on-mounted IFF

STATUS

Unspecified models of the EL/M-2200 series are stated to be in service in Israel and elsewhere.

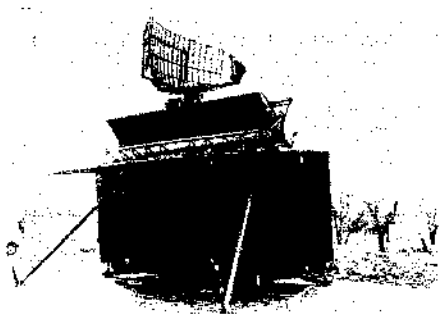
MM/SPQ-3 COASTAL RADARS

The SPQ-3 series of radars comprises a variety of equipment conbinations, centred on co-mounted I/J-band and E/F-band radars, configured to produce sets appropriate to coastal surveillance and harbour surveillance functions and related applications. The system is transportable by trucks or helicopters, and is generally intended to be integrated in larger defence control networks. The complete equipment is housed within two cabins, plus a trailer motor-generated power supply unit. The first cabin contains the two radar transmitter/receivers, and the associated antennas which are mounted on top can be folded inside for transport. The second cabin contains the operational part of the system, such as displays, processing unit, video recorder, and plotting table. The electronic recording system can be independently connected to the I/J-band or to the E/F-band radar, and is based on processing radar data (range scale, antenna speed, bearing etc) by means of a TV scan converter and connecting these to a magnetic recorder. Restitution of stored data is obtained by connecting the magnetic recorder output data to a TV-type display. Remote and local control facilities are provided.

The principal operational roles are medium to long range detection of air attack or of combined air/seaborne assaults by means of the E/F-band radar; and close to medium range surface surveillance by means of the I/J-band radar to assist defence against surface craft attack, landings etc. In the SPQ-3B version, a special feature is the detection and location of the splashes caused by air-dropped mines in harbours or confined waters.

Features of the E/F-band radar include: variable-frequency transmission; random PRF; high directivity antenna pattern; Dicke-fix IF receiver; and linear-logarithmic IF receiver. The I/J-band equipment has most of these features with the exception of the Dicke-fix, and two back-to-back antennas as compared with the single horn-fed parabolic reflector of the E/F-band unit. Both are essentially very high image resolution systems with low average emitting power, particularly suitable for operation (by means of frequency and polarisation decorrelation) in high traffic density environments. Sector transmission is possible.



Scan converter displays are provided and there are facilities for video recording and replay. Digital and analogue format remote data transmission outputs are available.

STATUS
Production.

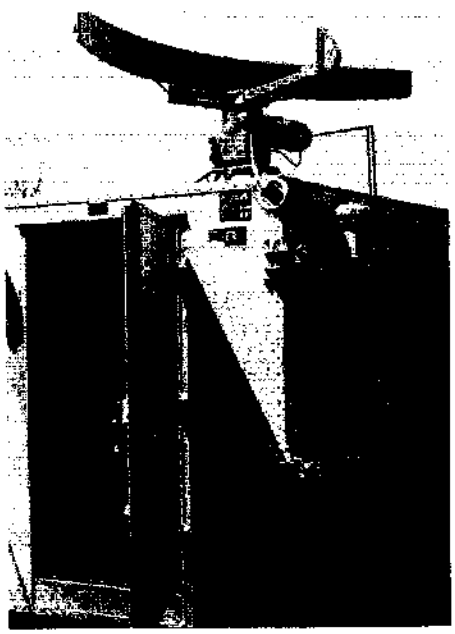
HSS-1 HARBOUR SURVEILLANCE RADAR



The HSS-1 harbour surveillance radar system is essentially a very high resolution equipment with a low emiting power, which is particularly suitable for operation (thanks to frequency and polarisation de-correlation techniques) in high traffic density environments (eg. harbours, river estuaries or restricted channels) or as a precaution against infiltration etc.

The system is characterised by a very narrow beam antenna system, X-band frequency diversity operation, a dedicated anti-clutter video processing channel, and a semi-mobile equipment configuration. (See illustration.)

STATUS
Currently in production for undisclosed customers.

LPD-20 SEARCH RADAR

The LPD-20 is a search and acquisition radar developed to counter air threats from low- and very low-level targets in the region below the useful coverage of other radars. Two basic versions have been designed:

(1) Integrated version: The radar can easily be fitted into the Contraves Super Fledermaus family of fire control systems. This simplest arrangement employs the PPI display as the fire control system, so that the search radar is unattended and a single operator is able to control the complete radar system for both search and tracking of targets
(2) Autonomous version: The LPD-20 used as an autonomous radar set is equipped with a separate PPI display, for alerting light AA weapons (guns or very short-range SAM) for different purposes (target designation to light unslaved AA artillery emplacements, low and very low altitude surveillance, etc).

To provide additional operator safety, the PPI display (where remote control of the radar set also takes place) may be sited in a protected and defiladed position, at a distance up to 100 m from the radar site.

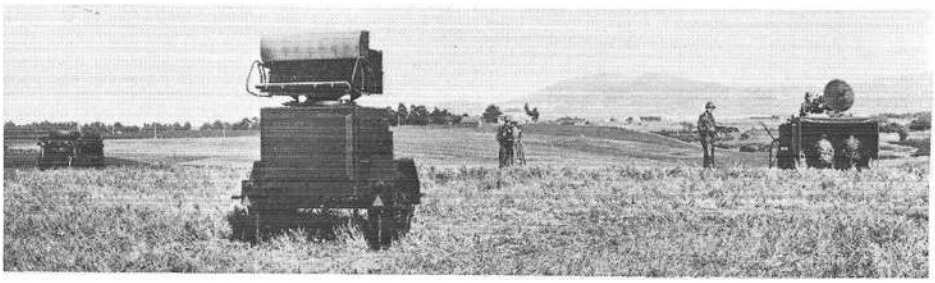
IFF facilities are also integrated into the radar system. Contraves Italiana SpA in September 1974 concluded an agreement with Cossor Electronics Ltd by which integrated IFF facilities produced by the UK firm can be provided as a customer option for LPD-20 systems.

The main parts of the radar are:

(1) a rotating section, comprising antenna, transmitter/receiver, signal processor, and modulator
(2) turning gear
(3) a cabin containing power supplies and operational controls
(4) trailer chassis.

System weight (trailer version) is 2500 kg.

The LPD-20 is a fully coherent pulse-doppler radar. An MTI improvement factor of better than 50 dB is claimed, together with a detection range of about 20 km on targets travelling at speeds between 20 and 410 m/s at heights up to 4000 m. Angular resolution is of the order of 1·4° and range resolution about 500 m. Rapid reaction to sudden low-level threats is aided by a high data rate, the use of a common PPI for search and fire control, accurate target range and azimuth



designation data and transfer from search radar to fire control radar in two to three seconds. Provision is made for the incorporation of IFF Mk 10/SIF facilities into the basic LPD-20 radar. Furthermore, as an optional alternative to the autonomous version, an automatic air target data distribution and display system can be provided, which allows forwarding of target data information to other users. This system consists of a data distribution unit (TD/TU) built into the display unit and a unit for the reception and display of air targets data (TD/DU) which is associated with the user's weapon or weapons.

Numerical data corresponding to target position and identification (polar or cartesian co-ordinates and IFF) is transmitted by the TD/TU (FSK modulator and buffer amplifier) through a two-wire field telephone line or radio link to the user's TD/DU (filter and demodulator), where it is displayed in numerical form. A maximum of three targets can be handled simultaneously by the system. Maximum range of telephone transmission amounts to about 5 km. The TD/DU is provided with autonomous supply (rechargeable DC battery). Data transmission is uni-directional (from display unit to weapons).

STATUS

The radar has undergone rigorous field tests in Italy and elsewhere and is now in series production. Although detailed information has not been released, this system is known to be widely used in many parts of the world. Over 150 units have been produced.

Current production of the Super Fledermaus fire control system (**2376.151**) incorporates modifications to enable it to be associated with the LPD-20.

Typical deployment of Super Fledermaus fire control system with LPD-20 radar (integrated version)

ALERTER RADAR

The Alerter pulse doppler search/acquisition radar and command post system was developed by Contraves for air surveillance at low altitude and the co-ordination and control of associated weapon systems.

The following specific tasks are performed:

Automatic detection of targets at low and very low altitude either in a fixed position or on the move

Target identification

Threat evaluation

Automatic assignment of targets to a maximum of 12 targets

Simultaneous engagement of 12 targets

Control and co-ordination of the operational status of the weapon systems

Exchange of data with other battlefield radars and easy integration into a higher level air defence system.

Alerter comprises the following basic units: shelter cabin and operational console with computer radar indicator; cradle with telescopic antenna mast; and power generator.

The system is installed on the M548/6 carrier vehicle; all parts are mounted on a unified mechanical interface structure which makes it possible to install the system easily on other available vehicles.

The antenna can be elevated up to ten metres through its telescopic mast in order to help conceal the vehicle, giving greater flexibility in selecting operational locations.

The shelter is detachable from the carrier vehicle and can be placed in a defiladed position up to 100 metres away, thereby achieving protection against defence suppression systems.

Alerter can be combined as a surveillance and detection radar with any AA guns and SAM systems which do not have their own electronic surveillance sensor. It can also be used as a command and co-ordination post for AA weapon systems connected directly to a higher level air defence centre.

CHARACTERISTICS

Frequency: X-band, frequency agile
Type: Coherent, pulse-doppler, pulse compression
Detection range: Up to 23 km
Processing: TWS, threat evaluation
Presentation: CRI (computer radar indicator)
Transport: Train or helicopter

STATUS

Extensive trials performed successfully with Oerlikon 35 mm self-propelled twin AA gun type GDF-CO2.

CONTRACTOR

Contraves Italiana SpA, Via Affile 102, Via Tiburtina Km 13150, 00131 Rome, Italy.

SHORAR SEARCH RADAR

The short range and acquisition radar (SHORAR) is a search, acquisition and target designation system which has been developed from the Alerter radar (**4018.153**). It is designed for use against medium, low and very low airborne targets and can be installed on a variety of vehicles, such as the M113, M548 etc, and also on two-wheel trailers.

To allow for installation on different types of vehicle, the equipment is designed in three modules: an antenna and transceiver assembly mounted on top of the carrier vehicle, an operations console assembly and an electronic cabinet, the latter two being accommodated inside the vehicle. The radar has been specifically designed as a low power consumption and lightweight system to enable it to be used in a variety of situations.

SHORAR is a fully-coherent X-band pulse-doppler system for high clutter rejection, very low target detection and high azimuth angular discrimination. Doppler filtering and data processing are performed by a digital computer system for flexibility in different scenarios. Track-while-scan and automatic threat evaluation are incorporated, as are multiple target handling and a search-on-move capability.

SHORAR antenna and transceiver assembly

CHARACTERISTICS
Frequency: X-band
Azimuth accuracy: 0·5° rms
Range discrimination: better than 100 m
Antenna scan: 60 rpm
Radial speed range: 16 - 400 m/s
Max range: 17 - 25 km
Overall system weight: 530 kg (1226 lb)

STATUS
In series production.

PLUTO LOW-COVERAGE SURVEILLANCE RADAR

Pluto is a low-coverage surveillance radar for air and coastal defence, designed to detect medium- low- and very low-flying aircraft and small surface vessels under the most adverse environmental conditions (ECM, atmospheric and sea clutter etc). The radar is suitable for fixed and/or mobile installations and can operate either independently or be integrated into a complete defence system. Design features include the following:

Capability to detect and measure the range and azimuth of surface and air targets at medium and low altitudes up to a maximum range of 110 km.

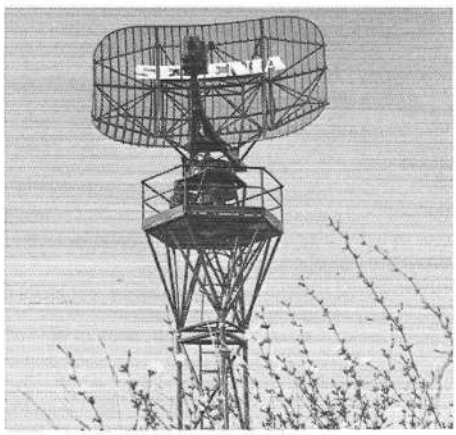
High accuracy and resolution, integral target designation capability and flexibility to interface computer-assisted display and defence systems.

Pulse compression of the radiated waveform with a resultant small scale radar cell size, ie resultant visibility even of very slow moving targets such as small ships (FPB).

Sophisticated ECCM processing with visibility maintained even in presence of heavy active and passive jamming.

Good adaptability and CFAR characteristics under various environmental conditions, ie capability to detect targets and reject interference by automatic evaluation and selection of the best transmisssion and processing configurations.

Capability of operating in frequency-agility from sweep to sweep, with clutter rejection and sub-clutter visibility of moving targets outgoing or incoming at speeds up to Mach 3 by means of sophisticated MTI processing techniques.



Antenna pattern with high directivity and very low sidelobe levels.

Large transmission bandwidth.

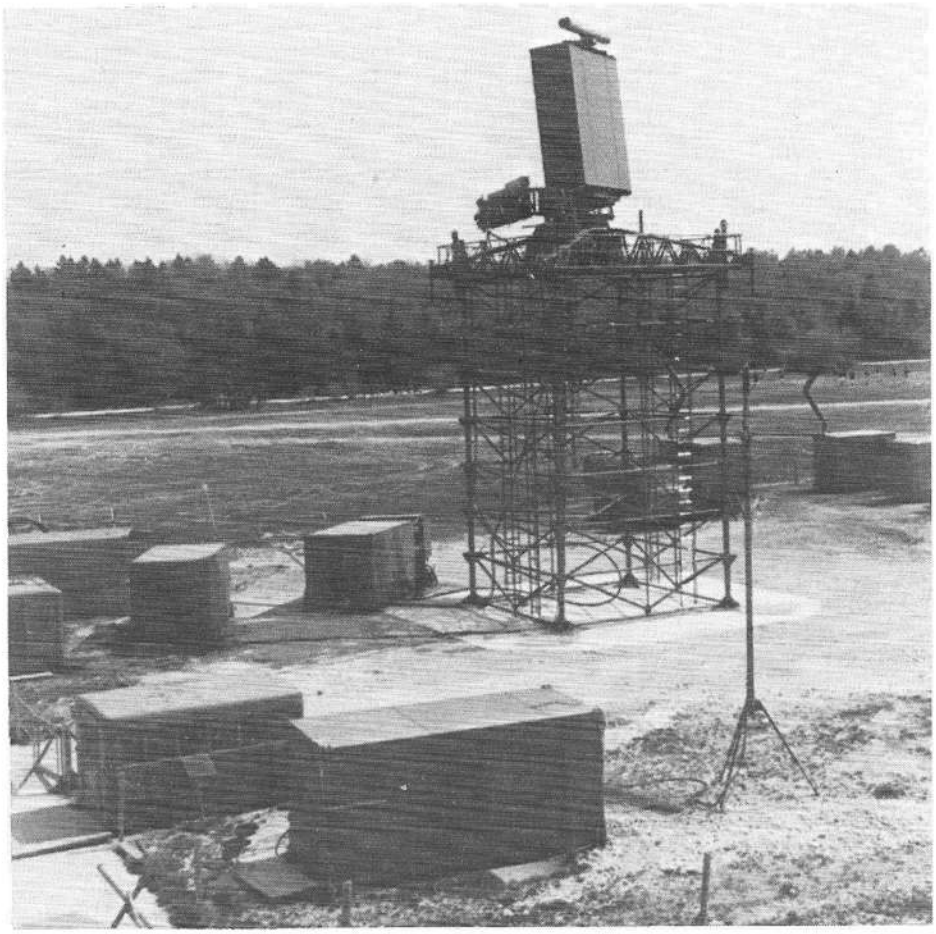
High MTBF and reduced MTTR.

High reliability, maintainability and supportability.

BITE facilities.

Pluto low-coverage radar deployed

CHARACTERISTICS
Antenna
Type: Reflector, feed
Frequency: E/F-band
Polarisation: Horizontal or circular, selectable
Beamwidth: Horizontal 1·5°; vertical 4°
Beam shape: Horizontal - pencil beam; vertical - super-cosec² matched to a very high clutter environment
Scan rate: 15 rpm
Tilt: -2 to +5° adjustable
IFF antenna: Integrated



Transmitter
Type: Coherent chain
Final stage: TWT
Frequency: E/F-band
Bandwidth: 10%
Peak power: 135 kW minimum
Transmitted waveform: Phase coded (code agility)
PRF: Prefixed or random stagger
Operating modes: Fixed frequency; random/pre-programmed frequency agility; adaptive frequency selection (option)
Receiver
Type: Superheterodyne/Dual conversion; RF adaptive clutter attenuator
MTI channel: Linear amplifier
Normal channel: Dicke-fix
Signal processor
Detectors: I & Q phase detectors A/D converters
Anti-clutter filters: MTI processor
MTI velocity response: >Mach 3
Matched filter: Digital
Amplitude detectors: Digital modulus extractor
Azimuth correlator: Moving window and pattern recognition
Jam strobe: Unambiguous azimuth information (option)
Plot extractor
Rate: Compatible with narrow-band transmission
Message format: Programmable
Information: Azimuth, range, quality, decoded
Configuration: 1 shelter plus antenna
Transport: C-130/160, road, rail and helicopter
STATUS
In production.
CONTRACTOR
Selenia-Industrie Elettroniche Associate SpA, Via Tiburtina Km 12400, 00131 Rome, Italy.

1953.153
RAT-31S TRANSPORTABLE 3-D RADAR

The RAT-31S has been designed as a highly mobile three-dimensional radar capable of performing a wide range of operational functions associated with air defence, tactical air applications, and civil/military air traffic control. The construction method employed makes the system equally suitable for air- or land-mobile applications. The system comprises an antenna group, a transmitter shelter, a receiver and signal processing shelter and a primary power supply. The antenna group can be moved by a trailer or by a demountable running gear, which is the preferred method when using C-130 aircraft for transportation. The shelters may be moved by any of the methods complying with NATO STANAG standards.

The operating frequency is in the E/F-band and the RAT-31S is intended for aircraft detection and range, elevation and azimuth target measurements at high, medium, and low altitudes. Comprehensive ECCM facilities include the ability to operate in frequency agility from pulse-to-pulse, and/or within pulse-groups, with an automatic adaptive transmission frequency selection. Height measurement of detected aircraft is compatible with frequency agility, and the sub-clutter visibility is sustained even when operating in pulse-to-pulse frequency agility.

The RAT-31S uses a novel antenna system that employs a system of three stacked beams with a phased array control of the elevation of each beam. The configuration is that of a rear-fed planar array, which avoids aperture blocking, minimises sidelobes, and provides good mutual screening characteristics. A coherent chain transmitter, with a TWT final amplification stage is used, which facilitates the frequency agile features of the radar. A staggered position and phase code is used in the transmitted pulse. Features of the receiver include: monopulse operation with Dicke-fix processing; anti-clutter filtering by means of a double canceller; adaptive

Selenia RAT-31S transportable 3-D radar deployed with an MRCS-403 mobile reporting and control system station

clutter attenuator; coherent limiter; and moving window azimuth correlator.

CHARACTERISTICS

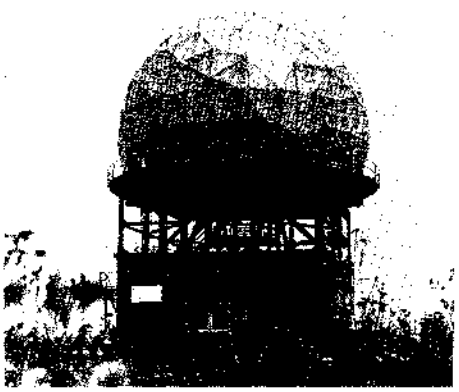
Antenna
Type: Rear-fed planar array
Polarisation: Linear horizontal
Beamwidth: 1·5° (azimuth and low elevation beams)
Azimuth scan mode: Mechanical rotation over 360°
Scan rate: 5 - 10 rpm
Elevation scan mode: Electronic by phase control from 0 - 21°
Number of beams: 3 different groups of beams are radiated on 3 separate bandwidths
Pattern: Multiple pencil beams
Transmitter
Type: Coherent amplifier chain
Final stage: TWT
Peak power: 135 kW minimum
Duty ratio: 2·8%
Average PRF: 450 Hz
Max unambiguous range: >300 km
Stagger sequence: Variable
Transmitted waveform: 3 separate coded waveforms
Receiver
Type: Dual conversion
Receiving channels: 3, sum and difference
MTI/receiver: Adaptive to clutter level
Normal receiver: Dicke-fix, all beams; log for jam strobe; log for AFS; and linear for raw video
Range gating: The ACA adaptive switching is controlled by a clutter mapper. The normal/MTI channel selection is controlled by an adaptive channel selection mapper
Signal processor
Detectors: I and Q phase detectors
A/D converter: 8-bit
Normaliser: Digital, coherent limiter
Matched filters: Digital matched filters
Final detector: Modulus extractor
Azimuth correlator: Moving window
Height computation: Monopulse processing and azimuth averaging by means of a microprocessor
Plot extractor
Rate: Compatible with narrow-band transmission
Message format: Programmable
False alarm rate: 10^{-6}
Mechanical
Configuration: 2 S-280 type shelters plus antenna
MTBF: 450 h
MTTR: 35 minutes

STATUS

The RAT 31S is in full production. It is operational in the mobile air defence system, MRCS-403, delivered to Austria (see **3326.181**). Two MRCS-403 systems were ordered by the Italian Air Force in early 1984 and systems have also been sold to other countries. Negotiations are in progress for the sale of a significant quantity of additional systems to an undisclosed state.

In March 1983 an agreement between Selenia and the Sperry Corporation (USA) was revealed that covers the joint development of a long-range version designated RAT-31SL.

CONTRACTOR



Selenia-Industrie Elettroniche Associate SpA, Via Tiburtina Km 12400, 00131 Rome, Italy.

1959.153
ARGOS-10 EARLY WARNING RADAR

The Argos-10 is a high-power, modern early warning search radar, with an effective range in excess of 250 nautical miles (460 km). It incorporates a transmitter designed and manufactured by the Heavy Military Electronics Systems Division of the General Electric Company. The salient features include: a high-power coherent transmitter chain; full adaptability to fixed and/or moving clutter; environmental pattern recognition; high resistance to ECM; reception status matched to the actual environment; fully digital signal processing; integrated primary/secondary video extractor; and modular construction.

The antenna is a large lattice construction with a lattice boom projecting from the lower edge to support the dual horn feeds which provide for dual beam operation. This element of the Argos-10 radar has a marked resemblance to the antenna and feed of the Canadian Raytheon ASR-803 D-band airport surveillance radar, and may be the same design. Provision is made for enclosing the antenna assembly in a protective radome. An auxiliary antenna can be added if required for multiple stand-off jammer cancellation and to provide for unambiguous jam-strobe indication.

The transmitter is water cooled and operates in the D-band. The output has not been stated but is probably several megawatts. A codified output pulse is produced and there is a code agility facility. In accordance with the jamming situation encountered, adaptive frequency selection is available, other

Argos-10 high-power early warning radar in protective radome

operating options being MTI-compatible frequency agility and random frequency agility. The receiver incorporates dual-beam coherent combination; a low-noise RF amplifier; parallel channels for multiple jammer coherent cancellation; and linear with adaptive clutter attenuator facilities.

The digital signal processor has phase and quadrature channels, a three-pulse digital MTI double canceller, and clutter map storage for adaptive clutter cancellation. There is a low velocity clutter filter for reducing or eliminating the effects of rain or chaff. Real-time sensors are provided for moving clutter cancellation and rain contour mapping. Automatic optimum channel selection is incorporated. Measures employed to eliminate second and third time around echoes comprise a pattern recognition technique and multiple stagger codes. There is also a time on target dual threshold integrator in the signal processor section.

Plot extraction with a 10^{-6} false alarm rate in a combined clutter/jamming environment is performed by the video extractor, which also includes a primary/secondary plot combiner, and an interface-buffer to a central computer for narrow-band transmission.

STATUS

Prototype evaluation tests began in late 1977, these running concurrently with series production against NATO and Italian Government contracts placed in 1976/77. At least ten sets have been produced and commissioning of the first Argos-10 station began in March 1978. Among these orders are one system to be installed on the island of Sicily under NATO project 130, and a number to be used for updating the Italian air defence network. It is understood that in some instances the Argos-10 will be used in conjunction with fixed or semi-permanent RAT-31S 3-D radars.

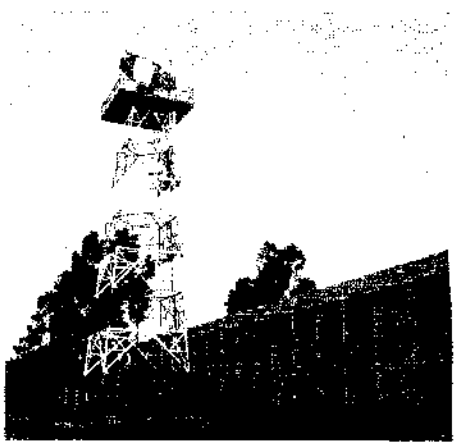
2248.153
SELENIA CIVIL/MILITARY RADARS

The Selenia series of air traffic control radars consists of three types of equipment:

(a) D-band high power long range radar ATCR-22
(b) E-Band medium power terminal area radar ATCR-33
(c) D-band medium power terminal area radar ATCR-44.

The equipment is designed to be used in both civil and military applications.

ATCR-22 Primary En-route Radar



The ATCR-22 is a high power 23 cm wavelength, fully solid-state (except for the magnetron and thyratron), search radar for use in both military and civil environments. In an air traffic control configuration the radar consists normally of an antenna group, two transmitter units, two receiver units and the common wave-guide system. In the dual channel version, a dual frequency diplexer allows the radar to work in frequency diversity. A third single channel can be used as a hot stand-by to any of the two main channels. Two antenna systems are available, the G-14 high gain, extra long range antenna and the smaller G-7 antenna, both equipped with a dual feed.

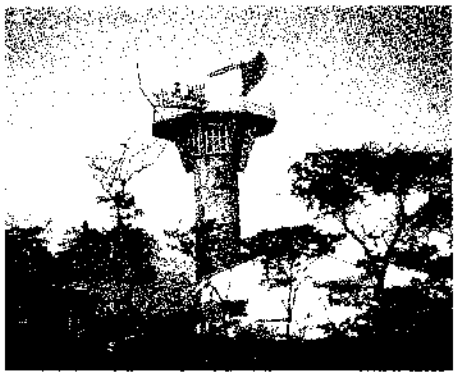
A clutter mapper is also provided: this device automatically defines areas in which MTI video is desired because of clutter, but in other areas normal raw video is displayed. A video correlator eliminates 'second time round' echoes and rejects non-synchronous returns and noise. It can be automatically introduced, checking on the level of residues. Log-FTC is introduced when needed in both MTI and normal operation. A special output displays rain contours. A FAN circuit guarantees a constant false alarm rate of 10^{-6}. Provision for on-mounting SSR is standard and the antenna has a triple channel rotating joint.

The ATCR-22 can be controlled and checked out remotely. A performance monitor continuously monitors noise figure, transmitted and received power. Alarms are initiated (remotely, if required) when these pass a preset threshold.

A built-in extractor performs a very sophisticated pattern analysis of each returned echo. A micro-computer keeps tab on all processing done to the individual echoes, controls the returned signal for multiple targets, defines the plot position with an unsurpassed accuracy, and provides feedback loops to the entire system in order to protect subsequent tracking system or transmission lines against overload.

The accuracy obtained by this method equals or surpasses the accuracy of raw video

ATCR-33 installation in Nigeria



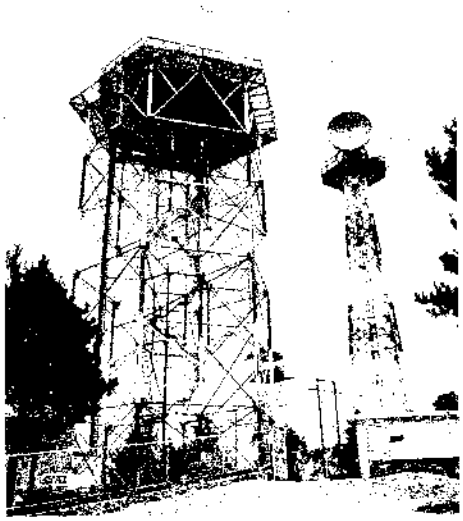
CHARACTERISTICS

G-14 antenna group
Operating frequency: 1250 - 1350 MHz
Polarisation: Horizontal and circular (switchable)
Turning rate: 5, 6 or 7·5 rpm (other rates available upon request)
Feed type: Dual horn

G-7 antenna group
Operating frequency: 1250 - 1350 MHz
Polarisation: Horizontal through elliptical to circular
Turning rate: 5 - 10, 6 - 12 or 7·5 - 15 rpm, other dual rates available upon request
Feed type: Integrated 8 horns
Transmitter
Magnetron: M5051 (1250 - 1310 MHz) or M5052 (1350 - 1355 MHz)
Peak power: 1·8 MW minimum
Average power: 2250 W (minimum output of magnetron)
PRF (average): 300 - 800 pps, staggered in 6 different repetition periods
Adaptive MTI, MTD and ECCM facilities are available as options
STATUS
In current production.

ATCR-33 Primary Terminal Area Radar
This equipment is an E-band 10 cm medium power radar suitable for approach or GCA surveillance. It employs the same receiver as the ATCR-22 and is equipped with the G-33 antenna. This turns at 15 rpm and with the transmitter operating at 1000 pps, the coverage achieved on a small jet aircraft with the single channel ATCR-33 is about 45 nautical miles (83·4 km) in range and over 6000 metres in height. Short-range low cover properties make the system very suitable for aircraft recovery.
CHARACTERISTICS
Transmitter
Peak power: 0·5 MW minimum
Average power: 500 W (minimum output of magnetron)
Frequency: 2·7 - 2·9 GHz
PRF: Staggered in 6 different repetition periods
G-33 antenna group
Operating frequency: 2·7 - 2·9 GHz
Polarisation: Variable from linear to circular through all degrees of ellipticity
Coverage: Modified cosec² with improved high elevation angle cover
Turning speed: 15 rpm (other speeds available on request)
Main beam
Horizontal beamwidth (3 dB): 1·45° ±0·05°
Gain: 33·5 dB
Main sidelobes: Better than -25 dB
Auxiliary beam
Horizontal beamwidth (3 dB): 1·45° ±0·05°
Gain: 32 dB
Main sidelobes: Better than -25 dB
Operating temperature range: (indoor units) 0 - 50°C; (outdoor units) -40 to +70°C
Adaptive MTI, MTD and ECCM facilities are available as options
STATUS
In production.

ATCR-44 Primary Radar
This radar is a medium powered version of the ATCR-22 employing a peak power of 500 kW and is especially suitable as an approach radar or for GCA surveillance. Either the G-21 or the G-14 antenna can be used according to operational requirements. With

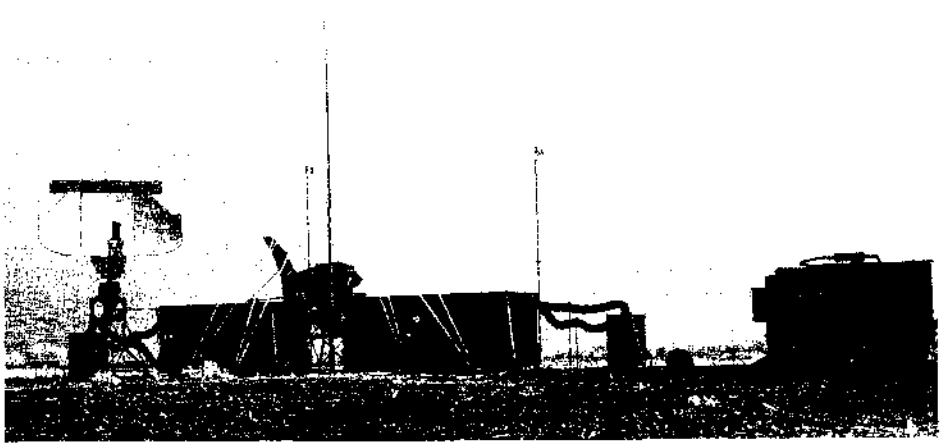


Selenia ATC radar installation in Zimbabwe

the antenna rotating at 15 rpm, the range coverage on a small jet aircraft is over 60 nautical miles (111 km) in single channel, with a height coverage of over 9000 metres. In dual diversity the range coverage on the same aircraft is over 75 nautical miles (139 km) with height cover over 12 000 metres. In its normal version, the radar has a PRF of 1000 pps with a pulse width of 1 μs giving an average power output of 500 W. The pulsed magnetron is tunable over the frequency band 1280 to 1350 MHz. The receiver/MTI chain is identical to that of the ATCR-22 and features the same digital processor resulting in a system that is flexible, reliable and easier to maintain. As with the ATCR-22, a clutter map is provided to delineate segments in which MTI video is desired; in all other segments the video is normal. Video correlator, video integrator and plot extractor are also identical to those of the higher-powered radar.
CHARACTERISTICS
Transmitter
Magnetron: 5J26 (air cooled)
Tuning range: 1280 - 1350 MHz
Peak power: 0·5 MW
Average power: 500 W
PRF: Up to 1000 Hz
Antenna: As for ATCR-22
Operating temperature range: (indoor units) 0 - 50°C; (outdoor units) -40 to +70°C
Adaptive MTI, MTD and ECCM facilities are available as options
STATUS
In production.

SELENIA SIR Secondary Surveillance Radar
The new Selenia secondary surveillance radar family is a modular system. The SIR is normally a dual-channel system with automatic changeover and housed in a single cabinet. The addition of modules will convert the basic conventional SSR version (SIR-R) to a monopulse equipment (SIR-M) and a mode-S version (SIR-S). The system is designed so that the total cost of expansion is borne by the units added, to maintain minimum cost in each phase.

An SSR channel consists of a programmable transmitter, a receiver, a processor/controller and a power supply. The processor/controller is a firmware programmed unit, which forms part of the fully-programmed built-in extractor, and provides all



ATCR-22 installation in Mexico

control signals, timing, BITE, remote control functions and narrow band formatting. All programmable functions of the transmitter and receiver are also provided by the processor unit.

The complete radar is fully solid-state and includes range-azimuth programmed STC, sophisticated degarbling and defruiting, staggered trigger, programmable mode interlacing and narrow-band plot transmission. It is fully compliant with ICAO and STANAG recommendations.
CHARACTERISTICS
Transmitter
Frequency: 1030 ± 0·1 MHz
Pulse duration: 0·8 μs
Modes: 1, 2, 3/A, B, C, D (S optional)
Interlace modes: Programmable
PRF: 100 - 450
Azimuth programmability: 5 levels in 128 sectors
Receiver
Frequency: 1090 MHz
Bandwidth: 8 MHz
STC programmability: 40 × 128 azimuth cells
Configuration: Sum receiver (SIR-R); matched sum and difference receiver (SIR-M/S)
Antenna (SIR-R sum/difference)
Length
4·1 m: beamwidth 4°; gain 19 dB
8·2 m: beamwidth 2·35°; gain 21 dB
Antenna (SIR-M/S open array)
Length: 8·6 m; beamwidth 2·35°; gain 19 dB
Processor/controller
Data word: 16 bit
Instruction word: 24 bit
Instruction time: 0·2 μs
Memories: Data (RAM); programmes (PROM)

SELENIA MOBILE GCA SYSTEM
The Selenia mobile ground controlled approach system consists of an airport surveillance radar (ASR), a precision approach radar (PAR) and an IFF/SSR surveillance radar (SIR). It is suitable for both military and civil purposes and is transportable by helicopter, fixed-wing aircraft, road, rail or ship. The system is operational within two hours of arrival at the site. It is easily adaptable for installation at fixed sites and can be used autonomously or integrated with existing ATC equipment.

The operation shelter is fully equipped with two PPI displays with presentation of aircraft identity and video maps, and two AZ-EL displays for PAR information. VHF/UHF air-ground and ground-ground communications are integrated and autonomous power generators are provided. The complete system is designed to operate over the environmental temperature of -40°C to +70°C and in wind speeds up to 100 km/hr.

Selenia mobile GCA deployed

The ASR is a medium-power 10 cm wavelength, solid-state search radar. In the dual channel configuration the equipment works in frequency diversity, providing a range coverage of 75 nautical miles on a target such as a T-33 aircraft. The main feature of the radar is beam switching with beam combination, a system which allows the creation of a third beam with a null on the horizon and adaptive choice of auxiliary or main beam. Also provided are programmed adaptive clutter attenuation, and in-phase and quadrature MTI.

The PAR provides accurate range, height and azimuth information on aircraft within the entire volume of 20° in azimuth and 10° in elevation out to a range of 20 nautical miles. The transmitter operates in X-band and provides coverage to either end of a single runway and to either end of at least two crossing runways by reorientation of the antenna.

CHARACTERISTICS

Airfield surveillance radar

Frequency: 2·7 to 2·9 GHz

Configuration: Single or dual channel

Antenna: Modified cosec; 15 rpm turning speed; beamwidth 1·45°; polarisation continuously variable from linear to circular

Transmitter: Magnetron, 500 kW peak power, 1 μs pulse length, average PRF 1000 typical

Precision approach radar

Frequency: 9 – 9·18 GHz

Configuration: Single or dual channel

Volume coverage: 20° azimuth; -1° to +9° elevation; 20 n miles range

Accuracy: 0·3% horizontal; 0·2% vertical; 1% of the range

Antenna: Double cosec²; beamwidth 0·6° × 2·3° in azimuth and 0·6° × 5·9° in elevation

Transmitter: Magnetron; 200 kW peak power; PRF 3000 Hz average; pulse width 0·25 μs in normal mode, 0·4 μs in MTI mode

IFF/SSR radar

Antenna: 14 ft (4·27 m), on-mounted

System: Dual channel with automatic changeover

Modes: 1, 2, 3/A, B, C.

SENTINEL RQT-9X PORTABLE INFANTRY RADAR

The Sentinel RQT-9X is a lightweight, man-portable battlefield surveillance radar. It provides instantaneous detection and location of any moving target at ranges from 0 up to 3·8 km.

The radar design, with the exception of the transmitting tube, is all solid-state and is based upon the technique of transmitting a continuous wave radio frequency signal for search in azimuth (surveillance mode) and a continuous wave with 0 to 180° phase modulation according to a pseudo-random code for ranging (ranging mode). In both cases frequency modulation of the transmitted signal is added to achieve better performance. Change over from surveillance to ranging mode is obtained simply by operating a switch.

CHARACTERISTICS

Antenna system

Polarisation: Vertical

Azimuth beamwidth (3 dB): 4°

Elevation beamwidth (3 dB): 12°

Gain: 26 dB

Transmitter

Klystron: VA210 B modified

Power output: 40 mW

Type of emission: CW-FM with 0 – 180° phase modulation by a pseudo-random code

Code element width: 0·4 μs

Receiver

Noise figure: 16 dB

Display: Aural

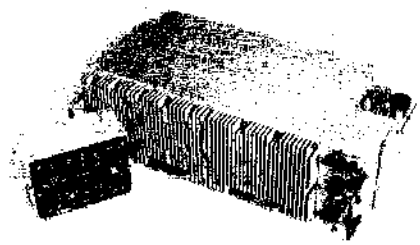
Detection frequency bandwidth: 50 – 1530 Hz

STATUS

The equipment was type approved by the Italian Army in 1970. It is in service with the Italian infantry and has been supplied to the armies of other countries. No longer produced.

CONTRACTOR

Selenia-Industrie Elettroniche Associate SpA, Via Tiburtina Km 12400, 00131 Rome, Italy.



3279.153

SIT 431 (AN/TPX-54) IFF INTERROGATOR

The system consists of an interrogator unit, a sum-and-difference antenna and up to six AN/UPA-59A decoders. In SIF operation the primary controls are provided on the UPA-59As. In Mode 4 operation the interrogator is used with an external KIR-1A/TSEC computer. The Mode 4 controls and the secondary SIF controls are contained in a master control box remoted to the display area. An IFF system fault indicator is also included in this unit.

The receiver/transmitter module contains a 1500 W transmitter, a dual-channel receiver and RF interface module. The transmitter module is a completely solid-state unit. A dual-channel receiver provides the receiver sidelobe suppression (RSLS) function when operated with either a sum-and-difference antenna or a sum-and-omni antenna. The use of RSLS provides a means of artificially sharpening and controlling the antenna beamwidth for received signals. One of the unique features of the receiver is the six-stage logarithmic IF amplifier. The output of each stage varies linearly as a logarithmic function of the input. Thus a large dynamic range is obtained without appreciable distortion even at very large signal levels.

An ISLS control gate diplexed into transmitter sum channel controls RF switching action. An omni antenna (AS 177) may be connected to the difference antenna connector for RLS operation or, alternatively, the dual-channel receiver may be operated on sum channel only (single-channel operation). In order to provide flexibility for any variation in antenna systems the interrogator is designed to allow removal of the diplexer module and replacement with an integral RF switch. This RF switch module is used in those applications where a dual IFF RF rotary joint is available. Modifications are not required, selection of the applicable modules is all that is necessary to satisfy various antenna arrangements.

SIT 431 (AN/TPX-54) IFF interrogator

The signal processor consists of a coder, defruiter, evaluator and video interface module. As an option a computer interface can be provided. The coder module provides SIF modes 1, 2, 3/A, C and Mk XII Mode 4 challenge pulse to the transmitter. The SIF challenge pulses are generated by the coder, and the Mode 4 challenge pulses are supplied by the KIR computer. ISLS pulses are generated by the coder for both SIF and Mode 4. The coder is programmable to accept an interface pattern of up to five modes. Mode 4 can be used either interlaced or on an override basis. The coder initiates challenges either from manual commands via switches located on a challenge gate or from an associated computer.

The defruiter module accepts receiver video and applies it to shift register memory. On successive PRPs the incoming video is compared to the video received from the memory. When pulse-to-pulse correlation is obtained, video is supplied to the associated UPA-59A decoding units.

The Mode 4 reply evaluator accepts receiver video and detects Mode 4 triple-pulse video. The triple-pulse decoded video is provided to the KIR-1A/TSEC for time decoding. The evaluator utilises real-time processing for target detection and microprocessor technology for the reply evaluation.

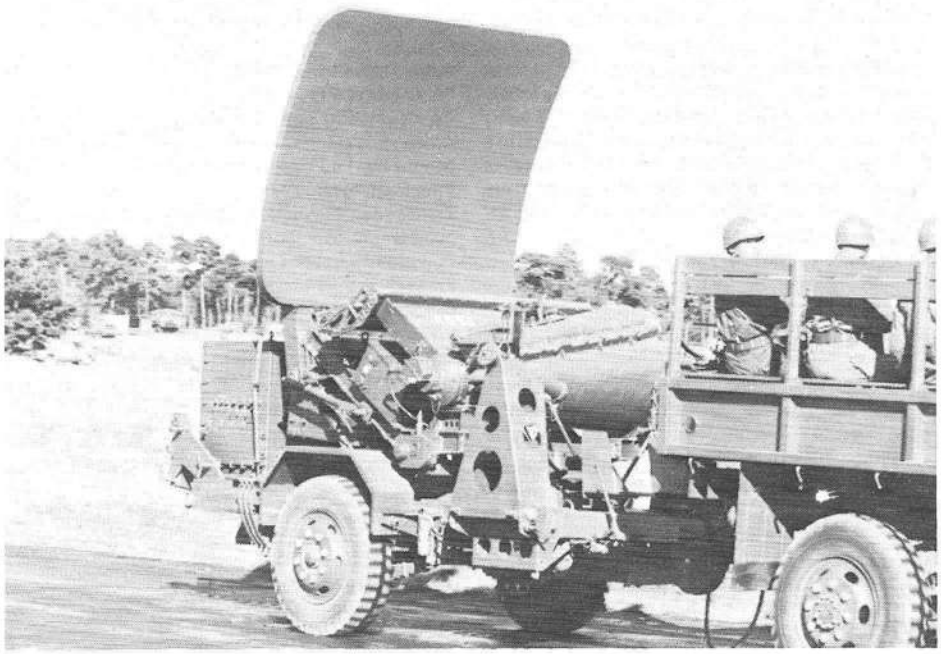
JAN/MPQ-N1 (TYPE 92) MORTAR LOCATING RADAR



The Type 92 mortar locating radar is apparently a Japanese licence-built version of the American AN/MPQ-4 equipment which is produced by the General Electric Company. The Japanese model, designated JAN/MPQ-N1, is thought to have essentially the same performance as the US-built radar which is described in entry **2497.153**, later in this section of *Jane's Weapon Systems*.

The purpose of these radars is to detect and locate enemy mortar positions so that counter-battery action can be carried out. The two-beam intercept principle is employed, first-shell acquisition is possible and the system can handle multiple targets.

It is usual for the reflector to be folded down when the Type 92 mortar locating radar is being towed
(K Ebata)

STATUS
Operational with the Japanese Ground Self-Defence Force.

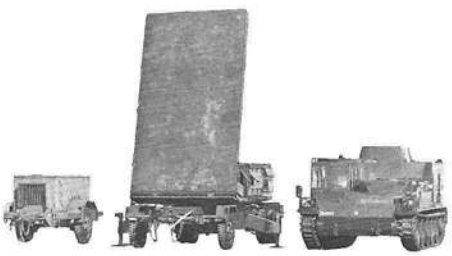
4141.153
J/MPQ-P7 ARTILLERY LOCATING RADAR

This artillery locating radar is apparently of Japanese design, but it is not known if there has been any technical collaboration from America or elsewhere, although there is an obvious similarity with the recent Hughes AN/TPQ-36 and AN/TPQ-37 mortar and artillery locating radars (**2848.153** and **1976.153**). Like the US-designed radars, the J/MPQ-P7 employs electronic scanning of a planar array antenna to generate the multiple beams necessary for detection and trajectory analysis of incoming projectiles. In this respect the Japanese equipment is so far the only known comparable radar to appear from beyond the American defence industry for operational service. The moderately large antenna array is transported on a wheeled trailer towed by a tracked vehicle which houses items of equipment and the radar crew. The antenna is erected when deployed, but folds flat for transit. Electronic beam steering probably obviates any need for the array to rotate in use. It is likely that a sufficiently broad azimuth coverage arc can be achieved by electronic scanning to provide surveillance of the designated threat direction(s).



Few technical details have been obtained but it is reported that the equipment has a peak output power of 250 kW, operates in the I/J-band (former X-band), and is capable of ranges of more than 30 km.

STATUS
In service with the Japanese Self-Defence Forces.

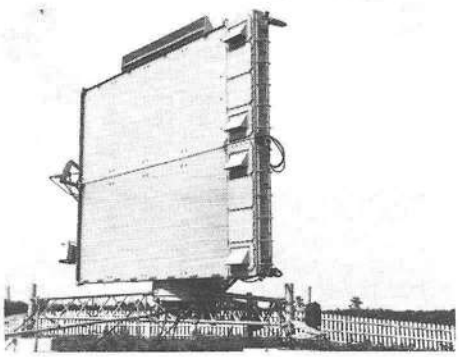
NPM-510 MOBILE 3-D RADAR

The NEC NPM-510 3-D radar is a highly mobile system with several novel features. Among these are the antenna system, which is rotated in azimuth but electronically scanned in elevation and which consists of a planar array that can be folded for transport, and a rapidly erected inflatable equipment shelter.



A compact and lightweight system relying extensively on solid-state technology the radar is claimed to be highly reliable. Salient features of the circuitry are a CFA transmitter chain, chirp pulse compression, digital MTI and automatic target detection, tracking, and altitude computation.

STATUS
The radar has been supplied to the Japan Defence Agency.

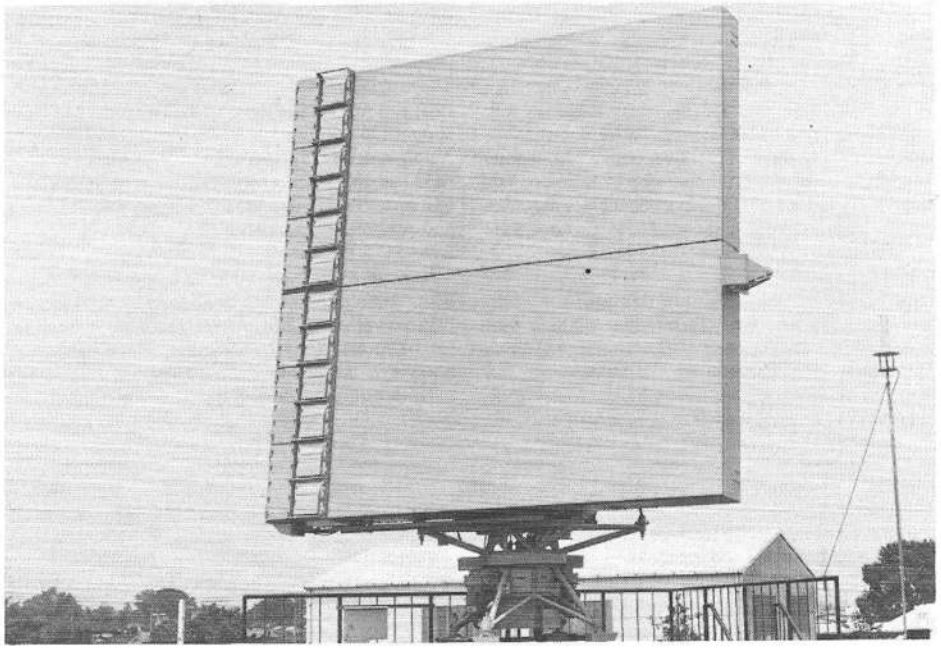
3702.153
NPG-880 3-D AIR DEFENCE RADAR

The NPG-880 is a static three-dimensional air defence radar developed by NEC in Japan; a mobile version, NPM-510, is also produced (**2298.153**, above). Both equipments employ an antenna that embodies a unique phase/frequency scanning technique of a planar phased array in elevation, with mechanical rotation in azimuth. A combination of serpentine feed and ferrite phase shifters is used for scanning a pencil beam in elevation.

The radar embodies energy management concepts and signal processing techniques giving high detection and stable accuracy, with a TWT and CFA transmitter chain, chirp pulse compression and amplitude comparison for height measurement. The advanced digital signal processing techniques used for clutter reduction and rejection (and ECCM) significantly enhance performance for automatic detection and tracking under severe clutter and jamming environments.

The NPG-880 is capable of direct interfacing with any automated air defence network, and it is linked with air defence ground environment and air defence command post systems. The system has dual channel configuration with high reliability design features and substantial built-in-test equipment to minimise system down-time.



The general configuration of the NPG-880 can be seen from the nearby photograph. The associated transmitter/receiver, display, and other electronics can be housed either in permament or temporary buildings.

STATUS

Supplied to the Japanese Air Self-Defence Force.

2297.153

AIR TRAFFIC CONTROL RADARS

Numerous radars covering most aspects of civil aircraft movement are made by the NEC Corporation. These radars are made primarily to comply with ICAO and other civil aviation specifications: some of them have been supplied to the Japan Defence Agency (JDA) and these are briefly described below.

Air Route Surveillance Radar (ARSR)

D-band long-range surveillance radar intended for en route air traffic control.

NEC provides two types of ARSRs, the NPG-434 (magnetron transmitter version) and the NPG-630 (klystron transmitter version), which are used with the NPG-905A secondary surveillance radar (SSR), radar data transmission systems such as the NPG-359 radar microwave link (RML) or the NZG-594 radar video bandwidth compression (VBC) system and associated equipment.

The NPG-434/NPG-630 ARSR employs modern computer-aided design, a dual beam antenna, solid-state circuits and advanced digital signal processing techniques providing extended coverage of more than 200 nautical miles and 70 000 feet. The NPG-359 all solid-state RML (which is operated in the 7 GHz band and has a standard transmission range of 50 km) is based on the high reliability and perfected system design techniques of NEC's microwave equipment.

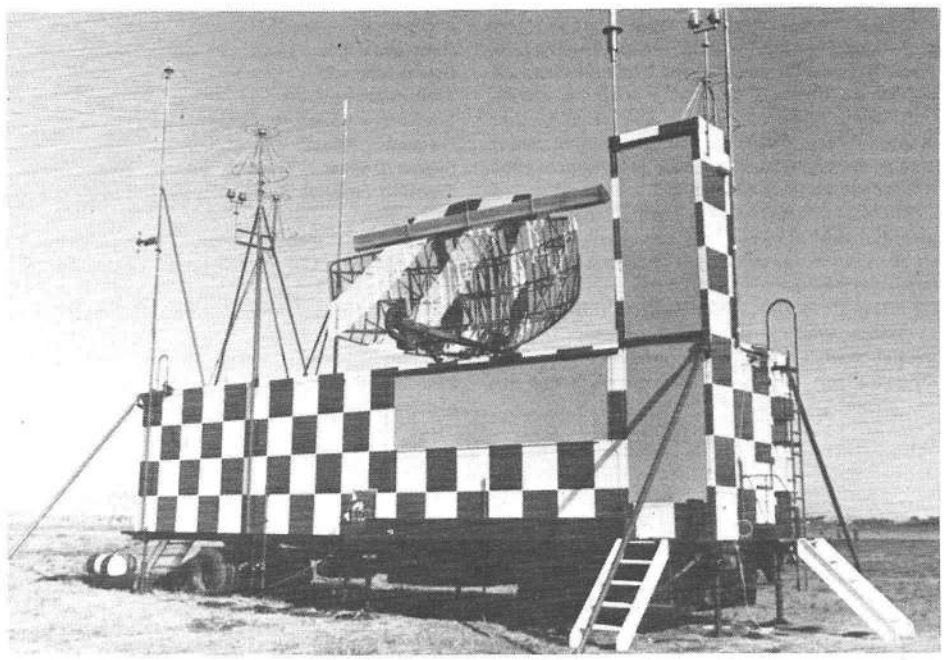
NEC has developed the NZG-594 VBC system which makes it possible to transmit ARSR raw radar video and SSR digitised radar data utilising narrow-band 12 voice telephone channels (48 kHz) and one channel of the telecommunication network as a transmission means.

Fourteen of these systems have been supplied to the Japan Civil Aviation Bureau (JCAB).

Airport Surveillance Radar (ASR)

NEC manufactures an E/F-band surveillance radar for use in terminal area air traffic control. Three versions exist: the NPG-360 and NPG-1240 which have a range of 64 nautical miles and 40 000 feet on small commercial aircraft and the NPG-460 which has a range of 80 nautical miles and 50 000 feet on a jet fighter. Many radars in various combinations have been supplied to JDA, JCAB and foreign customers. These versions have beamwidths of 1·2°, data renewal rates of 15 rpm and digital MTI. NPG-360 has a 500 kW magnetron transmitter and a transistor RF amplifier giving an overall noise figure of 3·5 dB; the NPG-1240 is a klystron version of the NPG-360 and the NPG-460 has a 3·5 MW transmitter with a transistor RF amplifier, as in the NPG-360.

Precision Approach Radar (PAR)



The NPG-435 is a PAR which has been designed to a standard above the ICAO requirement making it suitable for fighter airfields. Detection range is more than 15 nautical miles.

Secondary Surveillance Radar (SSR/SIF)

The NPG-905A is a complete ICAO-specification SSR system with interrogator/responsor decoder and defruiter and SIF capability. A large number of

Surveillance radar display, PAR display and associated equipment of NEC GCA NPG-864

NPM-554 mobile GCA system

systems have been supplied to the Japanese military and civil aviation authorities.

Ground Controlled Approach Radar (GCA)

The NPM-554 is an integrated system comprising ASR, PAR, and SSR/SIF elements together with communications sub-systems. These sub-systems are essentially those described above but slightly reconfigured to suit the integrated installation. The secondary radar antenna is in a linear array mounted on the primary radar antenna. These systems have been supplied to the JDA.

Fixed Type GCA

The NPG-864 is a system featuring a high performance alpha-numeric radar display that automatically detects and tracks aircraft equipped with a beacon transponder, then correlates them with flight plans previously registered at a terminal ATC. In addition to conventional GCA component elements such as NPG-460 ASR, NPG-435 PAR, NPG-905A SIF, CCU and associated equipment, it features a data processing system to conduct the above functions. These equipments are installed in shelters at the ASR, PAR and ACC operational areas. The radar has been supplied to the JDA.

Automated ATC System

NEC has developed a sophisticated ATC automation system for the JCAB and semi-automated air warning and control systems for the JDA.

STATUS

All the above are believed to be operational with the JDA. Three other radars developed by NEC are the high-power NPG-434 ARSR magnetron version, NPG-630 ARSR klystron version, which have been bought by the JCAB and the NPM-510 mobile 3-D radar described in **2298.153**.

4605.153

XJ/FPS-3 AIR DEFENCE RADAR

The XJ/FPS-3 air defence radar is a next generation phased array radar project which is intended to be the main air defence/interceptor control radar of the Japanese Base Air Defence Ground Environment (BADGE) air defence system. Current plans are for eight XJ/FPS-3 sites, each with a long- and short-range radar antenna.

STATUS

Three Japanese companies, Mitsubishi Electric, Japan Electric and Tokyo Shibaura Electric are tendering for the project, development of which should be complete by early 1987. The second development phase was allocated 4500 million yen (£13 million) in the 1984 defence budget. Technical and operational tests will follow the end of the development phase and a purchase decision is expected in 1990.

NETHERLANDS

3283.153

FLYCATCHER RADAR

The radar employed in the Signaal Flycatcher low-level anti-aircraft weapon control system (**2301.181**) is essentially a repackaged version of that developed for the Leopard 35 mm AA tank CA1 (**2302.153** below), allied to an SMR digital computer.

The computer is also used to generate track data in two dimensions for three additional targets, of particular importance for fast target change in a multi-target environment and when the radar is connected to a mix of weapons, such as medium calibre guns and surface-to-air missiles. In addition to this computer-assisted track-while-scan capability, provision is made for the display of targets acquired by other systems.

The general arrangement of the Flycatcher radar employs coaxial mounting of the search and tracking antenna as compared with the separate positions used in the 35 mm AA tank installation. TV tracking is incorporated. The main characteristics are otherwise similar for both versions of the radar.

STATUS

Deliveries to the Netherlands forces for defence of air bases and missile batteries began in 1978. The system has also been ordered by Thailand and several other countries.

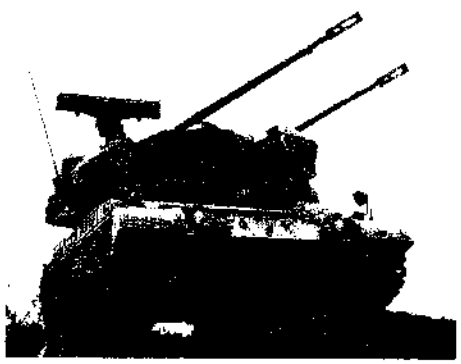
CONTRACTOR

Hollandse Signaalapparaten BV, Zuidelijke Havenweg 40, PO Box 42, Hengelo, Netherlands.

2302.153

INTEGRATED RADAR SYSTEM FOR 35 mm AA TANK

One version of the 35 mm AA tank systems described in the Systems section (**2370.131** in 1977 and earlier editions) is equipped with an integrated radar system designed and manufactured by NV Hollandse Signaalapparaten. This fire control system is mounted on a Leopard tank chassis armed with twin, rapid-firing 35 mm Oerlikon AA cannon. The Signaal system is based upon the well-proven advanced integrated radar technology in which the same I-band transmitter is used for both search and tracking purposes. A dual-band tracking radar operating in both I- and Ka-bands, with a broad beamwidth compared with that of the search antenna and a very small beamwidth for tracking the extremely low flying targets, reduces reaction time to the barest minimum and allows the tracking of the lowest, tree-top level aircraft. Simultaneous search transmissions are continued through the entire tracking phase, permitting complete coverage against further airborne threats to be maintained. Rapid automatic or manual switching facilities allow the system to cope with a multi-target environment.



The radar system has been designed to detect and identify aircraft at very low to medium altitudes and to track them automatically. It has the following important features:

(1) integrating all-weather search and tracking systems with a very short reaction time
(2) search while tracking through 360°
(3) search on the move, with compensation for vehicle's speed
(4) good performance in clutter and ECM environment
(5) compact rugged design and module concept to facilitate maintenance
(6) dual frequency tracking radar
(7) integral IFF.

CHARACTERISTICS

Antenna system

Search antenna: Slotted waveguide type
Length: 1·5 m
Horizontal beamwidth: 1·4°
Vertical beamwidth: 30°
Polarisation: Horizontal or circular
Rotational speed: 60 rpm
Range: 15 km
MTI improvement factor: 30 dB
Tracking antenna: Parabolic with cassegrain reflector and monopulse feedhorn
Diameter: 0·6 m
Beamwidth: 4·2°
Transmitter/receiver
Transmitter power: 160 W average
Frequency: I-band
Search channel: MTI with double canceller (digital)
Tracking channel: Pulse doppler and built-in anti-image radar
ECCM: Digital video correlator (ISU), pulse-length discriminator (PLD). Passive tracking in I-band, PRF stagger
Noise figures: Search receiver 7 dB, tracking receiver 9 dB
Radar display and control panels
PPI: Diameter 25 cm, north orientated clutter-free picture, compensated for vehicle's speed. Arrangement of controls to high standard of human engineering. IFF completely integrated with the search system
Power consumption: 200 V 380 Hz approx 2 kVA

Signaal integrated radar system for 35 mm AA tank

STATUS

A pre-production series of five and a main series of 95 units are now in service with the Royal Netherlands Army.

Hollandse Signaalapparaten BV, Zuidelijke Havenweg 40, PO Box 42, Hengelo, Netherlands.

POLAND

2340.153
POLISH RADAR

Little information is available on Polish radar developments. It is known, however, that the Industrial Institute of Telecommunications in Warsaw has for many years been working on radar developments and some definite information has been made available on the radars that have been developed for civil ATC purposes.

As an illustration of radar capability, therefore, it may be of interest to note a few details concerning one of these radars, the Avia B D-band airways surveillance radar.

Avia B is a 23 cm wavelength radar using high-power magnetron transmitters and a low-noise parametric amplifier in the receiver. Operating in frequency diversity it has two 1·5 MW peak power transmitters. The parametric amplifier used in the receiver is an original Polish development. The radar has an MTI system, and staggered PRF is used to eliminate blind speeds in the practical range of aircraft performance. The polarisation of the transmitted radiation may be varied from linear to circular.

Maximum range on a 15 m² target with 90 per cent detection probability is 240 km with a ceiling of 26 000 m.

CHARACTERISTICS
Avia B
Operating frequency: 1310 and 1346·2 MHz
Peak power output: 2 × 1·5 MW (frequency diversity)
PRF: 400 Hz mean (recurrence 7:8)
Pulse length: 3 μs
Noise factor: 3·5 dB
Fixed echo suppression: 30 dB
Antenna rotation speeds: 5 or 10 rpm
Antenna gain: 32 dB
Horizontal beamwidth: 1·3°
Vertical beamwidth: 40°
Polarisation: Variable from linear to circular

SOUTH AFRICA

4601.153
EMVA MK10B MUZZLE VELOCITY RADAR

The EMVA Mk10B is a doppler radar analyser designed to measure muzzle velocity over the range 30 to 3000 m/s. The equipment can be used for guns of 20 mm calibre or larger. The instrument consists of an antenna which can be mounted on the gun or tripod, plus a processor with a liquid crystal display and a hard copy printer. Power is by standard 24 V DC batteries.

The equipment is triggered automatically by the radar echo from the shell when the gun is fired. An external trigger unit is also provided which operates on the muzzle flash or projectile shadow and when connected to the antenna head, overrides the automatic radar echo trigger. Up to 100 readings are taken before the shell is out of range and are then analysed to give muzzle velocity.

CHARACTERISTICS
Range: 30 - 3000 m/s
Accuracy: ±0·05%
Dimensions
Antenna head: 30·5 × 14·5 × 16·5 cm
Processor: 65 × 38 × 29 cm
Weights
Antenna head: 9 kg
Processor: 30 kg

SWEDEN

1957.153
GIRAFFE SEARCH RADAR

Giraffe is the family designation of a mobile search pulse doppler radar system developed by Ericsson in Sweden. The basic version, PS-70/R, is designed for use with the new Swedish Army/Bofors short-range surface-to-air missile system RBS 70 (**2348.131**) or any short-range missile or AA gun system. The complete radar together with radio communication equipment, tactical control facility and power supply is linked with a number of firing units for precision target designation and combat control.

A prominent feature of this installation is the use of a folding mast for the antenna, giving an effective operating height of 12 m. Together with excellent clutter suppression characteristics (MTI improvement factor is better than 50 dB) this gives the Giraffe very low altitude coverage. The range coverage is 40 km in the surveillance mode and 20 km in the target designation mode.

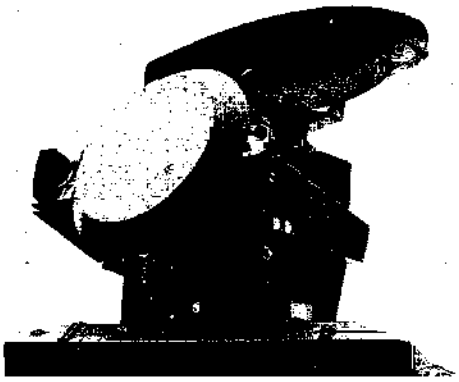
The radar employs a broadband TWT final amplifier which delivers 15 kW peak, 300 W average, over the G/H-band. The high gain, low sidelobes antenna generates a cosecant-squared beam up to 60° with an azimuth beamwidth of 2°. Digital doppler processing and constant false alarm circuitry are used to automatically extract, detect and present the target of interest. A digital plan position indicator presents video signals and target tracking symbols. The target data link constitutes the interface between the search radar and the firing sites. Information about target geographical co-ordinates, speed and course is derived and transmitted from the target data transmitter, which is located in the search radar. The

Ericsson Giraffe tactical radar deployed and ready for use

target data receiver, located at the firing site, performs certain calculations, generates signals for slewing the gun or missile sight towards the target and displays information as to whether the target is engageable or not.

The Giraffe search radar is offered with comprehensive ECCM options and an IFF equipment can be installed. Training equipment, available as an optional accessory, can easily be installed in the cabin without requiring any connections to external units.

The basic Giraffe radar parameters provide for more than adequate range and altitude coverage required by any AA artillery or short-range surface-to-air missile system. The adaptation to different short-range systems is achieved mainly by modifying the interfacing target data receiver. To extend the range coverage required for medium-range surface-to-air missile systems, a more powerful transmitter can be installed. This constitutes the only major modification of the basic design. The Giraffe concept in general and its MTI performance in particular, suit the system for handling the low altitude air surveillance task in early warning and air command systems.



Naval versions (**4299.253**) for installation on board fast patrol boats and up to frigate size ships are available. They combine air surveillance with superior MTI performance, surface surveillance and surface fire control with high resolution capability in one radar only. The MTI improvement factor gives naval versions excellent sea skimmer detection capability.

CHARACTERISTICS
Radar
Frequency: G/H-band (former C-band)
Output power: 15 kW (peak), 300 W (average)
MTI improvement factor: 50 dB
Pulse length: 3 or 6 μs
Range coverage: 20 or 40 km
Target velocity range: 30 - 375 m/s
Antenna revolution rate: 60 rpm
Antenna gain: 29 dB

Beamwidth azimuth: 2°
Elevation pattern: Cosec² to 60°
PRF: Either staggered or switched every antenna revolution
Mechanical
Total weight: 6500 kg (excluding vehicle)
Transport width: 2·5 m
Transport height (on vehicle): 3·4 m
Antenna operating height: 12 m
Interior volume: 12 m³
Interior height: 1·7 m
STATUS
The PS-70/R model has been ordered by the Swedish Defence Materiel Administration for use with the RBS 70 AA missile system and deliveries have commenced. In addition, the Swedish Defence Materiel Administration has ordered the more powerful version of the Giraffe, PS-707/R, for a medium-range surface-to-air missile system, and this is now in production. An AA artillery version has also been ordered and is in production for a number of foreign governments. Yet another version for a different short-range surface-to-air missile is in production. A shipborne version of the Giraffe radar (**4299.253**) has been ordered by the Swedish Government for fitting in 'Spica II' fast patrol boats and by Canada for fitment in the new Canadian Patrol Frigate. A contract worth $9·5 million has been received from the Norwegian Army for the basic Giraffe. The radar is already in service in Norway under previous contracts. More than 250 Giraffe systems have been ordered since 1978 and the radar is in service in ten countries outside Sweden.

Ericsson Radio Systems AB, Defence and Space Division, 431 26 Mölndal, Sweden.

2357.153
UAR 1021 COMBINED SEARCH AND TRACK PULSE-DOPPLER RADAR
This combined fully coherent search and track pulse-doppler radar is a successor to the earlier ECSTRA I equipment. It employs a single I-band transmitter which feeds the independent search and track antenna by way of a power splitter. The tracking subsystem uses a monopulse technique with a cassegrain antenna; the search system uses a cheese antenna or a cosec² antenna with integrated IFF dipoles.

Important features of the equipment are the high clutter attenuation resulting from the coherent pulse-doppler system; the ECCM capability resulting from the broad-band system (900 MHz), and the possibility of operating either on a fixed frequency (chosen from five with a change time of less than ten milliseconds) in the pulse-doppler mode or with random pulse-to-pulse frequency agility within 900 MHz in the non-doppler mode; the monopulse angular tracking system; and the digital range tracking system.
CHARACTERISTICS
Frequency: 8·6 – 9·5 GHz
MTI improvement factor: 45 dB
Peak power: 26 kW
Noise factor: 12 dB
PRF: 3 different triplets in 4·8 – 8·1 kHz interval with rapid cyclic switching
Pulse width: 1·5/0·5 μs selectable
Tracking antenna gain: 36 dB
Tracking antenna diameter: 1 m
Range coverage: PD-mode 0·3 – 18 km; FA-mode 0·3 – 25 km
Acquisition interval: 1120 m
Velocity window: 22 – 385 m/s
Angle tracking accuracy: 1 mrad
STATUS
In production for the Contraves Skyguard system (**2377.151**). The related UAR 1302 equipment, a coherent-on-receive system, is an integral part of the Marconi S800 series of anti-aircraft radars (**2464.153** and **2466.153**) and has been in production since early 1975.

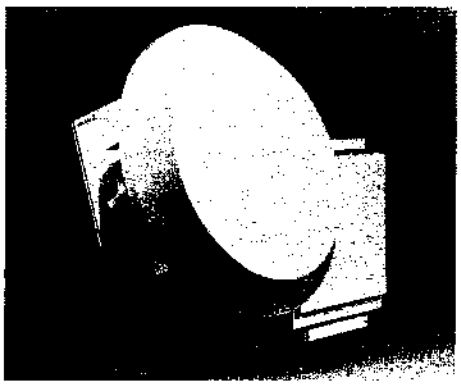
Ericsson Radio Systems AB, Defence and Space Division, 431 26 Mölndal, Sweden.



UAR 1021 combined search and track radar in Contraves Skyguard system

---

5771.153
EAGLE FIRE CONTROL RADAR
The Ericsson Eagle fire control radar is a 'silent' system intended for use in mobile ground and naval-based air defence systems. The equipment operates in the Ka-band, enabling tracking of low flying targets. The Eagle system has been designed with an extremely low radar signature which has been achieved by pulse compression, high antenna gain and almost no sidelobes, in combination with low output peak power. The radiation pattern and a new transmission technique is claimed to make it impossible for escort or stand-off jammers to degrade the radar performance.

The system consists of two units; antenna/transceiver and signal processor, with a total system weight of 130 kg. It is able to track two targets simultaneously, permitting fast lock-over between targets, air-to-surface missile alert or closed-loop fire control. A special operational mode which allows simultaneous pulse-to-pulse frequency agility and MTI is provided. Adaptive MTI provides for automatic wind compensation.
STATUS
In development. Ordered by three customers outside Sweden.
CONTRACTOR
Ericsson Radio Systems AB, Defence and Space Division, 431 26 Mölndal, Sweden.

Eagle fire control radar

5772.153
HARD 3-D SEARCH RADAR
The Ericsson HARD (helicopter and aircraft radar detection) is a new 3-D local search and acquisition system for ground-based and naval air defence systems. It is a pulse doppler radar having a phase-controlled planar array antenna with electronic elevation scanning. Target data in elevation, azimuth and range suitable for missile and gun air defence systems is provided. A version of this radar will form part of the Swedish Army RBS 70M air defence system and will also include Giraffe search radars (**1957.153**).

The HARD radar is a 'silent radar', so-called because of low peak output power and high antenna gain, together with low sidelobes and simultaneous MTI and frequency agility. The manufacturer states that it is not possible for a jammer to detect the radar outside the main lobe or for an anti-radar missile to get enough updating energy unless it is being tracked.

HARD consists of two units; an antenna/transceiver and a signal processor with a total system weight of 110 kg. The transmitter is completely solid-state and is based on pulse compression techniques with a multi-frequency capability. Threat evaluation and separation of helicopter and aircraft/missile targets are carried out automatically. The system also has automatic detection and tracking for several targets simultaneously.

The system is able to operate on a moving vehicle with automatic compensation for any platform movements.
STATUS
In production for the Swedish armed forces.
CONTRACTOR
Ericsson Radio Systems AB, Defence and Space Division, 431 26 Mölndal, Sweden.

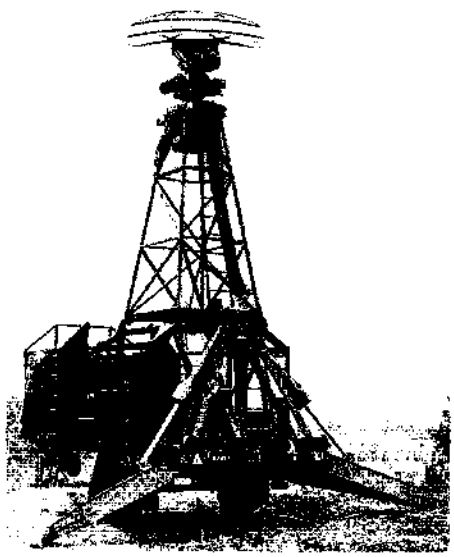
4029.153
9KR 400 COASTAL RADAR
The 9KR 400 consists of a 9GR 600 I-band frequency-agile transceiver (**1546.253**), a 9GA 205 antenna and a variable number of displays and/or automatic plot extractors, permitting narrow-band transmissions. It forms the main sensors element of the 9KA 400 Mareld coastal artillery fire control system (**1548.181**) and the 9CSI 600 STINA naval command system (**4028.281**).

The transceiver is completely solid-state with the exception of the magnetrons. The wide-band frequency agility capability offers very high jamming resistance, very long range, and good tracking accuracy. Alternatively, the radar can be run in a fixed-frequency mode for MTI operation.

Other applications are shipborne or ground-based, and further entries can be found in the appropriate sections of this volume.

CHARACTERISTICS
Operating modes: Frequency agility/fixed frequency/MTI
Transmitter tubes (2 off): Magnetron VJ1180/YJ1181
Frequency agility range: Minimum 400 MHz, typically 450 MHz within 8700 – 9500 MHz
Frequency shift: Randomly within frequency agility range from pulse-to-pulse
Pulse peak power: 200 kW

Pulse width/PRF: Typically 1 μs/1000Hz and 0·25 μs/3000 Hz
Receiver
Frequency range: 8500 - 9600 MHz
IF: 30 MHz
Noise figure: Typically 5·5 dB, max 7 dB with low-noise preamplifier
Receiver characteristics: Lin and log, log/lin, STC
Operational features: Image rejection mixer, Dicke-fix receiver, PLD, IAGC, narrow band jamming suppression, passive ECM mode
Transceiver dimensions: 1200 × 635 × 510 mm
Weight: Approx 225 kg
Antenna 9GA 205
Reflector type: Parabolic
Frequency range: 8·5 - 9·6 GHz
Rotation speed: Up to 40 rpm
Beamwidths
Horizontal: 0·6°
Vertical: 4°
Gain: 40 dB
Sidelobes
Within ± 10° of main lobe: -26 dB
Otherwise: -33 dB
Aperture: 4500 × 625 mm
Weight (including turntable): 260 kg
STATUS
In service. 9KR 400 coastal radar systems form part of the new network for the Yugoslav Navy, integrated with 9LV 200 shipborne tactical systems.
CONTRACTOR
Philips Elektronikindustrier AB, 17588 Järfälla, Sweden.



PEAB 9GA 205 antenna

5773.153
GA 250/K AND GA 250/X ANTENNAS
Philips Elektronikindustrier has designed two antenna systems known as the Types GA 250/K and 250/X. These antennas are designed for a variety of fire control radars, such as the 9KA 500 mobile coastal artillery fire control systems (**4318.281**).
CHARACTERISTICS

	GA 250/K	GA 250/X
Frequency	15·9 - 17·1 GHz	8·5 - 9·6 GHz
Beamwidths		
Horizontal	0·7°	1·2°
Vertical	2·2°	4°
Gain	42 dBi	38 dBi
Polarisation	Vertical	
Type	Parabolic, hornfed	

Reflector: Low drag, air porous cast aluminium
Rotation speed: Two speed ratio 1:2 in interval 6 - 60 rpm plus adjustable sector scan
Aperture: 2·3 × 0·55 m
Weight (including turntable): 160 kg

Philips Elektronikindustrie AB, 17588 Järfälla, Sweden.

GA 250 antenna in the 9KA 500 fire control system

UNION OF SOVIET SOCIALIST REPUBLICS

2860.153
BACK NET GCI RADAR
An early Soviet ground control interception (GCI) radar and a predecessor of Barlock (**2861.153**), the radar known to NATO as Back Net has a six-feed antenna system similar to that of Barlock.

Multiple feeds are widely used in Soviet surveillance and GCI radars. Part of the reason for this is the possibility of increasing the total radiated power within the confines of component limitations; but another reason is the possibility of using such antenna systems to provide some form of height information.

Other predecessors of Barlock include Big Bar A (**2862.153**) and Big Mesh (**2863.153**) both of which also have six-feed antenna systems.

2861.153
BARLOCK GCI RADAR
This large ground control interception and search radar is trailer mounted equipment that has two large truncated paraboloid reflectors with clipped corners.

Operating frequencies of the radar are in the E/F-band. Each of the reflectors is fed by three feeds so that six stacked beams result, each beam having a power output in the region of 1 MW. These beams may enable the radar to be used as a height indicator, but it is also likely that they are part of a system for providing surveillance cover over different altitude bands. Both the reflectors can be adjusted in elevation angle by the operator while the radar is operating to permit manual variations of vertical cover. Individual frequency bands for the stacked beams are:

2695 - 2715 MHz
2715 - 2750 MHz
2815 - 2835 MHz
2900 - 2990 MHz
2990 - 3025 MHz
3080 - 3125 MHz

Known to the Soviet forces as P-50 this radar has a PRF of 375 pps and pulse widths of 1·83 to 3·1 microseconds for the E/F-band transmission and 2·4 microseconds for a D-band identification (IFF-type) secondary radar transmitter that is often found in association with Barlock.

Range capability of Barlock is about 300 km, range accuracy is about 90 m, and angular accuracy about 0·5°. The entire trailer body rotates for azimuth scanning at rates up to about 12 rpm.
STATUS
Known to have been in operational use since at least the mid-1960s and widely deployed in the USSR and friendly nations.

Barlock GCI radar deployed

Inside view of Barlock operations vehicle, showing one of the plotting positions

2862.153
BIG BAR A GCI RADAR

A ground control interception radar with a six-feed antenna system similar to that of Barlock (**2861.153**). See also entry for Back Net (**2860.153**) above.

A significant difference is that the two antennas are arranged to provide V-beams in elevation, thereby making possible heightfinding by means of this technique. The rear, upper antenna is displaced so that the major axis of the elliptical reflector is tilted about 25 to 30° from the horizontal.

2864.153
DOG HOUSE ABM RADAR

One of several large fixed phased-array radars deployed by the Soviet authorities for missile detection. Dog House is the NATO name given to a radar with a very large array antenna.

Complicated signal processing is used in the installations to which these large antenna arrays belong. It is believed that this is an area where Soviet technology is somewhat weaker than, say, that of the USA; and in support of this view it has been pointed out that such signal processing techniques are not much used in smaller Soviet radar installations and that this may be because they have decided to apply limited resources first and foremost to the solution of such critical problems as strategic missile defence.

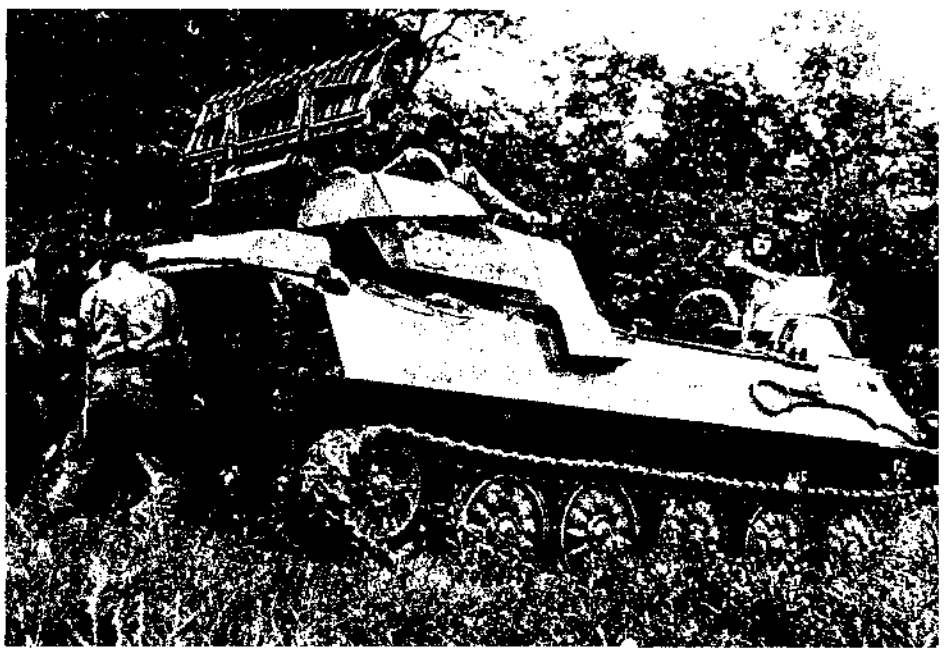
The principal known use of the Dog House radar is as the intermediate range radar of the Moscow ABM complex. It accepts targets from the long-range Hen House radar (**2879.153**) and hands them on to the Try Adds radars. Dog House operates in the VHF band at around 100 MHz – hence the need for the very large phased array to achieve a sensible beamwidth. It is said to be capable of radiating a peak power up to 20 MW and to have a PRF of 50 pps – which is broadly consistent with its reported range of some 1500 nautical miles (about 2800 km).

STATUS

Operational in the Moscow ABM network.

4329.153
BIG FRED ARTILLERY/MORTAR LOCATING RADAR

The Soviet Union artillery/mortar locating radar (NATO reporting name Big Fred) is a mobile system normally fitted to armoured vehicles. Information on the equipment is scanty but it is believed to be similar to the Cymbeline system manufactured by EMI of the United Kingdom (**1018.153**). The radar is believed to operate in J-band. The antenna folds flat in the forward position for travelling.



OPERATION

The system enables the operator to plot two points in the shell or mortar bomb trajectory and measure the slant range and bearing to each of these positions. The time taken for the projectile to travel between the two points is also measured and the on-board computer uses this information, together with the pre-set elevation angles, to determine the position of the enemy mortar or howitzer. This information is then passed to the field artillery for counter-action.

STATUS

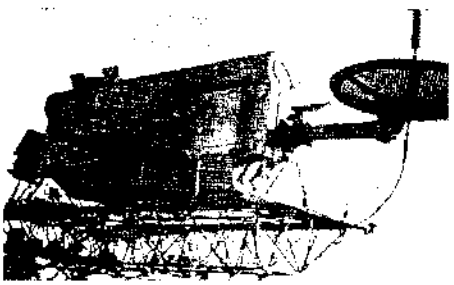
Big Fred is fitted to the multipurpose armoured vehicle MT-LB and the ACRV-2 (armoured command and reconnaissance vehicle) of the Soviet Army. The Yugoslav Army has recently taken delivery of a number of the former vehicles fitted with Big Fred.

The Soviet forces also use a BMP MICV fitted with the Small Fred radar. Small Fred is believed to operate in J-band with a detection range of 39 km and a tracking range of 7 km.

Soviet 'Big Fred' radar is used by Warsaw Pact and other friendly states as well as the USSR

2863.153
BIG MESH GCI RADAR

A ground control interception radar with a six-feed antenna system similar to that of Barlock (**2861.153**). See also entry for Back Net (**2860.153**). Like Big Bar A (**2862.153**), Big Mesh has the rear, upper antenna array tilted to one side to permit heightfinding by the V-beam method.



2866.153
FAN SONG MISSILE CONTROL RADARS

Fan Song is the NATO code-name given to a family of computing radar installations that have been developed for use with the Guideline (SA-2) surface-to-air missile (**2942.131**).

Seven of these radars have so far been identified (by suffix letters A to G) and common to all of them are the detection and tracking of the target, the command guidance of the missile and the tracking of the missile. It is said that these radars can handle up to six targets at once and guide three missiles at a time. It appears, however, that the missile must pass through the guidance beam within a few seconds (reportedly six) of launch if it is to be acquired and steered towards the selected target. A further problem appears to be a limitation in the amount of steering information that the missile is capable of receiving from the ground station. Nevertheless, Soviet forces have kept Guideline (in various versions) in service for many years and it has been used in action successfully by the North Vietnamese: although possibly expensive in operation, therefore, the system as a whole would appear to be effective.

Operational deployment of Fan Song C

Rear view of Fan Song radar group showing details of antenna feed arrangements

Details of some of the Fan Song series are given below. All members of the series contain as a major element a track-while-scan radar which scans a designated sector with two flapping fan beams radiated from two orthogonal antenna systems. The flapping motion has a sawtooth profile and uses the electromechanical system known as the Lewis scanner. The 'fan' in the code-name refers to these fan beams and the 'song' to the bird-like sound of the demodulated radiation from these radars.

STATUS

Fan Songs of various kinds are in service with Guideline missiles in the USSR, satellite and client countries and are also deployed at Soviet air bases in Afghanistan.

2867.153
FAN SONG B MISSILE CONTROL RADAR
Fan Song B is an E/F-band member of the Fan Song series (see **2866.153** above). Radiation from its two Lewis scanners is at 2965 to 2990 MHz for one and 3025 to 3050 MHz for the other: peak power output is in the region of 600 kW and the equipment has a first-time-round range capability of between 60 and 120 km.

The equipment is trailer-mounted and the scanned sector can be changed by rotating the trailer and tilting the whole superstructure. The sector scanned is about 10° high and 10° wide, these dimensions being the approximate fan beam width, the beam width in the scanning direction being only about 2° for each beam.

A small parabolic antenna, mounted at one end of the horizontal Lewis scanner is used to transmit UHF command guidance signals to the missile.

2868.153
FAN SONG E MISSILE CONTROL RADAR
Fan Song E is a G-band member of the Fan Song radar series (see **2866.153** above). Similar in many respects to Fan Song B (**2867.153**) its main differences are the frequency of the radiation from the Lewis scanners and the fan beam (and hence the sector) dimensions. The beams in Fan Song E are about 7·5° wide in the fan and about 1·5° wide in the scanning direction, carrier frequencies are 4910 to 4990 MHz and 5010 to 5090 MHz and peak power is about 1·5 MW. Unambiguous range is 70 to 145 km.

In addition to the antenna for the command guidance signals, which is similar to that of Fan Song B, Fan Song E has two further parabolic dishes mounted on top of the horizontal Lewis scanner. One of these is horizontally and the other vertically polarised and their purpose is to provide a lobe on receive only (LORO) feature. This is an ECCM technique in which the scanning action of the Lewis scanner is restricted to the receive channel by diverting the transmitted signal, which otherwise would be radiated from the scanner, into a dummy load. This signal is then replaced by a signal from one of the parabolic dishes (the other being for use with the other Lewis scanner) of sufficient power to operate the whole system.

The reason for adding the LORO facility is that by monitoring the Lewis scanner radiation an enemy pilot can tell roughly whether or not he is the prime focus of the attention of the ground forces. If he is, he can employ deceptive electronic countermeasures (DECM) to confuse the radar – such countermeasures typically involving an apparent shift of target angle.

STATUS
G-band Fan Song radars are in widespread use with Guideline missiles. A version that has been dubbed Fan Song F has been reported, identified by a box-like housing on top of the radar shelter. This is said to contain a visual observer's position (with or without optical aids is not known) to assist target and/or missile acquisition. The extent of operational deployment of this modification is not known.

2871.153
FIRE CAN FIRE CONTROL RADAR
This E-band trailer-mounted radar appears to have been derived from the American SCR-584 radar that was extensively used during the latter years of the Second World War and which was supplied to the Soviet forces by the USA. A typical war-time application of the SCR-584 radar was its use on the 'Diver' gun sites that were set up on the east coast of Britain to combat the V1 attack. The radars then were used with a 3·7 inch (94 mm) AA gun and the electronic predictor. The Soviet radar appears to be used with smaller 57 mm and 85 mm guns.

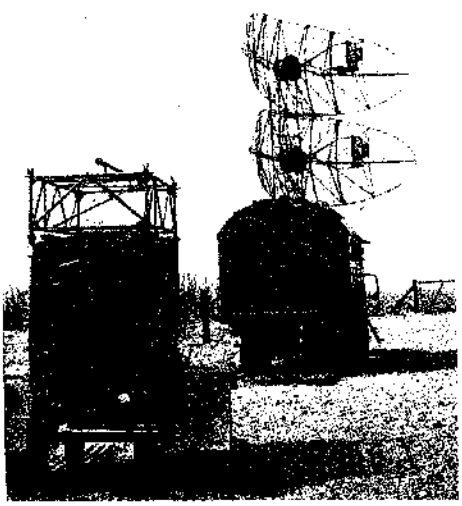
Fire Can operates at a frequency of 2700 to 2900 MHz, has a pulse width of 0·3 to 0·8 microseconds and a PRF of 1840 to 1900 pps. Peak operating power is believed to be about 300 kW.

Like the SCR-584, the Fire Can antenna is a parabolic dish, perforated to reduce weight and windage, that is mounted on a pedestal on top of the flat roof of the radar trailer. Power is radiated from a rotating dipole feed driven from the rear of the dish and signals from the common T/R system are used, in the tracking mode, to operate a lock-follow system that produces tracking accuracies of about 1·6 minutes of arc in azimuth and 2 minutes in elevation.

The radar can also be operated in a search mode with the antenna rotating continuously in azimuth and nodding in elevation. In this mode the antenna, which has a diameter of about 150 cm, produces a pencil beam with an effective beamwidth of about 5°. In this mode all received signals are displayed on a PPI but the dipole feed is driven all the time so that the operator can switch rapidly from search to track.

It is believed that Fire Can can acquire targets (search mode) at a maximum range of about 80 km and track them from about 35 km. Tracking accuracy in range is said to be about 13 to 15 m.

STATUS
In service. It is reported that some 75 of these radars were at one time deployed for use in North Viet-Nam.



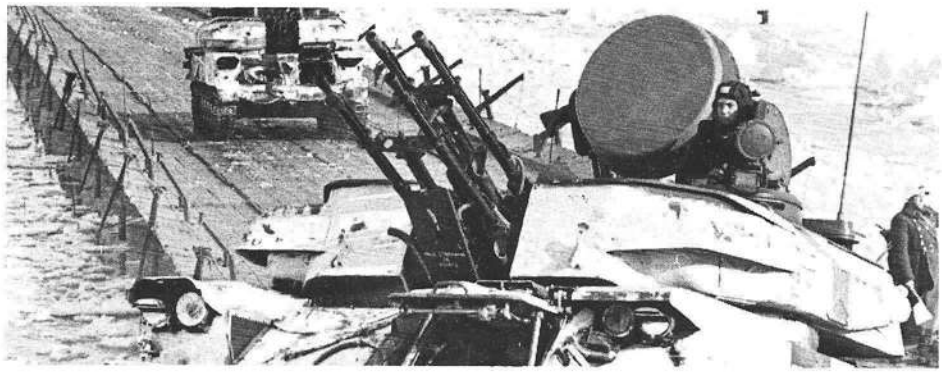
2872.153
FIRE WHEEL FIRE CONTROL RADAR
Fire Wheel is the NATO code-name for another SCR-584-derived fire control radar similar to Fire Can and Whiff (**2871.153** and **2893.153**).

2873.153
FLAP WHEEL FIRE CONTROL RADAR
Flap Wheel is the NATO code-name for a conical scan radar that is believed to have much the same range of operating frequencies as Gun Dish (**2876.153**). It is used to provide fire control data for 57 mm and 130 mm AA guns.

2874.153
FLAT FACE TARGET ACQUISITION RADAR
Flat Face is the NATO code-name of a radar known in the USSR as the P-15. It is a vehicle mounted acquisition radar that is used in conjunction with the Low Blow missile control radar (**2884.153**) and the Goa surface-to-air missile (**2938.131**).

This radar operates in the UHF C-band and radiates its signals from two elliptical paraboloid reflectors each measuring about 11 × 5·5 m. The radar has a range capability of about 250 km with a range accuracy of about 90 m and an angular accuracy of about 0·5°. Frequency bands are about 810 to 850 MHz and 880 to 950 MHz, PRFs are 200 to 800 pps and 600 to 680 pps. Vertical beamwidth is about 5° and horizontal about 2°. Peak power is about 500 kW.

STATUS
Operational in Egypt and Viet-Nam, where 40 Flat Face radars have been reported. Deployed generally with Goa missiles but also reported with tank and motorised infantry divisions. May also be in use with SA-8 Gecko missiles.



Soviet Flat Face mobile radar unit

2875.153
GAGE ACQUISITION RADARS
Gage is the NATO code-name for an acquisition radar that is used in conjunction with the Yo-Yo missile control radar (**2895.153**) which in turn is used with the early Soviet surface-to-air missile Guild (**2944.131**). Operating frequency is believed to be about 3 GHz and peak power about 2 MW.

2876.153
GUN DISH FIRE CONTROL RADAR
This broad-band fire control radar is used in conjunction with the quadruple 23 mm AA gun mounting on the ZSU-23-4 SP AA vehicle (**5548.103**). This vehicle is used by the AA battalions of the armoured and mechanised divisions of the Red Army and of other Warsaw Pact armies. The NATO code-name Gun Dish is obviously prompted by the appearance of the ZSU-23-4 vehicle.

Designed as it is to oppose low-level aircraft attacks the system of which Gun Dish is a part has to have a short reaction time. The guns can be slaved to the radar in elevation and are mounted, in the ZSU-23-4, in a rotatable turret on which the radar is mounted also and which contains a fire-control computer. A more recent application of this radar that has been reported is its installation on BRDM-2A AFVs mounting SA-9, Gaskin surface-to-air missiles (**3072.131**).

The Gun Dish radar operates in J-band with a frequency range of 14·6 to 15·6 GHz. The panoramic search radius extends up to 50 kilometres and the target tracking range up to eight kilometres. Antenna diameter is one metre.

Gun Dish fire control radar with 23 mm AA guns on ZSU-23-4 SP AA vehicle (Novosti)

2878.153
HEIGHTFINDING RADARS

Several basically similar nodding heightfinder radars have been identified and named by NATO. The generic code-name is Cake, and variants on this basic concept are known by such names as Patty Cake, Rock Cake, and Sponge Cake.

These radars, with their large, peel-shaped nodding antennas typically radiate beams with a width of some 3·5° in the vertical plane. Nodding frequency is typically about 30 to 40 cycles/minute and range is upwards of 200 km. One such radar, Sponge Cake, has a range in the region of 300 km, with a range accuracy of about 2·5 km at 200 km.

All appear to operate at frequencies somewhat above 2 GHz and to have peak powers around 3 MW.

STATUS

Operational.

2877.153
HEN SERIES EARLY WARNING RADARS

Several exceptionally large early warning radars observed by American reconnaissance have been given a series of names containing the word 'Hen'. First to be so named was Hen House (**2879.153**): others whose names have been reported are Hen Egg, Hen Nest and Hen Roost. Few details have been received concerning these radars: the notes below summarise the available information.

Hen Egg

Operating frequency around 2 GHz. Peak power around 3 MW. Pulse width 5 to 15 microseconds and PRF up to 300 pps. These figures suggest the high mean power of about 5 kW per beam.

Hen House

Measures 300 × 20 m high. Thought to have an early warning and tracking role in the Soviet ABM system. Probable detection range 3200 nautical miles. (See **2879.153**, below.)

Hen Nest

Operating frequency about 800 MHz. Peak power about 3·5 MW.

Hen Roost

Operating frequency not definitely known but thought not to be less than 500 MHz. Peak power similarly believed to be about 5 MW. 2 × 2° beam.

STATUS

All these Hen radars – and probably several others – are believed to be operational although it is quite possible that some of them are only experimental designs (albeit used operationally) that may well not be repeated.

2879.153
HEN HOUSE ABM RADAR

This is the name given by the US authorities to a very large Soviet array that was first detected in the late 1950s and was at that time thought – if indeed it was a radar – to be part of a detection tracking and control network for satellites.

Subsequently, however, it was discovered that these enormous radars perform an important early warning and tracking function in the Soviet ABM weapons system, providing radar coverage comparable with that planned for the US Safeguard (**2798.131** in 1977 and earlier editions) system. No details of the radar are known other than that the antenna array is exceptionally large – perhaps as much as 300 m long and 20 m high. This billboard array is said to be inclined at about 45° from the vertical.

It is reported, however, that the performance of Hen House is comparable to that of the FPS-50 detection radars (**2511.153**) of the American BMEWS system (**2525.181**) – ie a detection range in the region of 3200 nautical miles (about 6000 km) and a track-while-scan capability. It is believed to operate on about 150 MHz and has been reported as having a variety of PRFs from 25 to 100 pps, variable pulse widths, a complicated beam scan pattern with two beams scanning in azimuth, two scanning in elevation and one scanning in a circular pattern. Peak power is believed to exceed 10 MW.

STATUS

Hen House radars have been reported as being operationally deployed near Irkutsk, near the Barents Sea and in Latvia not far from the Baltic. See also general notes on the 'Hen' series (**2877.153**).

2880.153
KNIFE REST A EARLY WARNING RADAR

Knife Rest radars, as they are known to NATO, have the Soviet designation P-10. They were the forerunners of the Spoon Rest radars (**2889.153**). The array consists of four Yagi antennas in two crossed-brace supported pairs one above the other, each pair mounted on each side of a single tubular support carried on the turning gear. The whole unit is fixed to the top of a tubular mast, braced by guy-ropes.

Knife Rest A has an operating frequency band of 70 to 73 MHz, radiates about 100 kW peak power, has a pulse width somewhere between 4 and 12 microseconds and horizontal and vertical beamwidths in the region of 20 to 25°. Range capability is somewhere around 350 km.

STATUS

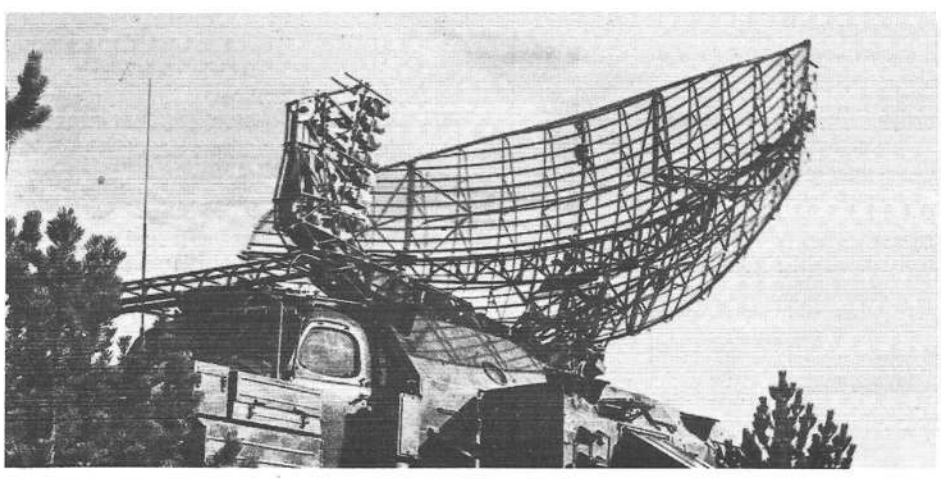
Operational – certainly in Viet-Nam – although the more modern Spoon Rest was deployed in the same theatres.

2881.153
KNIFE REST B AND C EARLY WARNING RADARS

General characteristics of these early warning radars are similar to those of Knife Rest A (**2880.153**) except that the range capability is lower at only about 90 km. Knife Rest B is shown to operate in the frequency band 83 to 93 MHz. Another difference is that Knife Rest B is a vehicle-mounted system, with the antenna array carried on a rectangular cross-braced sectional mast instead of the tubular pole used in Knife Rest A.

STATUS

Knife Rest B was certainly operational in Viet-Nam.



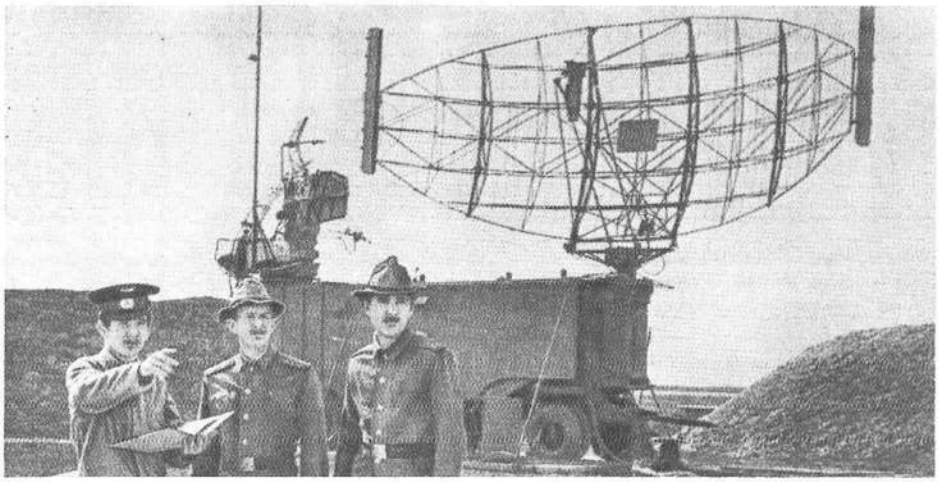
2937.153
LONG TRACK SURVEILLANCE RADAR

Long Track is the NATO code-name for a tactical surveillance radar used with surface-to-air weapon systems as an early warning/putter-on.

Long Track is commonly associated with the Ganef missile system (SA-4 – **2934.131**). It is also associated with the Gainful, SA-6 (**2930.131**) and Gecko SA-8 (**3209.131**) systems. In all cases the radar is mounted on a tracked carrier vehicle. It operates in E-band with a range and altitude in excess of 150 km and 30 000 metres respectively.

STATUS

Operational, certainly with SA-4 missile and possibly elsewhere. Used for SA-4, in conjunction with the Pat Hand fire control radar (**2936.153**).



Soviet 'Long Track' radar is used by client states as well as USSR, this one serves with Yugoslav forces

3294.153
LONG TALK RECOVERY RADAR

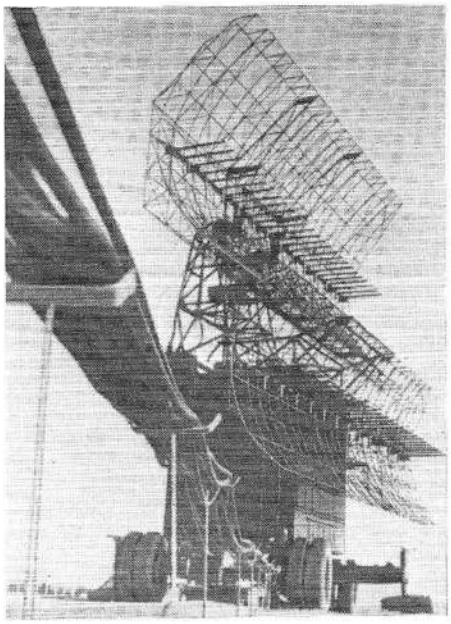
Long Talk is the air search and surveillance radar element of the Soviet standard ground controlled approach and aircraft recovery system used at Soviet air bases. The other elements of the system are the precision azimuth and elevation tracking radars known to NATO as Two Spot (**3295.153**) that form the precision approach radar portion. In some installations all three radars are mounted on one long four-wheeled trailer vehicle, which may also house the two- or three-man operating crew, but the Two Spot installation has been observed mounted on a platform above the driving cab of a standard military truck.

The Long Talk antenna has a moderately large elliptical paraboloid reflector, illuminated by radiating elements carried on a pyramid-shaped strut built up of four tubes. At the horizontal extremities of the reflector, one or two vertically positioned supplementary antennas which could be IFF units are located. Some installations have one such item on each end of the primary radar reflector, others have one only. A radar similar in general appearance to Long Talk and with one vertical supplementary attached to it is reported under the code-name One Eye.

Checking siting of Long Talk air search radar at a Soviet installation. Note associated heightfinder and approach radars

A number of Long Talk radars have been deployed at Soviet air bases in Afghanistan, associated with Two Spot precision approach radar (**3295.153**).

2884.153
LOW BLOW TRACKING AND MISSILE CONTROL RADAR



Low Blow is the NATO code-name given to a family of I-band radars used with land-based Goa (SA-3) missiles (**2938.131**). These radars are not the same as those used with shipborne Goa missiles which are known as Peel Group radars (**1323.253**). The name Low Blow reflects the ability of the radar to guide the missile towards low-flying targets through heavy clutter.

Like the Fan Song series (**2866.153**) the Low Blow radars use pairs of electromechanically scanning trough antennas mounted orthogonally, but to improve low-angle performance the troughs are mounted at 45° from the horizontal. It appears, too, that the troughs are not Lewis scanners but a form of organ-pipe scanner.

Carrier frequencies of the Low Blow family lie in the 9000 to 9400 MHz band, PRF between 1750 and 3500 pps with unambiguous range correspondingly lying between 40 and 85 km. Radiated beamwidth is in the region of 12° in the fan and 1·5° in the direction of scan. Pulses are between 0·25 and 0·5 microseconds in duration and peak power output is around 250 kW.

STATUS

Operational with Goa missiles. Commonly associated with Flat Face (**2874.153**) or Squint Eye (**2891.153**) acquisition radars.

3296.153
NYSA C LONG-RANGE RADAR

Nysa C is a long-range, early warning air defence radar, according to East German sources, being used in Warsaw Pact states as a part of the overall air defence system to provide target information for interceptor aircraft and surface-to-air missiles.

The antenna array consists of two large parabolic cylinder reflectors mounted one above the other, both facing the same way, carried on a large trailer cabin. The two reflectors are presumably to provide separate high and low cover radiation patterns, and each is fed by a horizontal row of 26 dipole elements. The operating frequency may be in the VHF or UHF band and high power levels are probably employed.

Nysa C long-range early warning radar operated by the Polish air defence forces

2936.153
PAT HAND FIRE CONTROL RADAR

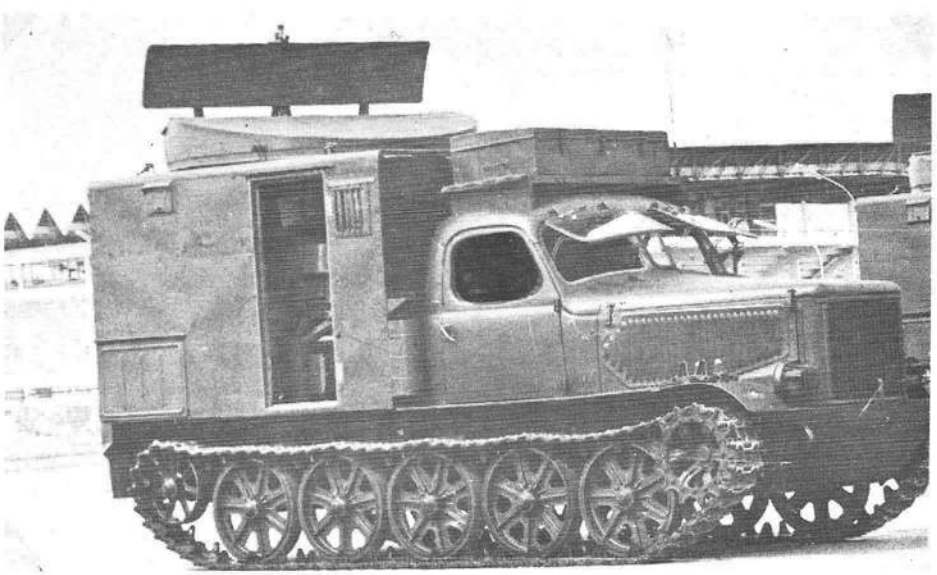
Little information is available on this radar which is used in conjunction with the SA-4 (Ganef - **2934.131**) surface-to-air missile system. Pat Hand is, of course, a NATO code-name.

In normal operation the Pat Hand radar is put on by the Long Track surveillance radar (**2937.153**). It acquires and tracks the target, provides command signals to guide the missile, and tracks the missile by a secondary radar process using a missile-borne beacon transponder. Pat Hand works in the H-band and is mounted on a tracked carrier vehicle.

STATUS

Operational with SA-4 missiles.

2974.153
SCORE BOARD IFF RADAR



Score board is the NATO code-name for an IFF-type ground interrogator used by Soviet forces. Presumably very early equipment, it has an antenna array consisting of two horizontal rows of two radiators per element, the two double rows being mounted one above the other to give a four-array of what appears (in some poorly reproduced pictures) to be a total of 32 dipole radiators. The whole is mounted on a rectangular rotatable framework.

STATUS

Apparently operational.

4328.153
PORK TROUGH (SNAR-2) COUNTER-BATTERY RADAR

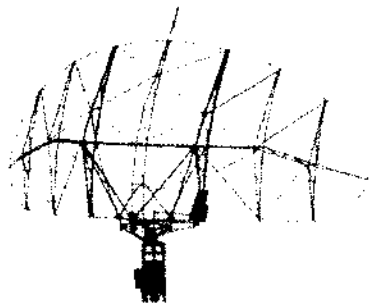
Pork Trough (SNAR-2) is a counter-battery radar designed to locate enemy artillery in order to provide position information to its own guns for counteraction. It operates in J-band and uses a small parabolic cylinder antenna. The antenna and operations cabin are mounted on an AT-LM light tracked artillery tractor. No other information is currently available.

Soviet Pork Trough weapon locator radar is a highly mobile self-contained unit

3289.153
SIDE NET HEIGHTFINDER

Side Net is a large transportable nodding heightfinder radar, usually employed in conjunction with early warning surveillance radars such as Barlock, Back Net, and Tall King to provide GCI facilities. Operating frequency is in the range 2560 to 2710 MHz with an effective range of about 180 km at heights up to 32 000 m. The large (8·5 × 3·5 m) elliptical paraboloid antenna is mounted on a pair of lattice trunnions cantilevered from the sides of the cabin containing the associated electronics. The cabin can be rotated in azimuth.

Developed in the early 1960s, Side Net has been exported to countries outside the Soviet Union that have been supplied with Goa and Guideline surface-to-air missile systems.



3290.153
SQUARE PAIR GUIDANCE RADAR

Square Pair is the NATO code-name of a target-tracking and missile guidance radar associated with the SA-5 Gammon long-range air defence missile system (**2940.131**). It is understood to be normally co-located with Back Net (**2860.153**) heightfinder radars, and to be widely deployed within the Soviet Union. No technical or physical characteristics have been obtained to date, but Square Pair is thought to have been operational since 1964.

3291.153
SQUAT EYE ACQUISITION RADAR

Squat Eye is an air search and target acquisition radar, sometimes used instead of Flat Face (**2874.153**), and with Low Blow (**2884.153**) for Goa SA-3 (**2938.131**) air defence missile batteries. Such applications appear to be those where low altitude coverage is of particular importance.

The antenna is of relatively large dimensions and of elliptical paraboloid configuration. It is usually mounted on top of a slender rectangular lattice tower of sectional construction to increase the effective operating height. About 500 kW transmitter power is likely and the radar's role may be essentially that of a gap-filler. A maximum range of about 200 km has been estimated. Squat Eye is reported to employ the same electronics as the Flat Face radar (**2874.153**).

Squat Eye acquisition radar

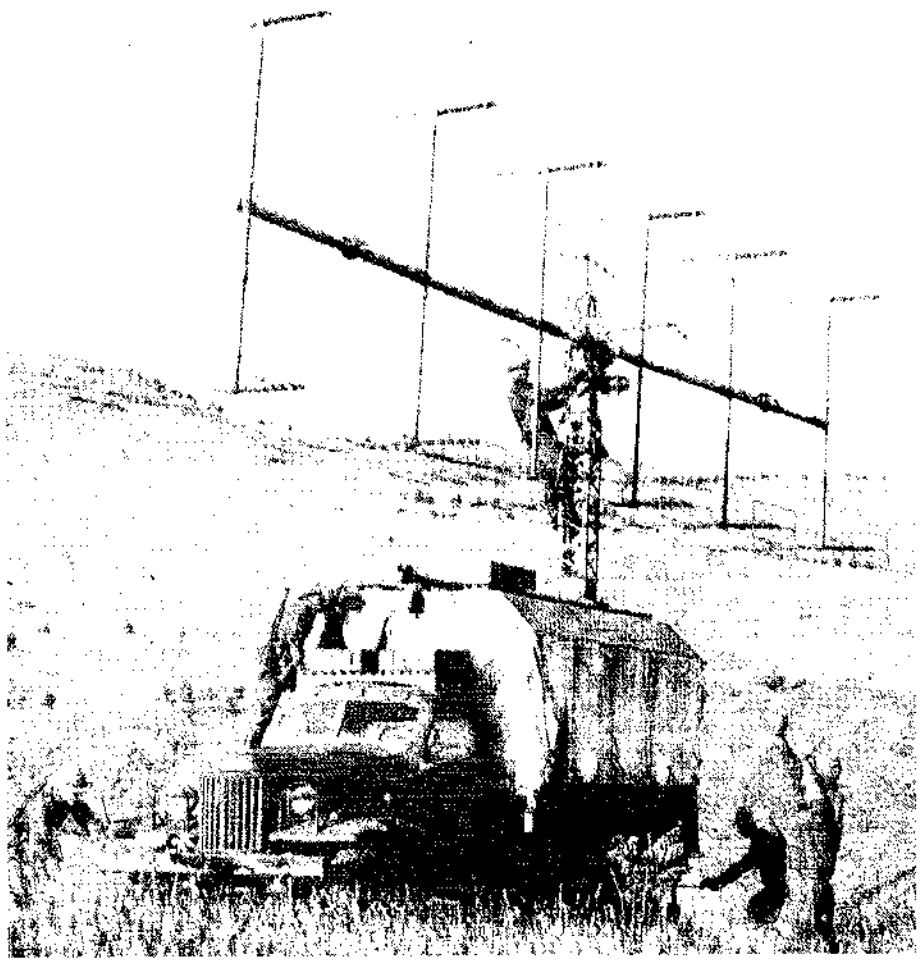
2891.153
SQUINT EYE ACQUISITION RADAR

This air target acquisition radar is used in place of Flat Face (**2874.153**) and in conjunction with the Low Blow missile control radar (**2884.153**) and the Goa surface-to-air missile (**2938.131**) in circumstances in which good altitude cover is required.

STATUS

Operational.

2889.153
SPOON REST A EARLY WARNING RADAR



Known in the USSR as the P-12, the radar known to NATO as Spoon Rest A is an early warning radar that is used sometimes in conjunction with the Fan Song radars (**2866.153**) and the Guideline surface-to-air missile (**2942.131**).

This is a VHF radar working in the 147 to 161 MHz, A-band and radiating at about 350 kW peak from a Yagi array. Range capability is up to about 275 km and antenna beamwidths are around 2·5° in the vertical and something over 1° in the horizontal plane.

The radar is a heavy one and is mobile in two vehicles, one carrying the generator and the other the antenna array and the radar cabinets.

STATUS

Operational, certainly in Viet-Nam, where 34 sets are believed to have been used operationally, and in Egypt where one was captured by the Israeli forces.

Deployment of Spoon Rest A (P-12) early warning radar

2885.153
STRAIGHT FLUSH FIRE CONTROL RADAR

Straight Flush is the NATO name given to the radar and command guidance system used with the SA-6 Gainful (**2930.131**) surface-to-air missile system and possibly with the SA-11 (**4470.131**). It is believed that the system performs the following functions -

Limited search
Low-altitude detection/acquisition
Target tracking and illumination
Missile radar command guidance
Secondary radar missile tracking

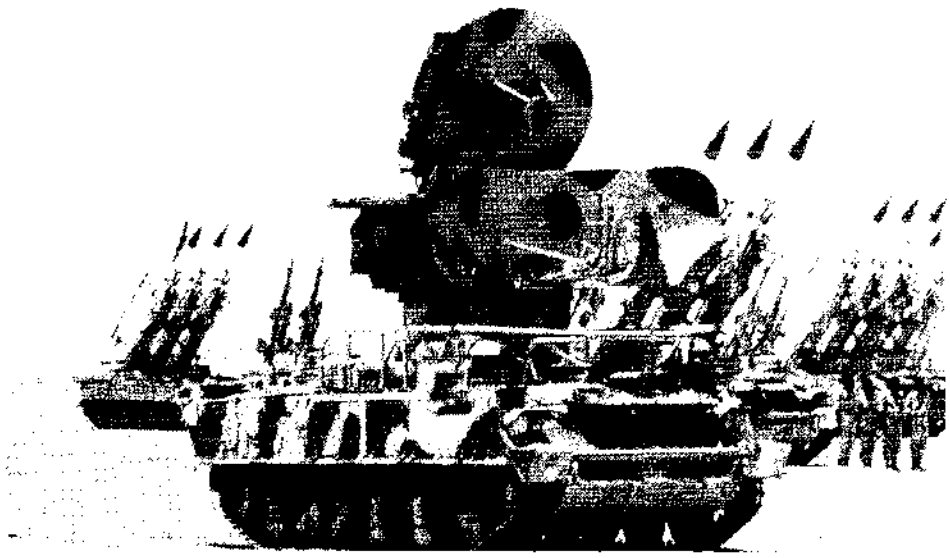
Reports of the frequencies used for these functions have not been entirely consistent. It seems, however, that the first three functions are performed in G/H-band, the low altitude function being performed at about 5 GHz and the high-altitude functions at about 6 GHz. Target tracking (and probably illumination) is an I-band function at around 8 GHz and so probably is the command link, while the secondary radar response for missile tracking is probably at a rather lower frequency. Range is believed to be 60 to 90 km, with a maximum altitude coverage of 1000 metres.

The arrangement of the system can be seen in the accompanying picture. The upper, tracking, radar antenna assembly is assumed to be able to rotate independently of the lower antenna and it is further assumed that the two antennas and associated apparatus can be rotated relative to the carrying vehicle on a turntable which is presumably located at the top of the circular turret on which the whole assembly is mounted. Examination of the original photographs suggests that the lower antenna may be pivoted so as to execute a sector scan of some kind and there is some indication that it can be tilted up or down, presumably to compensate for vehicle attitude.

These observations are consistent with the assumed functions listed above; the combined radar superstructure is probably too massive for any kind of continuous circular search process and the arrangement probably provides for a slow circular search into an associated sector scan, the circular motion being halted when a target is located and resumed only if the target starts to move out of the sector.

The feed arrangements of both antennas are interesting. The lower antenna appears to have two feeds (which can be seen more clearly in the original picture) the upper one consisting of a single horn, which presumably produces a low-angle pencil beam, and the lower feed comprising two or possibly three horns which may well produce a slightly shaped high-cover beam. There could be more sophistication to it than this but if so it is not obvious or obviously likely. The use of two separate feeds, however, is consistent with the suggestion that the low- and high-altitude patterns are radiated at different frequencies.

There is, however, some additional waveguide in this feed which is not explained by what has been said above. It appears to be for a higher radiation frequency (than G/H-band) and could be for one of the other functions (command link or secondary radar – more probably the former). Finally it looks as though both parts of the main feed have a quarter-wave-plate circulariser in front of them. If this is a correct reading of the photographs it tends to date the technology of the equipment: a radar of this sort built in the West in the late 1960s would have used waveguide circularisers. It also looks as though the third (higher-frequency) feed bypasses the plate which makes sense.



Turning now to the upper antenna, the function of the tripod-mounted device projecting in front of the dish is not clear. The remainder of the assembly is fairly evidently a conical scanning system using a rotating feed driven by a motor in the housing at the rear of the dish. This housing also almost certainly contains the microwave transmitter/receiver stages to avoid the need for multiple rotating waveguide joints.

Two of the struts supporting the projecting device appear to be simple metal rods or tubes secured to the face of the dish, the third (bottom) strut, however, is different, fairly certainly passing through a hole in the dish, and could be a waveguide. The way in which the upper struts meet the 'device' seems a little clumsy if they are no more than supports however, and while it may be that the 'device' is yet another antenna of some sort, we incline to the view that it is either another quarter-wave plate or a beam-spoiler for some operational purpose and that the bottom strut is merely a kind of push rod (hence the need to go through a hole – a waveguide would not) for moving the 'device' into and out of the way.

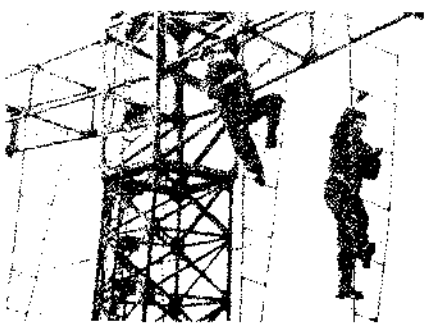
Apart from the microwave stages of the tracking radar it seems probable that the bulk of the radar electronics is housed in the bin-shaped structure beneath the tracking radar pedestal. The turret may be assumed to house the displays and control gear.

STATUS

Operational. Radars of this type were used with Gainful missiles in the 1973 Arab-Israeli War.

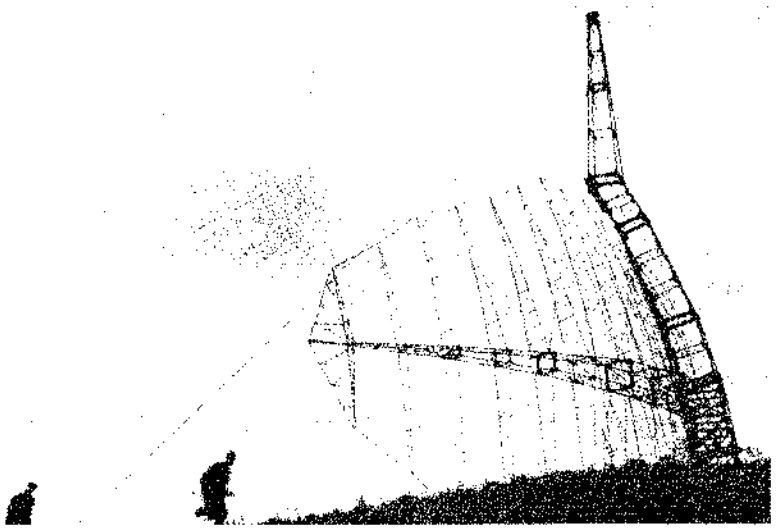
Straight Flush fire control radar. Note pairs of AFV-mounted SA-3 (Goa) missiles in the background
(Sava Haery/SIPA Press)

3293.153



TALL KING EARLY WARNING RADAR

Tall King is the name given by NATO to a large early warning radar P-14 for air defence of the Soviet Union and Warsaw Pact states. The origin of this name can be guessed quite easily from the impressive appearance of the structure which incorporates a reflector estimated to measure about 15 m high by 25 to 30 m wide, surmounted by a pylon of perhaps another five metres or so to which are attached the guy-ropes needed to steady this large array.

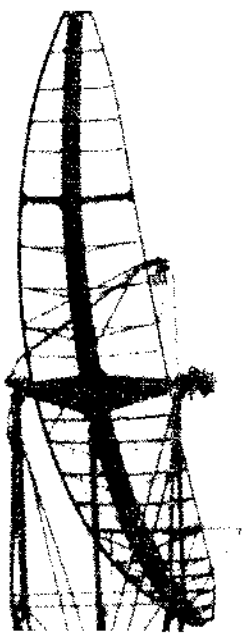


The method of illuminating the antenna is not clear but operation at metric wavelengths, probably between 150 MHz and 180 MHz, is almost certain. The effective range is probably at least 500 km or 600 km. Tall King is reported to have been introduced in the 1950s to provide early warning against high-altitude intruding aircraft. Although obviously a fixed-site radar, sectional construction is employed so that, although a lengthy undertaking, Tall King is capable of transportation and re-siting without undue difficulties.

It is believed that Tall King radars have been deployed in Afghanistan to survey activities on the borders with China and Iran.

Side Net (**3289.153**) transportable heightfinder radars have been associated with Tall King installations.

Close-up of Tall King early warning radar showing technicians carrying out either final stages of erection or routine maintenance



Soviet Tall King early warning radar

2892.153

TOKEN EARLY WARNING AND GCI RADAR

This E/F-band early warning and ground control interception (GCI) radar is similar to the US CPS-6B radar (the first V-beam radar). Like Barlock (**2861.153**) it has twin truncated parabolic mesh reflectors. Five beams are produced and in the GCI role it has a range of about 150 km and can measure to within 0·5° in azimuth and 300 to 1500 m in elevation. In the early warning role it has a range of 250 to 300 km and a range accuracy of about 1 km.

Thin Skin heightfinder radar

3292.153

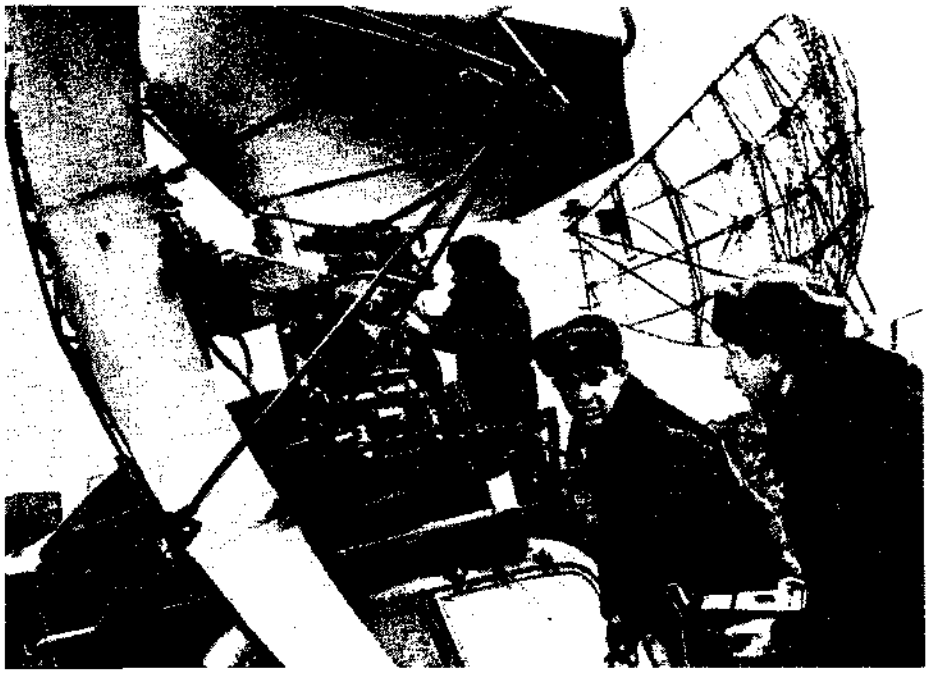
THIN SKIN HEIGHTFINDER RADAR

Thin Skin is the NATO name for an H-band nodding heightfinder radar, generally deployed as part of a ground control interception formation. Both trailer and track-mounted versions have been observed and its operational role is probably in support of tactical air defence units. In all cases it will be associated with a search and surveillance radars to provide them

with complementary height information on targets detected. This radar is reported to be associated with Soviet Ganef, Gainful and Gecko surface-to-air missile regiments. Range is approximately 240 km.

STATUS

First reported in 1965, Thin Skin has since been supplied to nations outside the USSR, both within and beyond the Warsaw Pact states.



3295.153
TWO SPOT PAR

Two Spot is the NATO code-name of the radar group employed by Soviet air forces for use in precision approach radar (PAR) aircraft recovery and landing guidance. It is usually associated with the Long Talk air search radar (**3294.153**) which provides aircraft with ATC and homing directions to the airfield, and positioning for the PAR 'talk-down' landing itself. In some installations the Two Spot and Long Talk systems are both mounted on the same trailer vehicle, but Two Spot has also been observed mounted on a platform above the driving cab of a truck.

There are two antennas, both of parabolic section, one for elevation tracking and the other for azimuth. They are carried on a combined mounting, which permits limited rotation of the whole assembly to enable the system to be aligned to the bearing of the runway in use. The antennas and other items can be folded for transit. The operating frequency is in the I/J-band.

Two prominent discone VHF or UHF communications antennas for the ground/air link used for talk-down are carried on a tubular mast, and these may be the origin of the NATO code-name.

Several Two Spot PAR systems have been deployed at Soviet air bases in Afghanistan, associated with Long Talk radars (**3294.153**).

Vehicle-mounted version of Two Spot PAR

2893.153
WHIFF FIRE CONTROL RADAR

This is a van-mounted E/F-band gun fire control radar. Like Fire Can (**2871.153**) it is derived from the American SCR-584 equipment that was supplied to the USSR during the Second World War.

Construction and performance are generally similar to those of Fire Can. The antenna gain of Whiff, however, is somewhat greater.

2895.153
YO-YO MISSILE CONTROL RADAR

An early missile control radar, Yo-Yo is used to control the Guild (**2944.131**) surface-to-air missile (SA-1).

It is reported that this radar can track more than 30 targets at a time. Flapping beam techniques are used for target tracking and the radar uses six rotating antennas to cover a scanning area of some 70° both in azimuth and in elevation. Operating frequency is around 3 GHz and peak power around 2 MW.

4602.153
PSNR-1 BATTLEFIELD RADAR

The PSNR-1 is a portable battlefield radar used in reconnaissance companies of Soviet tank and motorised rifle regiments. It operates in the 9-6 GHz band with a maximum range against vehicles of 10 km and 5 km for personnel. The equipment is tripod mounted, can be carried by three men and takes approximately 15 minutes to prepare for operation. Divisional anti-tank battalions are believed each to have three systems for target acquisition purposes.

UNITED KINGDOM

1018.153
CYMBELINE MORTAR LOCATING RADAR

Cymbeline (British Army nomenclature: Radar FA No 15) is an extremely rugged self-contained radar (including power supply) with a detachable display unit. The radar is mounted on a four-legged structure supported on screw jacks fitted with hydraulic absorbers. It is produced in two versions: Mk 1, which is the towed version and Mk 2 which is the self-propelled variant.

The equipment is transported either on a two-wheeled trailer or on an FV432 armoured personnel carrier (**5007.102** in 1979-80 and earlier editions). In the latter mode the screw jacks are replaced by an automatic hydraulic levelling system.

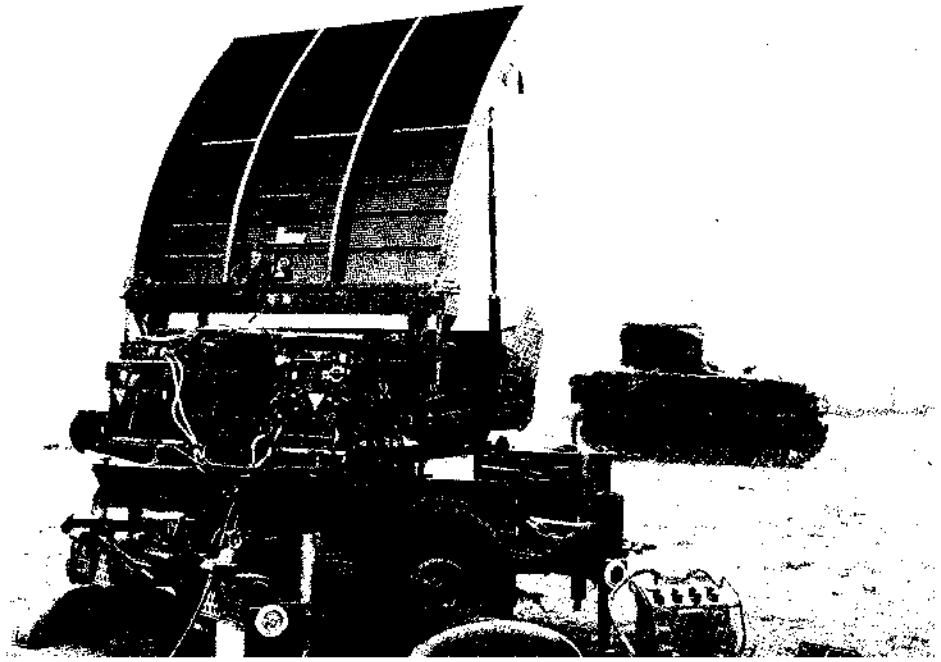
The antenna system consists of a Foster Scanner which illuminates a parabolic cylinder reflector and produces a pencil beam scanning in azimuth. The complete radar head can be rapidly rotated to cover any required sector; for example, 180° rotation in 15 seconds. When in transit the reflector folds down.

Below the antenna is an equipment box which houses the main electronics unit, the power unit, and the display unit during transit.

The main electronics unit contains the transmitter/receiver and the radar timing and computer modules.

The display and co-ordinate indicator units can be removed from the equipment box for remote operation for distances up to 15 metres. The display unit consists of a short-persistence 'B' scope on which the radar returns are displayed. It also carries all the controls necessary for the operation of the radar. The mortar co-ordinates are displayed on the co-ordinate indicator which can be used at distances up to two metres from the display.

OPERATION



The radar enables the operator to plot two points in the bomb trajectory, and to measure the slant range and bearing to each of these positions. The time taken for the bomb to travel between the two points is also measured and the computer uses this information together with the pre-set elevation angles to determine the firing position of the mortar. This entire process takes place in about half a minute.

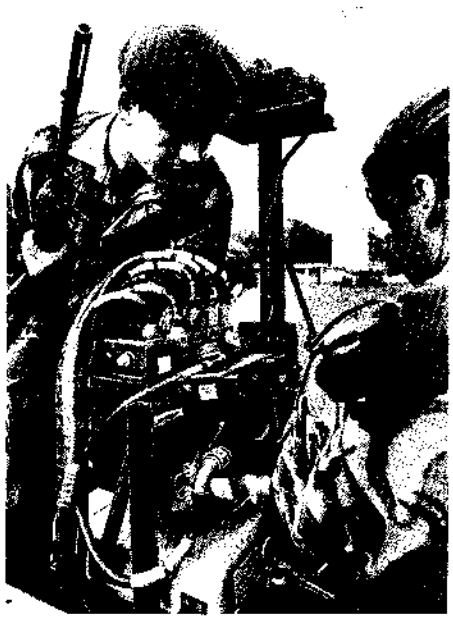
Additional facilities have been provided to ensure the maximum accuracy of location and ease of operation over a wide range of operational conditions. For maximum range performance a switched single beam is used, and an additional beam position is available to alert the operator for making the first interception. For short range work a double-beam mode of operation may be selected to obviate operator reaction time errors. This facility also improves the multiple target capability.

Provision has also been made for the internal fitting of an optional digital data storage module. This enables the radar returns to be stored to provide a long-persistence display so that operator concentration can be reduced while improving the marking accuracy. Data storage also improves multiple handling capability.

CHARACTERISTICS
Frequency: I/J-band
Peak power: 100 kW
Antenna: Foster Scanner with reflector
Sector scan: 720 mils
Bearing limits: 12 000 mils total rotation
Speed of rotation: 200 mils/s
Presentation: 'B' type display with displayed 0 – 20 000 m and selected 4000 m and 8000 m zones
Minimum range: 1000 m
Max displayed range: 20 000 m
Weight: 390 kg
Radar reliability: 200 h MTBF (excluding power source)
STATUS
Deliveries to the British Army commenced in mid-1973 and the first delivery of the self-propelled version was made in January 1975. A dedicated mortar locating battery has now been formed. Total deliveries to the British Army and 16 overseas countries had reached 300 sets by January 1985 and are continuing.

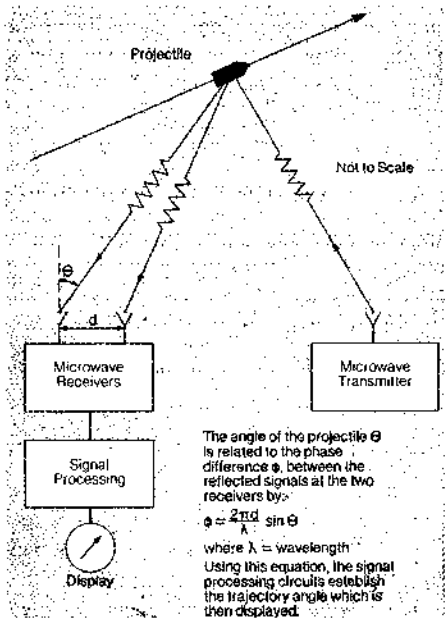
An MTI modification has been introduced recently to give a considerable performance improvement in clutter and ECM conditions.
CONTRACTOR
Thorn EMI Electronics Ltd, Hayes Division, Dawley Road, Hayes, Middlesex UB3 1HN, England.

Cymbeline mortar locating radar



3490.153
RADAR GS20 HOSTILE FIRE LOCATOR CLARIBEL

The Claribel hostile fire locator radar GS20 is designed to provide vehicles of any type or fixed locations with an automatic warning of sniper fire and an indication of the direction of the source of such fire. It is intended to eliminate the problems and disadvantages of locating snipers by traditional methods based on such techniques as the 'crack and thump' acoustic method.



The radar is a CW equipment based on an I/J-band Gunn diode microwave transmitter, and is all solid-state. No mechanical scanning is involved and a number of sensors are arranged around the vehicle (or fixed position) to provide all-round coverage. A circular display unit indicates the direction of hostile fire sources within 30° sectors, the appropriate sector(s) normally being illuminated before the sound of the shot reaches the vehicle. Usually one display is mounted in front of the commander of the vehicle with a second display located in a convenient position for viewing by the other members of the patrol. The GS20 incorporates a second shot capability, so that the location of two snipers firing from different sites can be identified simultaneously. Another useful feature in vehicle installations is an orientation facility which ensures that the information displayed is continuously updated to compensate for any evasive action that the vehicle driver may take after sniper's shot(s).

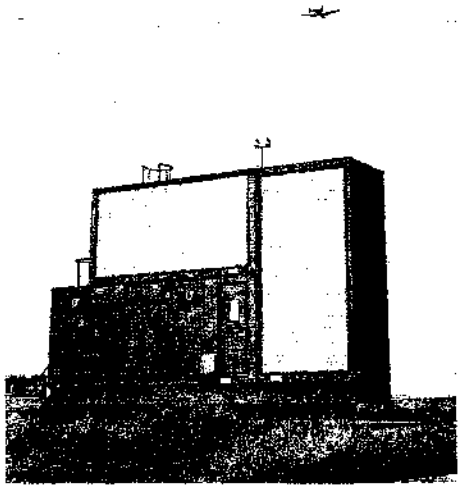
A recent development now enables GS20 to transmit the displayed information, plus an alarm and vehicle identification code, to follow-up vehicles and/or command operation posts.

A typical vehicle GS20 installation would consist of four radar heads, commander's display unit, crew display unit, orientation unit, central processor and power unit.
OPERATION
The direction of source of any shot detected is derived from calculation of the trajectory of the projectile and extrapolation back to infinity. Computation is performed by a digital machine. The instantaneous angle of the projectile relative to the radar is obtained by the use of multiple receiver antennas and comparing the phase of the signals received simultaneously in each antenna. The doppler shift of the returns is measured and used to determine the projectile speed, so that signals from slow moving objects such as stones can be ignored.

Radar GS20 in use with the British Army

Operating principle of the GS20 hostile fire locating radar

DEVELOPMENT
The radar GS20 was developed for the British Army jointly by the UK MoD and MESL.
STATUS
In service with the British Army.
CONTRACTOR
Racal-MESL Radar Ltd, Preston Road, Linlithgow, West Lothian EH49 6EU, Scotland.



3715.153
FALCONER PRECISION APPROACH RADAR

In 1979 Cossor Electronics was awarded a contract to provide new precision approach radars (PARs) for MoD airfields in the UK and abroad. The new radar, designated the Cossor Falconer, will replace the SLA-3 generation of equipment currently in service, which will progressively reach the end of its useful life by 1985. It carries out the same essential functions of providing runway approach and landing guidance to aircraft equipped with two-way communication in either VHF or UHF.

The Falconer consists of radar-head equipment installed in a transportable cabin together with ATC display consoles and associated remote control equipment in the operations room. In addition, the radar head cabin is fitted with a display console for engineering use or, with the addition of suitable communications equipment, for use as a stand-alone or fall-back control position. The radar head installation is transportable by road or air and can be quickly and easily reassembled at another site.

The radar-head is a dual-channel system employing solid-state circuit elements, except for the main modulator thyratron and coaxial magnetron. Modular construction is used wherever possible; moreover, the widespread use of small easily replaceable modules ensures relatively inexpensive replacement costs. The use of digital circuitry also maintains drift and significantly reduces warm-up time.

The clear air range of the system on a 1 m² target has been calculated as 33 km; in operation this has reached 42 km so that the operational requirement of 28 km is comfortably exceeded. To enhance target detection in range and in adverse weather conditions, the radar incorporates selectable linear/circular polarisation, a digital MTI and a video correlator to reject uncorrelated clutter returns. A second-time-around rejection circuit and FTC and GTC circuits are also included. In addition, a five-stagger PRF is used to eliminate blind speeds between 20 and 600 knots.

Cossor Falconer installed at RAF Wyton

Falconer display in control tower at RAF Wyton

Significant cost savings are being achieved by the use of customers' existing antennas; Cossor being able to refurbish and modify these to interface with the new radar. A modern simplified drive is fitted, together with a direct digital angle data take-off for improved stability.

Each system comprises an azimuth and elevation antenna installed in a robust module mounted directly onto the cabin exterior. Each antenna has a beamwidth of 0·5°, in its principal plane with a scanning rate of approximately one second. The elevation antenna scans vertically from -1 to +6°, while the azimuth antenna scans from -10 to +10°. Resolution is such that two targets at the same range can be distinguished at 0·6° separation in elevation and 0·8° separation in azimuth. In range, two targets can be distinguished with a separation of 60 m.

Two display consoles are provided for fitting in the operations room. Each has a 16 inch (41 cm) azimuth/elevation display, an electronic map generator with associated controls and a removable desk unit. Each display shows both azimuth and elevation information from maximum range to touchdown. The displays also contain an operator control which can slew to tilt the antenna to optimise radar returns; the relative position of each beam being indicated on the radar display by an area of intensified or de-intensified range markers. Remote control facilities are provided to transfer data between the radar head and the operations room over distances in excess of 3000 m. The control facilities permit selection of either of the two radar channels virtually instantaneously and control the performance of the selected channel while providing continuous status information on both channels. The system also provides remote control of the antenna and cabin turntable positioning to any one of four preset positions with return status indication.

While employing cross-site coaxial cabling as the normal link between the radar head and the operations room, provision is made for housing extra units for the remote control system to be operated over a microwave link for any special site or operational reasons.

STATUS

Cossor is supplying a total of 44 static and 2 mobile Falconer systems for RAF and MoD airfields in the UK and elsewhere. The four-year delivery programme started in 1981, with full flight testing completed by mid-1982 and systems are in full operational service with the Royal Air Force. In mid-1984 a Falconer system was supplied to the Zimbabwe Air Force.

FIRELIGHT TARGET ILLUMINATING RADAR

Firelight is a target illuminating radar for use with the Bloodhound and Thunderbird surface-to-air guided missile systems. The equipment is land mobile and air-transportable and the complete radar is housed in a single trailer.

Basically an I/J-band CW doppler auto-follow radar, the equipment also performs the function of illuminating the target and thereby providing the reflected radiation to activate the semi-active homing system of the Bloodhound and Thunderbird missiles. In addition it has a limited target search facility and is equipped for target identification. Firelight went into service in December 1962 and has been progressively updated to incorporate later techniques.

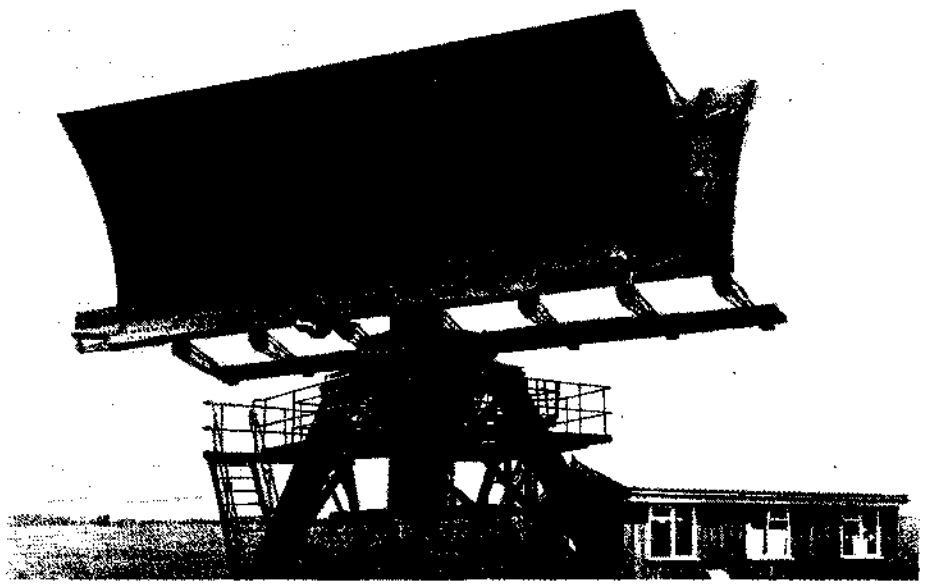
Further information is given under this entry number in previous editions of *Jane's Weapon Systems*.

CONTRACTOR

Ferranti Plc, Radar Systems Department, Ferry Road, Edinburgh EH5 2XS, Scotland.

2458.153

MARCONI HIGH-POWER STATIC SURVEILLANCE RADARS (LINEAR FED)



Included among the range of Marconi high-power static radars is a family of surveillance radars using single curvature reflectors illuminated by linear feeds. The antenna system may comprise single or back-to-back dual reflectors operating in E/F- or D-band. The later antennas feature a squintless feed (see **1168.153**). A range of transmitter/receivers can be operated singly or in diversity.

Members of this family believed still to be operational are:

Types S247, S266: EF- and D-band back-to-back antennas Type SA116, 45ft (13·72 m) aperture. Transmitter/receivers SR1000 2·5 MW E/F-band; SR1030 2·25 MW D-band.

Type S647: E/F- and D-band back-to-back antennas Type SA116, 45 ft (13·72 m) aperture. Transmitter/receivers S2012 2·25 MW E/F-band; S2011 2 MW D-band.

Type S631: E/F- and D-band back-to-back antennas Type S1011 and S1014 with squintless feeds, 45 ft (13·72 m) aperture. Transmitter/receivers in diversity 2 × S2012 2·25 MW E/F-band; 2 × S2011 2 MW D-band.

Back-to-back D-band (front) and E/F-band antennas with squintless linear feeds on S631 surveillance radar

Type S690: E/F- and D-band back-to-back antennas Type S1011 and S1014 with squintless feeds, 45 ft (13·72 m) aperture. Wide-band coherent transmitter/receiver S2018 3·3 MW E/F-band, S2019 3·3 MW D-band.

E/F-band antennas for all the above have a parabolic section while the D-band antennas are cosecanted.

Other radars in the earlier series which were specified but are not known to be operational were:

S255: Single 45 ft (13·72 m) D-band cosecanted antenna.

S265: Back-to-back 45 ft (13·72 m) E/F-band parabolic and cosecanted antenna.

S320: Back-to-back 45 ft (13·72 m) D-band parabolic and cosecanted antennas.

MARCONI MOBILE AND TRANSPORTABLE TACTICAL CONTROL RADARS

This entry relates to a pair of radars, Types S330 and S404, developed on a British defence contract for use with the Thunderbird guided weapon system (**2460.131** in 1977 and earlier editions).

Little information concerning these radars is available for publication. The S330 is a surveillance radar with back-to-back antennas working in E/F-band and D-band; the S404 is a heightfinder working in G/H-band. In operation these radars are used for tactical control in association with a sophisticated display and data processing system such as Nomad (**2421.181** in 1976 and earlier editions). Both radars are fully mobile and air-transportable. They are not, however, the only mobile and transportable Marconi radars and attention is drawn to **1168.153** (in 1980-81 and earlier editions) which deals with the S600 series.

STATUS

In service.

CONTRACTOR

Marconi Radar Systems Ltd, Writtle Road, Chelmsford, Essex CM1 3BN, England.

2462.153

MARCONI LONG-RANGE HEIGHTFINDING RADAR TYPE 669

This is a long-range E/F-band heightfinder radar capable of providing at least 17 heights per minute with an overall accuracy of ±1500 ft (457 m) at 150 nautical miles (280 km). Discrimination at this range is better than 900 ft (247 m). Modes of operation are single shot, automatic, or manual searchlight, burn-through, volumetric, and sector scan. The single curvature linear fed antenna has very low sidelobes and is hydraulically driven for minimum response times. Either manual or automatic height extraction is available.

The radar is a derivation from the S269 radar, 14 of which are used in the NADGE chain stretching 3000 miles (4828 km) from Norway to Turkey, itself a derivation from the S244.

The total number of Marconi heightfinders supplied to NATO has now reached 40.

CHARACTERISTICS

Antenna

Gain: 40·5 dB

Vertical beamwidth: 0·6°

Sidelobes: -20 dB

Nod duration: 2 s

Slew rate: 90° in 2·5 s

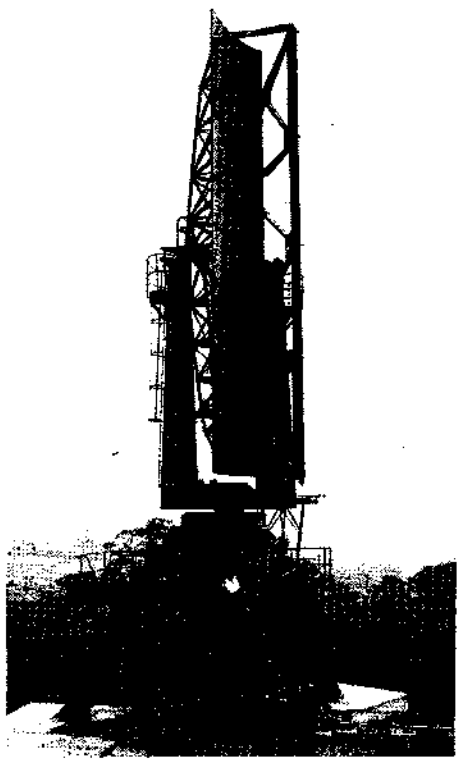
Transmitter

Peak power: 2·25 MW

Pulse length: 2·5/5 μs

PRF: 300/600

Receiver



Noise figure: 3·8 dB

Heightfinding radar Type 669

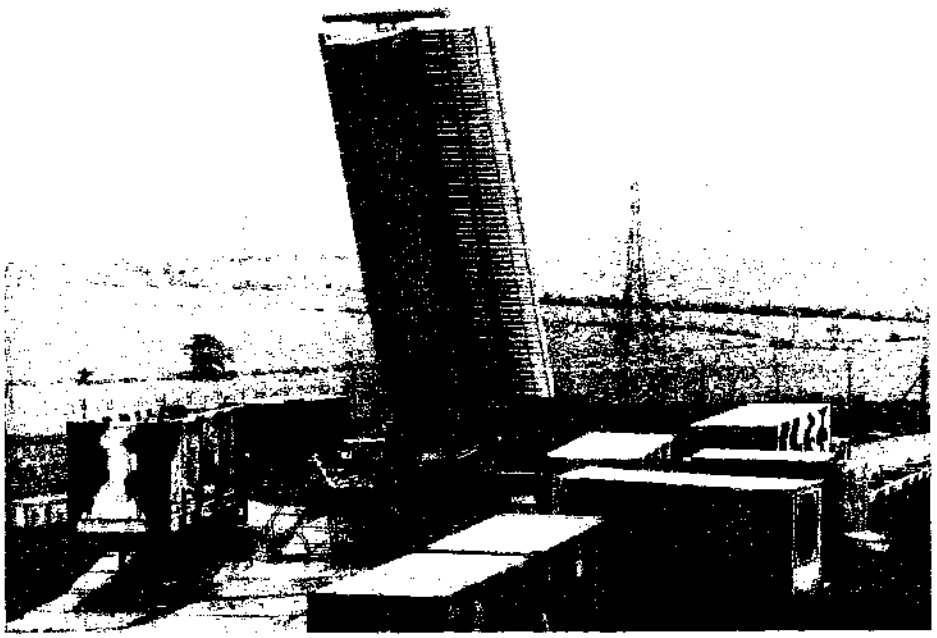
3491.153

S713 MARTELLO 3-D SURVEILLANCE RADAR

The Marconi S713 Martello three-dimensional surveillance radar is a mobile D-band long-range equipment designed to provide complete air defence coverage throughout the 1980s and 1990s. An alternative version, the S723, is described under entry **4798.153**.

The system consists of the antenna, a radar container, a cooling/air conditioning unit and a power generation unit which are all based on the ISO freight container concept so that they can be transported by standard prime movers or carried in transport aircraft such as the C-130. The radar can be ready for action within six hours of arrival at its operational site. The antenna consists of 60 identical horizontal linear array elements, vertically stacked, each with its own receiver. The antenna rotates at six revolutions per minute and each array receives returns which are assembled into a passive IF beam-forming network. This forms eight beam patterns to achieve the required vertical cover and heightfinding accuracy. Cover is provided from the radar horizon up to 30°, with height measurement up to 24° elevation. The array is tilted back at an angle of about 14°, the bottom beam being flat along the ground and all beams being fixed in elevation. The array can be operated in winds of up to 70 knots, and is designed to withstand gusts up to 120 knots.

Range and bearing information is obtained by conventional scanning with elevation data being derived by monopulse processing of the signals in adjacent beams. Since this processing is carried out on a common radiated frequency, accurate height measurements are achieved even when the transmitter is in the frequency agile mode. The three-dimensional data is then processed to deal with clutter, chaff and ECM conditions and correlated with extracted SSR/IFF information before onward transmission to either a local or remote operations centre.



Pulse compression and doppler filtering are also employed to give moving target detection in conditions of clutter and heavy chaff accompanied by significant wind shear.

STATUS

In production. Seven Martello radars have been ordered. Of these, five were ordered for the Royal Air Force, three in March 1982 and a further two in September 1982. These last two plus two more ordered at the same time by the UK MoD for Denmark were the S723 version and were purchased using NATO infrastructure funds at a cost of over £20 million. (See entry **4798.153**).

CONTRACTOR

Marconi Radar Systems Ltd, Writtle Road, Chelmsford, Essex CM1 3BN, England.

S713 Marconi Martello mobile 3-D surveillance radar

4798.153

S723 MARTELLO 3-D SURVEILLANCE RADAR

The S723 Martello radar is a later version of the earlier S713 system (**3491.153**) and differs considerably in both physical appearance and technical characteristics. Physically, the S723 presents a different appearance having a wider horizontal but shorter vertical aperture. Technically, the new planar array antenna incorporates integral solid-state transmitters giving a 'fail-soft' capability, combined with high performance receiver modules. Two versions of the S723 are available, S723A and 723C, the latter having six elevation beams as opposed to eight for the S723A.

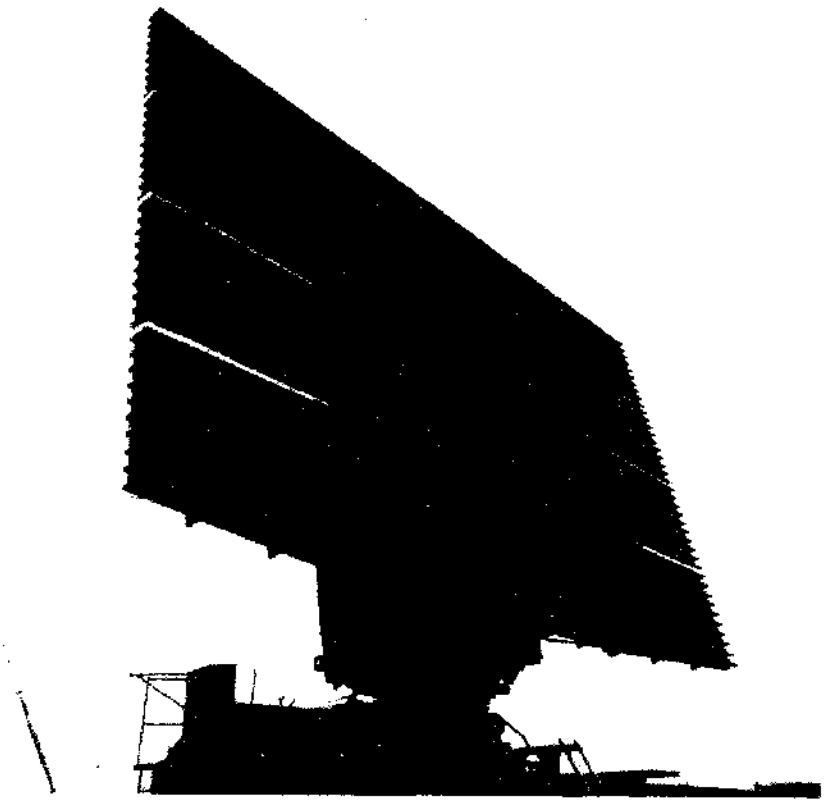
The S723 is a 3-D stacked beam radar with a parallel receiving system for height finding. Bearing, range and height are available on every target on each revolution of the antenna. The planar antenna is a vertical stack of array elements each fed from solid-state transmitters housed in the antenna spine. Each element has its own high performance receiver. The transmitted RF power is fed to each array with appropriate phase and amplitude relationship to obtain a cosecant squared vertical cover with narrow azimuth beamwidth and low sidelobes.

Returns from the targets are received by all arrays. The individual receiver outputs are then combined in a passive beam-forming network which synthesises either eight or six elevation beams matched to the required elevation cover. All beams have pulse compression and full adaptive signal processing is provided out to maximum range. Target bearing and range are automatically extracted from a series of individual returns by the plot forming system and monopulse measurement of returns in adjacent beams yield corresponding height data.

The trailer-mounted antenna accommodates the solid-state transmitters, the receivers, the beam-forming network, and the IFF/SSR interrogator and its co-mounted antenna. The electronics container houses the eight or six adaptive signal processors, the 3-D plot extraction system, the IFF/SSR data extractor, the plot correlation and digital data link equipment, and a radar management console.

CHARACTERISTICS

Instrumented range: 270 nm
Instrumented height: 200 000 ft
Instrumented azimuth: 360° at 6 rpm
Range accuracy: 525 ft
Height accuracy: 1700 ft (S723A); 2000 ft (S723C)
Azimuth accuracy: 0·13°
Detection range: 270 nm (S723A); 230 nm (S723C) (for small aircraft)



STATUS

In production. Four S723 systems have been ordered, two for the UK and two for Denmark under NATO ground defence update requirements. The first UK system has been delivered. Four systems have been ordered by Oman.

Marconi Radar has teamed with Raytheon to bid for a $500 million contract for CONUS FARR (Federal Aviation Agency Radar Replacement), a civil/military radar network of 48 minimally attended radars for the JS Joint Surveillance System (JSS).

CONTRACTOR

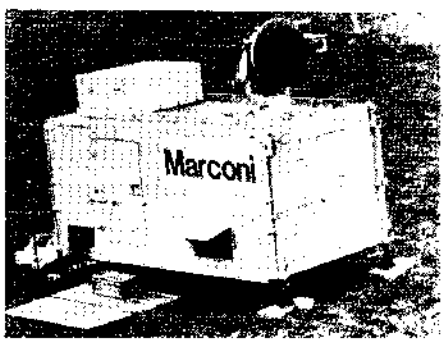
Marconi Radar Systems Ltd, Writtle Road Works, Chelmsford, Essex CM1 3BN, England.

S723 Marconi Martello 3-D radar's new planar array antenna is noticeably smaller than the earlier S713 Martello

2464.153

MARCONI 800 SERIES RADARS (LAND-BASED)

The Marconi 800 series of surveillance and tracking radars was introduced in 1972. The early members of the series (type numbers in the range 801-839) are all naval radars and are described in the next section of the book. Type numbers in the ranges 840-849 and 850 onwards have been allocated to coastal defence radars and land-based weapon radars respectively. Several radars of these types have so far been announced and are briefly described below.



Type S841 is a coastal defence surveillance radar which provides and continuously updates accurate range and bearing co-ordinates on surface targets for weapon fire control systems.

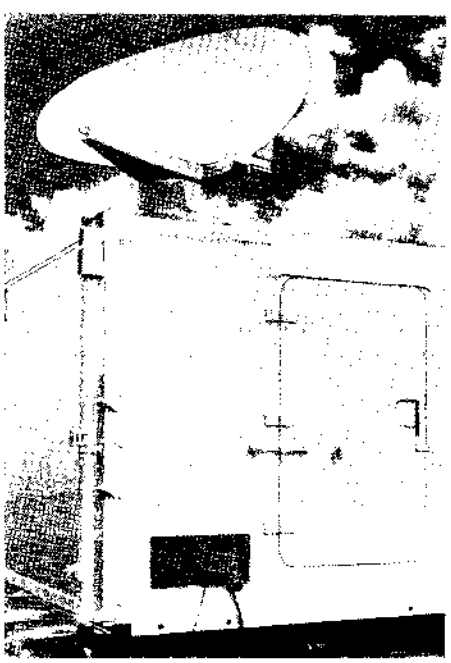
The radar operates at a fixed frequency, selected in the band 9·3 to 9·5 GHz; it incorporates track-while-scan, digital range, and bearing data extraction and has an autonomous fixed coil display. Several sizes of antenna are employed.

The ST850/M target tracking radar and television system has been designed, in co-operation with Short Brothers and Harland, as an integral part of the Tigercat weapon system (**2465.131**) to improve its performance in conditions of poor visibility by giving a dark fire capability.

The ST850/M is contained in a mobile air conditioned cabin with the radar director on its roof. The system is simple to use, is flexible in operation, and can be speedily deployed. This radar is more fully described in **2466.153**. The ST850/G target tracking radar is a derivative of the ST850 which incorporates a Sperry general-purpose digital computer for the prediction of aim-off to give blind fire gun control. Without the TV system, this unit will control small calibre rapid fire AA guns and the complete equipment gives maximum flexibility to a combined missile/gun point defence system.

The ST855/856 are range instrumentation radars incorporating full facilities for data recording and analysis. The ST857/858 is similar equipment designed to interface with customers' own instrumentation. A major feature of the ST858 is its ability, when locked on to an aircraft target, to instantaneously change over to track a small object leaving the aircraft. Tracking of projectiles with calibres down to 20 mm is possible.

ST850 transportable tracking radar



The S860 is a mobile surveillance radar designed to support the ST850 radars through the provision of target positional data. The S860 is an I/J-band, 200 kW (peak), surveillance radar with a typical range of 60 km against high level targets. Digital MTI is incorporated and there is provision for IFF. The radar is mounted on top of a manned cabin with a dual operator position feeding target co-ordinate data to up to three fire control units. Two PPI displays are fitted, each capable of rate-aided tracking on four targets. Allocation of target data to the selected fire control unit is fully automatic on operation of the appropriate key. Co-ordinate data are parallax corrected to ensure speedy target acquisition and to reduce reaction time.

STATUS

Land-based 800 series radars are in production for the UK MoD and other customers. S860 and ST850 units have been supplied overseas as part of the Short Brothers Radar Enhanced Tigercat 2 air defence missile system. The Royal Aircraft Establishment employs an ST858 as a precision tracker for range instrumentation.

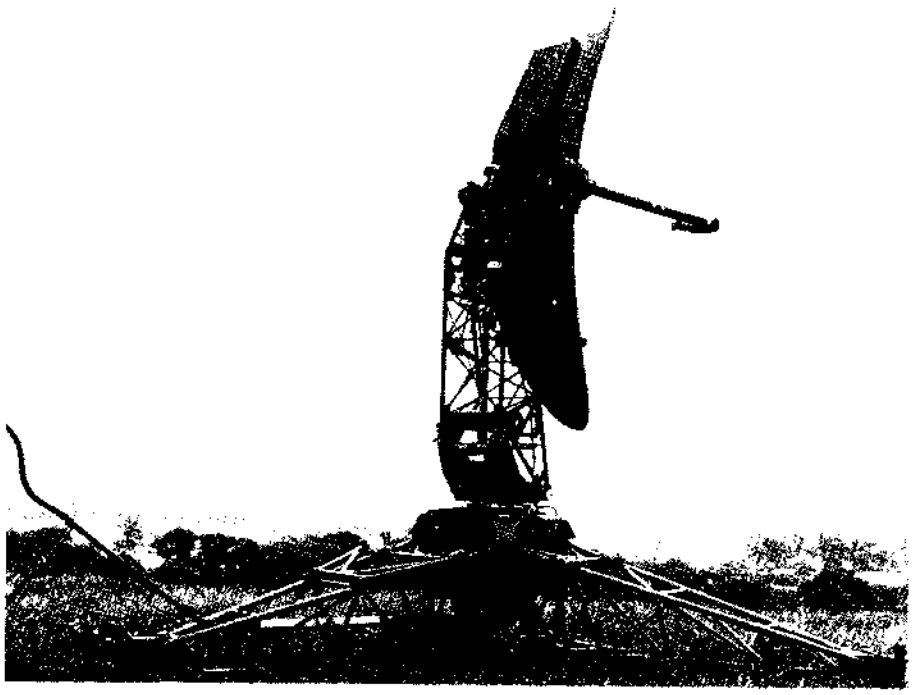
2479.153
MARCONI S613 HEIGHTFINDING RADAR

This is a mobile/transportable heightfinder radar working in the G/H-band. It integrates with any of the surveillance radars in the S600 to S605 range, utilising the same form of construction. The digitally controlled antenna is capable of providing 22 heights a minute and the height is automatically extracted, a unique facility in mobile systems. Modes of operation are normal, sector scan, and volumetric scan.

CHARACTERISTICS



Antenna
Gain: 39·5 dB
Vertical beamwidth: 0·9°
Sidelobes: –25 dB
Nod duration: 2 s
Slew rate: 180° in 2 s
Transmitter
Peak power: 1 MW
Pulse length: 2/5 μs
Receiver
Noise figure: 4·5 dB

STATUS

This radar has been supplied to the UK MoD, NATO, and a number of other nations.

Marconi S613 heightfinder radar

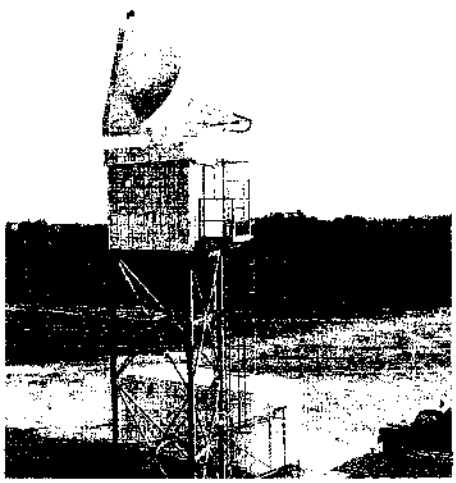
5615.153
MARCONI S500 SERIES STATIC AND TACTICAL AIRFIELD SURVEILLANCE RADARS

The S500 series of radars is designed primarily for static and tactical airfield surveillance. It is also suitable for low cover and gap filling with its good sub-clutter visibility in fixed and moving clutter and its excellent ECCM capability. The series comprises six systems: S511, S512, S513, S525, S531 and S532, operating in the 10 cm or 23 cm frequency band.

In the E/F band there are four systems: the S511 and S512 static equipments and the S531 and S532 tactical systems. All use the same antenna, signal processing and display systems and differ only in their transmitter/receivers.

The high performance antenna consists of a double curvature cosecant squared carbon fibre reflector and a double horn system to provide dual beam operation. Variable polarisation between linear (vertical) and circular is provided on the lower beam and fixed circular polarisation on the upper beam. In the static versions the antenna is mounted on a modular tower, with a choice of height.

The S511 and S531 use a transmitter/receiver Type S2022 which incorporates a tunable magnetron driven by a highly stable, modular, solid-state modulator with a fail-soft capability, and a high stability Coho-Stalo receiver. Frequency diversity using two transmitter/receivers is available.



The S512 and S532 use a rugged, wide-bandwidth, cathode modulated TWT transmitter/receiver S2062. This coherent transmitter/receiver uses pulse compression techniques and provides full frequency flexibility (block by block and pulse by pulse frequency agility).

A signal processor, S7113, with adaptive beamswitching, eliminates moving and fixed clutter and reduces tangential fading. Temporal thresholds (clutter maps) ensure constant false alarm rates under all conditions. A plot extractor, S7204, provides the necessary interface between the signal processing and the data handling system. The Marconi Astrid display system, which permits remote operation up to two miles (3·2 km), is available for use with these radars.

The tactical radars S531and S532 are transportable by road, rail and C-130 type aircraft with a time-in-service on a new site of three and a half hours using a team of four people.

In the D-band there are two static radar systems: S513 and S525. The S513 is for military and civil approach/departure and terminal area control. It employs a rugged dual beam antenna based on the S1020 and a stable transmitter/receiver S2027, with the S7113 signal processor. Good sub-clutter visibility with clutter mapping and adaptive beam switching is provided on all types of clutter.

Longer range performance is available with the S525 which uses the S2019 wideband, high power transmitter/receiver. An adaptive signal processor, S7128, with pulse compression and full frequency flexibility gives good ECCM performance as well as good sub-clutter visibility.

S511 airfield surveillance radar

Both systems use the Plot Extractor S7204 to give the necessary output for data handling, either locally or at a remote control centre.

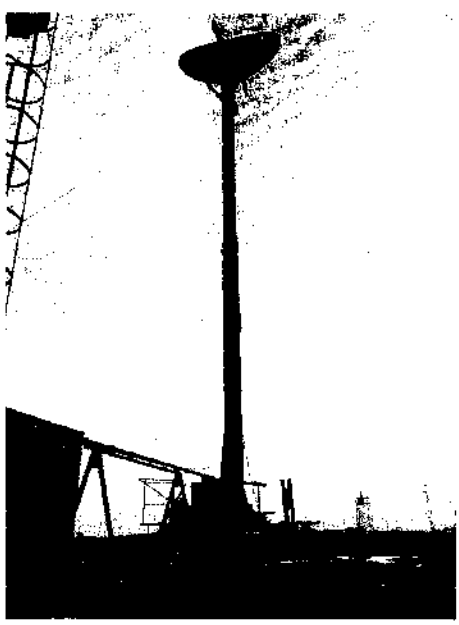
CONTRACTOR

Marconi Radar Systems Limited, Writtle Road, Chelmsford, Essex CM1 3BN, England.

4630.153
MARCONI S700 SERIES MOBILE RADAR SYSTEMS

The S700 series of radars is intended primarily for mobile military use. The series comprises five systems: S704, S705, S706, S711 and S712.

The S704 and S705 are long range radars in D and E/F band respectively, having 25 foot (7·6 metre) single curvature antennas with linear squintless feeds giving cosecant squared cover. The intrinsic sidelobe performance of these antennas is ideal for military operation. Both systems use high power (3·3 MW) wideband transmitter/receivers with pulse compression techniques and full frequency flexibility which, with the S7128 adaptive signal processor and S7204 plot extractor, give good clutter and ECCM performance. The S704 operates with antenna S1061 and transmitter/receiver S2109, and the S705 with antenna S1062 and transmitter/receiver S2018.



The S706 is a medium range equipment operating in E/F band using the same antenna, S1062, as the S705. The transmitter/receiver uses the rugged wide-bandwidth cathode modulated TWT system S2062. Pulse compression and full frequency flexibility is an essential part of the design and with a signal processor and plot extractor provides high quality performance in clutter and ECCM.

The S711 is a short-to-medium range radar for low-level and gap-filling roles. It operates in E/F band and uses a high performance double curvature, cosecant squared, carbon fibre reflector, horn-fed antenna, S1074. This antenna can be hydraulically elevated up to 65 feet (20 metres) for visibility over local obstructions. The S2062 transmitter/receiver, S7113 signal processor and S7204 plot extractor provide the necessary high performance.

The S712 is a short-to-medium range radar for low level defence. It operates in the E/F band and has a linear antenna with a parabolic cover profile mounted on the equipment container. The same transmitter/receiver, signal processor and plot extractor are used as with the S711.

Marconi S711 radar antenna on a 60 ft mast

5869.153
MARCONI OTH RADAR

Although no details have been released, Marconi Radar is known to be studying the development of over-the-horizon HF radar systems. Two systems are being considered, a conventional long-range land-based equipment using skywave techniques similar to the General Electric CONUS-OTH-B described in detail under entry **5617.153**, and a medium-range surface wave version for application in over-the-sea early warning systems. The latter version employs the well-known water coupling effect whereby transmissions tend to hug the water to provide detection capability well beyond the radar horizon.

It is understood that studies and development work on both systems is being funded jointly by the UK MoD and Marconi itself.

STATUS

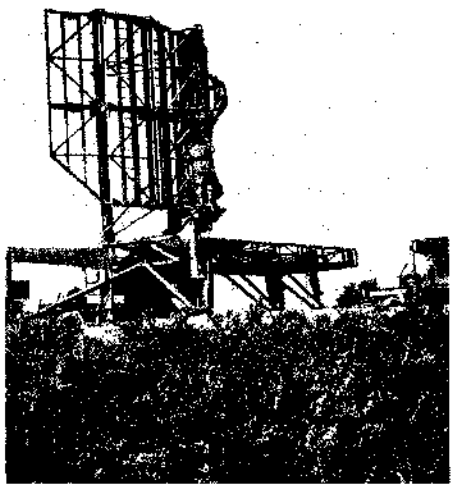
In design study and early development.

CONTRACTOR

Marconi Radar Systems Ltd, Writtle Road, Chelmsford, Essex CM1 3BN, England.

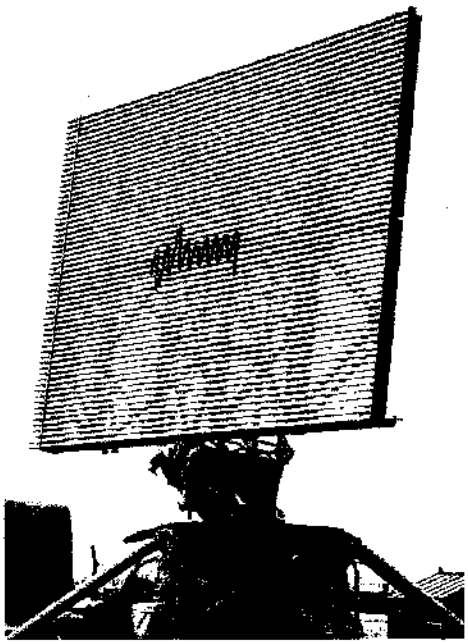
2484.153
PLESSEY AR-3D THREE-DIMENSIONAL AIR DEFENCE RADAR

AR-3D is an E/F-band air defence surveillance radar giving three-dimensional information on targets by mechanically rotating the radar beam in azimuth and electronically scanning in elevation. All elements of the system are trailer-mounted for transport by land, sea or air.



The AR-3D antenna, which combines mechanical scanning in azimuth with electronic scanning in elevation, consists of a compact circular polarised linear array positioned at the focus of a simple parabolic cylinder reflector. The reflector has a height of 4·9 m and a width of 7·1 m. The azimuth sidelobes of the antenna are -36 dB in the 5 to 15° sector and -48 dB in the 15 to 90° sector. An alternative 5·5 m planar array antenna is also available which combines lower sidelobes and accurate beam formation for improved ECCM performance. This latest antenna folds in half for transportation by C-130 aircraft. The electrical characteristics of both antennas are identical to allow retrofit of the new antenna, if required. The transmitter consists of a coherent two-stage E/F-band transmitter. Each of the two stages uses a linear beam pulse microwave tube. Both tubes are designed for excellent phase, noise, and amplitude performance commensurate with the pulse compression and MTI requirements. The transmitter has a peak pulse of 1·11 MW (mean power 10 kW) and a bandwidth of 200 MHz.

The signals received from the antenna are amplified in a wideband (200 MHz) amplifier. After amplification the signals are separated into channels representing elevation bands of approximately 2° (bandwidth 20 MHz per channel). The signals are then time-compressed to 0·1 microsecond and their frequencies measured to enable the fine elevation within each beam to be obtained.



The function of the plot extractor is to detect targets which meet prescribed criteria. This target information is then fed to tracking and display equipment in the form of digital words containing three-dimensional positional information as polar co-ordinates. The on-line processor stores the positional data, carries out azimuth and height calculation, and takes into account various corrections. Plot and track data are then transmitted to the local displays and modems as required.

The varying demands of air defence are met by supplying AR-3D in different operational configurations, as a radar reporting post, control and reporting post, or command and control post. The different requirements are met by variants of the processing and control cabin, with hardware and software organised in modular packages appropriate to the specific function.

As a reporting post the AR-3D provides two operational consoles with automatic plot extraction and reporting to a remote centre of up to 40 combined primary radar and IFF/SSR plots. As a control and reporting post with five operational consoles, automatic initiation and tracking of up to 40 aircraft is provided with automatic reporting of data to a remote operations centre, while up to eight simultaneous computer-aided interceptions can be controlled. The command and control post additionally varies in providing for autonomous computer-aided control of own aircraft and missiles.

Plessey AR-3D radar being deployed with reflector

AR-3D planar array antenna

CHARACTERISTICS

Coverage: Adjustable. Typically 180 nm on 2 m² target

Radiation: Frequency selective within E/F-band. The operating bandwith is 200 MHz. Independent frequency selective filters for each of 13 elevation channels, each having a bandwidth of approximately 20 MHz. The data below refer to linear polarisation

Antenna 'A'

Type: Linear array and parabolic cylinder

Polarisation: Circular

Beamwidth (azimuth): 1°

Beamwidth (elevation) 2°

Peak sidelobe (azimuth): 25 dB

Peak sidelobe (elevation): 23 dB

Scanning angle: 30°

Gain: 41·3 dB

Adjustment: +4, -2°

Rotation rate: 6 rpm

Antenna 'B'

Type: Planar array, horizontal slotted waveguide radiator and serpentine slow wave feed

Polarisation: Linear

Beamwidth (azimuth): 1·5°

Beamwidth (elevation): 1·5°

Peak sidelobe (azimuth): 35 dB typical

Peak sidelobe (elevation): 25 dB

Scanning angle: 20°

Rotation rate: 6 rpm

Transmitter

Peak pulse power: 1·11 MW

Mean power: 10 kW

PRF: 250 pps

Frequency band: E/F-band

Bandwidth (to 1 dB): 200 MHz

Pulse length: 36 μs

PA tube: High power klystron grid modulated

Transmit modes: Continuous or fast on/off

Receiver

Bandwidth: 20 MHz/channel

Compression ratio: 130:1 (lower channels)

Accuracy

Elevation: 0·15°

Range: 15 m

Range resolution: 40 m

STATUS

In production and in service with the UK MoD and a number of overseas countries. Two AR-3D systems have been deployed in the Falkland Islands.

CONTRACTOR

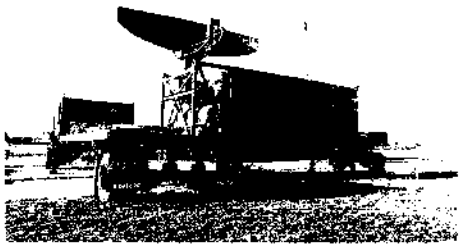
Plessey Radar Ltd, Oakcroft Road, Chessington, Surrey KT9 1QZ, England.

1141.153
PLESSEY AR-15M MOBILE SURVEILLANCE RADAR

The AR-15-M is a mobile radar system for air defence and ATC medium range surveillance and approach roles. In its air defence role it optimises coverage against low flying targets and operates as a manual reporting post

The system, providing both primary and secondary radar/IFF facilities, is a mobile unit with a cross country capability which includes the possibility of deployment in desert conditions: the equipment is installed in containers which can be loaded into C-130 transport aircraft when detached from the trailers. The configuration of equipment is as follows:

Antenna Trailer



A special-purpose trailer carries the primary radar reflector antenna, turning gear and IFF/SSR antenna. Facilities are provided to hoist the antenna on to the cabin.

Radar Cabin

The cabin, which is trailer mounted for transportation, contains a dual magnetron transmitter/receiver, the IFF/SSR interrogator/receiver, signal processing and displays. The equipment is of solid-state design and incorporates an ECCM receiver and an advanced digital target indicator. The cabin also contains two operational displays and ground/air communications equipments. It is air conditioned and provides storage for carried spares, test equipment and ancillaries. Jacking gear is fitted to facilitate loading and unloading from the trailer as well as for levelling for operation.

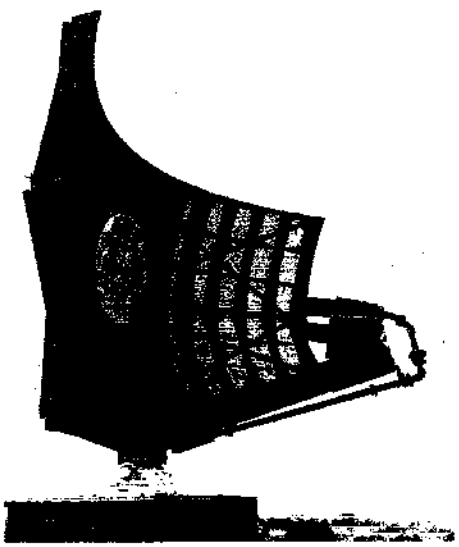
Diesel Generators

Two mobile diesel generators are used for supplying power to the system. One of these is for stand-by purposes. In addition, further cabins can be provided to house the crew and to provide mess facilities if required. The two diesel generators have adequate power to provide the local domestic supply for the crew.

AR-15M mobile surveillance radar

STATUS

In production.



CONTRACTOR

Plessey Radar Ltd, Oakcroft Road, Chessington, Surrey KT9 1QZ, England.

5608.153
WATCHMAN AIR SURVEILLANCE RADAR

Watchman is the latest addition to Plessey's S-band medium-range surveillance radar series. It is designed to offer high performance in terminal area and approach surveillance, fighter recovery, GCA surveillance, approach control, radar sequencing control, outbound control and helicopter surveillance.

New technology in microwave generation and signal processing and the use of a TWT in the transmitter has permitted advanced capabilities and considerable flexibility in the frequency and pattern of transmitted pulses. A dual pulse train is used consisting of a very short pulse (0·4 μs) giving high discrimination at short ranges, and a much longer pulse (20 μs) for detecting aircraft which have small echoing areas at long ranges. The long pulse is compressed in the receiver using a surface acoustic wave equaliser. Signal separation is achieved by using different radio frequencies for the long and short pulses. Target detection is further enhanced by interchanging these frequencies every nine pulse repetition intervals.

Watchman air surveillance radar

Watchman thus provides frequency diversity operation with a single transmitter, and the overall stability of the latter contributes significantly to the anti-clutter performance of the system. High receiver sensitivity is provided by low noise field effect transistor (FET) radio frequency amplifiers, one for each beam. A beam switching system ensures that only the selected beam output is passed to the main receiver as required.

In the signal processor, the adaptive moving target detector provides maximum target detection against clutter. Radar returns are processed in parallel through normal radar, ground clutter filter and moving clutter filter channels each of which uses both in-phase and quadrature processing. Target detections from all three processing channels are automatically integrated and passed on for transmission to the display system. This ensures that the operator views a clean video picture, and also provides considerable 'fail-soft' capability. Compatibility with staggered PRF operation ensures good velocity response free from blind speeds and immunity to second-time-around clutter returns.

Transmission of the control and signal data between the radar head and display sites is via a two-core fibre-optic cable link. In addition to the advantages of lightweight and low cost, the complete electrical isolation of the optical link provides absolute immunity to any form of electro-magnetic interference.

An autonomous display is also available to complement the flexibility of Watchman. Designed for high reliability and ease of both operation and installation, each display console incorporates all the requisite hardware and software facilities associated with the accurate display of primary radar signals. A selection of high resolution digital maps may be generated from internally stored data. Supporting ATC data and, where required, SSR plot data and labels, can be selectively displayed with or without primary radar video.

The Watchman system can be used in both civil and military applications. For the military requirement, the equipment is likely to have to operate in a jamming environment in addition to providing a basic control service. Desirable ECCM characteristics such as low antenna sidelobe level, PRF stagger, pulse compression and moving clutter filter, have already been included as standard items in the system but improved ECCM facilities may be required. To further improve the system's resistance to ECM, extensive frequency agility modes can be made available by simple replacement of the driver source by a variant with selected multi-frequency capability.

A number of additional options are also available, these include primary plot extraction, IFF and secondary surveillance radar.

The Watchman display system is a self-contained, intelligent equipment which allows it to be configured for military and civil uses and for static and tactical air defence.

CHARACTERISTICS

Frequency: 2750 - 3050 MHz
Antenna: Two-beam, horn fed, double curvature reflector
Beamwidth (azimuth): 1·45°
Rotation rate: 15 rpm
Transmitter
Type: Solid-state driver with TWT output power amplifier
Mean power: 1·1 kW
Pulse pattern: Short pulse (0·4 μs) followed by long pulse (20 μs)
Receiver
Type: Low noise FET RF amplifier, double superheterodyne IF with pulse compression
Noise factor: 2 dB
Pulse compression ratio: 50:1 (long pulse only)
Signal processor
Type: Adaptive moving target detector
MTI improvement factor: 46 dB

STATUS

In production. On 1 June 1983, Plessey announced an order from the UK MoD for a number of Watchman systems to be installed at MoD airfields. The initial order is for at least 30 systems with a probable total of 39 for the UK. The value of this order is believed to be about £25 million. In August 1983 three systems were ordered by the Finnish Air Force for delivery commencing in 1985. The value of this order, which includes spares, training, documentation, etc, is in excess of £4 million. An option on four further systems was also placed. Civil airfield orders have also been placed and an order has been received from an unnamed African country for joint military/civil applications. By February 1984 £29 million worth of Watchman radars had been ordered. More than 200 display consoles have been ordered by the UK MoD and a number of other countries.

4631.153
TRANSPORTABLE WATCHMAN DEFENCE RADAR

Transportable Watchman is a mobile S-band radar designed to meet a wide range of tactical requirements. Roles include gap-filling, forward area alert, coastal surveillance, missile and gun acquisition, surveillance for a ground approach control system and automatic plot reporting. The basic configuration allows operation as a manual reporting post and can be extended to operate as an automatic post with fall-back for limited control. The system can function autonomously, with its own communications and power supplies, or it can be integrated as a gap filler into a larger air defence system.

Two equipment cabin configurations are available. The first is a single equipment cabin and antenna; both units are transportable by road trailers, heavy lift helicopters or C-130 type aircraft and can be deployed in less than one hour. The antenna is mounted on the cabin during operation. The cabin contains an IFF interrogator/receiver and interference blanker, two operational displays and VHF/UHF communication equipment.

The second configuration consists of two smaller equipment cabins and an antenna mounted on a pallet. All three units are mounted on mobilisers for transport, providing cross-country mobility. The system can be transported by medium lift helicopters or C-130 type aircraft for tactical deployment. During operation the antenna is mounted on the cabin holding the primary radar, IFF interrogator/receiver and monitor display, while the other cabin contains two (optionally three) autonomous displays and VHF/UHF communications equipment. The radar cabin and operational display cabin can be separated by up to 4 km, with transmission of control and signal data between them via a two-core fibre-optic cable link.

Two antenna configurations are available, a horn-fed low sidelobe reflector incorporating an integral IFF feed or a high gain horn-fed reflector which provides low sidelobes, with additional high angle enhancement.

The transmitter is the same system as used in the Watchman series (**5608.153**) and uses a solid-state driven, high power TWT amplifier providing wide bandwidth for frequency agile operation.

Options include primary and secondary plot extraction, plot combination, two autonomous displays based on the latest microprocessor technology and data communications to allow operation as an autonomous reporting post.

Transportable Watchman radar

CHARACTERISTICS

Frequency: S-band

Antenna	**A**	**B**
Beamwidth	1·5° azimuth	1·5° azimuth
Gain	30 dB	33·8 dB
Polarisation	Variable, linear/ circular	Circular
Rotation speed	10/20 rpm	12/15 rpm

Transmitter: Solid-state, air-cooled
Peak power: 60 kW
Mean power: 1·1 kW
Pulse pattern: Fixed frequency, pulse-to-pulse agile, burst-to-burst agile
Receiver: Low noise FET amplifier, double superheterodyne IF with pulse compression
Noise factor: 2 dB
Pulse width: 0·4 μs (compressed)
Signal processor: Adaptive moving target detector I & Q processing

STATUS

In production for the UK MoD and other countries.

CONTRACTOR

Plessey Radar Ltd, Oakcroft Road, Chessington, Surrey KT9 1QZ, England

5774.153
WATCHMAN COASTAL DEFENCE RADAR

This is a variant of the basic Watchman S-band radar (**5608.153**) with extensive target tracking and data handling facilities for the coastal defence role. The system is designed for operational use in either a static role, in containers or customer supplied buildings, or in cabins for transport by road, rail or air for rapid tactical deployment.

Watchman consists of a frequency agile transmitter/receiver plus signal, MTI and IFF processing units mounted inside a cabin, with a high performance dual-beam primary antenna, incorporating IFF, mounted on top. A second cabin contains the necessary data processing, autonomous display consoles and communications.

Special signal processing techniques are used to ensure optimum detection of surface and slow low level contacts in all conditions, including severe ground, sea and rain clutter, ECM and ECCM. Primary and secondary radar data is processed and tracked to provide a surface and air picture on high definition displays. The displayed information can be used either for local control or can be re-transmitted to a command headquarters.

CONTRACTOR

Plessey Radar Ltd, Oakcroft Road, Chessington, Surrey KT9 1QZ, England.

4607.153
GUARDSMAN DEFENCE RADAR

Guardsman is a two-dimensional mobile radar system designed to meet the requirements of low level surveillance and anti-aircraft artillery alerting. It will also act as a coastal surveillance radar where reliable detection has to be achieved in the presence of heavy sea clutter.

The system is contained within a single cabin for vehicle mounting which gives cross-country mobility for rapid tactical deployment. An antenna mast allows the antenna to be elevated rapidly to a height of 9·5 metres. The system contains its own prime power generators and is transportable in aircraft of the C-130 type. With a trained crew of two, the system has an in-action time of less than 15 minutes. System 'march-order' action time is less than 5 minutes.

Guardsman features a low sidelobe antenna, a high power wide-bandwidth transmitter and advanced digital signal processing. These provide optimum detection in all forms of ECM and severe clutter likely to be encountered in the forward battle area or in coastal surveillance. At the same time they yield a low constant false alarm rate for maintenance of target tracks.

An associated on-mounted IFF antenna and interrogator/receiver provides secondary plots which can be extracted and combined with primary plots. The combined plots can be transmitted to a track extractor for generation of sensor tracks to an operations centre.

The Guardsman radar can be configured to a variety of uses, for example an autonomous plot/track reporting post or an alerting radar for gun or missile batteries via a command post. It can also be integrated into a long range surveillance air defence system. Alternative communication sub-systems are available for each tactical role.

Guardsman is the C-band variant of the Watchman radar system (**5608.153**) and the two systems are similar in many respects.

CHARACTERISTICS

Frequency: C-band
Antenna: Low sidelobe, line fed parabolic cylindrical reflector with integrated IFF
Azimuth beamwidth: 1·5°
Polarisation: Linear (circular/linear selectable optional)
Rotation rate: 1, 30 or 60 rpm (depending on instrumented range)
Transmitter: Solid-state driven TWT amplifier, fixed frequency, multi-mode operation
Receiver: Low noise FET RF amplifier, pulse compression

CONTRACTOR

Plessey Radar Ltd, Oakcroft Road, Chessington, Surrey KT9 1QZ, England.

5775.153
GUARDSMAN COASTAL DEFENCE RADAR

This is a version of the basic Guardsman C-band radar (**4607.153**) which has been designed for coastal defence operations. The system is highly mobile and is designed for high accuracy detection of surface vessels and low flying aircraft in adverse environmental and ECM conditions. Information obtained is used either for local control or is transmitted to a central headquarters.

Guardsman consists of a single equipment cabin with an antenna mounted on a folding mast. The antenna assembly includes an IFF aerial with the associated equipment contained in the cabin. The latter contains the transmitter/receiver, data processing system, display and communications equipment. The cabin is trailer mounted to provide cross-country mobility and to enable the system to be deployed rapidly. It can be transported by rail or in an aircraft such as a C-130.

CONTRACTOR

Plessey Radar Ltd, Oakcroft Road, Chessington, Surrey KT9 1QZ, England.

3649.153
AR-320 THREE-DIMENSIONAL AIR DEFENCE RADAR

The AR-320 is an advanced three-dimensional radar system produced jointly by Plessey Radar and ITT-Gilfillan. It meets all aspects of performance stipulated by the NATO Air Defence requirements for radars in the E/F-band.

The system is self-contained in a number of vehicles and is suitable for transport by land, sea or air. It is designed to provide the optimum combination of long range, fine resolution, good performance in ECM and clutter, high reliability, ease of maintenance, and system survivability. The state-of-the-art digital processing and low sidelobe antenna provide immunity to active and passive jamming, inter-jammer visibility, detection probability in the presence of clutter, and constant low false-alarm rate.

The associated radar-mounted SSR/IFF interrogator/receiver provides secondary plots which are extracted and correlated with primary plots. The combined plots are then transmitted to an operations centre for use in the tracking process. These capabilities, and the common module concept of the radar, ensure that it can be configured to meet a variety of tactical or strategic operational needs, and can be used either independently or integrated with a national defence system.

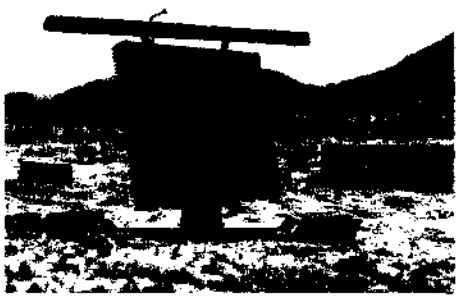
Field Deployment

For tactical operations, the various system elements are installed in cabins mounted on trailers and self-powered vehicles for transport by land, sea or air. The system is designed for rapid deployment and, with a trained crew, can be dismantled, set up, and brought into service again within six hours, transportation time excluded. Typically, the vehicle group will consist of:

(1) an antenna assembly transported on a flat-bed trailer or rail car. In transit the radar antenna is folded down by means of a hydraulically operated mechanism; an attached IFF antenna can be easily removed and stowed
(2) a trailer-installed transmitter cabin containing primary and secondary radar transmitters
(3) a trailer-mounted processing and display cabin containing signal processing equipment, the radar management suite, operations consoles, and the radar environment simulator
(4) transportable diesel-electric generator(s) able to provide power for the complete system
(5) a trailer-installed cabin containing workshop, human support and storage facilities.

The entire vehicle group can be transported to a prepared or unprepared site and operated as a field group with radio link communications to a reporting post or sector operations centre.

Radome Installation



Where environmental conditions require, the vehicle group can be housed under cover with the radar antenna protected by a rigid radome. In this configuration the antenna is hoisted into the radome and supported on structural cross-members.

Silo Installation

An alternative arrangement allows for installation of the antenna and associated electronic sub-systems within a below-ground shelter or silo. The antenna is permanently mounted on an elevator and, for operational deployment, is raised and unfolded hydraulically. The antenna is capable of rapid retraction into the silo when required. The radar hardware in this configuration is arranged in equipment rooms in conjunction with associated power supplies, heating and ventilation equipment.

CHARACTERISTICS

Long-range high-cover performance within E/F-band
High gain, narrow pencil beam with ultra-low azimuth and elevation sidelobes
Planar phased array utilising within pulse, phase/frequency elevation scan
Wideband frequency agility
SSR/IFF antenna
Wideband transmitter with mean power greater than 24 kW
Variable pulse length and PRF
Multi-channel, pulse compressed signal processing
Digital MTI processing with velocity compensation for good anti-clutter and ECCM performance
Small resolution cell to resolve multiple targets and maximise signal to clutter detectability
Fully automatic, 3-D plot extractor
Accurate 3-D co-ordinates from every plot
High performance Series 9 display system with digital display drive
Bright, synthetic presentation with high quality characters and excellent registration accuracy
Radar environment simulation for operator training
High reliability and availability
Wide environmental tolerance
Transportable configuration for rapid field deployment

AR-320 3-D air defence radar antenna

DEVELOPMENT

The AR-320 air defence radar is the result of collaboration between Plessey Radar Ltd and ITT-Gilfillan, combining the ITT-Gilfillan Series 320 3-D antenna and transmitter with Plessey AR-3D receiver, signal processor, displays and software. The Series 320 radars represent a family of defence radars based on three-dimensional radars developed for the American Services by Gilfillan, such as the AN/SPS-48 (**1252.253**) and AN/TPS-32 (**2516.153**) which have since been supplied to a number of other countries.

The Plessey AR-3D is a 'within-pulse' frequency scanning radar, in quantity production. The combination of techniques provide an inertialess elevation scan of a single pencil beam which can be accomplished by either frequency or phase control to

steer the beam in space. This technique maintains high resolution throughout the coverage volume, high data rate and accurate target location.

STATUS

The AR 320 is in production and six systems were ordered by the UK MoD in early 1983. These are the last major radars in the current improvement programme for the UK air defence network. Three will be NATO funded and three will be funded by the UK government.

CONTRACTORS

2425.153

RAPIER SEARCH AND ACQUISITION RADAR

This system is an integral part of the Rapier anti-aircraft guided weapon system (**2424.131**). Little information has been officially released on this part of the system, and the following is an assessment based on available data.

This equipment comprises a primary surveillance radar working in conjunction with a computer and a secondary radar (IFF) interrogator to locate, identify and, where appropriate, initiate the tracking of enemy targets. The whole equipment is located in the fire unit of the Rapier system.

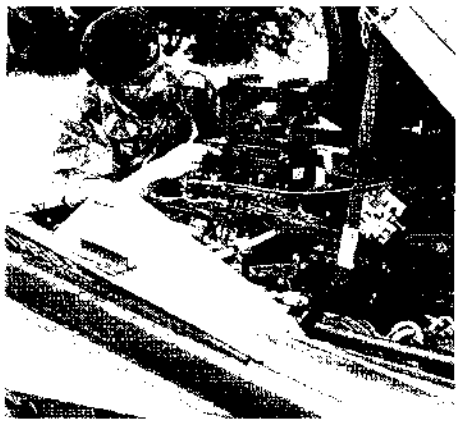
In the search mode the radar (coherent pulsed doppler equipment) scans continuously through 360° in azimuth. When a target is detected its azimuth range and velocity are measured, and on the same scan it is interrogated by the IFF whose antenna is combined with that of the primary radar. If a 'friendly' response is received the information on that target is cancelled from the system and the search continues without interruption.

If the target is adjudged hostile an arm signal is sent to the remainder of the equipment and the measured co-ordinates are used to direct the tracker (see description of Rapier) and the launcher towards the target.

It is, of course, possible that a friendly target might fail to respond to the IFF interrogation on a single pass of the surveillance system (eg because of an unfavourable aspect of the airborne antenna) but the system allows for a 'friendly' response to be accepted before the engagement has gone too far.

STATUS

Since the complete equipment forms an integral part of the Rapier system, deployment and similar details given in the description of the weapons system apply equally to the search and acquisition radars.



An autonomous version of this radar, known as Possum, has been developed by Racal for battlefield surveillance against aircraft (**5765.153**).

CONTRACTORS

Primary radar and antennas

Racal Radar Defence Systems Ltd, Davis Road, Chessington, Surrey KT9 1TB, England.

Cossor IFF transmitter/receiver on the Rapier

Cossor Electronics Ltd, The Pinnacles, Elizabeth Way, Harlow, Essex CM19 5BB, England.

5765.153

POSSUM AIR DEFENCE SURVEILLANCE RADAR

Possum is a mobile air defence surveillance radar developed by Racal from the search and acquisition radar for the Rapier missile (**2425.153**). It provides warning of the presence of fixed-wing aircraft and helicopters, and has been designed to provide excellent detection performance against low echoing area low-level targets with velocities between subsonic and supersonic. The system is an F-band pulse doppler radar which measures the range, azimuth and radial velocity of aircraft within a range of 15 km, and the range and azimuth of hovering helicopters within 7 km. Azimuth data on ECM is also provided. The operator is presented with azimuth, range and radial velocity data on each target in PPI format, and a direct indication of direction and number of ECM sources. Data may be selected and sent directly to surface-to-air weapon systems to provide an automatic response. A fully integrated IFF system is available.

The basic equipment consists of a planar array antenna, solid state drive unit, doppler receiver/processor and a display/control unit. With the exception of the display/control unit, the complete system is mounted on a trailer towable by a Land-Rover. The display/control unit may be mounted in the towing vehicle or deployed remotely up to 30 m away from the radar.

CHARACTERISTICS

Transmitter

Frequency: 3·1 – 3·3 GHz

Output power: 2·5 kW peak

Pulse width: 8·5 μs; 94·5 μs

Antenna

Polarisation: Horizontal

Beamwidth: 8° horizontal; 20° vertical

Rotation rate: 60 rpm

Performance

Azimuth cover: 360°

Elevation cover: -5° to +40°

Detection: 2m² radially moving target at 15 km range and a typical height of 3·5 km; hovering helicopter at 7 km

STATUS

Due to be in production by the end of 1985.

CONTRACTOR

Racal Radar Defence Systems Ltd, Davis Road, Chessington, Surrey KT9 1TB, England.

5766.153

MSR MILLIMETRIC SURVEILLANCE RADAR

MSR is an advanced millimetric surveillance radar designed specifically for defence weapons such as surface-to-air missiles and guns. The equipment is a CW doppler system, operating in M-band, using surface acoustic wave (SAW) signal processing techniques to achieve high performance against difficult targets such as attack helicopters hovering null-down in heavy ground clutter. Target velocity, and hence the doppler frequency of the received signals, is the discriminant used to eliminate false alarms due to unwanted signals from ground clutter or slow moving targets. Fixed-wing aircraft have relative velocities within the pass band and helicopters are detected by recognition of the doppler returns from the rotor blades.

MSR is claimed to have a range and altitude performance which is well in excess of all current and projected point defence systems, and with azimuth and elevation accuracy such that automatic handover to an associated tracker is achieved in minimum reaction time. Alternatively, the radar will provide automatic launch of 'fire and forget' missiles without the incorporation of tracking or fire control facilities.

The MSR system employs an unusual antenna system to allow complete flexibility of the scan pattern, and also different rates between fixed and rotary wing aircraft. The equipment is small and lightweight, and is fully portable for either vehicle mounting or free standing on a tripod base. It can be dismantled easily into three individual man-portable units.

STATUS

In development.

Racal MSR system

2428.153
SCORPION TARGET ILLUMINATING RADAR

Scorpion is a target illuminating radar used with the Bloodhound surface-to-air guided missile system. Intended primarily for use with static installations of this system, the equipment can nevertheless be dismantled into transportable units.

Basically an J/J-band CW doppler auto-follow radar, the equipment also performs the functions of illuminating the target and thereby providing the reflected radiation to activate the semi-active homing system of the Bloodhound missile. In addition it has a limited target search facility and is equipped for target identification.

More detailed information is given under this entry number in previous editions of *Jane's Weapon Systems*.

CHARACTERISTICS
Type: Static CW doppler auto-follow radar
Frequency: I/J-band
Main antenna: 4·2 m diameter
Facilities: Search and follow. Target identification
Associated system: Bloodhound SAGW system
CONTRACTOR
Marconi Radar Systems Ltd, Writtle Road, Chelmsford, Essex CM1 3BN, England.

2439.153
RAPIER BLINDFIRE TRACKING RADAR

The DN 181 Blindfire radar was developed by Marconi Space and Defence Systems, with Marconi Avionics as a major sub-contractor. This development was carried out on a UK MoD funded programme with BAe as prime system contractor. The radar tracker, with the Rapier SAM (**2424.131**) is designed to meet the threat posed by low-level strike aircraft which can operate at night and in low visibility. Addition of the Blindfire radar gives the system an all-weather/night capability to extend the original 'clear-weather' Rapier devised by BAe with optical tracking to meet this threat. With the radar tracker in the system, the operator has a choice, until the moment of launch, of which system will be the most efficient for the engagement.

The radar uses differential tracking for simultaneous target and missile tracking. An electronic angle tracking receiver incorporated within the tracker detects boresight errors for accurate positioning of its own antenna and the angular difference between the missile and target sightlines for the generation of command guidance signals. The extremely narrow beamwidth, coupled with precisely positioned individual range gates for target and missile, is the key to the accuracy and very low-level capability of the system, and also reduces the chances of background clutter, such as ground echoes or rainfall, obscuring the target echo. A number of other electronic measures are also designed into the system to minimise the effect of clutter and other unwanted signals, both spurious and deliberate.

The tracking radar is initially alerted to a hostile aircraft by the system surveillance radar, which indicates the approximate direction of the threat. The tracking radar will immediately swing on to this bearing, and rapidly establish the exact bearing, range, and height of the target. When the radar is locked on to the target, the missile is launched and this, too, is tracked by the radar. The difference between the target and missile angles is instantly derived within the system and commands are automatically transmitted to the missile to guide it on to the target.

The radar tracker is a self-contained, 'plug-in' unit, and requires no extra personnel to operate it.

STATUS
The initial UK MoD production contract was awarded in early 1973 and the equipment is now in service. Full production is continuing for the British Army, Royal Air Force and other operators of Rapier.

The DN 181 tracking radar also forms part of the RN Type 911 system (**5630.253**) ordered by the UK MoD for the lightweight Seawolf programme.

Marconi Blindfire tracker radar

CONTRACTOR
Marconi Space and Defence Systems Ltd, Warren Lane, Stanmore, Middlesex HA7 4LY, England.

2466.153
ST850 TIGERCAT RADAR

Designed for use with the Tigercat surface-to-air missile system (**2465.131**) the ST850/M radar with its associated television equipment gives the missile system an all-weather capability as well as enhancing the clear-weather performance through the provision of a television auto-gather facility. In conditions where the missile is visible, it is automatically gathered within a few seconds of launch after which the engagement is completed automatically or manually using the television monitor.

The radar is housed in a mobile cabin and can be integrated with the S860 mobile surveillance radar.

The radar may assume control of either of two Tigercat fire units, providing fully automatic control of the channel whilst the second channel reverts to optical control.

The ST850 is fully autonomous and can carry out its own low-level search in which the antenna is rotated at 40 rpm in a spiral scan. A PPI display unit is provided.

The cabin contains the equipment cabinets: one bay houses the tracker servo drive circuits and the I-band transmitter, a second houses the receiver and signal processing equipment and the last the ARCU.

System controls and monitoring/indicating equipment are located in a separate control console sited at one end of the cabin. Two operator positions are provided at the console, one for the unit commander and the other for system control.

The cabin is fully air conditioned and its dimensions are approximately 3·7 m long by 2 m high by 2 m wide. It is fitted with attachment points for mobilisers, screw jacks for levelling, and lifting eyes for transportation.

The director is mounted on the roof of the cabin. It carries a one-metre diameter antenna and the TV camera. It is capable of continuous rotation in azimuth, being mounted clear of the cabin roof so that radar and TV visibility extends from an elevation of 85° to a depression of 5°. When the equipment is sited higher than the surrounding terrain, targets flying below 0° elevation level can be tracked.

Facilities are incorporated in the director support framework on the cabin, so that the director can be lowered from its operational position into the cabin for stowage during transportation, when its overall height is 2·4 m.

The antenna is of the twist-cassegrain type. A four-horn monopulse feed and comparator provide three separate RF outputs (viz sum, elevation difference, and azimuth difference signals) for processing in the IF receivers to produce acquisition and auto-follow data. High accuracy of angular data results from the combination of a narrow pencil beam and the monopulse signal processing.

The TV camera is aligned to the radar boresight and provides optical information on the target being tracked by the radar. This system consists not only of a conventional camera and display, but also a data processing system which permits guidance of the Tigercat missile on to the TV line-of-sight.

The pulse modulated transmitter employs an I-band magnetron to deliver a typical power of 160 W mean and 180 kW peak. The magnetron is motor tunable over the frequency band 8·6 to 9·5 GHz, being manually controlled from the radar console.

The local oscillator is a solid-state microwave source with voltage tuning to permit automatic frequency control, which controls the oscillator frequency to follow the tuning of the magnetron and maintains the correct intermediate frequency in the receiver.

The RF portion of the receiver system is housed on the elevation assembly behind the antenna. The IF outputs are connected via coaxial cables and the azimuth slip-ring unit to the IF portion of the receiver, which is housed in one of the equipment cabinets in the cabin.

The signal processing equipment has two channels: the main one for acquisition and tracking of the wanted target; the subsidiary one for acquisition and tracking of the missile. All functions are carried out automatically using digital techniques under control of the master programming unit.

The master programming unit organises the operational sequence of the radar in response to commands from the operator at the control console, and signals from the radar sub-system.

In a mixed defence environment employing both missiles and guns, the ST850/M fire control unit is

Tigercat deployed showing ST850 radar on right

extended by the addition of a general-purpose digital computer, to form the ST850/MG. This latter unit provides prediction of aim-off and automatic system control, thus allowing blind-fire gun control, as in the Marconi/Sperry Sapphire lightweight gun fire control system (**1828.261**).

In support of the ST850 Series tracking radars, the mobile surveillance radar type S860 is available. The S860 is fully autonomous with its own operators and provides a control designation facility for the larger site. Target data, parallax-corrected, are automatically passed to the selected fire control unit.

STATUS

800 Series radars are in production for the UK MoD and other customers. ST850 units have been supplied as part of the Short Brothers Radar Enhanced Tigercat 2 air defence missile system.

CONTRACTOR

Marconi Radar Systems Ltd, Writtle Road, Chelmsford, Essex CM1 3BN, England.

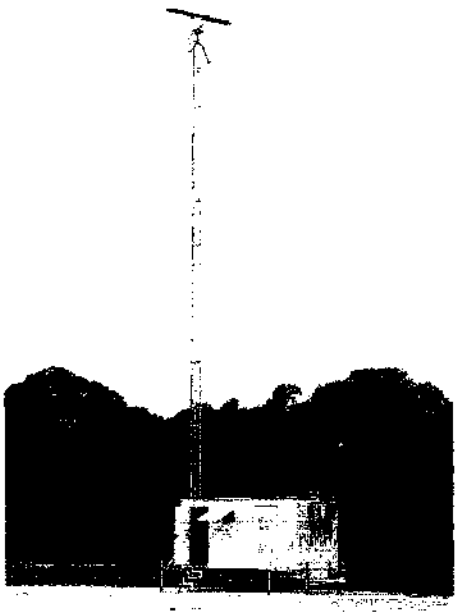
B&P MOBILE SURVEILLANCE RADAR

This is a mobile radar unit designed for maritime surveillance in both military and security spheres. It consists of a purpose-built vehicle housing a marine radar equipment, plus power supplies and communications equipment. The rotating antenna unit, which also contains the transceiver, is mounted on the vehicle and can be elevated to any height up to 60 feet. During transit the mast is lowered and swung flat over the top of the vehicle. In order to present a low profile, arrangements have been made so that the antenna can be operated in this position. The operations cabin contains two displays, a conventional 12-inch PPI and a three-colour video. The three colours of the latter display denote signal strength; red, yellow and green in descending order. A cursor provides range and bearing of targets at the bottom of the colour display in alpha-numeric form. Both displays are fed with raw radar information and give overall coverage out to a maximum range of 32 km.

Any maritime radar, cable-fed from the antenna unit, can be used although the standard fit is a Japanese Fortuno X-band system. The addition of an extra processing unit will extract the necessary information to give various alpha-numeric presentations if required.

The vehicle is fully equipped and is divided into two parts, an engine compartment housing an 11 kW output diesel generator, and an operations cabin containing the displays, radiotelephone equipment and the necessary system and power supply controls. The complete unit weighs about 5 tonnes, including fuel supplies for seven days, and is towed to the operating site. Once in position it takes a maximum of 15 minutes to become fully operational.

CHARACTERISTICS



Frequency: X-band
Power output: 5 kW
Range: 32 km
Antenna rotation speed: 26 rpm
Field of view: 10°

STATUS

In production.

ZB 298 SHORT-RANGE GROUND SURVEILLANCE RADAR

The ZB 298 battlefield surveillance radar was developed by GEC Avionics Ltd to meet a British General Staff requirement (which in turn conformed to the NATO basic military requirement) for a portable battlefield radar, and has since been supplied to overseas customers. The radar can be transported by two soldiers and operated by one man to give an all-weather, day and night facility to detect any significant movement on the battlefield. This includes the location and recognition of men singly or in groups, single or multiple vehicles and low-flying helicopters. ZB 298 can also be used in a counter-insurgency role in keeping watch on sensitive areas such as an airfield.

Targets can be detected on land or over water at ranges from 50 metres to 20 km and the radar can be used for observing ground or sea bursts of artillery or mortar fire and for fire correction.

The original 6 km version of ZB 298 is designated by the British Army as Radar GS no 14 Mk 1. The range of the radar has twice been extended and it is now available in a 20 km version. The opportunity was taken while incorporating the 20 km modification, to introduce major engineering changes in the display unit and tripod which utilise the most up-to-date component technology. Supporting equipment for the ZB 298 includes a training simulator, to give realistic training in the classroom, special test equipment for rapid check-out and fault-finding and a telescopic mast to elevate the radar head thereby improving surveillance coverage.

More detailed information on ZB 298 can be found under this entry number in previous editions of *Jane's Weapon Systems*.

ZB 298 mounted on a Spartan combat reconnaissance vehicle (Alvis Ltd)

CHARACTERISTICS

Operating frequency: I-band
Range: Max 20 000 m; minimum 50 m
Range resolution: 35 m
Range accuracy: 25 m
Antenna beamwidth: 90 mils vertical; 90 mils horizontal
Bearing resolution: 100 mils
Bearing accuracy: 15 mils
Elevation limits: ±350 mils

STATUS

In service with British, Danish, Dutch, and certain other armies.

GEC Avionics Ltd, Applied Physics Division, Elstree Way, Borehamwood, Hertfordshire WD6 1RX, England.

4600.153

FASTAR BATTLEFIELD SURVEILLANCE RADAR

FASTAR is a man-portable radar for use in the battlefield forward area as a surveillance and target acquisition aid. It consists of an I-band, non-coherent pulse doppler radar, based on the ZB 298 equipment (**2490.153**), and an operator's control and display unit.

Moving targets, at ranges of up to 20 km, can be detected automatically and presented on the display unit at the same 1:50 000 scale as a military map. Any target can be selected by the operator using a joystick control to obtain an immediate display of the target's range, bearing and grid reference. The display incorporates an electro-luminescent flat panel, which is activated and controlled by the joystick, and presents simple instructions to guide the operator through the setting-up procedure. The radar memory stores moving target positions and the display can show target trails over a period of time.

STATUS

In early production.

GEC Avionics Ltd, Elstree Way, Borehamwood, Hertfordshire WD6 1RX, England.

5627.153
PACER MK 2 MUZZLE VELOCITY RADAR

Pacer Mk 2 is a private venture equipment which has been developed to measure muzzle velocities of artillery guns, naval guns and mortars during operational firing missions. It uses doppler radar techniques to measure the velocity in the range from 100 to 1400 metres per second to an accuracy of 0·1 per cent.

The system consists of only two units; a sensor unit containing all the electronics which can be mounted either on a non-recoiling part of the gun or on a free-standing mount, and a small hand-held terminal display and control unit which is connected by a cable. The radar transmitter is switched on automatically at the moment of firing, by a flash detector, and is automatically switched off after the measurement is complete. This takes between 0·1 and 1 second, depending on muzzle velocity, and the very short measurement period brings detection and ECM risk to a minimum.

The measured muzzle velocity is shown directly in metres per second on the alpha-numeric liquid crystal display, to two decimal places, and the data on up to 16 rounds can be stored in memory. These can be recalled as necessary and any number can be averaged.

Pacer Mk 2 can be connected directly to a fire control computer via its internal interfaces.

CHARACTERISTICS
Frequency: 10·5 GHz
Output power: 500 mW
Transmission time: 0·1 – 1 s
Velocity range: 100 – 1400 m/s
Accuracy: 0·1%
Beamwidth: 10° vertical; 15° horizontal
Calibre: 75 mm and above

STATUS
One Pacer Mk 2 equipment was ordered by the Sultanate of Oman in late 1983 and two systems by West Germany in late 1984.

5767.153
TYPE AA5504 MUZZLE VELOCITY RADAR

The type AA5504 is a small, lightweight muzzle velocity radar for field artillery use. It is designed for both towed and self-propelled guns and is mounted on the elevating part of the gun, the muzzle velocity measurement being automatically compensated for recoil.

To ensure low detectability the chosen transmission frequency is in the 24 GHz band, which has a high range attenuation. In addition the transmitter is only switched on as the gun fires for a maximum period of one second. The use of the higher frequency also allows an electrically larger antenna to be accommodated within a given volume with a consequent reduction of sidelobes. These features, together with the employment of a spread spectrum transmitter technique, result in a very low detectability level.

CHARACTERISTICS
Transmitter power: 5 mW
Calibre range: 20 – 203 mm
Velocity range: 100 – 1000 m/s
Accuracy: 0·1% + 0·15 m/s (1 sigma)
Firing range: 30 rounds/minute

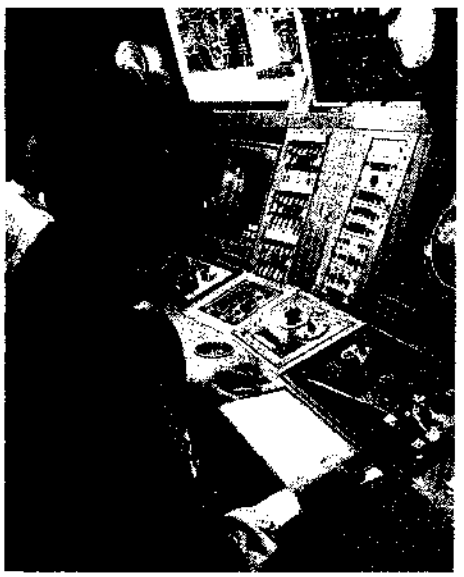
CEL 850 IFF INTERROGATOR

The Cossor CEL 850 IFF interrogator system is based on the CRS 390 transmitter/receiver which is the standard unit employed in a wide variety of IFF/SSR applications where identification facilities are required in association with long- or medium-range primary radars. These may be fixed or mobile, and one of four standard antennas will normally be employed, either on-mounted with the primary radar scanner, or with its own turning gear. Characteristics of these antennas are given below.



Apart from specially-designed IFF equipments for applications such as the Rapier (**2424.131**) and Bofors RBS 70 missile systems, the Cossor CEL 850 IFF system using the CRS 390 transmitter/receiver is normally used. Its compatibility with a wide variety of primary radars, coupled with features that permit ready interfacing, suit it for either slaved, on-mounted or autonomous operation. Small size, lightweight and rugged construction make it suitable for mobile applications, and it is also used at sea. Operating features include: wide range of acceptable trigger pulses; external computer control facility; external modulation facility; flexible mode programme; video outputs to match processing system needs. A logarithmic receiver coupled to special video processing circuits make the equipment particularly resistant to ECM interference.

CHARACTERISTICS
Antenna CRS 320
Length: 9·65 m
Weight: 305 kg
Gain: 23 dB (minimum)
Half-power beamwidth: 2·2°
Antenna CRS 389
Length: 4·35 m
Weight: 79 kg
Gain: 17·5 dB (minimum)
Half-power beamwidth: 4·5°

CRS 381 3 m SSR/IFF antenna on-mounted at the upper edge of an AR-1 airfield radar

Antenna CRS 379
Length: 1·16 m
Weight: 13·8 kg
Gain: 16 dB (minimum)
Half-power beamwidth: 12·5°
Transmitter/receiver CRS 390
Transmitter section
Frequency: 1030 MHz
Power output: 33 dBW
Modes: 1, 2, 3/A, B and C; external modulation
PRF: 150 – 1000 Hz
Mode interlace: Single, dual or triple
Receiver section
Centre frequency: 1090 MHz
Tangential sensitivity: Not less than –85 dBm

Cossor CVP 190 modular multi-role video processor system in use with a CEL 850 IFF system (control panel to left of right-hand display)

Bandwidth: 10 MHz, at -3 dB points
Video outputs: 2 – 5 V, adjustable into 75Ω
Identification pulses: Pre-trigger; mode pulse pairs
Display trigger pulses: +5 V into 75Ω between P3 and P3 + 60 μs

STATUS
More than 90 complete systems have been ordered.

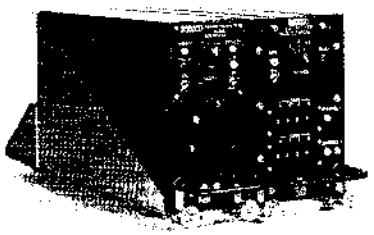
Cossor Electronics Ltd, The Pinnacles, Harlow, Essex CM19 5BB, England.

3693.153
870 SERIES IFF INTERROGATORS

This series of Cossor IFF interrogators is intended to equip short- and medium-range primary radar systems, where there is often a requirement for the hardware to be relatively compact. For example, in land-mobile units, there is a need for rapid and positive target identification because speed of response is essential, but space considerations may also be critical. For these reasons, IFF 870 equipments interrogate on one mode at a time and process up to two reply codes at a time. For ease of integration the hardware has been constructed as two units: a transmitter/receiver and a defruiter/decoder. Various packaging arrangements have been developed for specific applications. In some cases there are also special antenna arrangements but otherwise one of the four standard Cossor units, CRS 320/379/381/389 described in **3692.153**, is employed.

Specific models of the IFF 870 series that have been identified include:



IFF 875 for Contraves LPD-20 radar (**1529.153**)

IFF 878 for LM Ericsson Giraffe mobile radar (**1957.153**)

IFF 879 for Signaal Flycatcher mobile radar (**3283.153**)

STATUS
All the above versions are in production.

CONTRACTOR
Cossor Electronics Ltd, The Pinnacles, Harlow, Essex CM19 5BB, England.

Cossor IFF 875 interrogator equipment as configured for use with Contraves LPD-20 primary radar

3694.153
880 SERIES IFF INTERROGATORS

The Cossor IFF 880 series of equipments were designed for use in forward battle areas in which there may be a multiplicity of air defence weapons and probable targets. Because of the highly effective nature of many of these weapons, lack of an identification facility with each weapon could lead to the inadvertent destruction of valuable friendly aircraft engaged on strike, interdiction or air defence operations. It was to meet this need that the IFF 880 range of interrogators was introduced with the aim of providing equipments suitable for application to weapons as a stand-alone, self-contained IFF system. Interfaces for integration with towed air defence guns, turret-mounted AA guns, man-portable air defence missiles, and vehicle-mounted air defence missiles have been developed. Outputs from the IFF can be used to inhibit firing, or to provide visual or aural status indications. Integration with primary radars is also possible where required.

Packaging of the transmitter and receiver units is configured to suit the weapon system being equipped. Usually there are requirements for minimum dimensions and weight together with special mounting arrangments. The requirements are easily met by the small size of the equipment. Similarly, a special-to-type antenna is provided in most cases. A typical IFF 880 application is the IFF 880B for the Swedish RBS 70 air defence missile system (**2348.131** and **3617.131**). Variants of the IFF 880B are available for man-portable, Land-Rover mounted and armoured vehicle installations of RBS 70.

IFF 880L

This version has been designed for use with the Short lightweight multiple launcher (LML) missile system. It operates as an add-on unit and is self-powered by a battery. The IFF transmitter/receiver/processor unit is attached to the leg of the LML with the antenna secured to the top face of the head. Friend or foe status is indicated by audio tones. Weight of the system is 7·5 kg for the interrogator and 2 kg for the antenna.

IFF 880/1 Free-standing IFF System

This derivative of the IFF 880 series has been designed for operation by an air-defence weapon detachment commander and requires no modification of in-service weapons. The system comprises a transmitter/receiver/processor unit, which is normally carried in a haversack, an antenna which is hand-held and an interconnecting cable fitted with quick release connectors. Incorporated in the antenna array is an optical aiming system.

In operation, the commander sights the target through the antenna and interrogates the target, using the trigger fitted by the hand grip. The status of the IFF system and whether the target is friendly or hostile is indicated by a light emitting diode incorporated in the antenna unit.

Typical applications are provision of IFF facilities to Blowpipe, SA-7 and other short-range air defence systems. The characteristics of the system are similar to those of the IFF 880 series. Weight of the system is 5 kg for the interrogator and 1·5 kg for the antenna.

CHARACTERISTICS
Transmitter frequency: 1030 MHz
Power output: 13 dBW (P1, P3), 18 dBW (P2)
Modes: 1, 2, 3/A
PRF: Presettable
Receiver frequency: 1090 MHz
Tangential sensitivity: –76 dBm
Bandwidth: 8 MHz at –3 dB points
Antenna gain: 10 dB
Antenna beamwidth: 20° – 11° – 8° at 3 dB points in azimuth depending upon transponder performance
Dimensions: 355 × 180 × 152 mm, interrogator and antenna but less bracket
Weight: 5·3 kg (less bracket)

STATUS
IFF 880, IFF 880B and IFF 880L are in production for several users. IFF 880/1 is in advanced development.

COSSOR MONOPULSE SECONDARY SURVEILLANCE RADAR

The Cossor monopulse secondary surveillance radar (SSR) provides accurate and reliable track data in environments which cause errors in conventional SSR systems. It has been designed to take advantage of the advances in code extraction techniques which enable garbled transponder replies to be decoded successfully. Unlike conventional SSR, a monopulse system measures the bearing of an aircraft from each received frame and code pulse of its transponder reply. An average of these measurements gives consistent, high accuracy azimuth data even in areas where normal sliding window extractors would output track errors caused by 'fruit' and 'missed replies'. The Cossor system consists of the CRS 512 antenna (**5622.153**) the SSR 950 interrogator and the CVP 250 plot extractor.

The CRS 512 large vertical aperture antenna, combined with low sidelobe levels, is designed to provide a considerable improvement in SSR system performance. It reduces the incidence of ground reflections and false targets caused by local buildings, parked aircraft, etc. The SSR 950 interrogator has been designed to meet the requirements of ICAO Annex 10 and was developed specifically for monopulse operation. It includes two matched logarithmic receivers for monopulse operation plus a third receiver for receiver sidelobe suppression. Other main features of the SSR 950 are improved sidelobe suppression (site selectable), programmable gain time control in range and azimuth, digital plot extractor interface and computerised management system interface. The interrogator has been designed to be readily extendable for Mode S operation when this comes into operation. The CVP 250 plot extractor, which is built into the same cabinet as the SSR 950, uses advanced microprocessor technology and incorporates extensive self-test and fail-soft features. Target reports are compiled using monopulse data from the SSR 950.

STATUS
The Cossor monopulse SSR system has been selected by the UK MoD to equip its military airfields

SSR 950/CVP 250 monopulse interrogator

throughout UK and West Germany. Installation is due to commence in 1986. The SSR 950 and the CVP 250 are essentially the same as those currently being installed throughout the UK on behalf of the Civil Aviation Authority (CAA) as part of the new civil radar network. The CRS 512 LVA antenna is also being supplied to both the MoD and the CAA; one of these units is undergoing evaluation trials by the CAA during 1984.

In mid-1984 Cossor received an order from Canada for 41 dual channel monopulse SSR systems as part of the country's major radar replacement programme. Equipments are also being supplied to Saudi Arabia and Switzerland.

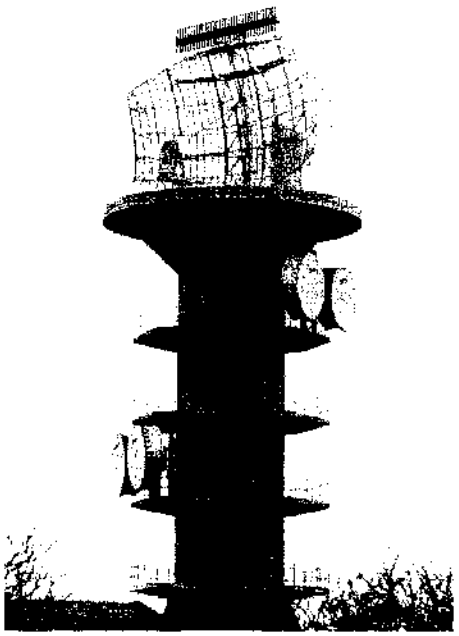
CONTRACTOR

Cossor Electronics Ltd, The Pinnacles, Harlow, Essex CM19 5BB, England.

5622.153

CRS 512 SSR ANTENNA

The CRS 512 is a large aperture secondary surveillance antenna designed as a replacement for the familiar linear array which has been the standard antenna since SSR was first introduced. The large vertical aperture, which measures 5 ft (1·53 m), contains a vertical array of radiating elements which give more flexibility in the control of the transmit and receive patterns and provides improved performance. This system overcomes the disadvantages of linear array antennas, which can cause gaps in radar coverage and false replies due to reflections from local terrain and buildings, caused by its narrow aperture.



New constructional techniques have been employed for the radiating elements to minimise weight while retaining strength. This has resulted in keeping the weight to approximately 500 lb (227 kg) for an antenna length of 28 ft (8·25 m). The open array construction also reduces wind resistance and has been designed to withstand a wide range of environmental conditions. The CRS 512 is available for use at airfields, where reflection problems can be most severe, and also for long range surveillance with good coverage at low angles of elevation.

STATUS

In production with more than 70 equipments ordered.

CONTRACTOR

4603.153

MESSENGER SECONDARY SURVEILLANCE RADAR

Messenger is a monopulse secondary surveillance radar (SSR) designed for future requirements of select addressable systems, such as implied by the US/UK current Mode S plans. Messenger consists of a large vertical aperture (LVA) antenna, an interrogator/responder and a decoder/plot extractor, the electronics being mounted in a standard 19-inch rack housed in a transportable container.

The LVA antenna produces three azimuth patterns at the SSR transmit and receive frequencies of 1030 and 1090 MHz, symmetrically disposed about the boresight and forming the means of effecting interrogation sidelobe suppression (ISLS), improved interrogation sidelobe suppression (IISLS), received sidelobe suppression (RSLS) and monopulse direction finding (MDF). The antenna is manufactured to a computer-optimized electrical design giving a high forward gain of better than 29 dB and a robust mechanical construction to ensure operation and survival in severe environmental conditions. The LVA antenna reduces the incidence of ground reflections and false targets caused by local buildings, parked aircraft, etc.

Marconi Messenger LVA antenna

The interrogator/responder consists of three associated units; interrogator, monopulse multiple receiver and a performance monitor. It is completely solid-state, including the final output power stage ranging from 500 W to 2 kW, and is capable of being upgraded to include operation to Mode S standards at a much higher duty cycle than standard SSR. This will enable full SSR data link facilities to be established when international agreement on signal formats and protocols have been ratified. Much of the technology involved in Messenger is derived directly from the Marconi Martello air defence radar (**3491.153**). The monopulse receivers are housed in a separate unit; their balanced outputs allowing accurate direction finding of targets on single inputs (monopulse DF) over the full antenna beamwidth and suppression or flagging of replies not received by the main beam (RSLS). Off-boresight azimuth processing employs the module developed for the Marconi GWS 25 tracking radar (**1562.253**).

The decoder/plot extractor uses monopulse decoding equipment having special logic included to ensure retention of wanted data in poor or ambiguous signal conditions. The circuits are constructed on printed circuit boards interconnected by a fast multi-highway system. Outputs to companion circuit boards in the same unit are used to form data plots expressing the range, azimuth identity and altitude code of all SSR targets in the radar cover. Decoding and plot extraction modules are combined to provide a high speed data bus and unlimited capability for system configuration and reconfiguration.

Data can be outputted in a number of different formats including that specified by the UK MoD. Standard modems are used to interface the decoder/extractor output, via telephone cable, to the local display and data handling equipment.

STATUS

In development. System trials took place during 1984 with production units due to be available from mid-1985.

UNITED STATES OF AMERICA

1949.153

COBRA DANE RADAR

Cobra Dane is the code-name of a large phased array radar at Shemya Air Force Base in the Aleutian Islands under USAF Program 633A. Its purpose is the detection and tracking of ICBMs, SLBMs and satellites. It is a new type of radar which has replaced two existing radars of the old intelligence variety (AN/FPS-17 and AN/FPS-80), which were themselves pressed into service to undertake Spacetrack duties. They had a limited real-time tracking capability and the new Cobra Dane installation is intended to remedy this shortcoming.

The large fixed phased array of this radar measures about 30 m in diameter and is composed of about 35 000 elements of which some 15 000 are active elements. The system will survey a 2000-mile (3220 km) corridor to collect data on Soviet missile development flights, provide early warning of ICBM launches, detect new satellites, and update known satellite parameters.

The array provides coverage over a 120° sector of the Soviet missile test range, and in its space tracking role the Cobra Dane installation has a range of 25 000 nautical miles (46 000 km). In its data collection role on Soviet missile flights, Cobra Dane has the ability to track up to 100 objects simultaneously with precise data on up to 20 targets. These data are processed at the Shemya site and transmitted to the USAF Foreign Technology Division.

Employed as an early warning system, Cobra Dane has the capacity to track 200 targets and provide detailed information on these to NORAD Headquarters. Among the latter data will be predicted impact locations in the USA.

The installation comprises a total of 12 transmitting groups, each incorporating eight TWTs, with a peak power of 16 MW and an average level of 1 MW.

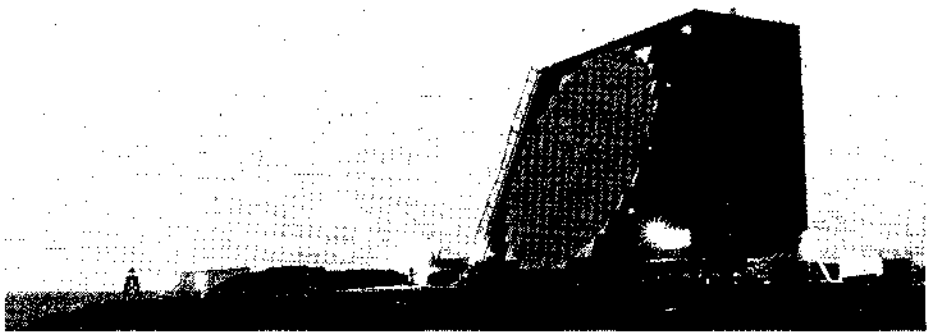
DEVELOPMENT

The responsible agency is the USAF Electronic Systems Division. The project was authorised in 1971 and Requests for Proposals were issued in 1972, funding being approved in that year also. A contract for $39·6 million was awarded to Raytheon in July 1973. Construction was well advanced at the close of 1974 and the system testing was completed in late 1976.

STATUS

Cobra Dane achieved First Operational Capability in 1977. Total cost is estimated at $68 million.

Eventually it was planned to close down the



BMEWS radar at Clear, Alaska, when the ability of Cobra Dane and the new West Coast SLBM phased array radar (Pave Paws) to take over Clear's warning functions have been determined. Currently Cobra Dane augments the BMEWS system in early warning.

However, in the meantime, plans have been implemented for a 'three-element' BMEWS improvement programme to provide more precise data on the character and size of a missile attack. These modifications will ensure the continued usefulness of BMEWS well into the 1980s.

A similar project named Cobra Judy, a shipborne phased array radar for endo-atmospheric tracking to complement Cobra Dane is now in operation in the Pacific (**4301.253**).

CONTRACTOR

Raytheon Company, Equipment Division, Wayland, Massachusetts 01178, USA.

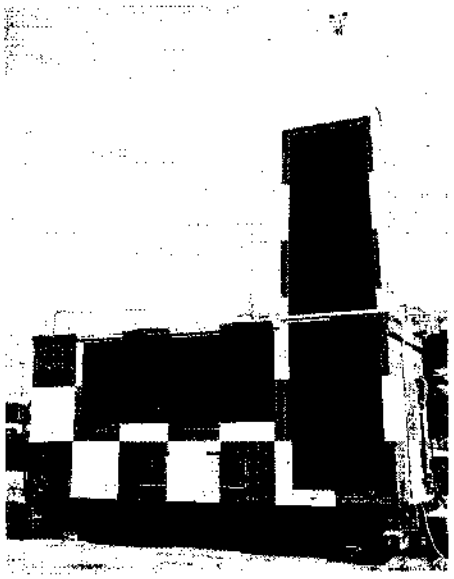
Giant radar at Shemya Air Force Base, near western tip of the Aleutian island chain off Alaska, is a phased array system. Known as Cobra Dane, it is used for tracking Soviet ballistic missile flights. Cobra Dane was constructed by Raytheon Company under contract to USAF Electronic Systems Division

---

3714.153

AN/FPN-62 PRECISION APPROACH RADAR

The AN/FPN-62 is an updated version of earlier equipment in which new electronics have been substituted for older, more difficult to maintain hardware. The original azimuth and elevation antennas are retained, these being electronically scanned elements providing separate beams for tracking of an approaching aircraft in azimuth and elevation. Guidance signals are normally passed back to the aircraft voice radio link. Operation is in the radar I-band.



STATUS

The AN/FPN-62 was developed by Raytheon in a competitive programme sponsored by the USAF for the updating of fixed PAR facilities based on the AN/CPN-4, AN/MPN-13 and AN/FPN-16 equipments. This resulted in a contract for the upgrading and supply of 40 systems for the USAF, and the prototype was produced in 1976. By mid-1979 more than 20 systems had to be delivered.

In 1979, Cossor Electronics, the Raytheon UK subsidiary, won a similar contract for the upgrading of RAF SLA-3 PARs, and is engaged on the production of an Anglicised version of the FPN-62 which is designated the 'Falconer' by Cossor. The UK concern will supply 43 static and two mobile systems for use at home and overseas RAF bases.

CONTRACTOR

Raytheon Company, Equipment Division, Wayland, Massachusetts 01178, USA.

QUADRADAR Mk V ATC RADAR

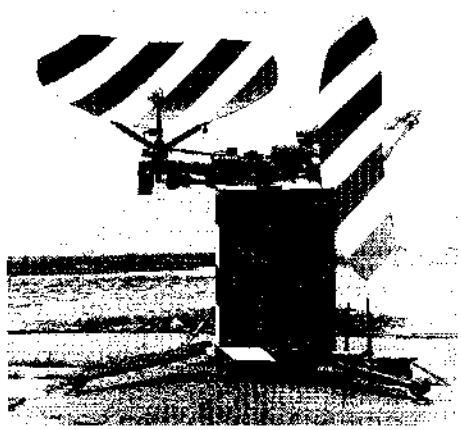
The Quadradar Mk V is a multi-function ATC radar providing four functions: air surveillance, precision approach, heightfinding and airfield taxi control. The radar equipment is tripod mounted for siting adjacent to the airfield runway and normally operates unattended via remote control. The system includes cable remoting (up to 3000 m, or 10 000 feet).

The system has two mechanically operated antennas, scanning in azimuth and elevation on a time-shared basis, as required by the four modes of operation. The arrangement can be seen from the nearby photograph.

Further information is given under this entry number in previous editions of *Jane's Weapon Systems*.

CHARACTERISTICS

Transmitter



Frequency: 9000 - 9160 MHz, tunable

STATUS

More than 350 systems have been produced and are in operation throughout the world. Since its introduction in the late 1950s, the Quadradar has been continuously updated and today the Mk V constitutes a modern, completely solid-state ground control approach radar.

CONTRACTOR

ITT-Gilfillan, 7821 Orion Avenue, Van Nuys, California 91409, USA.

ITT-Gilfillan Quadradar Mk V ATC radar

4328.153

QUADRADAR MK VI ATC RADAR

Quadradar Mk VI was developed from the Quadradar Mk V and incorporates a high performance digital MTI feature. As with the Mk V, the equipment is a multi-function ATC radar providing air surveillance, precision approach, heightfinding and airfield taxi control.

The receiver/transmitter unit is a later development but the antennas and mechanical drive unit are the same as the Mk V. The indicator display unit is housed in a new design slanted face display unit but otherwise uses the same electronic components as the Mk V with some modifications for DMTI compatibility. The mechanically operated scanners perform in the same way as the Mk V.

CHARACTERISTICS

Transmitter

Frequency: 9100 - 9200 MHz, tunable

Pulse width: 0·26 or 0·5 μs selectable

PRF rates: 3300 pps; 3300 average with 7:8:9 stagger 1925 pps; 1925 average with 7:8:9 stagger

Peak power: 180 kW (nominal)

Beamwidth: Azimuth 0·95° × 3·5°, csc² to 30°; elevation 0·85° × 2·5°

Receiver

MDS: -108 dBm

IF: (1st): 290 MHz, (2nd): 60 MHz

Bandwidth: 2·5 MHz

Range scales: ASR: 1·5 nm (taxi) 5, 7·5, 15 and 30 nm (surveillance)
PAR: 3, 7, 15 and 30 nm

ITT-Gilfillan Quadradar with MTI

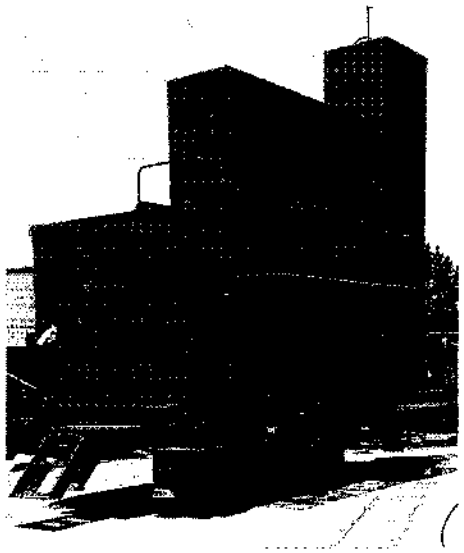
4076.153
SERIES 52 PRECISION APPROACH RADAR

The ITT-Gilfillan Series 52 is a turntable-mounted, precision approach radar (PAR). The radar data is remotely fed to control centres or control towers. Air traffic controllers provide precise approach guidance to aircraft down to the runway threshold through voice communications with the pilot.

The turntable is remotely controlled for aligning to cover multiple runway approaches. Up to six radar displays may be remotely controlled a maximum 3636 m from the equipment shelter. Radar ranges of 10, 15, and 20 nautical miles provide coverage for all types of aircraft and all traffic pattern variations. For transportation, the Series 52 is packaged into two major sub-assemblies: the shelter and turntable pallet.

Radar scan angles of 20° in azimuth and 8° in elevation are developed by the delta-A scanning antennas. These antennas feature minimum sidelobe performance and circular polarisation, coupled with a digital moving target indicator and integrated video. Dual channel radar transmitters and receivers, and high-gain, low-sidelobe antennas, remote control of PAR landing direction, and four sets of preset course and glideslope cursors are operational features of the Series 52 PAR.

CHARACTERISTICS



Frequency: 9000 - 9160 MHz
Peak power: 80 kW
Azimuth antenna gain: 39·7 dB
Elevation antenna gain: 40·3 dB
Max range: 20 nm
Resolution: 0·55° elevation; 0·85° azimuth; 48 m range

STATUS

Production.

CONTRACTOR

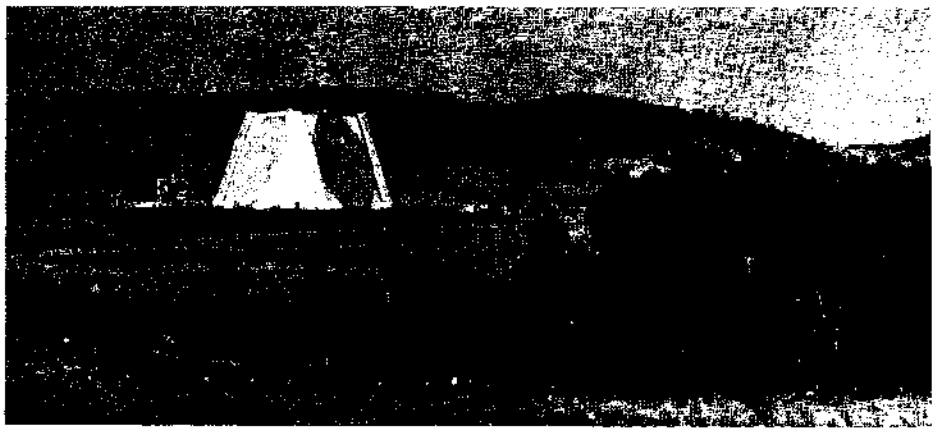
ITT-Gilfillan Series 52 PAR

3174.153
AN/FPS-115 PAVE PAWS RADAR



Pave Paws is the name given to a system of large phased array AN/FPS-115 radars to replace the 474N SLBM detection and warning system radars, AN/FSS - 7 (**2538.153** in 1980-81 and earlier editions). Raytheon was named as contractor to the USAF Electronic Systems Command in April 1976, when a contract valued at $46·6 million was awarded. This covered the first Pave Paws radar at Otis AFB, Massachusetts. A second site at Beale AFB, California has been built and both sites are operational. Two further sites at Robins AFB and near Goodfellow AFB are under construction.

Raytheon was expected to draw upon the experience gained with the Cobra Dane radar described above (**1949.153**), but it is understood that there are important technical differences between the two types of radar.

Pave Paws is an important addition to the World Wide Military Command and Control System (WWMCCS), and will be operated and maintained by the USAF Strategic Air Command. The radar's primary mission of detection and warning of SLBM attack also involves the provision of attack characterisation to the NORAD Cheyenne Mountain Complex, the Strategic Air Command and the National Command Authorities. The system's secondary role in support of the USAF Spacetrack system feeds in positional and velocity data for the display of all Earth satellites in orbit. Capable of multi-target tracking, it simultaneously detects and discriminates many objects, while providing early warning data, launch, impact, position and velocity information as required.

Automated features of the system include detection, track initiation, and mission decisions. Two standard computers, CYBER 174-12s, generally serve as the CPU, programmed for beam steering, the storage and display of data, as well as performing post-mission data reduction and analysis.

Pave Paws operates at UHF frequencies and employs solid-state technology more extensively than Cobra Dane, with transistors driving transmitters to produce radiation. In Cobra Dane TWTs are employed.

Pave Paws phased array radar installation at Beale AFB, California

Pave Paws consists of a pair of circular planar arrays about 30 m in diameter, each consisting of 5400 elements. The arrays are inclined from the vertical by 20° and mounted in adjacent sides of a building measuring about 32 m high, forming sloping walls on the seaward facing side of the structure. Combined coverage of the electronically steered beams from the two arrays is 85° in elevation and 240° in azimuth. Range is estimated as about 3000 miles (4800 km).

The Otis AFB Pave Paws was declared operational officially in April 1980, with the Beale AFB entering service the following summer.

In mid-1978 it was disclosed that concern over the possibilities of improved Soviet SLBM capabilities require the construction of two more Pave Paws radars to cover additional south-east and south-west facing arcs. These have now been designated as Robins AFB and a site 17 miles south of Goodfellow AFB. Raytheon received a $77 million contract in late-1983 to build the former. The contract included an option for the Goodfellow site which is also scheduled to support NORAD tracking of space objects. The option was exercised in January 1984. The Robins site is to be fully operational by 1986, and the Goodfellow site by 1987.

CHARACTERISTICS

Frequency: 420 - 450 MHz
Transmitter: Solid-state
Module peak power: 322 W
No. of active elements/modules (67% filled): 1792
Array type: Corporate feed, density tapered
No. of sub-arrays: 56
Antenna gain: 38·4 dB directive gain
Beamwidth: (transmit/receive): 2°/2·2° at boresight
Polarisation (transmit/receive): Right hand/left hand circular
Array diameter: 72·5 ft (utilised)
Face tilt: 20°
Azimuth: ±60°, 240° with two faces
Elevation: 3·85°

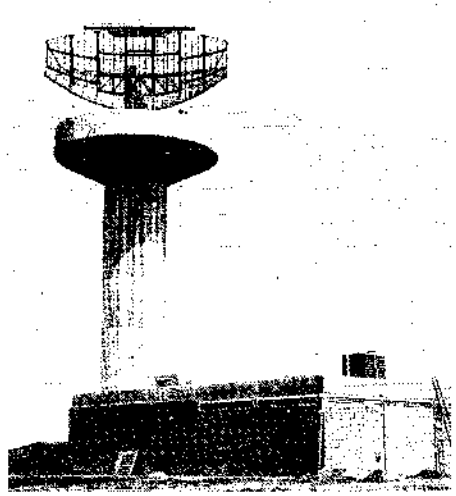
3149.153
BPS-1000 SURVEILLANCE RADAR

The BPS-1000 is a long-range D-band surveillance radar for air defence and ATC applications, introduced by Bendix in 1976.



The dual diversity transmitter is a coherent type using a long-life L3035 power klystron, and can be operated in either simplex or duplex modes. In the former mode, the second channel provides full redundancy except for the common antenna system. Predicted MTBF in this mode is better than 19 000 h. Solid-state receivers and processors contribute to the high overall reliability.

The coherent transmitter design eliminates second-time-around returns and permits the linear digital receiving system to achieve an MTI improvement factor of 45 dB. The receiver processor provides five basic receivers:

(1) normal
(2) Dicke-fix
(3) log
(4) MTI
(5) LINAR

With the exception of the Normal mode, all provide a constant false alarm rate (CFAR) output. Anti-jamming and weather countermeasures include: automatic clutter gating, delay-line blanking, leading edge blanking, wide dynamic range CFAR receivers, MTI anti-weather system. The LINAR and log receivers are also effective against weather interference and further rejection of rain clutter is provided by circular polarisation.

The log and Dicke-Fix receivers provide effective rejection of wideband noise jamming interference, and the Bendix LINAR receiver is effective against wideband and narrow-band noise jamming, as well as CW and swept-frequency.

Bendix BPS-1000 surveillance radar

The receiver processor provides outputs for manual and automatic systems, simultaneously. Computer driven displays may be used, in which case the Bendix radar data processor is added to facilitate the target and IFF/SSR data transmissions to the display sub-system. The computer-driven graphic displays employed operate in a distributed system without a central data processor. Consoles use identical hardware, and operation is determined by the program loaded and operator keyboard commands. Radar and IFF/SSR input data and data exchanges between consoles use a common bus. The displays track targets, store flight plans, calculate intercepts and transmit interceptor commands.

The antenna is a large aperture, dual-curvature structure of lattice construction with dual horn feed. There are provisions for SLC, SLS, and direction IFF/SSR antennas.

CHARACTERISTICS

Frequency: 1250 – 1350 MHz
RF output: 2 - 2·75 MW peak
4·3 - 6·0 kW average
Range (1 m² target): Over 200 nm (370 km)
Range accuracy: 0·12 nm (0·22 km)
Range resolution: 0·6 nm (0·11 km)
Pulse length: 6 μs
PRF: Selectable 350, 355, 360, 365, or 370 pps
MTI cancellation ratio: 40 dB, minimum
Azimuth accuracy: 0·135°
Azimuth resolution: 1·5°
Beam shaping (vertical): Cosec² to 50°
Beamwidth (horizontal): 1·3°

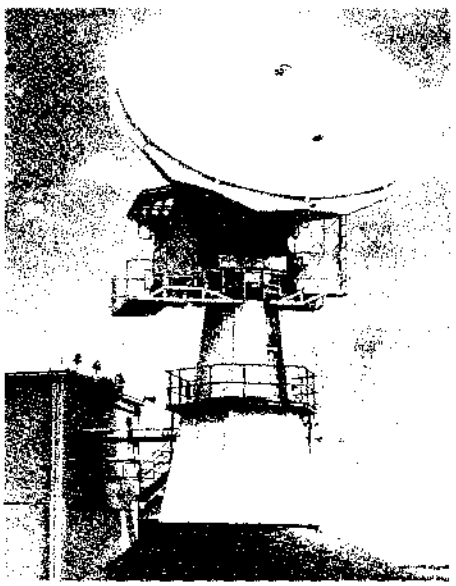
AN/FPQ-6 AND AN/TPQ-18 PRECISION INSTRUMENTATION RADARS

AN/FPQ-6 and its transportable version AN/TPQ-18 are high-accuracy, amplitude comparison monopulse, C-band instrumentation radars designed primarily for tracking long-range high-velocity targets such as missiles and re-entry vehicles. They can function either in skin-tracking (single-pulse) or beacon tracking (pulse train) modes. The only difference between the two radars relate to the arrangement of their constituent units.

Physically the radars are large, five transmitter cabinets and 60 cabinet racks being required to house the basic electronics. The antenna is 885 cm in diameter, uses a five-horn cassegrain feed and can be rotated continuously in azimuth, and from –2 to +182° in elevation. The transmitter has a peak power of 2·8 MW.

Targets can be tracked out to some 60 000 km and at target speeds up to 18 km/s. Several systems have differing configurations and performance including MW transmitters, pulse compression, 0·03 m/s rms accuracy pulse doppler, 'on-axis' computer aided tracking and low noise high gain feeds. Polarisation is console selectable. The antenna can track targets or be slewed at rates between 0·0006 and 28°/s. One unit was modified recently to track two in-beam targets simultaneously. It incorporates new integrated circuit design which greatly reduces size, power and air conditioning requirements. It is known as the AN/FPQ-19.

CHARACTERISTICS



Azimuth, elevation tracking precision: 0·05 mils rms at 20 dB S/N
Range tracking precision: 4·7 m rms at 20 dB S/N
Antenna beamwidth: 8 mils
Ro, IM², 0 dB S/N: 1000 km

STATUS

Eleven of these units are in operation at various USAF, US Army and NASA ranges.

RCA, Government Systems Division, Missile and Surface Radar, Moorestown, New Jersey 08057, USA.

AN/FPQ-6 precision instrumentation radar

2492.153
AN/FPS-6 HEIGHTFINDING RADAR

For many years the AN/FPS-6 radar has been the principal heightfinder used by US armed forces and many allied nations. At least 450 of these systems have been delivered, including the mobile version, the AN/MPS-14 (**2496.153**).

A high-power E/F-band nodding-beam radar, the AN/FPS-6 is noted for extreme accuracy at long range, and three available versions give it wide versatility under a variety of environmental conditions.

The arctic tower installation consists of a 50 ft (15·25 m) radome (either air-supported or rigid) mounted on a 25 ft (7·6 m), two-storey enclosed tower structure. De-icing is provided by a battery of infra-red lights inside the radome. Radome pressurising (when required), RF, and other electronic equipment is housed in the tower structure.

The temperate tower installation is designed for moderate or tropical climates. The 25ft (7·6 m) supporting structure for the antenna includes an enclosure for RF equipment.

The mobile version (AN/MPS-14) is a six-truck, three-trailer system designed for transport on short notice to new strategic or tactical sites.

AN/FPS-6 heightfinder radar, temperate tower and arctic tower versions

The reliability and capability of the basic AN/FPS-6 system has benefited from a continuous improvement programme. Sets with various improvements have been designated as AN/FPS-6A, AN/FPS-6B, AN/FPS-6C, AN/FPS-6D, AN/FPS-89 (**2513.153**) and AN/FPS-90. All these improvements are available in field conversion kit form for the updating of radar sets from earlier production.

CHARACTERISTICS

Peak power: 4·5 MW
Average power: 3·6 kW
Frequency: 2700 – 2900 MHz
PRF: 300 – 405 pps
Pulse width: 2 μs
Receiver sensitivity: NF <9·3 dB; MDS –108 dBm
Beam characteristics: Pencil beam
Beamwidth: Azimuth 3·2°; elevation 0·9°
Antenna azimuth rate: 180° in 4 s
Elevation rate: 20 or 30 mods/minute
Antenna gain: 38·5 dB

STATUS

Operational.

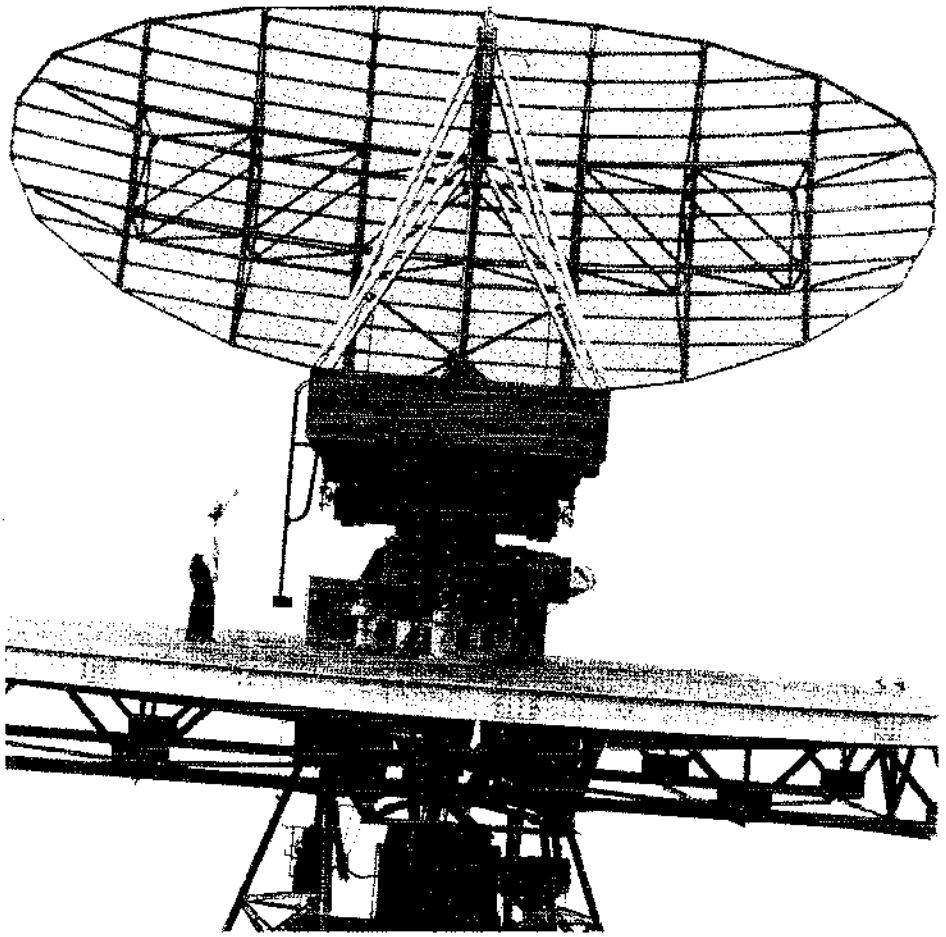
2526.153
AN/FPS-7 3-D SEARCH AND GCI RADAR

AN/FPS-7 is a very high power D-band (1250 to 1350 MHz) monopulse 3-D search radar. The equipment uses a stacked-beam heightfinding technique, the stack consisting of seven channels.



Search range is approximately 500 km and height coverage is up to 45 000 m. The transmitter output stage is a high power klystron which delivers 10 MW at any of up to ten preset transmitter frequencies and with a pulse width of six microseconds. A dual-channel transmitting system is provided. When channel A is connected to the antenna through the waveguide switch, channel B is fed to a dummy load. This feature permits full preventive maintenance to be performed without having the equipment off the air.

The basic radar uses several separate but identical receiving systems. Spare receiving channels are available, and may be switched in place of some of the active receivers. The receiver incorporates MTI and anti-jamming circuits.

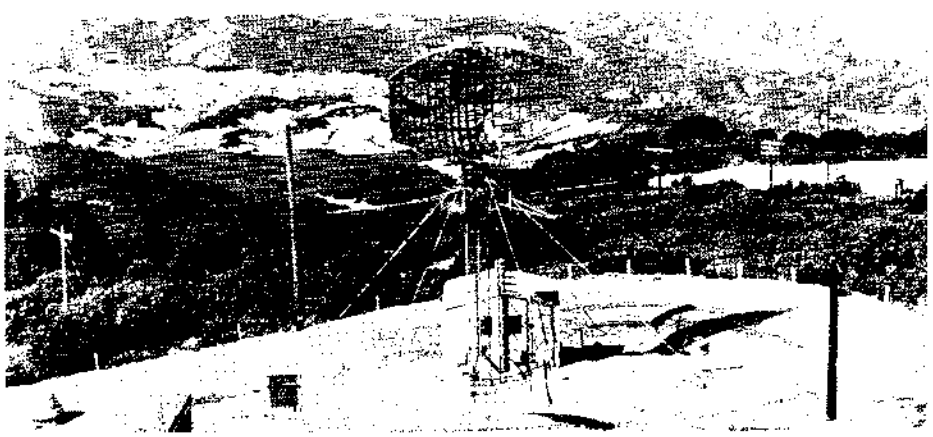
CHARACTERISTICS

Peak power: 10 MW
Average power: 14·5 kW
Frequency: 1250 – 1350 MHz
PRF: 244 pps
Pulse width: 6 μs
Receiver sensitivity: NF = 9·5 dB
Beam characteristics: Stacked beam, cosec²
Beamwidth: Azimuth 1·4°; elevation 18°
Antenna azimuth rate: 3·3, 5, 6·6 and 10 rpm

STATUS
Operational. About 30 units produced.
CONTRACTOR
General Electric Company, Electronic Systems Division, Syracuse, New York 13201, USA.

AN/FPS-7 3-D search radar

2493.153
AN/FPS-8 SEARCH RADAR



The AN/FPS-8 is a medium-power D-band search radar designed for aircraft control and early warning and is installed at commercial airports and military bases both in the United States and overseas.

In most installations the antenna is exposed, being mounted on a temperate tower. For severe environmental conditions, the AN/FPS-8 is self-contained in an arctic tower with a protective radome.

Over the years improvements have been made to the basic AN/FPS-8, culminating in the present version whose nomenclature is AN/FPS-88 (V) (**2512.153**).

The AN/FPS-8 also has two mobile versions, the AN/MPS-11 and the AN/MPS-11A (**2495.153**).

CHARACTERISTICS
Peak power: 1 MW peak
Average power: 1·1 kW
Frequency: 1280 - 1380 MHz
PRF: 360 pps
Pulse width: 3 μs
Receiver sensitivity: FPS-8: NF 9 dB; FPS-88: NF≈2·5 dB with parametric amp
Beam characteristics: Cosec²
Beamwith: FPS-88: azimuth 1·3°, elevation 58°; FPS-8: azimuth 2·5°, elevation 30°
Antenna azimuth rate: FPS-8: 0 - 10 rpm variable; FPS-88: 5, 10 rpm

AN/FPS-8 search radar

STATUS
Operational. Over 200 produced.
CONTRACTOR
General Electric Company, Electronic Systems Division, Syracuse, New York 13201, USA.

4327.153
AN/FPS-16 INSTRUMENTATION RADAR

The AN/FPS-16 tracking radar is designed specifically for range instrumentation purposes and is claimed to be the first to be so designed. Its transportable version is the AN/MPS-25. Both systems are C-band units. The antenna pedestal can be rotated continuously in azimuth and from −10 to +190° in elevation. First introduced in the mid-1950s, these units have been extensively modified in the intervening years, almost all now use integrated circuit electronics. Most of the 60 AN/FPS-16 and seven AN/MPS-25 radars have additional modifications including larger diameter antennas, 3 MW transmitters, low noise receivers and pulse dopplers.

CHARACTERISTICS
Angle tracking precision (20 dB S/N): 0·1 mils rms
Range tracking precision (20 dB S/N): 4·7 m rms
Azimuth tracking rate: 750 mils/s
Azimuth tracking acceleration: 1020 mils/s²
Elevation tracking rate: 400 mils/s
Elevation tracking acceleration: 1020 mils/s²
Ro, IM², 0 dB S/N: 235 km
STATUS
In current use. Units are in operation at United States and United Kingdom ranges.
CONTRACTOR
RCA, Government Systems Division, Missile and Surface Radar, Moorestown, New Jersey 08057, USA.

AN/FPS-16 instrumentation radar

2528.153
AN/FPS-20 - AN/FPS-100 FAMILY OF LONG-RANGE SEARCH AND GCI RADARS

AN/FPS-20 is one of a family of very long-range dual-channel search and GCI radars. It is widely used partly because it was one of the systems supplied under the MAP programme.

A D-band system, FPS-20 has a search range of some 350 km. The transmitter uses a power klystron with a 2 MW output. Pulse width is six microseconds and the PRF is 360 Hz. The antenna gain is 35 dB and the receiver noise figure 9 dB.

MTI is fitted and the radar has anti-jamming circuits. Data transmission facilities are included.

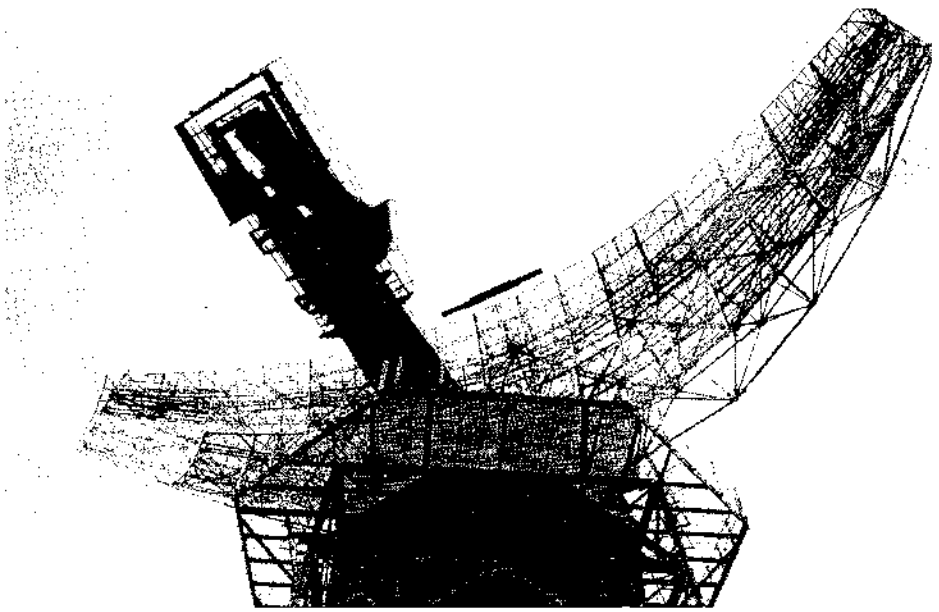
STATUS
In service in many countries. AN/FPS-20 and subsequent members of the family are used in the SAGE (**2803.181** in 1979-80 and earlier editions) and AWCS (**2533.181** in 1982-83 and earlier editions) systems. Other static radars in the family are AN/FPS-20A, 20B, -64, 65, 66, -67 and 100. AN/GPS-4 and AN/MPS-7 are the mobile versions.
CONTRACTOR
The Bendix Corporation, Communications Division, Baltimore, Maryland 21204, USA.

2494.153
AN/FPS-24 SEARCH RADAR

The AN/FPS 24 is a high power low frequency search radar. Each channel consists of 26 major cabinets, with an additional 11 cabinets that are common to both channels. It has very highly sophisticated anti-jamming features that make it extremely valuable in hostile environments.

The radar is usually installed in a six-storey building with the antenna on top. In severe climatic conditions the antenna is enclosed in a radome which is designed to withstand winds up to 150 knots. The overall antenna system weighs 92·5 tons.

CHARACTERISTICS

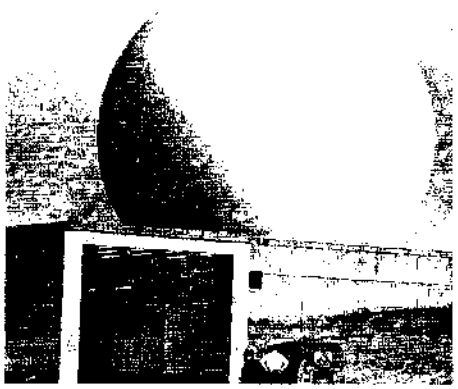


Peak power: 5 MW per channel
Average power: 25 kW with 278 pps, 18 μs pulse width
Frequency: 214 - 236 MHz
PRF: 278 pps
Pulse width: 6 μs without pulse compression; 18 μs with pulse compression
Receiver sensitivity: 4·5 dB NF; −113 dBm MDS
Beam characteristics: Cosec²
Beamwidth: Azimuth 2·9°; elevation 30°
Antenna azimuth rate: ¼ rpm CW or CCW; 5 rpm CW only

STATUS

Operational. Eleven systems have been built and are installed at USAF sites in the United States.

CONTRACTOR



General Electric Company, Electronic Systems Division, Syracuse, New York 13201, USA.

AN/FPS-24 search radar

2509.153
AN/FPS-49 EARLY WARNING AND TRACKING RADAR

One of the two basic types of radar used in the ballistic missile early warning system (BMEWS – **2525.181**), the AN/FPS-49 is a very large tracking racar that can also be used in a surveillance mode. It is installed at two of the three BMEWS sites, Thule (Greenland) and Fylingdales Moor (England). At the third site, Clear (Alaska), a slightly different radar, the AN/FPS-92 – which is an improved version of the AN/FPS-49 – is in use. Thus, the tracking radars at each of the three BMEWS stations have different designations, although they are essentially the same: Thule – AN/FPS-49A; Fylingdales Moor – AN/FPS-49; Clear – AN/FPS-92. The description that follows relates in the main to the AN/FPS-49 radars at Fylingdales Moor.

FPS-49 radar dome at Fylingdales Moor
(UK Ministry of Defence (Air))

The main reception and transmission element is a 25 m diameter parabolic reflector mounted on a conical pedestal and capable of being rotated in azimuth and elevated and depressed so as either to track a detected target or to search for one continuously. A variety of possible scanning patterns provides for a number of search modes as well as for target acquisition and tracking. Scan rates of at least 10° per second are attainable and the powerful hydraulic drive system employed is said to eliminate backlash.

Dish illumination is by four horns, to provide monopulse operation in both planes, with separate horns for reception. The system radio frequency is in the UHF band and the radar operates on several frequencies in that band. Having regard to this and the dish diameter it is probably reasonable to suppose that the beamwidth, between half-power points, is in the region of 1 to 2°.

Output power is in the megawatt region, PRF is 27 pps (pulse duration unknown) and maximum range is about 5000 km. Each radar has three power amplifiers and in normal operation two of these are on-line at a time while the third is a 'hot spare' feeding into a dummy load. The receivers incorporate low-noise parametric amplifiers.

The antenna structure is protected from the elements by a 43 m diameter radome. This is of honeycomb-sandwich construction and consists of two high-density skins 1 mm thick with a Kraft-paper honeycomb core 15 cm thick. The honeycomb is made up in hexagonal and pentagonal blocks and 1646 of these blocks make up the radome. The transmission efficiency of the radome is 98 per cent; the average boresight error is 0·1 mil and the maximum error 0·3 mil; the boresight error rate is 0·005 mil.

STATUS

Operational. There was an FPS-49 installation in use at Moorestown, New Jersey, which filled a role in the 474N SLBM detection and warning system (see **2538.153** – FSS-7 radar – in *Jane's Weapon Systems 1980/81*) but this was phased out in December 1974. See note on FPS-50 status (**2511.153**) below.

In early 1976 the US DoD revealed proposals for a 'three-element' BMEWS improvement programme which would consist of upgrading the tactical operations room, replacing the original computers which are becoming increasingly difficult and costly to maintain, and improving the radar resolution. These modifications will ensure the continued usefulness of the system well into the 1980s. In February 1978, RCA received a $4 million contract for the modernisation of the tactical operations rooms at the Clear and Thule stations. An option to carry out similar work at Fylingdales was exercised in February 1979.

CONTRACTOR

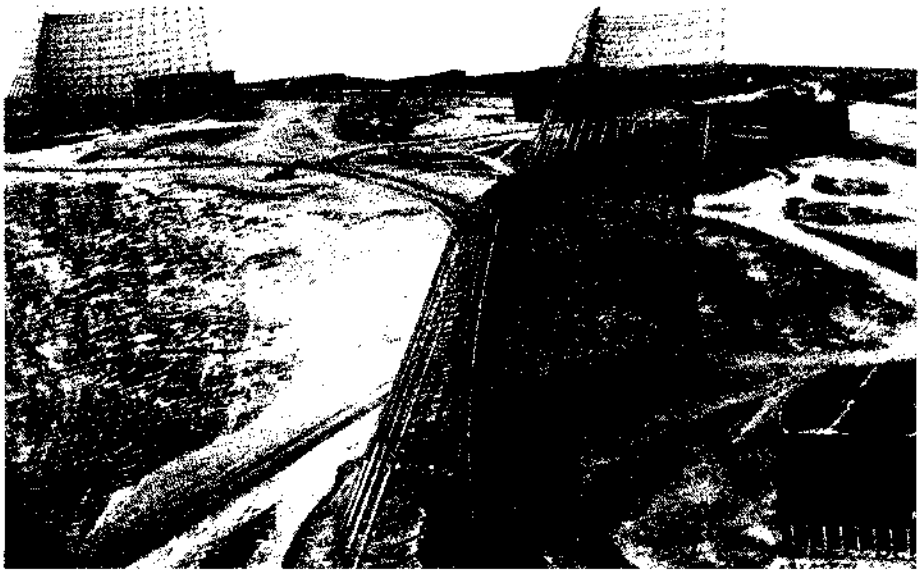
RCA, Government Systems Division, Missile and Surface Radar, Moorestown, New Jersey 08057, USA.

2511.153
AN/FPS-50 EARLY WARNING RADAR

AN/FPS-50 is the big static radar of the ballistic missile early warning system (BMEWS). It is installed at two of the three BMEWS sites at Thule (Greenland) and Clear (Alaska); there are three radars at one site, and four at the other.

The radar uses a fixed antenna system comprising a 122 m wide and 50 m high parabolic torus reflector which is fed by an organpipe scanner. Two narrow beams at two different angles of elevation are produced by this antenna and these two beams are caused to scan simultaneously over a sector in the near-horizontal plane so as to produce two horizontal direction fans, one above the other. As a missile passes through these beams its position and velocity co-ordinates are measured, from which can be calculated the trajectory, impact point, impact time and launch point.

A parabolic-torus reflector was chosen for this radar because it provides an economical measure of scanning the beam from a physically large antenna over a wide scan angle without deterioration of pattern over this arc. The disadvantages of the arrangement are the large size of the total assembly and the large sidelobes that appear in intermediate planes.



Scanning such a reflector can be achieved in various ways, but in the AN/FPS-50 it is accomplished by arranging a series of feeds on the focal points of the torus and switching the transmitter power from one point to the next with an organpipe scanner.

At Clear and Thule the AN/FPS-50 radar is used in conjunction with the AN/FPS-49A or AN/FPS-92 tracking radar. At the third station (Fylingdales Moor, England) only AN/FPS 49 or equivalent radars are used for early warning and tracking.

AN/FPS-50 early warning radar

CHARACTERISTICS
Peak power: 5 MW
Average power: 300 kW
Frequency: 425 MHz range
PRF: 27
Pulse width: 2 ms
STATUS
Operational, but see **1949.153** (Cobra Dane) and **1948.153** (Over-The-Horizon Radar) in 1979-80 and earlier editions, for probable changes in status of the BMEWS radars.

General Electric Company, Electronic Systems Division, Syracuse, New York 13201, USA.

AN/FPS-50 early warning radar

2546.153
AN/FPS-85 LONG-RANGE PHASED ARRAY RADAR

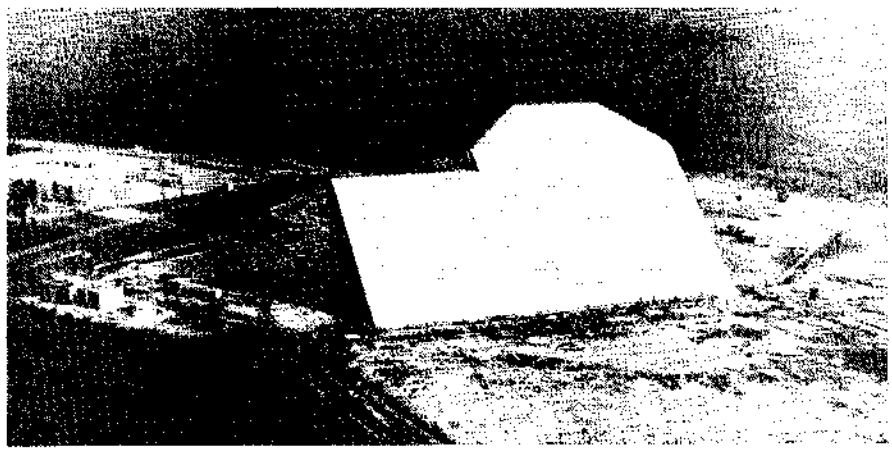
This is a very large fixed-array radar located in Florida with its principal axis aligned due south across the Gulf of Mexico and capable of transmitting and receiving over an arc extending 60° on either side of this axis.

A UHF system with a nominal frequency of 442 MHz, the radar uses separate transmit and receive arrays located side by side and both inclined at approximately 45° to the horizontal. Exact dimensions of the arrays are not known but the transmitter array is square, contains 5184 transmitter modules and has a side of something over 30 m. The receiver array is octagonal, contains some 39 000 antennas feeding 4660 receivers, and has a width of some 60 m.

Peak radiated power has been reported as 32 MW with a nominal transmitter beamwidth of 1·4°. Effective receiver beamwidth is said to be 0·8°. As already noted the radar beams are steerable over 120° arc in azimuth: in elevation the coverage is about 105° - from the radar horizon to 15° beyond the zenith. The radar is thus able to track objects northwards at high elevation angles. In the normal tracking mode the receiver complex uses a 3 × 3 matrix of 'beams' (ie receiving directions) in a monopulse mode for optimum resolution. Radiated energy can be varied, by using different modulations, to suit target requirements. In the original design only two energy levels could be selected but additional modulators are being provided to extend the range of choice and hence improve the efficiency of the radar.

This power level selection, together with all other control functions, is performed by IBM 360/65 computers, there being two of these in main and standby roles in the radar complex. These computers are programmed with both routine surveillance and routine and special tracking requirements, they carry in their memory orbital details of space objects for routine tracking so that the radar beam can, at an appropriate time dependent both on its position and the relative priority of the observation, be pointed in the direction in which the target would lie if its orbit had not been perturbed: since both intentional and accidental perturbation are common, the radar will normally have to execute a small search to locate and lock on the target.

Originally designed as the main US-based active sensor of the Spacetrack system (**2825.181**) the FPS-85 is now to be used also to supplement the FSS-7 radars of the SLBM detection system (**2810.181**) and to operate as an alternative space defence centre (ASDC). The FPS-85 receives its Spacetrack directions from NORAD space defence centre (SDC) which also has as its SPADATS inputs the BMEWS (**2525.181**) and the US Navy SPASUR sensors. At this centre all known data on space objects near the earth are filed in the computer memories and incoming data on a space object can be checked against these memories to determine whether or not it is a known object in approximately two seconds. To guard against computer or other failure at the SDC the same data are to be held on file at ASDC, which has an IBM 360/40 as well as its two IBM 360/65 computers, but in a form requiring more human intervention for a full search than is required at SDC. It is said that a full search at the ASDC may take one minute.



Similarly the SDC processes data from all SPADATS sensors fast enough to issue new orbital data for all stations three times a day, whereas the ASDC will be able to do this only once a day.

DEVELOPMENT
The FPS-85 was developed by Bendix, starting in 1962, and was the first large phased-array project in the USA. The first model was destroyed by fire in 1965 but was rebuilt and put into operation in 1969. It is currently operational in its Spacetrack role, dedicating approximately one-third of its time to space surveillance and the remaining two-thirds to routine and special tracking assignments from NORAD. It is also now operational as an ASDC.

It was modified, by the addition of the new modulators referred to above and of suitable software, to perform the SLBM detection function.

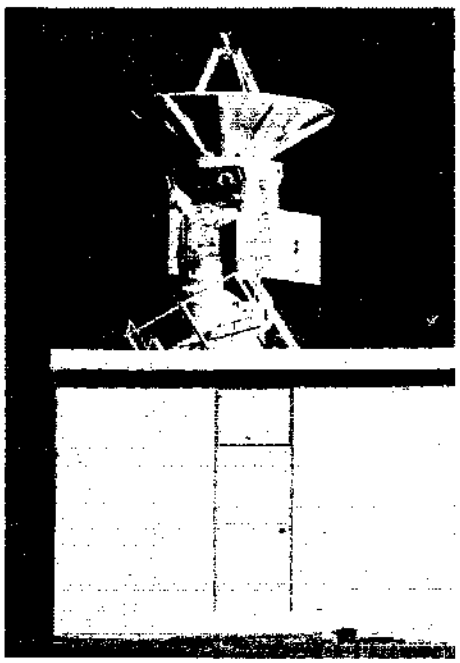
General Electric Company, Electronic Systems Division, Syracuse, New York 13201, USA.

2513.153
AN/FPS-89 HEIGHTFINDING RADAR

The AN/FPS-89 is a high-power (4·5 MW, peak) E/F-band nodding-beam radar. Accuracy of heightfinding is ±1000 ft (300 m) at 110 nautical miles (203 km) range. It is an improved version of the AN/FPS-6 radar (**2492.153**), and like the AN/FPS-6 it is available in an arctic tower installation, a temperate tower installation and a mobile version

An Italian licence-built version, AN/FPS-89S, is produced by GE, and among a number of improvements incorporated is a reduction in the receiver noise figure from 9 to 4·5 dB.

STATUS
Operational.
CONTRACTOR
General Electric Company, Electronic Systems Division, Syracuse, New York 13201, USA.



2847.153
AN/FPS-105(V) RANGE INSTRUMENTATION RADAR (CAPRI)

AN/FPS-105(V) is designed for range use to make accurate measurements of target position and velocity for performance evaluation. It can be installed either in a permanent ground station or be packaged for transportable use.

Its standard antenna is a 366 cm diameter solid-surface parabolic dish fed by a monopulse four-horn feed. Polarisation is vertical. The antenna can rotate continuously in azimuth and can be rotated through 200° (−10 to +190°) in elevation, a cable being used to avoid the need for a rotating joint. Microwave circuits are mounted on the rotating section of the antenna mounting. Larger antenna pedestals, 488 or 885 cm, are fitted to some systems. The transmitter will radiate single pulses, pairs, or triplets as required. Peak power is 1 MW and recurrence frequencies and pulse widths can be chosen for 160 and 640 pps and from 0·25, 0·5 and 1 microseconds respectively. Transmitter frequency is in the G/H-band.

The digital range tracker contains a precise frequency standard and 'nth time round' circuits to enable a relatively high recurrence frequency to be used despite the long measuring ranges. Automatic search and lock-on are provided during target acquisition. Twenty-five bits of range data are supplied by the system at data rates up to 40 times per second.

CHARACTERISTICS
Azimuth tracking rate: 850 mils/s
Azimuth elevation tracking acceleration: 800 mils/s²
Azimuth elevation tracking precision: 0·2 mils rms at 20 dB S/N
Elevation tracking rate: 500 mils/s
Range tracking precision: 4·7 m rms at 20 dB S/N
Unambiguous tracking range: 60 000 km
Ro, IM², 0 dB S/N: 200 km
STATUS
Five units of this configuration are in use at several US ranges.
CONTRACTOR
RCA, Government Systems Division, Missile and Surface Radar, Moorestown, New Jersey 08057, USA.

AN/FPS-105 (V) range instrumentation radar

4326.153
AN/FPS-117 AIR DEFENCE RADAR

The AN/FPS-117 solid-state radar system is an L-band, three-dimensional air defence radar designed to provide long-range accurate aircraft identification and position data for air defence, navigational assistance and tactical control for both close air support and counter air operations.

The system provides automatic adaptation to, and rejection of, land, sea and weather clutter by using clutter rejection processing. Adaptability in siting the radar is achieved by low-beam coverage enhanced by MTI processing, with doppler filtering for look-down beam positions on elevated sites. Sidelobe nulling is used to eliminate ground clutter for high beam positions.

The planar array measures 7·3 × 7·3 metres and produces a series of pencil beams phase-positioned to scan in elevation up to 20° while the complete antenna rotates in azimuth. The elevation scan consists of 5 to 100 nautical miles short-range beams, and 100 to 250 nautical miles long-range beams. The use of pencil beams is designed to obtain elevation coverage while eliminating clutter problems associated with large transit beamwidths. The transmitter/receiver system consists of 44 row transmitters, each containing eight 100 W RF solid-state power modules, and 44 receiver modules, all mounted on the rear of the array.

CHARACTERISTICS
Range: 200 nm
Accuracy: 0·25 nm
Altitude: 100 000 ft (30 480 m)
Elevation angle: −6 to +20°
Transmitter power: 24·75 kW peak
Frequency: 1215 – 1400 MHz
Bandwidth: 185 MHz
Agility: 20 frequencies (quasi-random selection, beam-to-beam)

STATUS
Successful trials of the AN/FPS-117 to replace older search and heightfinding radars in Alaska have been completed. In April 1983, General Electric announced a $77 million contract for eight systems with an option for four more, and in July 1983 the company received a $16·4 million contract to obtain long-lead items for the latter. In early 1985, a further ten systems were ordered by the USAF, at a cost of $58.8 million, to update the DEWS line. In January 1983 Hazeltine Corporation announced a $3·5 million contract for the supply of eight Seek Igloo IFF systems as an integral part of the AN/FPS-117. It is understood that a version of the AN/FPS-117 is one of several contenders for the US Federal Aviation Agency Radar Replacement (FARR) joint civil/military programme for minimally attended radars.
CONTRACTOR
General Electric Company, Electronic Systems Division, Syracuse, New York 13201, USA.

3713 153
AN/GPN-22 PRECISION APPROACH RADAR

The AN/GPN-22 precision approach radar (PAR) is intended specifically for use in fixed base high-density ATC system operations under all weather conditions. It operates in X-band and is a development of the high-performance AN/TPN-25 PAR (**3712.153**) used in the USAF AN/TPN-19 landing control system (**2537.153**). Both these radars employ phased array antennas to perform simultaneous scanning and tracking modes over the full radar coverage volume without any mechanical motion of the antenna. In the case of the TPN-25, up to six aircraft targets can be monopulse tracked simultaneously; in the case of GPN-22, the same number of targets can be handled but the coverage pattern measures 20 × 8° compared with the 20 × 15° of the earlier equipment. The range is about 35 km in both cases. Provisions are made for the display of landing aircraft position data in the operations centre up to 3500 m from the radar head.

The only significant difference between the GPN-22 and the TPN-25 is in the physical arrangements of the antenna. The GPN-22 feed assembly is supported by a boom structure projecting over the upper edge of the main reflector, whereas in the TPN-25 it is mounted beside the reflector.

STATUS
Deliveries have been made of 39 sets to the USAF, 2 sets to Austria and 11 sets to the Netherlands.
CONTRACTOR
Raytheon Company, Equipment Division, Wayland, Massachusetts 01178, USA.

2497.153
AN/MPQ-4 MORTAR LOCATING RADAR

The AN/MPQ-4 provides quick identification to pinpoint enemy mortar positions in map co-ordinates, enabling artillery units to launch counter-attacks. It uses a two-beam intercept principle of location with positive first-shell acquisition and has the capability for handling multiple targets.

All the equipment is mounted on two two-wheel trailers, each designed for its specific purpose. One trailer carries the primary radar equipment, while the other carries the primary power supply (a petrol engine generator set) and auxiliary equipment such as cable and spare parts.

The AN/MPQ-4 can be operated from virtually any

site and can be set up in 15 minutes. Once set up it can be operated by one man. The operating and control console may be used on the equipment trailer or in a remote location.

CHARACTERISTICS
Frequency: 16 GHz
Peak power: 50 kW (minimum)
PRF: 8·6 kHz
Pulse width: 0·25 μs
Detection range: 10 000 m (max); 170 m (minimum)
Sector scan: 25°
Elevation coverage: 6 to +12°
Accuracy: Within 50 m at 10 000 m
Presentation: B scope, 140 mm CRT
Weight: 2268 kg
Mounting: 2-wheel trailer
Antenna: Reflector with Foster dual scanner feed

STATUS
Operational. It is produced under licence in Japan as the Type 92 mortar locating radar JAN/MPQ-N1.

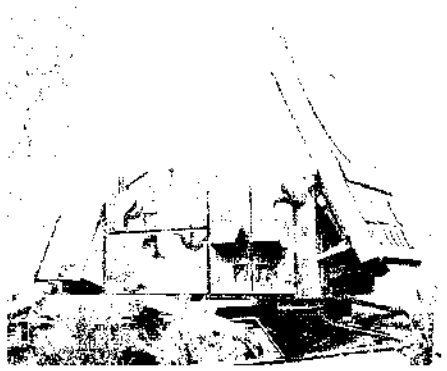
CONTRACTOR
General Electric Company, Electronic Systems Division, Syracuse, New York 13201, USA.

AN/MPQ-4 mortar locating radar

2500.153
AN/MPQ-10A MORTAR LOCATING RADAR

The AN/MPQ-10A radar was initially developed in August 1950 by the US Army Electronics Command and was the first American mortar locating radar system. A total of 485 radar sets were delivered to the US Army between September 1951 and September 1954. Radar AN/MPQ-10A is a mobile radar designed to locate and track mortar and artillery shells. It can be used with associated recording equipment to locate the point of origin and point of impact of the projectile. Further information is given under this entry number in previous editions of *Jane's Weapon Systems*.

CONTRACTOR
Sperry Corporation, Electronic Systems, Great Neck, New York, USA.



4478.153
AN/MPQ-53 GUIDANCE RADAR

The AN/MPQ-53 is a multi-function radar group which performs all the surveillance, IFF, tracking and guidance functions entailed in the Patriot (MIM-104) tactical air defence missile system (**2800.131**). The antenna array is a multi-element phased-array planar configuration carried on a semi-trailer chassis. The antenna unit has separate arrays for target detection and tracking, missile guidance and IFF functions. The last of these tasks is carried out by an AN/TPX-46(V)7 interrogator, using a supplementary array adjacent to the main circular search and track array on the antenna unit. Other supplementary arrays are for command and guidance signal and reception.

STATUS
In service with US forces, planned for NATO use in Europe.

CONTRACTORS
Prime contractor: Raytheon Company, Andover, Massachusetts, USA.

IFF interrogator: Hazeltine Corporation, Commack, New York 11725, USA.

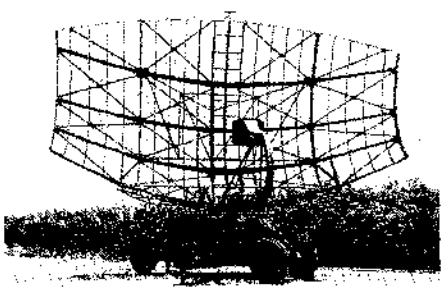
5628.153
REAL-TIME VELOCIMETER RADAR (RTVS)

This system is a transportable X-band CW doppler artillery tracking radar designed to measure and record target radial range, velocity, acceleration and angular position. The equipment is carried in two mobile elements; an antenna trailer which contains the transmitter and receiver plus the steerable antenna system and a control cabin which carries the operator control console and data processing units. The RTVS is intended to allow tracking of targets from 100 to 10 000 ft/s and will acquire and track targets down to 0·0032 m². Accuracy at 20 km is stated to be 1 ft/s for velocity, 1 ft/s² for acceleration and 6 m in range. Operating frequency of the radar is pre-tunable between 10 and 10·26 GHz.

Range in the system is determined without modulating the carrier by transmitting three carrier waves simultaneously and measuring the phase shift between transmitted and received beat notes. A high speed array processor is used to perform digital spectral analysis of the returned signal. The fast Fourier transform (FFT) processor extracts target velocity from the raw doppler signal, and spectral details of the transmitted signal resolve the difference.

Unambiguous real time ranging to 75 km is obtained from the FFTs applied to the doppler shifted return signal from the three transmitted tones, where the relative shift is proportional to range. The transmitter uses a stable UHF synthesiser and a low noise master oscillator klystron to drive the final power stage which consists of three klystrons.

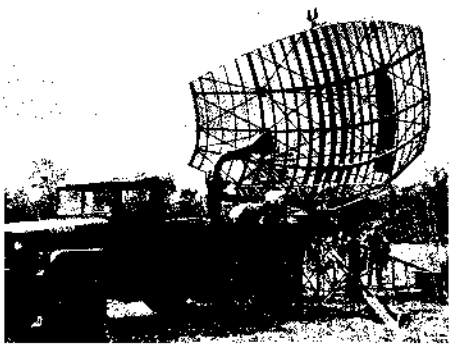
STATUS
In operational use at the US Army White Sands Missile Range.



CONTRACTOR
Datron Systems Inc, 20700 Plummer Street, Chatsworth, California 91311, USA.

2495.153
AN/MPS-11 AND AN/MPS-11A SEARCH RADARS

The AN/MPS-11 and AN/MPS-11A are mobile versions of the AN/FPS-8 medium-power D-band search radar (**2493.153**). The difference between the two mobile versions is that the AN/MPS-11 antenna is mounted after arrival at site on a manually erected tower, while the AN/MPS-11A antenna is permanently installed for transport and operation on a 40 mm gun carriage, permitting more rapid initial operating capability.



The AN/MPS-11 may be transported by aircraft or by two trailers and nine M35 trucks. Set-up time, with 15 men, is two hours.

STATUS
Operational.

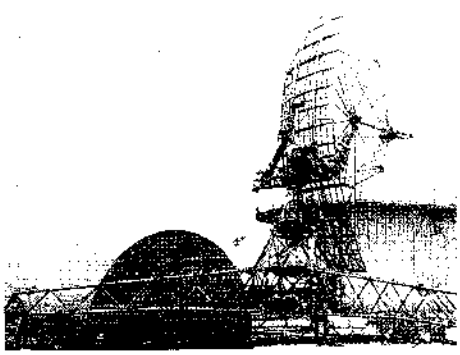
General Electric Company, Electronic Systems Division, Syracuse, New York 13201, USA.

AN/MPS-11 search radar

2496.153
AN/MPS-14 HEIGHTFINDING RADAR



The AN/MPS-14 radar is the mobile version of the AN/FPS-6 high-power E/F-band nodding-beam radar (**2492.153**). It is designed for transport by six trucks and three trailers to temporary strategic or tactical sites. Trailers are functionally designed for quick loading and unloading, and assembly and disassembly may be accomplished in rapid and efficient fashion.

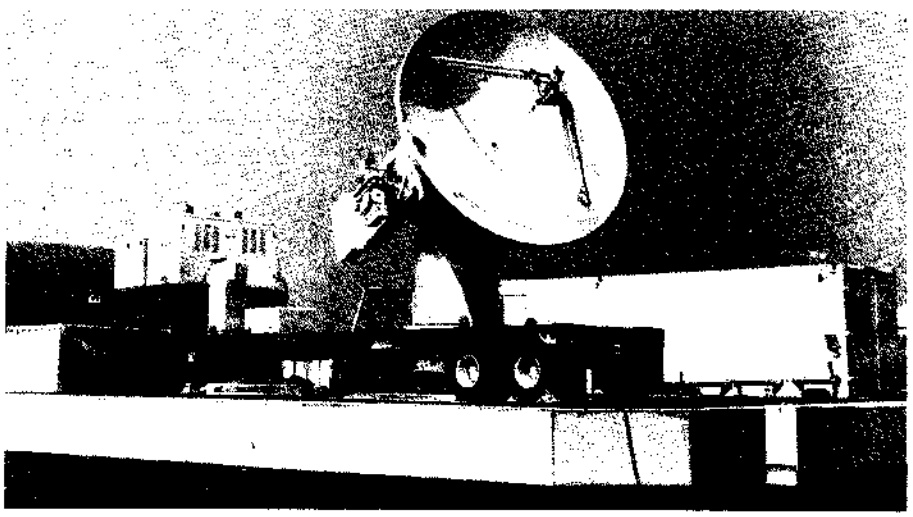
The trailers serve the dual purpose of transporting the equipment and supporting certain electronic components during operation. For example, the RF equipment need not be removed from the trailer for operation, and the entire unit is protected by a prefabricated shelter assembled at the site. The shelter is equipped with space heaters and lighting fixtures.

The AN/MPS-14 system's electronic components are identical to and interchangeable with those of the AN/FPS-6.

STATUS
Operational.

CONTRACTOR
General Electric Company, Electronic Systems Division, Syracuse, New York 13201, USA.

AN/MPS-14 heightfinder radar



2514.153
AN/MPS-36 INSTRUMENTATION TRACKING RADAR

AN/MPS-36 is a C-band mobile instrumentation radar built originally in 1970 for the US Army testing grounds at White Sands Missile Range.

The radar can accurately track targets travelling up to 36 000 knots at ranges up to 60 000 km. Data accuracy has been measured at one metre in range and target velocities within 5 cm/s on trajectories of missiles and missile re-entry vehicles.

Advanced integrated circuits are extensively designed into the equipment and pulse doppler capability is integral. A general-purpose computer has been integrated into the radar to provide pulse doppler signal processing. Polarisations are console selectable.

The radar is housed in a 12·4 m electronics trailer and a 366 cm diameter antenna is mounted on an 11 m pedestal trailer. With this arrangement, the radar can be moved from site to site by road, air, or sea and be operational within eight hours after arrival.

AN/MPS-36 missile tracking radar

CHARACTERISTICS
Transmitter power: 1 MW minimum
Antenna gain: 43 dB minimum
Antenna beamwidth: 1·2° max
Antenna sidelobes: 20 dB minimum
Pedestal coverage (elevation): -5 to -185°
Pedestal coverage (azimuth): Continuous
Azimuth tracking rate: 890 mils/s
Elevation tracking rate: 500 mils/s
Azimuth acceleration rate: 400 mils/s²
Elevation acceleration rate: 400 mils/s²
Azimuth tracking precision at 20 dB S/N: 0·2 mils, rms
Elevation tracking precision at 20 dB S/N: 0·2 mils, rms
Range tracking precision at 20 dB S/N: 2·7 m rms
Range rate tracking precision at 20 dB S/N: <0·03 m/s rms accuracy
Unambiguous range tracking: 60 000 km
Installation time to power on: 8 h max
Receiver noise figure: 4 dB max
Ro, IM², 0 dB S/N: 350 km
Reliability (design goal): MTBF 100 h

STATUS
The first equipment was delivered in 1970 and met or exceeded all design specifications. Fourteen radars are now operational at US test ranges and three have been provided to the Federal Republic of Germany. The radars are used for studies of weapons systems and space programmes.

CONTRACTOR
RCA, Government Systems Division, Missile and Surface Radar, Moorestown, New Jersey 08057, USA.

2540.153
AN/PPS-5 COMBAT SURVEILLANCE RADAR

AN/PPS-5 is a portable battlefield radar designed to detect and locate individual men up to 5000 m and groups of men or small vehicles up to 10 000 m. A later model, the AN/PPS-5B, which incorporates advanced technology, is now the standard equipment.

The AN/PPS-5 solves the major problems of personnel detection radars by providing automatic sector azimuth scanning and range coverage with visual display of moving targets over the sectors under line-of-sight surveillance. The radar can be switched from MTI operation to normal operation, permitting the operator to locate fixed targets.

A range-gated filter MTI processor is especially suitable for detecting targets moving as slowly as 1·6 km/h. Operation while scanning is silent.

The control/indicator unit provides remote control of the radar set with the appropriate readout and control devices as well as visual displays of 10 000 m range in 5000 m increments on both MTI and normal displays (A-scope and B-scope). Target range is measured by a manually controlled magnetostrictive delay line coupled to a counter; this system was selected instead of the more conventional pulse-delay system because it permits table calibration without having to add calibrators and to make slope, zero, and other adjustments. Target range is measured by a manual range control knob coupled to a direct-reading range counter. A range mark on the display scope shows the position of the range gate. An aural doppler processor consisting of a clutter filter and audio amplifier drives the headphones.

A 50-channel range-gated filter system is used to provide MTI over a 5000 m range. Each range-gated filter channel in the system sequentially covers a 100 m range increment. Each channel is identical in design. The outputs from the 50 filters are added to provide MTI video for the displays.

The selectable scan speeds are held relatively constant by a feedback motor-speed control circuit that supplies only enough power to meet the demand in the presence of varying wind loads; this conserves power. Azimuth co-ordinate readout is obtained remotely from a follow-up servo that repeats the antenna position data. To minimise power consumption, this control is used on demand by the operator only when fine azimuth data are desired.

One version of the radar set has been equipped with a 360° scan and a PPI display kit for the US Army Special Forces. Another version of the radar set has been installed in a vehicle and used for perimeter protection of air bases.

The equipment works in the 16 to 16·5 GHz band (tunable) and has a peak power of 1 kW and a PRF of 4000 pps. An accuracy of ±20 m in range and ±10 mils in azimuth can be achieved.

Physically the equipment consists of three rugged packages weighing about 40 kg. Power consumption is about 57 W.

STATUS
Quantity deliveries of the PPS-5 have continued over a period of some years. The PPS-5B is now the standard issue in the US Army. In addition to the USA, other unspecified governments have been using the AN/PPS-5A since 1967 and are procuring the AN/PPS-5B.

CONTRACTOR
Eaton Corporation, Command Systems Division, 815 Broad Hollow Road, Farmingdale, Long Island, New York 11735, USA.

5604.153
AN/PPS-6 BATTLEFIELD SURVEILLANCE RADAR

AN/PPS-6 is a man-portable tripod-mounted X-band non-coherent pulse-doppler radar capable of automatic scanning and giving an audible indication of the presence of moving targets. The transmitter/receiver and small parabolic antenna form a single unit which, with the angular control assembly, is mounted on a folding tripod, and the user has the option of manual control of the pointing direction or any of three azimuth sector scans.

There is also a choice of range sectors. A range gate enables the user to search an area of 45 m depth in range beyond a chosen range; in the automatic modes the equipment will either scan continuously an area extending in range for 315 m beyond a chosen range, or search, in alternate sweeps, this area and a further area extending from the 315 m range to 630 m beyond the chosen range. When a target is located its co-ordinates can be determined by manually adjusting the antenna and range control for maximum signal, and reading off the required angle and range.

CHARACTERISTICS
Frequency: 9 – 9·5 GHz
Range: Personnel 1500 m; vehicles 3000 m
Accuracy: Azimuth ±18 mils; range ±25 m
Sector scans: 600, 900 or 1200 mils
Weight: 20 kg
Power supply: Battery

STATUS
In current production and in service with US forces.

CONTRACTOR
General Instrument Corporation, Government Systems Division, 600 West John Street, Hicksville, New York 11802, USA.

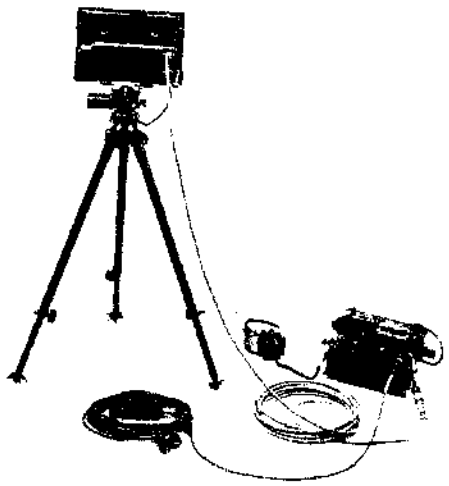
5616.153
AN/PPS-11/12 BATTLEFIELD SURVEILLANCE RADARS

The AN/PPS-11 is a hand-held battlefield surveillance radar which weighs only 4·5 kg. It is a modulated CW doppler correlation equipment, operating in Z-band with a range of approximately 1 km against vehicles and an accuracy of 8 m. The operation of the system is extremely simple in that once the equipment has detected a target in the 1 km range, the operator can narrow the options by selecting various range gates until the target is fixed and the range and bearing are available. An audio signal is also available for identification of the type of target.

An improved and expanded version of this equipment, known as the AN/PPS-12, weighs about 7 kg and has an increased range of up to 3 km. A number of refinements, such as automatic scanning, automatic target warning and simultaneous scan and search have also been provided.

CONTRACTOR
RCA, Government Systems Division, Missile and Surface Radar, Moorestown, New Jersey 08057, USA.

1947.153
AN/PPS-15A INFANTRY RADAR



The AN/PPS-15A is a J-band (former X-band), lightweight ground surveillance radar for the detection and location of moving targets such as men, vehicles, or boats. Range and azimuth of a moving target are read directly from solid-state LED displays, and the nature of the target is deduced from its aural signature. The radar set consists of the antenna assembly, control indicator, an antenna drive, a headset, a tripod, remote cable and an internal disposable battery which provides power for 12 hours continuous operation. The AN/PPS-15A can be hand-held, pintle or tripod mounted and remotely controlled. The control indicator and antenna assembly are integral for most operations but may be separated for remote operation at distances up to nine metres. Automatic sector scan can be centred on a selectable bearing, and the scan width also is selectable. Elevation control is manual.

Target returns are fed to an 'all-range' channel and a 'discrete-range' channel. During search, the all-range channel automatically discriminates against clutter and produces both aural and visual alarms when a moving target is detected. During ranging, the discrete-range channel produces a light display and an increased copper tone when a moving target enters a range gate positioned by an operator-control. Both channels are active during the search-range mode, enabling an operator to monitor detected targets on the all-range channel as he ranges a selected target by means of the discrete-range gate control.

CHARACTERISTICS
Frequency: Low J-band
Peak power: 50 mW
Antenna: 20 × 30 cm
Mode: Homodyne
Weight: 10·7 kg (remote operation)
Detection ranges: Personnel 1·5 km; vehicles 3 km
Battery: BA4386/PRC-25

STATUS
The AN/PPS-15A radar equipment has been US Army 'type classified' for use to the armed services, and the following have been delivered: 167 to Argentina, 213 to Canada, 25 to Norway, 150 to Spain, 40 to the UN and 1000 to various US military units. Additional sales have recently been made to the UN and Norway, and both Israel and Taiwan have taken delivery of an unspecified number. Advanced versions are being developed and tested.

CONTRACTOR
General Dynamics, Electronics Division, PO Box 81127, San Diego, California 92138, USA.

AN/PPS-15A lightweight ground surveillance radar

4324.153
AN/PPS-15B BASE SECURITY RADAR

The AN/PPS-15B is a development of the AN/PPS-15A and provides additional surveillance capability in a 350 m range segment, divided into seven 50 m range gates. The system is designed to detect and locate moving targets, eg vehicles and personnel, to provide perimeter surveillance for virtually any type of installation.

The 350 m segment may be positioned by the operator anywhere within the detection range of the system to provide surveillance without interference from, or alarms caused by, traffic moving inside the base perimeter itself. The seven range gates are individually displayed to provide automatic detection. Sector scan width is variable, by the operator, between limits of 22 and 180°. Five transmitter frequencies are available for selection by the operator. Power sources are supplied with the radar which can be operated from either AC (115 or 230 V) or DC (12 or 24 V).

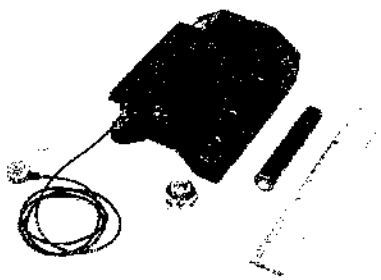
The AN/PPS-15B can be hand-held, pintle or tripod mounted and remotely controlled. Both aural and visual alarms are produced when a moving target is detected, and the LED type display is identical to that of the AN/PPS-15A.

CHARACTERISTICS
Frequency: Low J-band
Detection range: 3000 m
Remoting: 35 m
Power source (external): 115/230 V AC, 12/24 V DC
Weight
Radar: 15 kg (including DC power source and cable)
DC power source: 7 kg
AC power source/battery charger: 9·5 kg
Remote cable and reel: 7 kg

STATUS
In service with the US armed forces.

CONTRACTOR
General Dynamics, Electronics Division, PO Box 81127, San Diego, California 92138, USA.

AN/PPS-15B base security radar



5605.153
AN/PSS-10 BATTLEFIELD RADAR RECEIVER

The AN/PSS-10 is a miniature battlefield radar receiver, weighing only 680 grammes, which is capable of detecting battlefield radars at distances well beyond their effective detection range. It is designed for hand carrying and indicates direction and the type of radar being detected.

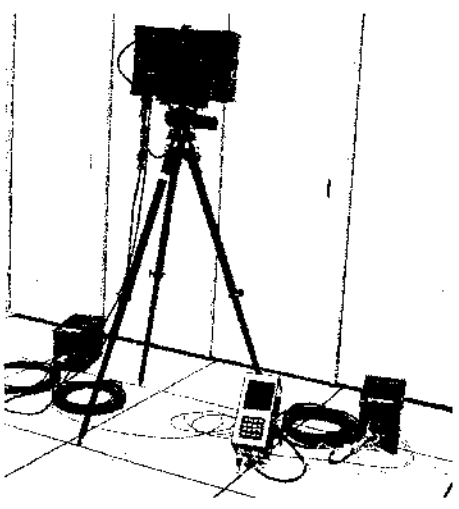
The unit comes with special cold weather kit which allows it to be operated in temperatures down to −48°C.

STATUS
The equipment has been developed under a US Army Electronics Command contract.

CONTRACTOR
General Instrument Corporation, Government Systems Division, 600 West John Street, Hicksville, New York 11802, USA.

AN/PSS-10 miniature battlefield radar receiver

4325.153
TYPE 386 GROUND SURVEILLANCE RADAR



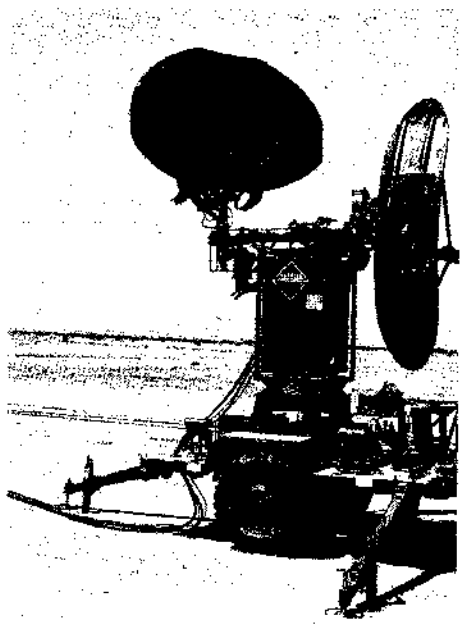
The model 386 radar is the latest in a range of ground surveillance radars produced by General Dynamics, and is a lightweight system with a detection range of 6 km. A number of advanced features have been incorporated, including a hand-held remote control/indicator unit with keyboard push-button controls and a 32 × 16 LED matrix synthetic B-scope display for visual presentation of moving target information. Target detection tracking and alarm warning is automatic and a radar netting capability is incorporated. Remote operation is available out to approximately 1·5 km using a standard military single pair field wire.

Both visual and aural warning is provided, target doppler being fed to the operator's headset for identification. Sector scan width is variable by the operator from 22·5 to 90°.

CHARACTERISTICS
Frequency: Low J-band (previously X-band)
Detection range: To 6 km
Modulation: CW pseudo-random code (PRN)
Power output: 100 mW
Sector scan width: Adjustable 22·5° to 90°
Weight: Basic radar (9 m remote) 12·6 kg; extended remote (optional to 1·5 km) 16 kg

STATUS
The radar has been demonstrated in US Army and US Air Force tests using RF and field wire links for remote operation.

CONTRACTOR
General Dynamics, Electronics Division, PO Box 81127, San Diego, California 92138, USA.



Model 386 lightweight ground surveillance radar

3129.153
AN/TPN-18A RADAR

The AN/TPN-18A ground controlled approach radar system, developed for the US Army, is a lightweight, tactical ground-based radar which provides precise three-function information to airport/heliport controllers. These functions consist of terminal area surveillance, precision approach for control of landings, and heightfinding for aircraft monitoring. This versatile system is readily transported by helicopter, cargo aircraft, or truck, and is suitable for truck/trailer mounting for full mobility in combat-related operations. The earlier TPN-8 version, designed for the US Marine Corps' military all-weather tactical operations, has since been adapted by other military services. Radar set AN/TPN-18A is a component of landing control central AN/TSQ-71A and AN/TSQ-72.

CHARACTERISTICS
Type: Pulse modulated
Frequency: 9 - 9·6 GHz
Peak power: 200 kW nominal
PRF: 1200 pps
Pulse width: 0·2 or 0·8 μs
Range: 8, 16, 32, and 64 km (128 km for IFF). 5, 10, 20, and 40 miles (80 miles for IFF)
Displays: Surveillance - PPI
Approach - B-scope
Elevation beam: 1·1° vertical, and 3·4° horizontal, vertical or circular polarisation
Azimuth beam: 3·5° vertical, cosec^2 to 27°, and 1·3° horizontal, horizontal or circular polarisation
STATUS
In US Army service.
CONTRACTOR
ITT-Gilfillan, 7821 Orion Avenue, Van Nuys, California 91409, USA.

ITT-Gilfillan AN/TPN-18A precision approach radar

2537.153
AN/TPN-19 LANDING CONTROL CENTRAL

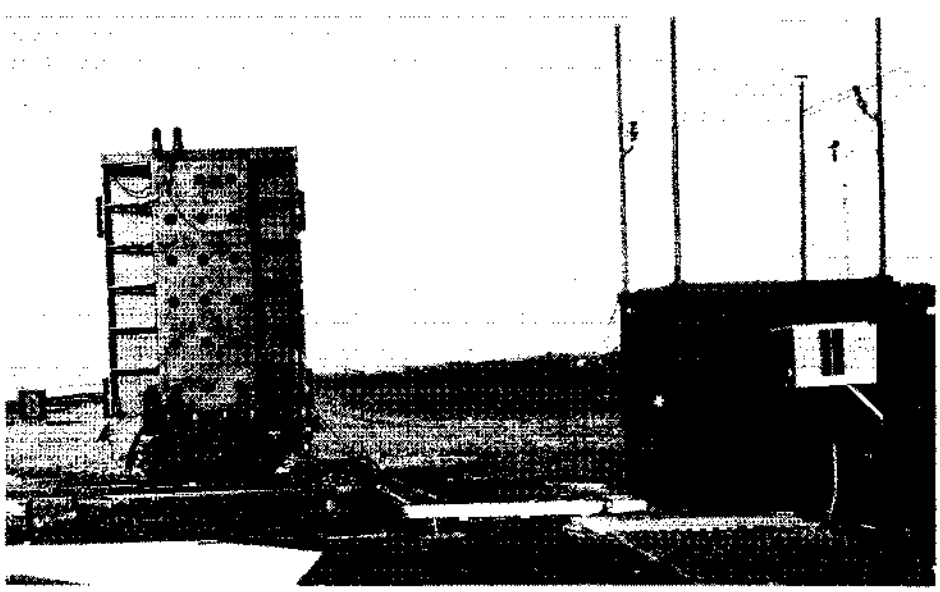
AN/TPN-19 is a terminal ATC system comprising an airport surveillance radar (ASR), a precision approach radar (PAR) (AN/TPN-24 and AN/TPN-25 respectively), and an operations centre. The radar systems are linked to the operations centre by microwave links (10 nautical miles). The system is designed for rapid world-wide deployment as well as fixed base installations. Packaging techniques make the system completely transportable by aircraft, helicopter or road vehicle.

The AN/TPN-24 ASR (**3711.153**) is a dual-channel, 2 × 500 kW E/F-band, MTI radar. Its most noteworthy features are a multiple (12) horn antenna feed which produces lobe-free coverage up to 12 000 metres and 60 nautical miles on a 1 m^2 target; a low-angle pattern which is electrically variable and programmable in range and azimuth to reduce clutter returns; a digital coherent and non-coherent MTI system to eliminate weather returns, and a staggered PRF to eliminate blind speeds below 1100 knots.

The AN/TPN-25 PAR (**3712.153**) is said to represent a significant advance in the state-of-the-art. Operating in I/J-band, it has a range of 20 nautical miles even with precipitation at 5 cm/hour. This results from the use of the narrow pencil beam (0·75 × 1·4°) produced by the 824-element phased-array antenna of 320 kW. A monopulse system, it can track up to six targets simultaneously. For multiple runway coverage the antenna assembly can be slewed through 270°.

In the GCA configuration there are three displays but through simple modular extension the system provides seven displays for a full RAPCON configuration. All displays are dual mode and can be changed to display either an ASR or PAR presentation simultaneously.

STATUS
Both the complete TPN-19 and separate examples of the two radar sets incorporated in it have been supplied or ordered for US and foreign forces. The US Air Force has 11 TPN-19s; Australia has one TPN-19, six TPN-25 PARs and one TPN-24 ASR; the Netherlands has fixed installations for six TPN-24 ASRs and 11 GPN-22 PARs (the latter being an improved TPN-25); Austria has one GPN-22 with options on more; the US Air Force is taking delivery of 39 GPN-22s; and West Germany is being supplied with 44 TPN-24s for fixed base installation.
CONTRACTOR
Raytheon Company, Equipment Division, Wayland, Massachussets 01178, USA.



4075.153
AN/TPN-22 PRECISION APPROACH AND LANDING RADAR

The AN/TPN-22 is a precision track-while-search radar that uses phase/frequency scanning to provide high data rates for automatic detection and tracking while simultaneously searching a 46 × 8° sector. The radar consists of antenna, transmitter, receiver, digital processor and sub-systems.

The AN/TPN-22 planar array antenna operates at I-band (former X-band) and radiates a computer-controlled pencil beam using phase/frequency scanning. The antenna consists of 94 electronic digitally controlled diode phase shifters feeding 94 serpentine arrays and incorporates circular polarisation for improved performance in bad weather.

The transmitter final stage consists of an air-cooled, high-power TWT using a solid-state regulated high voltage power supply and line-type modulator. The transmitter first stage is also a TWT amplifier.

The receiver, a double conversion superheterodyne configuration, uses a GaAsFET amplifier and provides flexible operation through the incorporation of STC, AGC, GAGC and CFAR features. A three-pulse (track mode) digital moving target indicator is provided for rain discrimination.

ITT-Gilfillan AN/TPN-22 precision approach and landing radar developed for the US Marine Corps

The data processor consists of an AN/UYK-20 general-purpose computer and a hard-wired special-purpose digital processor. The data processor controls and operates the radar under the local direction of the radar system operator or the remote command and control segment. The special-purpose digital processor provides major support to the general-purpose UYK-20 by performing general radar system control and communication functions. The digital processor also provides an interface with the general-purpose computer and the display, receiver, transmitter and antenna sub-systems.

The AN/TPN-22 precision approach and landing radar is an integral part of the Marine Air Traffic Control and All-weather Landing System (MATCALS) under production by the Naval Electronic Systems Command to upgrade air traffic control and all-weather landing control capabilities at Marine Corps' expeditionary airfields. The system is transportable by truck or helicopter.

The AN/TPN-22 provides three landing modes:
Mode I: automatic control via the aircraft flight control system from acquisition to touchdown
Mode II: control of cockpit landing display including pseudo-ILS flight path error presentation for pilot controlled approach and Mode I monitoring. Pseudo-MLS capability is planned
Mode III: ground controlled approach using voice communications between controller and pilot 'talkdown'.

CHARACTERISTICS
Frequency: 9 – 9·2 GHz
Peak power: 120 kW
Average power: 180 W
Pulse duration: 0·25 μs
PRF: 6000 - 4200 pps
Antenna
Azimuth scan: 46, 30 and 20° (30 and 20° steerable)
Elevation scan: 8°
Azimuth beamwidth: 0·98° at beam normal

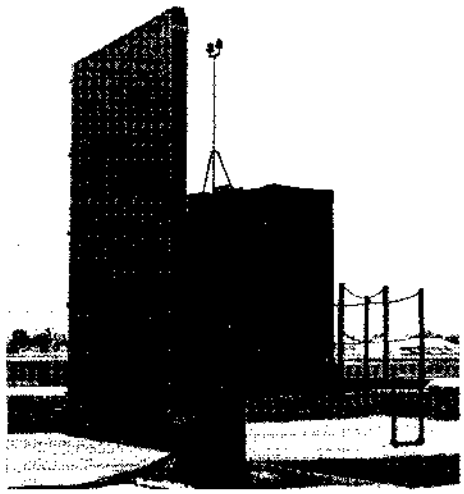
Elevation beamwidth: 0·67° at beam normal
Track data rate: Variable, approx 5/s (minimum) to 10/s (max)
MTI: 2-pulse canceller (search); 3-pulse canceller (track)
Track capacity: 6 targets simultaneously
Search data rate: 4 s max for 46° when tracking 6 targets
Detection: 10 nm on 2 m² target in 1-inch/h, 5 mile rain cell
Minimum range: 228 m from radar
Detection probability: 95% cumulative in acquisition gate
False alarm probability: 10^{-4} (false track)
Droptrack probability: 10^{-6} (false track)
Accuracy
Azimuth: ±0·086°
Elevation: ±0·057°
Range: ±3 m or 1% of range whichever is greater
System weight: 3628 kg (equipment group); 2494 kg (antenna group)
Set-up time: 1 h (4-man crew)

STATUS
A production system has been in operation at NATC Patuxent River, Maryland since 1981. Production is now completed. The first full-automatic (hands-off) landings to touchdown were conducted in April 1979 at Patuxent River.

CONTRACTOR
ITT-Gilfillan, 7821 Orion Avenue, Van Nuys, California 91409, USA.

4077.153
PAR-80 PRECISION APPROACH RADAR

The ITT-Gilfillan PAR-80 is a fixed site, turntable-mounted, precision approach radar (PAR) set that features a pencil-beam planar array antenna employing ferrite phase shifters for azimuth beam displacement and mechanical actuator for vertical beam positioning. Radar scan angles of 30° in azimuth and 7° in elevation when combined with the 10 or 20 nautical mile radar range provide large service volume coverage for all aircraft types and traffic pattern variations. The PAR-80 utilises circular polarisation for operation in adverse weather, with optional constant false alarm rate (CFAR) circuitry.



The radar set group (antenna, scan programmer, and the dual receiver/transmitters) are pallet-mounted on a turntable that is remotely controlled for coverage of multiple runway approaches. Control/indicators with an accompanying video processor may be remotely controlled from operations centres or control towers up to 3048 m distant.

The PAR-80 incorporates solid-state design, digital clutter-reduction sub-systems, dual-channel radar transmitters and receivers, high-gain low-sidelobe antenna, remote control of PAR landing direction with four sets of preset course and glideslope cursors and other features.

This equipment is related to the AN/TPN-22 (**4075.153**) and there are a number of common design features. The PAR-80 produces a greater RF output though, and the antenna and its mounting arrangements differ somewhat from those of the TPN-22.

CHARACTERISTICS
Frequency: 9000 - 9160 MHz
Pulse width: 0·2 μs
PRF: 3450 Hz
Peak power: 150 kW
Beamwidth: 1·1° horizontal × 0·6° vertical
Antenna gain: 45 dB
Sidelobes: -22 dB max
Max range: 30 nm
Resolution: 1·1° azimuth; 0·6° elevation; 70 m range
Receiver noise: 11 dB max
Signal processing: Lin/log FTC and linear; log CFAR (optional)

STATUS
ITT-Gilfillan was awarded a $41 million contract in 1979 for the producton and support of PAR-80 equipments to the Federal Republic of Germany. The radars are being installed at West German Air Force and Navy bases. A further contract for $11 million was awarded in 1981 for the supply of six systems to Belgian Air Force bases.

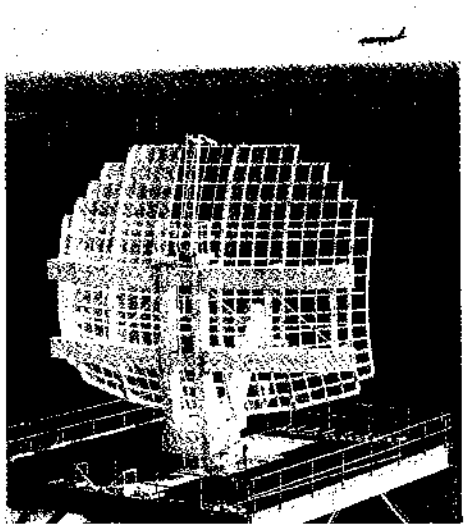
ARSR-3/ASR-30 SURVEILLANCE RADARS



The ARSR-3 and the ASR-30 are minimally attended L-band surveillance radars which are suitable for both civil and military requirements. The systems meet both FAA and military specifications and use the latest technology.

The ARSR-3 provides cover up to 200 nautical miles (370 km) in range and 100 000 feet (30 km) in elevation against a 2 m² target. A number of refinements are used to detect small targets against heavy clutter. These include dual beam elevation pattern to enhance short range detection, an antenna pattern which produces a sharp cut-off underside to reduce ground returns, and RF sensitivity time control to eliminate close-in ground reflections.

The ARSR-3 has complete redundancy in electronics with extensive built-in test equipment, and a demonstrated MTBF of 3000 hours. The system also has a very high weather clutter cancellation feature by the use of circular polarisation.

The ASR-30 is based on the ARSR-3 and is a dual channel L-band surveillance radar that will detect small aircraft (2 m²) out to 120 nautical miles (220 km). Using the circular polarisation mode, targets can be detected throughout severe weather conditions and it is claimed to reject weather with over 40 times the efficiency of S-band surveillance radars.

5779.153
ARSR-3D SURVEILLANCE RADAR

The ARSR-3D system is a new configuration 3-dimensional radar for joint use in air defence systems or civil en-route traffic control, and uses elements of the AN/TPS-70 (**4319.153**) and ARSR-3 (**5623.153**) radars. It operates in L-band and with the use of four-pulse, full-range MTI provides high weather and ground clutter rejection. Remoting of monitoring and fault isolation, plus key control features, allows unattended operation.

The system employs the ARSR-3 coherent L-band transmitter and antenna reflector together with the TPS-70 six-channel receiver and signal processor. It incorporates a post-detection processor that extracts the target data and correlates this with the integrated IFF for a combined target response. Probability of detection is given as 80 per cent at 200 nautical miles on a 2·5 m² target.

CHARACTERISTICS
Frequency: L-band
Instrumented range: 220 n miles (408 km)
Resolution: 1·35° azimuth; 500 ft (152 m) range
Height accuracy: ±2000 ft at 100 n miles

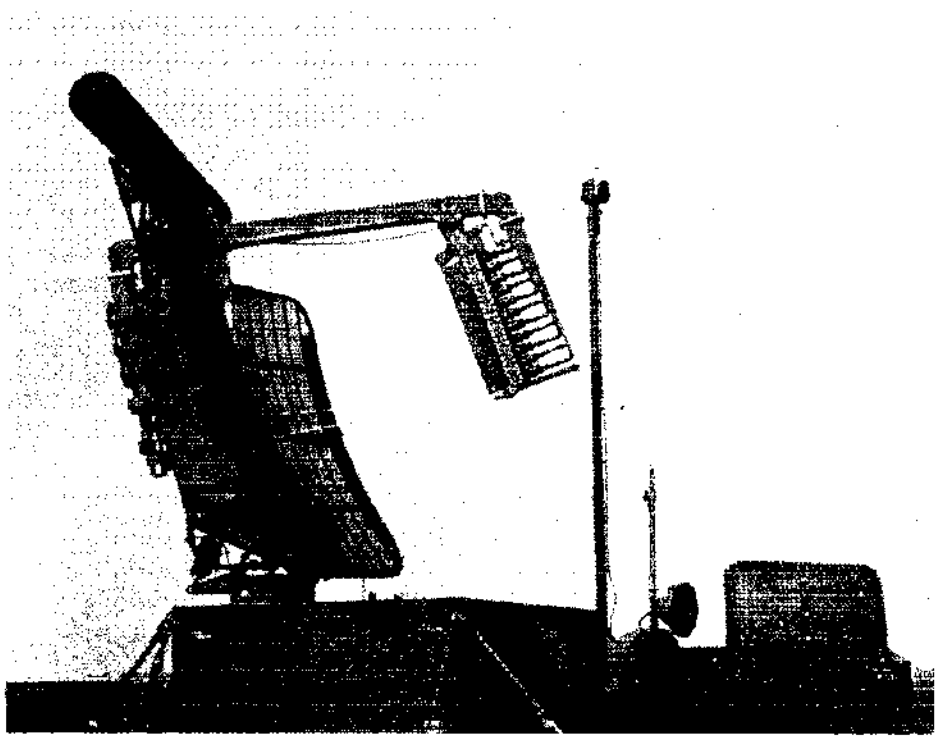
CONTRACTOR
Westinghouse Electric Corporation, PO Box 746, Baltimore, Maryland, USA.

5780.153
W-2000 3-D SURVEILLANCE RADAR

The Westinghouse W-2000 L-band radar is a 3-D system designed to meet the current and forseeable future requirements for air defence and civil surveillance systems. It is designed to provide accurate target data while operating in hostile environments caused by interference from active jammers, chaff, ground clutter, heavy precipitation and bird migrations. It is completely solid-state, can be configured for static or mobile applications and may be remotely controlled and monitored if minimally or unattended operation is required. An SIF/IFF system in integrated.

ECCM features include low sidelobes, a wide-band phase-steerable planar antenna, multiple and selectable receive beams, MTI processing, doppler filtering, pulse compression and a method of minimising false alarms. Coupled with these is jam strobe reporting and a jamming frequency avoidance system. This latter includes a signal analyser for clear frequency selection and frequency agility in burst-to-burst and pulse-to-pulse modes.

The spatial volume, up to 500 km in range and



30 000 metres in height, is covered by an optimum search pattern which is achieved by the use of three virtually independent radars operating at different frequencies and elevations. This system triples the available dwell time on all targets

CHARACTERISTICS
Frequency: L-band
Instrumented range: 270 n miles (500 km)
Height accuracy: ±1000 ft (305 m) at 100 n miles
Resolution: 1·4° azimuth; 500 ft (152 m) range
Antenna type: Phase steerable in elevation (6 simultaneous beams)
Gain: 39 dB receive; 35 dB transmit
Transmitter: Solid-state, distributed

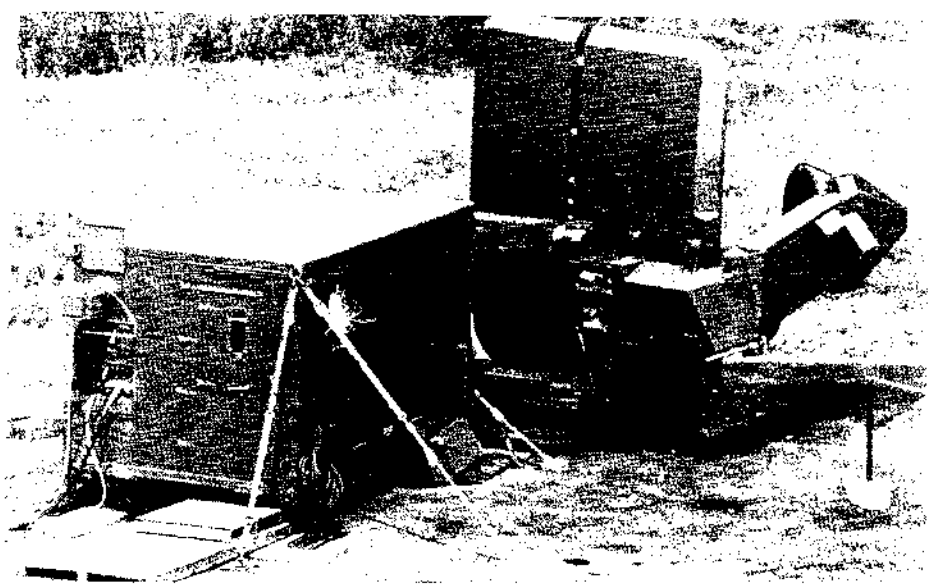
3711.153
AN/TPN-24 AIRPORT SURVEILLANCE RADAR

The AN/TPN-24 is the airfield surveillance radar employed in the AN/TPN-19 landing control central system (**2537.153**), and was originally designed for that system although it has subsequently been widely delivered separately for use on its own or with other equipment. The original version was designed and packaged for use as a highly mobile, tactical radar equipment, but other versions have been configured for different applications, including a fixed site variant, a tower-mounted model (ASR-910), and a semi static version designated the ASR-909. The antenna and transmitter/receiver units are the same in each version as those of the basic AN/TPN-24 (see nearby photograph).

CHARACTERISTICS
Radar: Dual channel, dual frequency, diversity. Redundant or single channel and spectrum filter options
Frequency: 2700 – 2900 MHz
Transmitter type: Magnetron
Peak power: 500 kW (per channel)
Pulse length: 1 μs
Pulse rate: 1050 pps, average
PRF: 12 staggers
Antenna size: 4·26 × 2·43 m
Azimuth beamwidth: 1·6°
Elevation beamwidth: 4°
Rotation speed: 13 rpm
Beam elevation tilt: −15 to −2°
Detection range: 110 km (clear weather, 1 m² target)
STATUS
In addition to those supplied for use in AN/TPN-19 systems (a total of about 12) more than 50 separate AN/TPN-24 sets have been supplied or ordered, including: 44 fixed base installations for West Germany and six similar installations for the Netherlands. The AN/TPN-24 has also been supplied to Australia and Austria.



AN/TPN-24 landing control central

CONTRACTOR
Raytheon Company, Equipment Division, Wayland, Massachusetts 01778, USA.

3712.153
AN/TPN-25 PRECISION APPROACH RADAR

The Raytheon AN/TPN-25 is the high-performance precision approach radar (PAR) developed for the AN/TPN-19 landing control central tactical airfield control system (**2537.153**). Designed to fulfil a requirement for a highly mobile system capable of assisting the landing of fixed-wing aircraft and helicopters in adverse weather conditions, the AN/TPN-25 can also be deployed at fixed bases. It employs a unique phased-array antenna that constantly scans the entire service volume of 20 × 15° and 35 km in range, as well as tracking up to six approaching aircraft in elevation and azimuth. No antenna movement is required except when it is necessary to re-orientate it to allow a different runway direction to be used. This can be performed under remote control to permit any one of four runways on an airfield to be served. The TPN-25 is capable of automatic remote feeding of guidance information to the landing aircraft via a data link.

Operation is in the radar I-band and no mechanical scanning is necesary. A four-lobe monopulse feed horn is directed at the main antenna reflector, radiation having to pass through a digitally-controlled microwave 'lens' consisting of an array of 824 phase-shifting elements. The latter are controlled to produce sharp, digitally-steered, step-scanned pencil beams.

AN/TPN-25 PAR

CHARACTERISTICS
Radar: Single-channel, dual function (scan/track)
Frequency: 9000 – 9200 MHz
Transmitter type: Solid-state oscillator with TWT and CFA amplifiers
Peak power: 320 kW
Pulse length: 1 μs
PRF: 3500 pps (average)
Stagger ratio: 3:2
Antenna beamwidth: 1·4° azimuth; 0·75° elevation
Detection range: 37 km (clear weather, trainer aircraft target)
STATUS
Production. Apart from about 12 sets supplied as part of complete US Air Force AN/TPN-19 systems, another eight equipments have been supplied to Australia, both as fixed-base systems and in the tactical mobile mode. A development of the AN/TPN-25, with higher performance characteristics, has been developed as the AN/GPN-22 and this has been ordered and supplied in quantity both to the US Air Force and to foreign customers (**3713.153**).
CONTRACTOR
Raytheon Company, Equipment Division, Wayland, Massachusetts 01178, USA.

2498.153
AN/TPQ-10 RADAR COURSE DIRECTING CENTRAL

The AN/TPQ-10 radar course directing central is designed to provide accurate all-weather guidance to aircraft for performance of close air support missions.

The equipment consists of a tracking radar and an operational shelter containing the radar controls, a computer, displays and communication equipment. Designed specifically for tactical air operations, it is easily transported by helicopter, cargo aircraft or truck.

Further information is given under this entry number in previous editions of *Jane's Weapon Systems*.

STATUS

Twenty-three production systems were built and delivered to the US Marine Corps from 1960 onward. The system saw extensive use in Viet-Nam, and is still in operational use in US Marine Corps air support squadrons.

CONTRACTOR

General Electric Company, Electronic Systems Division, Syracuse, New York 13201, USA.

1526.153
FORWARD AREA ALERTING RADAR AN/TPQ-32/MPQ-49/MPQ-54

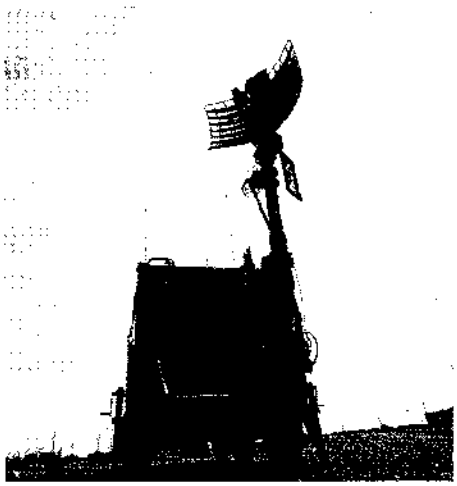
The forward area alerting radar (FAAR) has been designed to meet a US Army requirement for a lightweight early warning air surveillance radar to increase the effectiveness of air defence weapons, such as Chaparral and Redeye missiles and the Vulcan 20 mm gun system, against low-level aircraft attacks. It has been developed in both transportable and mobile versions, these being designated TPQ-32, MPQ-49 and MPQ-54, the latter two being the mobile versions. The principal system elements and operation are identical or similar in both.

The complete system comprises a 25 cm primary radar with an on-mounted secondary (IFF) horn antenna, shelter- or truck-mounted radar data extraction and processing units, operator's console, VHF data link and a number of remote target indicators for use at individual missile or gun sites. The weight of the system is given at 1865 kg.

The primary radar is a pulse-doppler system using a low-noise stable master oscillator, a grid-modulated TWT transmitter and an all solid-state homodyne (zero IF) receiver. The receiver translates target information to video frequencies which are range gated, doppler filtered, and compared with an alarm threshold. Target data are then transmitted via the VHF data link to remote sites, and presented on the operator's console CRT. The antenna measures 183 × 107 cm and is carried on a telescopic mast. The latter is of four sections, pneumatically operated, and capable of extension to a height of about 11 m. 360° coverage is provided. A horn antenna for the IFF is mounted on the upper edge of the main reflector. The IFF system used is the TPX-50, and this provides for either automatic or manual target interrogation.

The operator's console has a 25 cm diameter PPI display which normally presents only processed video which is time-shared with the PPI generator and the symbol generator to show targets, a 7 × 7 rectangular grid matrix, and target designation symbols for transmission to remote indicators via the data link. Controls are provided for selection of 'black-scope' or processed video display, sector blanking, threshold adjustment, automatic or manual IFF interrogation, IFF mode selection, radar transmitter/receiver control and self-test functions and data link operation. The console can be removed from the truck or shelter to enable the complete system to be operated from a position up to 50 metres from the radar site.

The VHF data link VRC-46 had three operating modes: data, voice, and rapid alerting and identification display (RAID). This link carries target information from the central operator's console to up to 12 remote target alert data display sets (TADDS) at weapon sites.



Each TADDS (GSQ-137) consists of a single 6 kg unit comprising a display, audio warning, and VHF receiver. The display consists of a replica of the 7 × 7 matrix appearing on the operator's PPI display with each square representing a specific area of the total radar coverage. The presence of a target in any one square, as determined by the central operator, is denoted by the appearance of a coloured disc in the appropriate square of the TADDS. Green discs denote friendly aircraft and red hostile. Plotting of target tracks is by means of a wax pencil. Controls on the TADDS unit provide for test functions, data link address code selection, and data link receiver frequency selection between 30 and 76 MHz. The lid of the unit carries a magnetic compass for orientation purposes.

One mobile version of FAAR, MPQ-49, is housed in a transportable S-250 shelter, utilising the six-wheel drive M561 vehicle as prime mover. The other mobile version is the MPQ-54 which is mounted on a trailer towed by an M35 truck. The system can also be carried by C-130 transport aircraft, or air positioned in a battlefield environment by a CH-47 helicopter. The TPQ-34 is a modified version of FAAR in non-mobile form, which provides all-weather target detection and location against personnel and vehicles in densely foliated environments. This version is also known as GSR, ground surveillance radar, TPQ-34.

Other applications ascribed to the system include 360° detection of first round mortar and rocket fire, and use as a tactical ATC centre. Although designed for essentially manual operation, FAAR is capable of integration with automatic air defence systems.

DEVELOPMENT

Development was undertaken by Sanders Associates Inc for the US Army Missile Command under a series of contracts. Prototypes were delivered to the US Army in late 1968 and early 1969, and initial production was ordered under a $7·4 million contract in March 1969. In addition to tests at US home bases and engineering establishments, FAAR has been deployed in south-east Asia in the TPQ-34 ground surveillance radar configuration. In this role, the IFF antenna is apparently deleted. Automated versions have been tested successfully.

FAAR AN/MPQ-49

An export version, LAADS, is described in **3123.153**. The most obvious external difference is the scanner which in LAADS is of less rectangular appearance.

STATUS

The first production model MPQ-49 was delivered to the US Army in January 1972, when it was stated that contracts amounting to $30 million had been awarded.

A second production award was made in May 1974 to Gyroscope, an operating unit of Sperry Division. Sperry Corporation has produced 86 MPQ-49s and associated assemblies (ie 1621 TADDS, 25 organisational maintenance test sets and ten support maintenance test sets). A total of 180 has been produced.

CONTRACTORS

Sperry Corporation, Electronic Systems, Great Neck, New York 11020, USA.

Sanders Associates Inc, Defensive Systems Division, 95 Canal Street, Nashua, New Hampshire 03060, USA.

3123.153
LAADS LOW ALTITUDE AIRCRAFT DETECTION SYSTEM

LAADS (an improved version of FAAR) is a transportable air defence radar system designed for the detection and identification of low-flying targets and for the co-ordination of defensive weapons directed against such targets.

The radar employed is a coherent, pulsed doppler D-band system using a TWT transmitter. The 12 operating frequencies are generated by highly stable master oscillators. A zero IF receiver detects moving targets, rejects fixed clutter, and presents analogue data to the digital data processor which drives the local PPI and generates digital data messages for broadcast. The radar location is fed into the processor and the target locations are then computed in map co-ordinates. Target data are corrected on each antenna rotation and transmitted to all associated weapons via the data link. Target track capacity is 64, instrumented range is 60 km with a 30 km range for hovering helicopters.

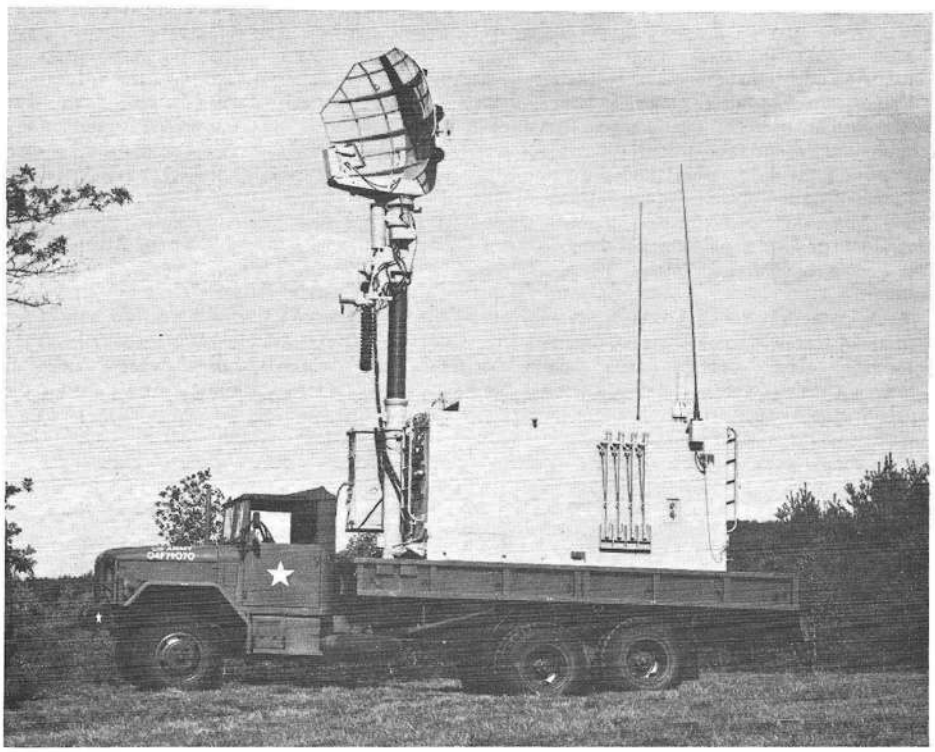
The weapon display unit (WDU) receives digital data messages and displays targets with respect to the weapon location (centre of display). Targets within 16 km from the weapon are displayed in near real-time with 1 km resolution. Flashing red dots show hostile targets (steady dot for friend). Previous positions are scanned to show target direction and to facilitate threat evaluation. The display mounts directly in front of the gunner, with a cursor showing direction of the gun. A hand-held version of the display is available for the unit commander or platoon leader.

The complete radar equipment, with positions for a crew of three, is housed in a standard US S-280 shelter. This is helicopter transportable or land-mobile on an M36 or similar 2½-ton truck. The system is also available for housing in an H-281 shelter for use on M548 tracked vehicles. The weight of the complete system is 3100 kg.

The 188 × 300 cm scanner is mounted on the shelter and is automatically raised and levelled from its folded stowed position. On-mounted antenna facilities are provided for the integrated IFF which is a modified AN/TPX 50. The LAADS scanner differs slightly from that of the related US Army FAAR (**1526.153**) in having a less rectangular profile, but in general the two equipments are essentially the same apart from the mode of mounting. The FAAR is, of course, a US Army system whereas LAADS is mostly exported.

OPERATION

The general concept of operation is similar to that of the earlier FAAR (**1526.153**) described above. A single radar is used to provide search, IFF and associated facilities for remote weapons positions. Each of the latter is provided with the necessary data link reception equipment and WDU to permit individual target engagement. The WDUs are LED matrix type displays and the VHF data link provides for an unlimited number of weapon sites within line-of-sight radio range (normally in excess of 15 km).



Provisions are made for linking other LAADS radars to form networks to give improved protection against 'nap-of-the-earth' attacks.

LAADS is able to serve and provide target acquisition data to an unlimited variety of weapon types, gun and missile systems, and it embodies the latest signal processing and ECCM techniques.

STATUS

The system has been delivered to an overseas government and negotiations have been opened with other undisclosed countries.

CONTRACTOR
Sanders Associates Inc, Defensive Systems Division, 95 Canal Street, Nashua, New Hampshire 03060, USA.

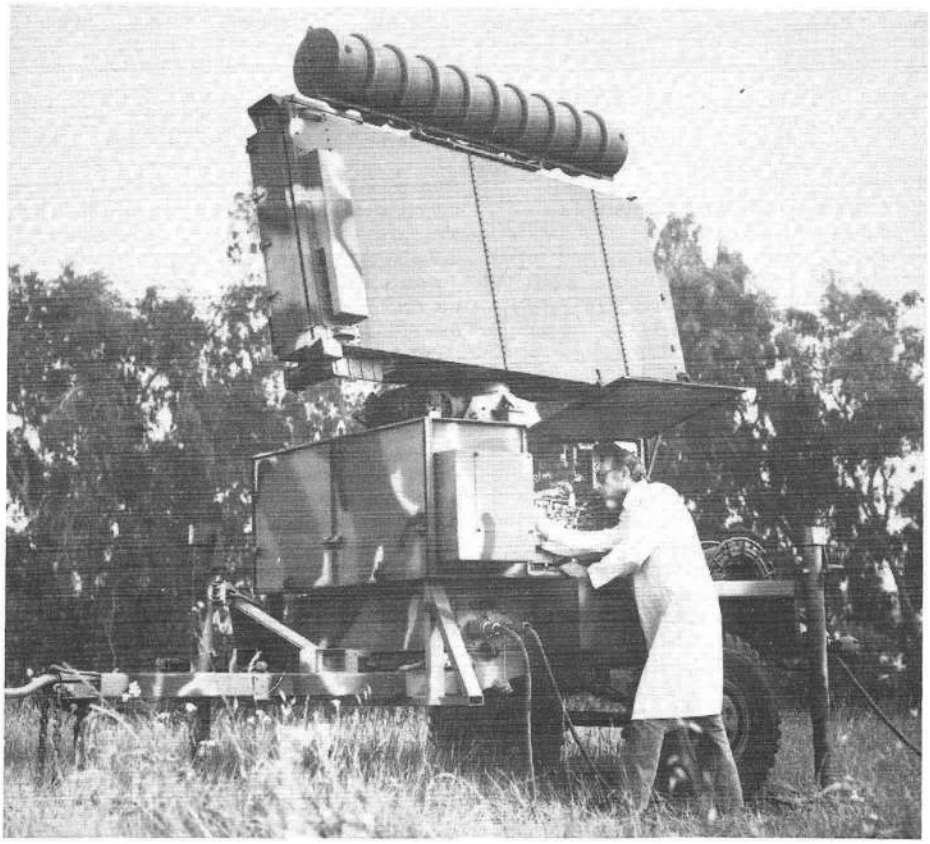
LAADS radar deployed

4323.153
HUGHES LOW ALTITUDE SURVEILLANCE RADAR

The Hughes Low Altitude Surveillance Radar (LASR) is designed as a three-dimensional air defence surveillance radar system for the detection and tracking of hovering helicopters and fast, low-flying aircraft. It is a later development of the AN/TPQ-36 system (**2848.153**) and has evolved from this system using 70 per cent common hardware.

LASR is an advanced short-range battlefield radar that automatically detects and tracks modern low-flying threats, such as heavily-armed pop-up helicopters and low-flying fixed-wing aircraft unmasking at low altitudes and short ranges. It provides very high three-dimensional accuracy in severe clutter and severe ECM environments.

The equipment features three-dimensional pencil beams and frequency agile phase beam scanning and provides accurate weapons cueing data. High-speed and hovering targets are detected as they appear at extremely low altitudes. LASR target reports are automatic and compatible with current and projected automatic digital data netting systems. Emission control techniques (blinking) and air space management functions are enhanced by the equipment's capabilities which enable radar-to-radar track correlation.



A low sidelobe, electronically phase-scan (elevation), pencil-beam antenna minimises clutter illumination for nap-of-the-earth detection, and reduces enemy ECM effectiveness and vulnerability to anti-radiation missiles. The antenna rotates mechanically in azimuth to provide 360° coverage with a variable rate azimuth scan. Beam scheduling is computer-controlled and adaptive to mission requirements.

LASR is transportable by light vehicles and aircraft and is available with antenna elevator mechanism. Logistics and support are simplified by extensive built-in-test equipment and automatic fault isolation. There are obvious benefits in the area of maintenance and repair because of its commonality with AN/TPQ-36.

STATUS
Still in the development phase. The system has been selected for the Norwegian Adapted Hawk (NOAH) programme. The contract, awarded in January 1984, calls for 18 systems to be delivered by a joint company (HKV), established by Hughes and Kongsberg Vaapenfabrikk. LASR has been demonstrated successfully against fixed-wing and helicopter targets from 10 to 6000 feet (3 to 1800 m) and from hovering to over 450 mph (724 km/h).

A new target cueing system, allowing shoulder-fired missiles to be fired at aircraft by day or night, uses the LASR to pinpoint incoming targets.

CONTRACTOR
Hughes Aircraft Company, Ground Systems Group, Fullerton, California 92634, USA.

Hughes LASR low-level air defence radar

2848.153
AN/TPQ-36 WEAPON LOCATING RADAR

The AN/TPQ-36 is an artillery, rocket and mortar-locating radar designed as a replacement for the AN/MPQ-4 and older technology weapon locating radars. Although designed to replace the AN/MPQ-4, the AN/TPQ-36 is more than a mortar locating radar and has proven to be very effective in locating artillery and rockets. Location of artillery at ranges beyond the capability of the AN/TPQ-36 is provided by the AN/TPQ-37 (**1976.153**), the other radar that makes up the Firefinder system. Using only a different computer software program, the same operations shelter can be used for either Firefinder radar.

Location of hostile artillery and mortars by the AN/TPQ-36 is completely automatic. The system electronically scans the horizon over a 90° sector several times a second, intercepting and automatically tracking hostile projectiles, then computing back along the trajectory to the origin. The co-ordinates and altitude of the weapon are then presented to the operator. Automatic location is so rapid that the co-ordinates of the weapon are normally with the operator before the enemy round lands.

In addition to its ability to locate artillery, a number of other modifications have been incorporated. The normal 90° sector can be expanded to as much as 360° for use in insurgency operations. The radar can also provide information on the hostile weapon's target by extrapolating the trajectory to the impact point, allowing the information to be used in the priority of return fire.

A very important feature for the modern hostile battlefield is the capability to track and locate weapons firing simultaneously from different locations. Using separate track channels, the radar can track several projectiles at once while continuing to scan for other projectiles in its 90° sector. A further feature allows the radar to ignore subsequent firings from weapon positions already located. As many as 39 different weapon positions simulating an artillery preparation for attack have been used in tests to demonstrate the capability of the system to provide numerous locations in a short period of time.

High mobility allows the system to be used as close as 2 km to the front line. Emplacement takes 15 minutes and displacement five minutes or less. The system can be mounted in a single vehicle plus trailer. Since the operations shelter weighs only 2500 lb (1136 kg), vehicles as small as 1½ tons can carry the shelter and pull the trailer.

The AN/TPQ-36 is a coherent, electronically-scanned, range-gated pulse doppler radar. Beams are

moved electronically in the horizontal dimension by phase shifts and in the vertical dimension by frequency shift. Ground, sky and electronic clutter are filtered by a signal processing software system which discriminates hostile projectiles from aircraft, birds, insects or other interference. The three-dimensional radar then tracks the projectiles, computing the firing point and providing the information to the operator within seconds of the firing. The extent of automation allows a single operator to perform all functions necessary to locate the hostile weapon and inform the counterfire systems.

Fault detection sensors constantly monitor performance of each sub-system and provide status information. Should a failure occur, built-in test equipment isolates the problem and informs the operator of the location of the problem, frequently the specific card that must be replaced. These corrective actions should reveal up to 90 per cent of all problems and can normally be accomplished in 15 minutes.

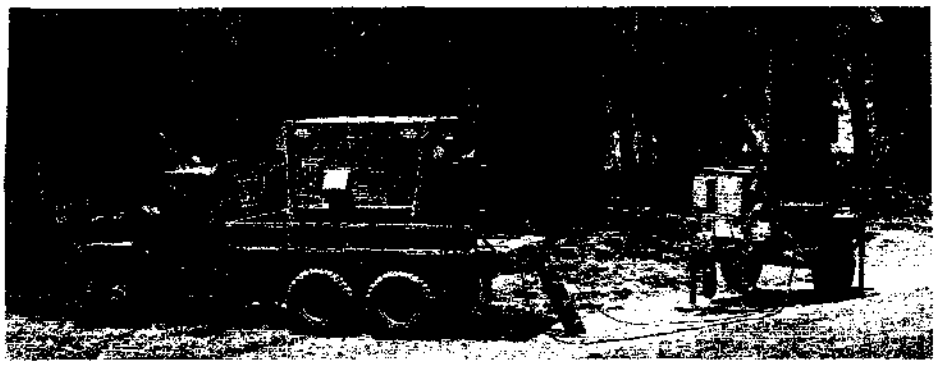
The AN/TPQ-36 has proven to be a reliable system. To date each radar is subjected to not only the normal 'burn-in' at +125°F (+52°C) but is screened for performance at -25°F (-32°C). The result is a reliability of in excess of 125 hours, validating an early field test MTBF of 93 hours. In addition to the high and low temperature screening, the performance of each radar is checked using live artillery and mortar firings.

STATUS

A full-scale three-year production contract was awarded by the US Army to Hughes in August 1978 for $166 million, with two additional option years; and over 250 systems have been ordered by the US Army and other defence forces, with a delivery rate of one per week. The US Army and Marines will receive 154 systems. In October 1980, to satisfy a requirement for the Netherlands, seven systems were added to the initial 154 ordered. By the end of 1984, all of the Netherlands systems and most of the US Army systems had been delivered and were operational.

Additional orders were received during 1982 and 1983 from the US Army for 37 radars for Jordan, Saudi Arabia, Pakistan and Thailand. In mid-1984 the South Korean Army placed a $58 million order for 12 systems. In December 1982 Hughes signed a $US44 million contract with Australia for seven AN/TPQ-36 radars, spares, training devices and support equipment for delivery beginning in 1986. An $11·2 million contract was awarded by Hughes to BAe (Australia) to provide the operations control centre for each system. At least 10 other nations have indicated intention of ordering systems.

It is understood that the two radars which were deployed to support the US Marine contingent to the Multi-national Peacekeeping Force in Beirut were left behind when the contingent left Lebanon.



Deployment of the AN/TPQ-36 to US Army and US Marine operational forces continued in 1984. Deliveries of the second foreign batch commenced in 1985.

Originally configured using the then standard Gamma Goat articulated vehicle, the AN/TPQ-36 now uses a 2½-ton truck to carry the operations shelter and pull the antenna/transceiver trailer. With its versatility of design, the shelter has been configured on the militarised 1½-ton pick-up truck, and will use the Mercedes Unimog for Australia.

An air defence variant, the Low Altitude Surveillance Radar (**4323.153**), has been successfully demonstrated to have the capability to track such different targets as pop-up helicopters and high speed fixed wing aircraft in high clutter environments. The first contract for production of this variant was awarded in January 1984. The high percentage of logistic commonality between the two systems should provide benefits in logistic support and life cycle cost effectiveness.

CONTRACTOR

Hughes Aircraft Company, Ground Systems Group, Fullerton, California 92634, USA.

AN/TPQ-36 weapon locating radar

1976.153

AN/TPQ-37 WEAPON LOCATING RADAR

The AN/TPQ-37 radar provides the US Army's first capability to locate hostile artillery and rocket launchers at their normal firing ranges. It is believed to be the only system with this capability anywhere in the world. Additionally, it is the first tactical radar in large scale production to use phased array techniques for scanning in both azimuth and elevation, by using miniaturised diode phase shifters distributed throughout the antenna.

The AN/TPQ-37 radar programme was initiated in response to the threat of massive concentrations of artillery and rockets in support of both offensive and defensive operations. Prior to this, there had been no effective means to locate and counter indirect fire, with combat troops having to analyse craters to estimate direction and range as a last resort.

The AN/TPQ-37 uses a combination of radar techniques and computer-controlled signal processing for detection, verification, tracking of projectiles, and extrapolating the track-data points to the location from which the projectile was fired. Once the origin of a projectile has been identified, that location can be provided by voice or digital data link to the fire direction centre for initiation of counterfire. These techniques are very similar to those applying to the AN/TPQ-36 weapon locating radar (**2848.153**) described above.

AN/TPQ-37 weapon locating radar

Like the AN/TPQ-36, the AN/TPQ-37 is a coherent, electronic-scanned, range-gated pulse doppler radar. The AN/TPQ-37 incorporates monopulse and its beams are moved in both azimuth and elevation by shifting the inter-element phase using diode phase shifters, the first such application in a tactical system. Significant improvements were incorporated into the AN/TPQ-37 before entering production, ensuring state-of-the-art technology, particularly in the antenna, signal processor and computer. Since then, lightweight kevlar armour plating has been added to protect the antenna.

Operationally the AN/TPQ-36 and AN/TPQ-37 will be complementary, the former between 1 and 4 km from the FLOT to provide for artillery counter-fire against mortars and close-in artillery. Three AN/TPQ-36 radars will be deployed in each division sector. The AN/TPQ-37 will be sited further behind the front line to locate opposing long-range artillery, with two AN/TPQ-37s to each division sector.

Together, the AN/TPQ-36 and AN/TPQ-37 are referred to as the Firefinder System. The modification of the programme to incorporate an operations shelter that can be coupled to and operate either the AN/TPQ-36 antenna or the AN/TPQ-37 antenna provides unique operational and maintenance advantages.

The AN/TPQ-37 consists of two vehicles and an antenna trailer. A five-ton vehicle carries the 60 kW generator and pulls the antenna trailer. The operations shelter is mounted on a 2½-ton vehicle. All components are air transportable in C-130 aircraft and are helicopter transportable. Crew size is between 8 and 12, though once emplaced normal operation can be carried out by a single operator.

STATUS

Since 1977 the US Army has ordered 72 systems, and delivery was completed in 1985.

A moratorium on international sales was imposed in 1981 after concern regarding transfer and potential compromise of high technology. After a study of this issue the moratorium was lifted in late 1983 and sales to US allies was authorised. Since that date the system has been ordered by a number of defence forces, including Saudi Arabia and Jordan. At least seven other countries have indicated an intention to procure the AN/TPQ-37.

Improvements in mobility have received high priority among the evolutionary changes incorporated during production. In addition to placing the operations shelter on a 2½-ton truck in place of the 1½-ton pick-up, the US Army is replacing the mobilisers initially used for the antenna/transceiver with a tandem-wheel trailer which promises much better stability. Mobility and field tests have shown that the antenna/transceiver can be easily mounted on the FVS carrier, the tracked vehicle chassis used for the Multiple Launch Rocket System in production for the US and several NATO nations.

Since the shelters for the AN/TPQ-36 and AN/TPQ-37 are identical, and operational procedures are similar, those countries that have procured the former will find the transition to the AN/TPQ-37 facilitated.

An air defence radar based on the hardware of the AN/TPQ-37, had been demonstrated in several locations both in the US and overseas. The VSTAR (variable search and track air defence radar) (**4080.153**) has demonstrated a capability to track small aircraft flying through heavy ground clutter and has tracked small sea-going vessels in sea state 4. Most of the VSTAR is common with the AN/TPQ-37 providing considerable logistic and support advantages.

Hughes Aircraft Company, Ground Systems Group, Fullerton, California 92634, USA.

2849.153

AN/TPQ-39(V) INSTRUMENTATION RADAR

AN/TPQ-39(V) is a one-man instrumentation radar of modular design which is available in fixed building and transportable versions. It is intended for range applications involving system evaluation, range safety, vehicle control or other target tracking uses.

Several variants are in use, including the digital instrumentation range (DIR) and Nike digital instrumentation radar (NIDIR). DIR operates at C-band while current units of NIDIR are at X band. Other variants are also available.

As the equipments names suggest, solid-state digital techniques are used extensively in the system. A digital computer is used as the basis of the system, with many radar functions (angle and range servos, AFC, AGC, target acquisition and detection, input/output and display control) provided by the radar computer programming.

Many optional extras have been selected for individual range requirements, such as parametric amplifiers, higher power transmitters, data recording facility, plotting boards adjacent to the operator's position, timing equipment and star calibration.

The following characteristics describe the basic DIR variant.

CHARACTERISTICS (DIR Variant)

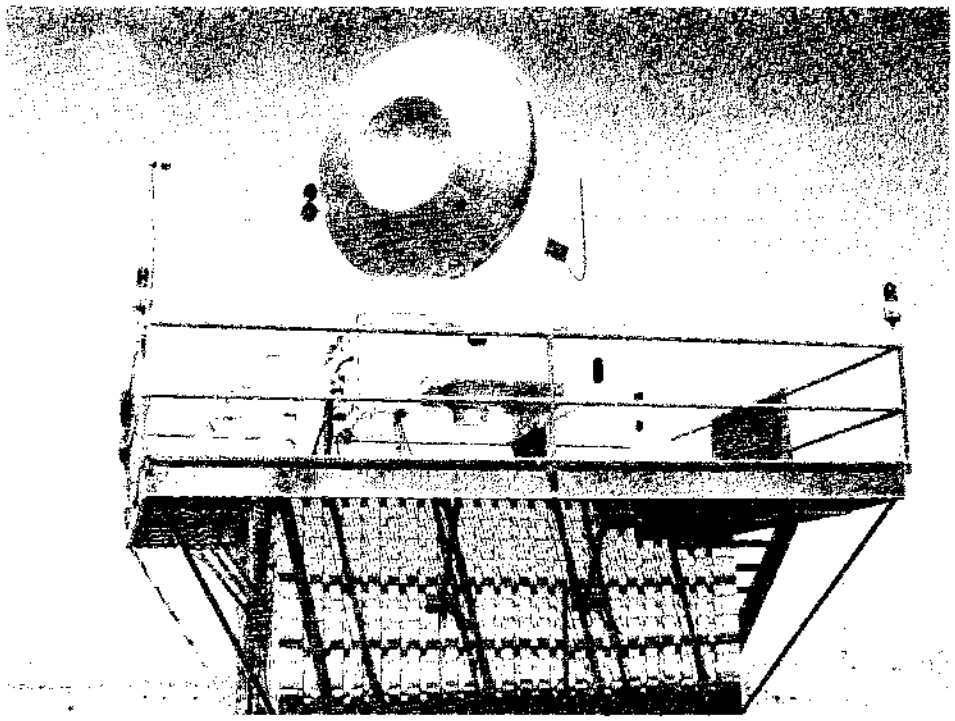
Azimuth, elevation tracking rates: 500 mils/s

Azimuth, elevation acceleration: 300 mils/s²

Azimuth, elevation tracking precisions: 0.3 mils, rms

Range tracking: 235 km at 640 Hz PRF

Ro, IM², 0 dB S/N: 93 km



Range tracking precision: 4·7 m

STATUS

Units are operational at US Army, Navy and Air Forces sites in the USA, and at the West German Aerospace Research Establishment (DFVLR) at Braunschweig. NIDIR variants are operated in the Far East, in the UK and at US Navy sites in the USA.

CONTRACTOR

RCA, Government Systems Division, Missile and Surface Radar, Moorestown, New Jersey 08057, USA.

NIDIR variant of the AN/TPQ-39(V) radar

2529.153

AN/TPS-21 AND AN/TPS-33 PULSE DOPPLER BATTLEFIELD RADARS

These two radars are I/J-band portable manpack systems used to detect persons or vehicles in motion on the ground. Targets are detected at ranges lying between approximate limits of 100 and 18 000 m with a range measurement accuracy of ±23 m or 1% per cent of range, whichever is the greater. Angular accuracy is ±25 mils.

Scanning is either manual or automatic in range with sector scan. For the TPS-21 radar detection is solely by audible tone in the operator's headphones; in the TPS-33 equipment there is also an A-scope display.

STATUS

Operational in US armed forces.

AN/TPS-32 3-D LONG-RANGE SURVEILLANCE RADAR

AN/TPS-32 is a ground-based, long-range, tactical, lightweight radar which automatically provides precise, three-dimensional position data on multiple targets. The equipment has been designed to operate as the primary 3-D radar sensor for the marine tactical data system. It also provides two positions for operators to vector interceptor aircraft to assigned targets. It is easily transportable by helicopter, cargo aircraft, or by conventional M35 truck. Automatic target detection, clutter elimination, and IFF are included.

Air search coverage of the radar extends to 300 nautical miles (556 km) in range to a ceiling of 100 000 ft (approximately 30 500 m). The search volume is obtained by continuous rotation of the antenna (at six rpm) in the azimuth plane and electronic frequency scanning, -1 to +18° in the elevation plane. The elevation scan is accomplished by changing the frequency of the E/F-band RF energy applied to the planar array, frequency-sensitive antenna. The antenna radiation appears as a series of pencil beams; each beam is 0·84° high and 2·15° wide.

The AN/TPS-32 radar consists of an antenna assembly and three shelters. Two of the shelters contain transmitter stages and the third contains receiver, data processing, including radar and IFF plot extractors, displays and system control equipment. In the transport condition, the radar set consists of two antenna array pallets, one tripod pallet, and three shelters. The complete system is helicopter transportable in six pallets and can be made operational in less than two hours.

To make the most efficient use of transmitter power, the peak power level and inter-pulse period are changed during the complete elevation scan to fit the coverage volume more precisely. This allows more energy to be spent in the longer range portions of the coverage volume at the lower angles of operation.

AN/TPS-32 long range surveillance radar

CHARACTERISTICS

Coverage

Elevation: 19° within interval -1 to +18° (electronically scanned)

Height: 100 000 ft (30·5 km)

Azimuth: 360° (mechanically scanned)

Displayed range: 2·5 nm (4·6 km) - 300 nm (556 km)

Data rate: 10 s

Probability of detection/range (1 m² target): 90% to 200 nm (371 km), 50% at 300 nm (556 km)

False alarm rate: <10 false target messages per azimuth scan

Accuracy (standard deviation)

Range: 750 ft (229 m)

Azimuth: 0·5°
Height: 1200 ft (336 m) at 100 nm (185 km), 3000 ft (914 m) at 300 nm (463 km)
Resolution
Range: 1500 ft (457 m) (manual), 2625 ft (800 m) (automatic)
Azimuth: 2·15°
Elevation: 0·85°
Transmitter
Operating frequency: 2905 – 3080MHz
Pulsewidth: 30 μs
Interpulse period: 1090 – 3772 μs
Peak power output
Three-stage RF amplifier: 60 kW peak (high elevation, short range and MTI)
Driver RF amplifier: 665 kW peak (medium elevation, medium range)
Final RF amplifier: 2·2 MW peak (low elevation, long range)
Radar antenna
Elevation beamwidth: 0·84° (nominal)
Azimuth beamwidth: 2·15° (nominal)
Gain: 41 dB (minimum)
Sidelobes (azimuth and elevation): 25 dB (minimum) referenced to peak of main beam
Polarisation: Horizontal
Rotational speeds: 6 rpm

STATUS

In 1975 this radar was selected as the basis of a new model of three-dimensional surveillance ordered for the Swedish Air Force. Sixteen are being used as part of a modernisation programme for the Swedish air defence system. The standard TPS-32 has been supplied to the US Marine Corps, Kuwait and Turkey.

In 1980, ITT-Gilfillan received a contract from the US Marine Corps to supply three fibre-optic data links to be used with the AN/TPS-32 air surveillance radar system. Each data link consists of a fibre-optic cable with modulator and demodulator equipment. The cable is 2 km long, and carries signals from the AN/TPS-32 radar system to the Marine Corps tactical data system (MTDS), part of the tactical air operations center (TAOC).

This is ITT-Gilfillan's second contract from the US Marine Corps for a fibre-optic data link to remotely feed signals from the AN/TPS-32 radar system. The first contract, awarded in early 1978, was delivered to the Marine Corps at Camp Pendleton in May 1979. This was transferred to the east coast in December 1979 and was later deployed with the Marine Corps for NATO exercises in Norway.

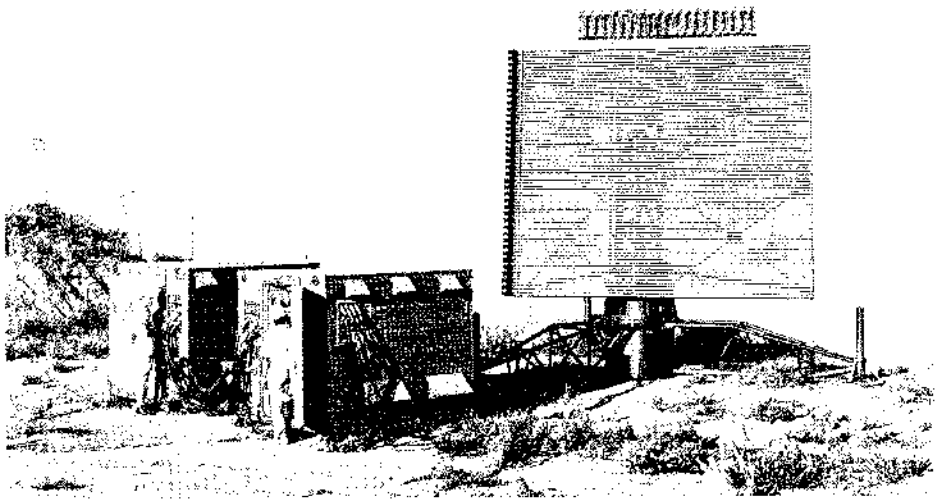
CONTRACTOR

ITT-Gilfillan, 7821 Orion Avenue, Van Nuys, California 91409, USA.

4078.153
SERIES 320 3-D AIR DEFENCE RADARS

The Series 320 3-D air defence radar utilises highly stable, modern state-of-the-art signal processing techniques to maintain target detection and a low false alarm rate in high clutter areas. Its operation is highly automatic and under computer control with extensive on-line monitoring of radar performance. Fault isolation is accomplished using computer diagnostic programs. The radar operates at E/F-band (former S-band) and is available in 150, 200 and 300 nautical mile range versions. Fixed site and transportable configuration of Series 320 modules have been specified, with frequency control and phase/frequency versions available.

This series of radars combine inertialess elevation scanning with groups of multiple pencil beams. Elevation scanning is accomplished by using either frequency or phase/frequency control to steer the pencil beam in space. This technique provides time on target for multiple pulse processing required for clutter suppression, while maintaining high resolution, high data rate and accurate target location. Phase/frequency control versions of the system provide frequency agility and clear channel operation.



The Series 320 planar array antenna with frequency-steered pencil beams subdivides the full elevation profile into elevation segments. Each segment is searched by five vertically positioned narrow beams each derived from five distinct RF frequencies until the full elevation sector is covered. The antenna is rotated in azimuth achieving full volumetric coverage extending to 300 nautical miles in range and up to 30 000 metres in altitude. A 2 m² target is detectable within this volume with a 99·5 percent probability or greater. Out to a range of 100 nautical miles, the accuracy of the radar is less than 450 metres in azimuth and 760 metres in height. The range accuracy is 18 metres.

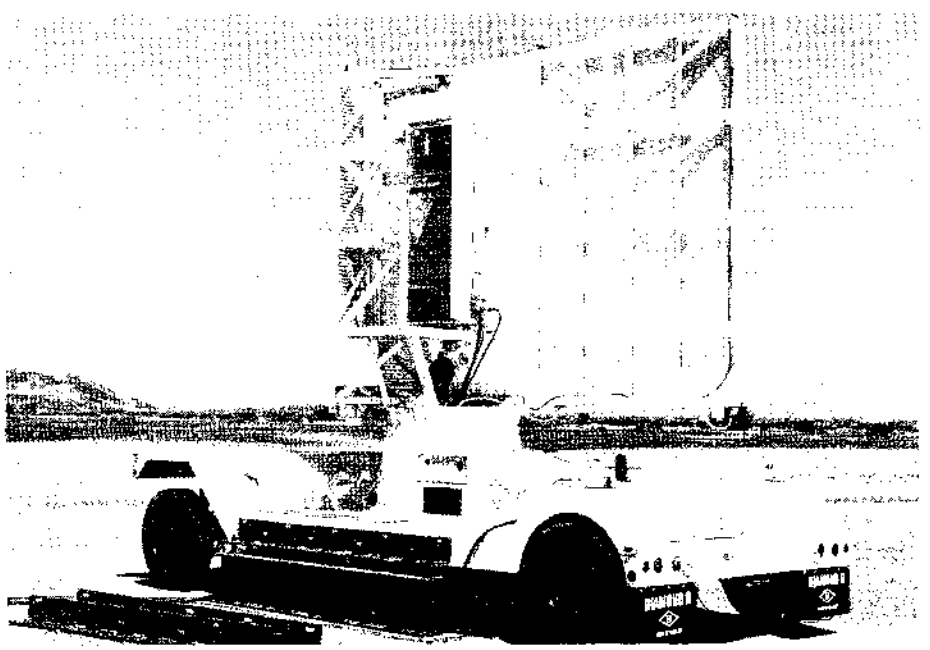
MTI is employed in areas where ground clutter is present. ECCM capabilities include jammer-frequency analysers, jammer-strobe reports and radar silence.

This radar system was developed by ITT-Gilfillan for the international market and has been ordered in a joint submission for a European air defence requirement. It is related in certain respects to the AN/TPS-32 (**2516.153**) above.

CHARACTERISTICS

Frequency: 2·9 – 3·1 GHz
Peak power: 150 kW/1·1 MW
PRF: Variable
Receiver noise figure: 2·5 dB
Antenna: 6·4 × 5·18 m
Gain: 41·2 dB
Azimuth beamwidth: 1·4° (0·84° optional)
Elevation beamwidth: 1·6° (2·2° optional)
Scan rate: 6 rpm

Typical deployment of ITT-Gilfillan Series 320 3-D transportable air defence radar system



Polarisation: Horizontal
Signal processor: Digital
Improvement factor: 40 dB
Detection performance (2 m² target): 200/300 nm (PD = 0·5)
Number of false alarms: 5/scan
Azimuth coverage: 360°
Elevation coverage: 0 – 20°
Height coverage: 0 – 30 000 m
Resolution at 100 nm: Range 125 m; azimuth 2·8°; elevation 3·5°
Accuracy (1 sigma at 100 nm): Range 18 m; azimuth 460 m; height 760 m (400 m with option)

STATUS

Gilfillan is known to have received contracts for four radars of this series from International Technical Products NV, these equipments being intended for the Philippines. An agreement with Plessey, UK, has resulted in a combination of the 320 3-D and the Plessey AR-3D being ordered by the UK MoD from Plessey as the E/F-band radar in the current improvement programme for the UK air defence network. Mobile phase-scanned antenna array of the ITT-Gilfillan ARBAT instrumentation radar showing an obvious family resemblance to the 3-D air defence radars produced by this concern

4079.153
ARBAT INSTRUMENTATION RADAR

The ARBAT (application of radar to ballistic acceptance testing of ammunition) equipment is an X-band pulse doppler range instrumentation radar used by the US Army. It is designed for ballistic testing of a wide variety of projectiles including new sophisticated ammunitions. The radar employs a

pencil beam planar array antenna for pointing accuracy and provides test results in both real-time on a CRT display and as hard copy. Data provided on test rounds fired includes position in space (X, Y and Z co-ordinates), velocity (X, Y and Z), event detection and impact data. A magnetic tape records target position, rate acceleration, drag vectors and radar cross-section at a 20 Hz rate for post firing analysis. The ARBAT system is packaged in two major equipment groups: the antenna/transceiver group and instrumentation van. It is capable of covering multiple firing positions from a single location or it may be sited down range to analyse terminal performance of long range projectiles.

Specified system accuracy requirements include 2 mils in azimuth and elevation, 0·05% in range and 1 m/s velocity.

STATUS
The ARBAT system is currently in service at Yuma Proving Grounds, Arizona, USA.

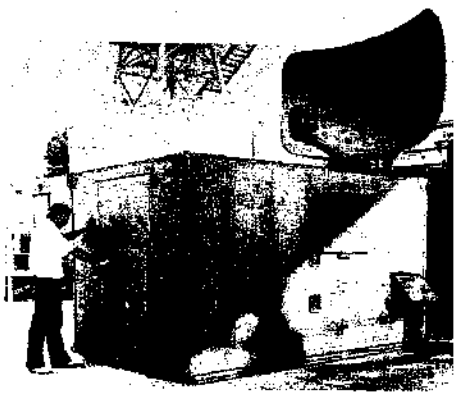
ITT-Gilfillan, 7821 Orion Avenue, Van Nuys, California 91409, USA.

4322.153
FALCON SERIES GPS-100 SURVEILLANCE RADAR



The Falcon (frequency agile low coverage netted) radar is a two-dimensional air/sea surveillance radar providing search, acquisition and tracking of low altitude aircraft and the simultaneous coastal surveillance and tracking of ships, small boats and low-flying helicopters. The automatic tracking of large numbers of aircraft and ship targets can be monitored by operators within the radar control cabin, and transmitted in digital format to air and surface control centres at a distant location to provide an overall command and control display from a number of Falcon radars.

The radar equipment can be installed in a protected bunker configuration, in a shelter, or in a mobile configuration, and is designed for unattended operation. Integrated IFF and radar tracks data can be transmitted by digital data link to air and surface operations centres.

The antenna is a dual beam reflector with a cosec² coverage to 25° elevation, and integral IFF. The transceiver is crystal controlled and uses a single-stage high-gain TWT.

The entire system is designed to incorporate strong ECCM capabilities and includes automatic built-in-test equipment to minimise maintenance requirements.

CHARACTERISTICS
Operating frequency: C-band
Antenna type: Reflector, high gain, dual-beam with very low sidelobes
Polarisation is circular, horizontal, operator selectable
Beamwidths: 2·4° (azimuth), cosec² to 25° (elevation)
Search scan: 360° at 6 or 12 rpm
Instrumented range: 100 or 160 km
Peak power: 60 kW
Mean power: 1500 W
Altitude coverage: 0 – 3000 m
Simultaneous tracks: Up to 100, air or surface
Availability: 99·6%
STATUS
In current quantity production. A number of foreign governments have expressed interest in Falcon-based coastal surveillance systems. An order for more than 24 systems has been received from Sweden and the first systems have been delivered. Two other countries have also selected the Falcon system. By December 1984, $80 million of orders had been received for the system, and its associated operations centre.

Falcon surveillance radar

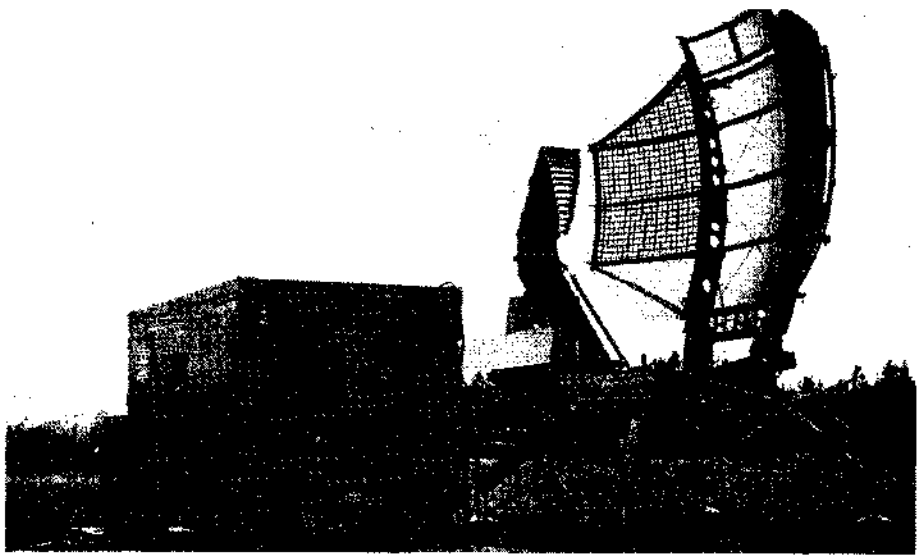
2530.153
AN/TPS-34 TRANSPORTABLE AIR DEFENCE RADAR

AN/TPS-34 is a tactical early-warning radar for use in forward air defence systems. It is said to be the first tactical radar to utilise the V-beam 3-D technique.

The radar provides long-range 3-D data on high-speed aircraft and missiles from battlefield sites. It can be transported by helicopter in units averaging less than 200 kg in weight and can be assembled and operating in less than eight hours from touchdown.

STATUS
In service in the British armed forces.
CONTRACTOR
Sperry Corporation, Electronic Systems, Great Neck, New York 11020, USA.

2517.153
AN/TPS-43E TACTICAL 3-D RADAR



AN/TPS-43E is a lightweight air transportable radar designed for use with manned aircraft or SAM batteries in a wide variety of tactical environments. It provides solid 3-D cover to 240 nautical miles on a fighter or fighter-bomber aircraft and measures heights over the full range by signal amplitude comparisons in six channels. Extensive clutter rejection and ECCM features are incorporated in the design, including a digital coherent MTI system, pulse-to-pulse frequency agility, jamming analysis and transmission selection (JATS), coded pulse anti-clutter system (CPACS) and sidelobe blanking. This latest model of the AN/TPS-43 includes extensive equipment refinements and increased operational capability.

For ease of air shipment the equipment divides simply into two pallet loads each of less than 3400 kg. One load comprises the shelter unit, transmitter/receiver and displays; the other consists of the antenna assembly, the feed and ancillary equipment. The entire equipment can be packed into two M35 trucks for road transport.

To minimise weight, light alloys are used wherever possible in the main mechanical structures and micro-miniaturisation techniques are used in the electronics circuits. The transmitter uses a completely solid-state modular modulator to pulse a linear beam twystron.

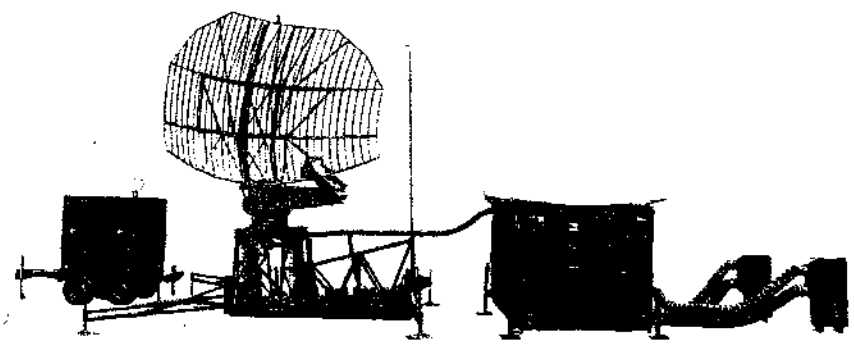
The feed array features the use of a stripline matrix to form the height-finding beams. The IFF antenna is a sum and difference type providing an interrogator sidelobe suppression (ISLS) capability. A small printed circuit reference antenna is mounted on the back of the radar feed to act as the radar sidelobe reference antenna; use of this latter antenna during the dead time between transmitter pulses is available for the JATS function.

CHARACTERISTICS
Range: Solid 3-D coverage on fighter-bomber aircraft to 408 km
Data rate: 10 s (6 rpm antenna)
Elevation coverage: 0 – 20°
Height accuracy: ±305 m at 100 nm
Electrical characteristics
Power output: 4 MW peak, 6·7 kW average
Frequency: 2900 – 3100 MHz in 16 discrete steps (with pulse-to-pulse agility)
Pulse duration: 6·5 μs
Antenna gain: Transmit, 36 dB; receive, 40 dB
Azimuth beamwidth: 1·1°
IFF azimuth beamwidth: 4° (or sum/difference ISLS antenna)
Noise figure: 4·5 dB
Prime power: 400 Hz 3-phase 120/208 V
Mechanical characteristics
Weight: Shelter module 3310 kg; antenna module 2050 kg
Transport: Single C-130 aircraft, 2 M35 trucks, 2 sets of transporters, or 2 helicopter loads
Road speeds: Up to 96 km/h
Air lift altitudes: Up to 15 000 m
Siting requirements: 6 × 10·5 m clear area on slope of 10% or less
Reaction time: 50 minutes with a 6-man team
Wind resistance: Operate to 52 knots, survive 92 knots (tied down)
Operating temperature: –40 to +125° F (–40 to +52° C)
Other
MTBF: 400 h
MTTR: 30 minutes
Outputs to: 3 120 m cables with storage reels
Operations centres PPI: 2 operational positions featuring AN/UPA-62 (40 cm) CRT, digital height readouts, and AN/UPA-59A active/passive IFF decoders. Each position also has access to built-in UHF ground/air communications and HF point-to-point communications facilities.

AN/TPS-43 search radar

IFF/SIF equipment: AN/UPX-23 interrogator set and AN/UPA-59A active/passive decoder
Transmitter tube: Linear beam twystron
STATUS
The TPS-43 series of radars (the latest versions are the E, F and G models) have been extensively deployed by the armed forces of the USA and up to 20 other countries. In 1981 the US Air Force placed another repeat order for the TPS-43E version and at that time there were 23 units in production with the latest solid-state modulator and IFF system. The latest versions also include a built-in programmable post processor for target extraction, target tracking and forward tell of data to automated command centres.

Among the known foreign users of this radar are Somalia, Morocco and Saudi Arabia, and civil derivatives have been supplied to several countries. One system was deployed by Argentina in the Falklands and was taken by British forces. It is believed to have been refurbished and updated in the UK.



Planned evolution of the series continues with the ultra-low sidelobe antenna (ULSA) which has a planar array. Westinghouse has received a $55 million contract to produce 19 ULSA units. An additional 46 units are likely to be required.
CONTRACTOR
Westinghouse Defense and Electronic Systems Center, Baltimore, Maryland 21203, USA.

2518.153
AN/TPS-44 TACTICAL SURVEILLANCE RADAR (ALERT Mk II A/O)
Alert Mk II (AN/TPS-44) is a lightweight, solid-state, transportable D-band air surveillance radar. It was designed for use anywhere in the world as the sensor for the forward air-control post of the US 407L system (TACS).

Alert Mk II is the latest version of the Alert radar series. Information of airborne targets is presented in the form of synchronised radar and IFF video on a 16-inch PPI display console. It also has optional provisions for supplying range and azimuth information to additional tactical operations centres.

The equipment consists of the Alert IIA radar set, a complete IFF/SSR system and the operator display console. All components are housed in two major packages; an equipment shelter houses the electronic components and display console and an antenna pallet carries the folding antenna and feed system, together with the pedestal and antenna drive system. The entire system can be transported by M35 trucks, C-130 aircraft, helicopters or towed on transporters. It can be converted from transport to operational configuration by a team of four people in less than 40 minutes.
DEVELOPMENT
Prototypes of the equipment were submitted to the US Air Force and successfully passed all tests. Following this the equipment was put into production, and by February 1983 deliveries were known to include 26 systems to the US Air Force, and 13 modified systems to other countries.

CHARACTERISTICS
Antenna
Type
Search: Modified parabolic
IFF: Integral with search radar feed system and reflector
Aperture, search
Horizontal: >45 m
Vertical: >2·7 m
Beamwidth (one-way), search and IFF
Horizontal: 3·8°
Vertical: 8° with cosecant squaring 7 – 27°
Polarisation
Search: Horizontal
IFF: Vertical
Type of feed: Search and IFF: horn
Beam pattern search and IFF
Horizontal: Conventional fan beam (cosine between 3 dB points), sidelobes 25 dB down, back lobes 30 dB down
Vertical: Conventional fan beam with cosecant squaring
Scan
Azimuth: 0 – 15 rpm, clockwise in automatic, or manually searchlighting, clockwise or counter-clockwise. Also available with 6 rpm clockwise fixed-speed option
Elevation: Manually adjustable, –3 to +6°
Transmitter
Power
Peak: 1 MW, or greater
Average: 1·12 kW at 800, 0·745 kW at 533, 1·12 kW at 267
PRF
Manually selectable: 800, 533, 400
Momentary selectable: ±10 μs stagger on 800 PRF. Also available with 4-pulse stagger to eliminate MTI blind-speeds
Frequency: 1·25 – 1·35 GHz, continuously tunable – over full range by local or remote tuning control
Tuning rate: 1 MHz/s
Pulse: Width automatically selected when PRF is selected:
1·4 μs for 800 PRF
1·4 μs for 533 PRF
4·2 μs for 267 PRF
2·8 μs for 400 PRF
Rise time: 100 ns, max
Receiver
Noise figure: Typically 3 dB, overall
Dynamic range: 65 dB
Choice of IF: Logarithmic, linear, or wideband limiting
Signal processing
MTI:
(a) Digital type
(b) Double (3-pulse) canceller
(c) Cancellation ratio – typical 40 dB
(d) Sub-clutter visibility –30 dB searchlighting, 20 dB scanning (6 rpm)
(e) Staggered PRF eliminates blind speeds
VSI:
(a) Digital type
(b) Feedback factor –0·875
(c) 2-channel: MTI and normal
(d) Railing suppression 12 dB minimum
Accuracy
Range: 0·5 nm on 400 PRF; 0·1 nm on 800 and 533 PRF
Azimuth: ±1°
Type of information displays
(a) PPI
(b) A-scope
(c) Output jacks and cabling provided for remote displays
STATUS
In 1980 it was reported that a number of the latest version of this radar, Alert IIA, were being supplied to Argentina for air defence use.

AN/TPS-44 tactical surveillance radar deployed

3282.153
AN/TPS-59 3-D TACTICAL RADAR
The AN/TPS-59 is a D-band, long-range 3-D air surveillance phased array radar. The export version is known as the GE 592. Claimed to be unique as a tactical radar, its transmitter is totally solid-state and power is generated by direct amplification at the transmission frequency using D-band power transistors. The antenna is a 9·1 m high by 4·9 m rotating planar array located about two metres above ground level. The three trailer assemblies used as the antenna support structure also carry the array sections during transport. The display and processing equipment, including an AN/UYK-7 general-purpose digital computer, are housed in two air-conditioned cabins (S-280), and these and three 45 kW diesel generators complete the TPS-59 system.

The antenna array is made up of 54 identical row-feed networks and associated row-level transceivers, comprising power supplies, transmitters, pre-amplifiers, phase shifters, duplexers and logic controls. Each set is housed in a single package directly behind the row feed. The vertical, or row-to-row distribution, is accomplished by three column feeds. The antenna rotates mechanically in azimuth, and a pencil beam electronically scans in elevation from 0 to 19° to cover the specified surveillance volume in a raster-scan pattern.

Two basic waveforms are used for the surveillance function: one throughout the short-range interval from 5·5 to 185 km, and the other over the long-range interval from 185 km to the limits of coverage. Eight pencil beams are used to scan the long-range interval in elevation, and 11 are used to cover the short-range. Provisions are made in the lower long-range and short-range beams to counter the effects of multi-path propagation, and a special low-angle heightfinding technique is employed. There is also a special weather mode of operation which automatically optimises energy management and MTI processing according to prevailing weather conditions. This is performed at intervals of five minutes to adjust to weather changes.

AN/TPS-59 3-D phased array tactical radar

In addition to its various functions in beam steering, energy management, and signal processing, the AN/UYK-7 computer stores the position of all detected targets (in three co-ordinates) and correlates the stored positions with fresh data on a scan-to-scan basis. It also performs the special range

correlation processing associated with second-time-around returns concerned with MTI operation, and correlates the data from targets in closely spaced beams to avoid the reporting problems associated with multiple detections. All monopulse calculations are performed in the computer.

All controls and indicators for the operation of the TPS-59 are located at the display console, at which there are two operators' positions with three CRTs. Two of these are PPIs and the other is used as either an RHI display or for the presentation of alphanumeric data. Other facilities include IFF controls, a performance monitoring status display, a clutter gating panel and communications controls.

The AN/TPS-59 is designed primarily to provide long-range surveillance of a tactical airspace to the tactical air operations central (TAOC). Its detection capabilities (500 targets per ten-second scan), 3-D positional accuracy, and console readouts and controls meet the requirements of an autonomous build-up or back-up ground control intercept role. The system's high data rate capability supports the additional ATC mission. The design specification includes threat criteria such as 1 m² scan-to-scan fluctuating targets flying at speeds up to Mach 4.

CHARACTERISTICS

Radiated peak power: 46 kW
Average duty cycle: 18%
Transmit gain: 38·9 dB
Effective receive area: 14·5 dBm²
Antenna sidelobe levels: -55 dB
System noise temperature: 540° K
Signal processing losses: 2·4 dB
Frequency: 1215 - 1400 MHz
Antenna beamwidth: 3·4° azimuth; 1·7° elevation
IFF subsystem: Modes 1, 2, 3A, C, 4
Surveillance coverage: 360° azimuth; 5·5-560 km range; 0 - 19° elevation; 30 500 m altitude
Frame time: 10 or 5 s
Detectability-in-the-clear: PD: 0·7 beyond 200 nm; 0·9 within 200 nm; FAR: 5 per scan
Accuracy: 24 m range; 3 mrad azimuth; 300 m height
Resolution: 60 m range; 3·4° azimuth; 1·7° elevation
Reliability: MTBF 1400 h
Maintainability: 40 minutes MTTR
Weight: 12 700 kg system; 2360 kg max package
Prime power: 89 kW (nominal)
Mobility: 1 h assembly; ½ h disassembly

DEVELOPMENT

General Electric was awarded a contract for the development of the TPS-59 for the US Marine Corps by the Naval Electronic Systems Command in 1972. It began US Marine Corps acceptance testing in 1976-77.

Based upon the modular nature of the antenna array and its 54 identical row/feed networks, and flexibility inherent in the digital signal processor coupled with extensive use of software control techniques, GE has produced designs for other derivatives of the TPS-59 for a variety of applications. Brief details follow:

***Fixed* 3-D long-range radar:** This has an antenna array measuring 7·3 × 7·3 m (the row/feeds are 50 per cent longer than the TPS-59) and a range capability of about 450 km.

Medium-range transportable 3-D radar: Antenna size 4·3 × 4·9 m, range 225 km, 50 track capability.

Long-range 2-D fixed radar: Antenna size 3·7 × 6·1 m with row/feeds disposed vertically instead of horizontally, range 370 km, track-while-scan processing.

Medium-range limited-sector 2-D radar: Antenna size 3·7 × 1·5 m with row/feeds disposed vertically, range 55 km, inertialess azimuth scan of 120°, track-while-scan processing.

A shipboard long-range 2-D radar using an array measuring 4·6 × 2·3 m contained within a 9·2 m diameter radome and with a range of 370 km has also been publicised.

STATUS

In 1980 GE received a $134 million contract for AN/TPS-59 radars for use by the US Marine Corps. This award followed a successful four-year test and evaluation programme. The 15 radars ordered under this contract are being delivered. A transportable version, the GE 592, is described below (**4321.153**).

CONTRACTOR

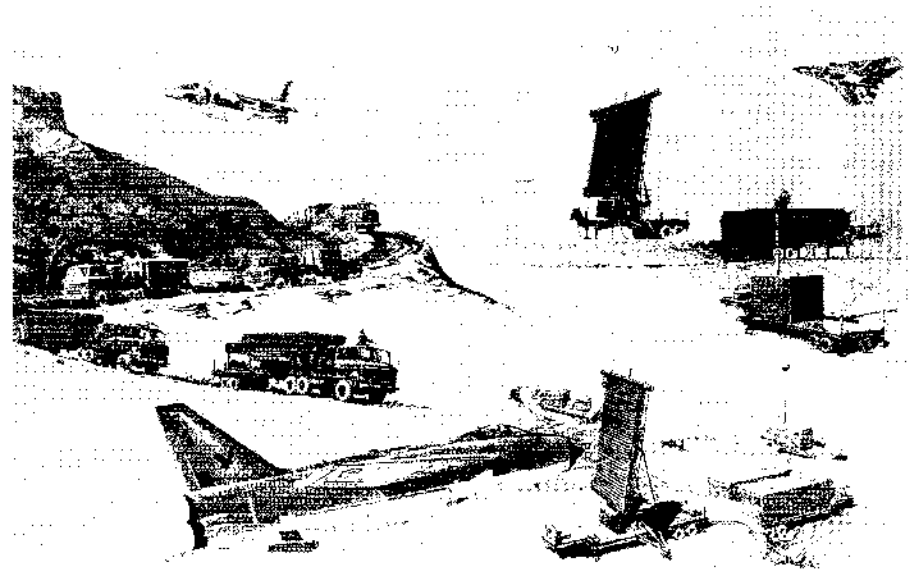
General Electric Company, Electronic Systems Division, Syracuse, New York 13201, USA.

4321.153

GE 592 TRANSPORTABLE AIR DEFENCE RADAR

The transportable GE 592 air defence radar system is the export version of the AN/TPS-59 system (**3282.153**). It is a completely mobile equipment and is totally solid-state computer controlled. Operating in L-band and comprising a complete air defence system with IFF or secondary radar for target identification, the equipment is housed in four enclosures and transported on four trailers.

The GE 592 is a versatile system and in its normal transportable configuration is moved by four vehicles which carry the antenna array, data and signal processing units, radar and control management and the power generation equipment. A fifth vehicle is needed to carry the microwave communication equipment, if required. The entire system can also be air-lifted by fixed-wing aircraft or helicopter.



The planar array measures 7·3 × 7·3 metres and phase positions a series of pencil beams to scan in elevation up to 20° while it rotates in azimuth. The transmitter/receiver group is located on the antenna and comprises 44 transmitters, each containing eight 100-watt RF solid-state power modules and 44 receiver modules. The IFF secondary radar antenna is mounted on top of the main array.

The data processor controller provides all radar operational management as well as on-line, automatic performance monitoring to detect possible system failures. The controller provides plot extraction data output and performs sweep-to-sweep and scan-to-scan correlations to reduce false alarms and multiple reports. It also provides automatic radar/IFF correlations as well as monitoring the system for adverse environmental and ECM effects.

Although the GE 592 is completely automatic in operation, it can also be controlled by manual override from operations consoles in the operations and control group trailer.

The secondary radar sub-system (SRS) provides identification, altitude, azimuth and range information on transponder equipped aircraft. The SRS radar coverage is 360° in azimuth, 400 km in range and up to 100 000 feet (30 480 metres) in height.

The complete radar system can be housed in a radome/shelter complex, if required. The equipment trailers can be dispersed in any location within 300 metres of the radome. If field dispersal is chosen, the array operates without a radome.

Composite impression of GE 592 transportable air defence radar systems in operational service as part of the UK air defence network in Scotland

CHARACTERISTICS

Frequency: 1215 - 1400 MHz
Range: Up to 400 km
Azimuth: 360°
Elevation: -4 to +20°
Height: 100 000 ft (30 480 m)
Range accuracy: 100 m rms (5 - 150 nm); 200 m rms (150 - 250 nm)
Height accuracy: 1200 ft (366 m) at 135 nm
Azimuth accuracy: 0·17°
Peak power: 25 kW
Beamwidth: Azimuth 2·2°, elevation 2°

STATUS

In 1980 two transportable GE 592 systems were ordered for installation in Scotland as part of the NATO air defence modernisation programme. These are now fully operational. A fixed-site system was delivered to Belgium in 1979 and the US Air Force is procuring two systems for the Seek Igloo air defence updating programme.

CONTRACTOR

General Electric Company, Electronic Systems Division, Syracuse, New York 13201, USA.

3475.153

AN/TPS-63 TACTICAL SURVEILLANCE RADAR

The AN/TPS-63 is a D-band air surveillance radar used to provide low altitude coverage for tactical air defence operations. This radar, with the companion equipment, AN/TPS-65 (**3476.153**), was built to meet US Marine Corps requirements, and both these radars feature extensive use of micro-electronic and solid-state techniques. An advanced MTI facility is claimed to provide a 90 per cent probability of detecting a 1 m² target out to the full instrumented range of 80 nautical miles (approx 150 km). The digital MTI uses a four-pulse canceller with variable time intervals between pulses to distinguish moving aircraft from ground returns while eliminating MTI radar blind speeds. There is an additional digital three-pulse MTI weather canceller and digital CFAR processing. Dual diversity operation is normal and there are built-in test facilities.

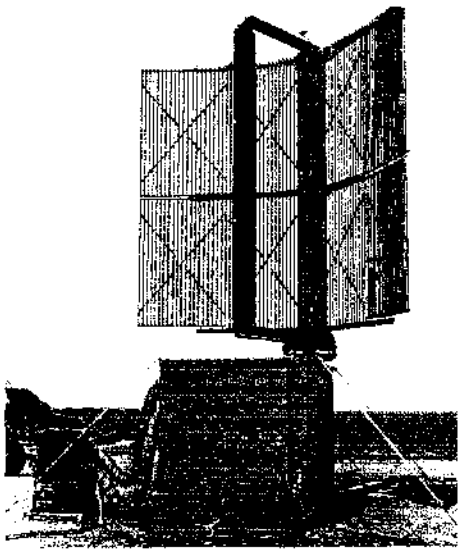
The AN/TPS-63 is designed for transportable or mobile applications, but fixed installations are also possible. The 4·9 × 5·5 m antenna is constructed of sections and the system can be operational within one hour of arrival at a new site.

CHARACTERISTICS

Frequency: D-band, dual diversity, 51 selectable frequencies between 1250 - 1350 MHz
Range: 80, 120 and 160 nm (operator selectable)
Data rate: 6, 12, 15 rpm (10, 5, 4 s)
Elevation coverage: 12 000 m shaped coverage to 45°
Power output: 100 kW peak; average 3 kW
Antenna gain: 32·5 dB
Antenna rotation: 6, 12, or 15 rpm

Angular resolution: 2·7°
Range resolution: 152 m
ECCM: Coded-pulse anti-clutter, frequency agility, PRF stagger
MTBF: 884 h
MTTR: 30 minutes
Weight: 3400 kg
MTI improvement factor: 60 dB

DEVELOPMENT



The AN/TPS-63 was designed and developed under US Navy contracts for use by the US Marine Corps in the latter's Tactical Operations Center to facilitate detection, automatic acquisition and target tracking of aircraft targets. The AN/TPS-65 version serves as the primary airfield surveillance radar sensor for the US Marine Air Traffic Control and Landing System.

STATUS

Over 60 systems have been delivered to the US Marine Corps and six international customers. A version of the TPS-63 has been designed for airship installation to give increased coverage. Entry **3162.353** under the Airborne Radar section gives more details.

CONTRACTOR

Westinghouse Defense and Electronic Systems Center, Baltimore, Maryland 21203, USA.

AN/TPS-63 tactical air surveillance radar, set up and ready for operation. A four-man team can erect and prepare the radar within an hour

3476.153

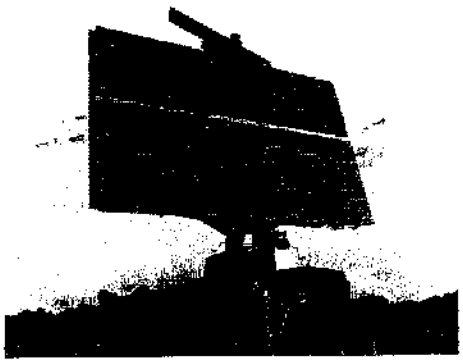
AN/TPS-65 TACTICAL SURVEILLANCE RADAR

The AN/TPS-65 is a member of the Westinghouse family of two-dimensional D-band air search radars which includes the AN/TPS-63 (**3475.153**) radars. The TPS-65 is a dual-channel system, using a single antenna, and has similar performance characteristics which suit it for its principal role as the primary airfield surveillance radar sensor for the US Marine Air Traffic Control and Landing System. This system provides automated and manual control information for aircraft landings at expeditionary airfields.

Essential details of the AN/TPS-65 are as shown for the AN/TPS-63, and the reader is referred to entry **3475.153** for the main characteristics.

STATUS

Initial production completed.



CONTRACTOR

Westinghouse Defense and Electronic Systems Center, Baltimore, Maryland 21203, USA.

4319.153

AN/TPS-70(V)-1 TACTICAL RADAR

The TPS-70(V)-1 is a mobile tactical radar designed to detect and track hostile aircraft in a variety of environments at ranges out to 450 km. It incorporates clutter rejection and ECCM features, with an ultra low sidelobe antenna making it very difficult for enemy countermeasures to detect and jam the system. Also incorporated are advanced signal analysis and processing and a digital coherent MTI system.

AN/TPS-70 tactical radar

The antenna, a flat-slotted array measuring 18 feet wide by 11 feet high (502×335 cm), is combined with programmable doppler signal processing and an automated target extraction/tracking computer to provide the total operational scenario capability for automated and manual command centres.

The complete system consists of the main antenna, with a secondary radar mounted on top and an operations/electronics cabin shelter unit. For ease of transport the TPS-70(V)-1 is deployed as two modules which can be carried to a forward position by either truck or helicopter.

The TPS-70(V)-1 is modular in design, the software being flexible to permit fast reprogramming to meet specific operational requirements. The system can be remotely controlled and can be operated either autonomously or as part of a larger network. Several versions are under development, including a medium range gap filler as well as a long range surveillance version. Another variant, known as the FPS-70, has been developed for fixed sites.

CHARACTERISTICS

Frequency: 2900 - 3100 MHz
Peak power: 3 MW (mean power 4·9 kW)
Range: 450 km
Height accuracy: 220 m minimal
Elevation coverage: 0 - 20° with option to -3°
Antenna type: Flat-slotted array
Antenna rotation speed: 6 rpm
Azimuth beamwidth: 1·6°

STATUS

In production for several overseas customers. Another version of the TPS-70, known as the TPS-70(V)-2, has been developed and the first prototype was delivered to Switzerland for evaluation in August 1984. This programme, known as TAFLIR, will lead to additional units after successful field trials. Two other variants, the TPS-70(V)-3 and (V)-4 are also available.

CONTRACTOR

Westinghouse Defense and Electronic Systems Center, Baltimore, Maryland 21203, USA.

5870.153

VIGILANT TACTICAL SURVEILLANCE RADAR

Vigilant is an S-band, medium-range 3-D mobile tactical surveillance radar that has been developed from the AN/TPS-70 system (**4319.153**). It is a full pulse doppler radar employing a four-pulse modified MTI to provide detection and fast response to low and medium altitude attack out to a range of 110 km (60 nm). It supplies simultaneous range, azimuth and height information of the smallest targets, and is designed to operate in an ECM environment as well as heavy ground and rain clutter.

Vigilant employs a planar antenna, similar to the AN/TPS-70, with a high scanning rate for fast reaction. The system will automatically initiate up to 1000 tracks and update each track on every antenna scan. A 'look-down' beam is provided for use when the equipment is deployed on a mountain top, to ensure detection of low-flying aircraft. An associated Vigilant mobile operations centre can be provided for autonomous or netted command and control. Alternatively it can be integrated with any other type of automated air defence system.

The complete system, including the operations centre, is transportable by two vehicles, and can be airlifted by standard cargo aircraft or helicopters. A crew of four can assemble or disassemble the radar within 30 minutes. Vigilant can operate completely unattended if required, all operational functions being controlled remotely via a narrow-band digital link. A built-in monitoring and fault isolation subsystem constantly indicates operational status and displays any fault at the radar and the remote site.

STATUS

Fully developed.

CONTRACTOR

Westinghouse Defense and Electronic Systems Center, PO Box 1693, Baltimore, Maryland 21203, USA.

4320.153

TWS-QR TRACKING RADAR

The TWS-QR (track-while-scan-quiet-radar) system is a tracking radar designed by Hughes Aircraft Company and intended for use with a variety of ground-to-air defence missile systems. It has been designed specifically to operate under severe ECM and to present the minimum possible 'target' to anti-radiation devices and artillery threats. A number of potential uses are envisaged, including that of the surveillance and control radar for advanced SHORAD weapon systems or air defence versions of the AMRAAM air-to-air missile systems.

TWS-QR is a three-dimensional X-band radar and employs a 45 rpm rotating antenna with multiple electronically scanned elevation beams which provide continuous 360° azimuth search surveillance and multiple target track functions with a high update rate. The antenna has been designed to ensure ultra-low sidelobe performance as a protection against ECM, and this, plus a low power waveform, is used to counter anti-radiation homing and artillery threats from passive position locating radars. A number of features are used to provide the essential high tracking accuracy, including single-dwell, unambiguous range and doppler measurement, a pencil-beam antenna, elevation monopulse, a high update rate, doppler processing and high resolution coded waveform.

Operationally there are number of possible uses for the TWS-QR system. These include use as a new sensor for SHORAD C² and as a sensor for a new generation LOMADS weapon system where the high data rate could be combined with a weapon system having inertial or other self contained guidance, eg an advanced Chaparral or an air defence version of AMRAAM.

In a tactical configuration, the entire system can be mounted on a single-axle trailer or a tracked vehicle

for rapid mobility and positioning.

DEVELOPMENT

The TWS-QR was designed and built under contract to the US Army Missile Command. The prototype model delivered in 1982 uses a specially designed antenna. The US Army has also proposed a large scale integrated circuit programme to reduce size, weight and power, and to upgrade processing.

STATUS

The first prototype model (Exploratory Development Model) was delivered in early 1982 and field tests began in mid-1982. The EDM system is mounted in two mobile vehicles. The antenna, transmitter and receiver are mounted on a standard HAWK trailer while the signal processor, displays, control and data recording/reduction equipment are based in a standard van.

CONTRACTOR

Hughes Aircraft Company, Ground Systems Group, Fullerton, California 92634, USA.

5868.153

ASTAR-2 AND ASTAR-3 SURVEILLANCE RADARS

Astar-2 and -3 are surveillance radar systems designed primarily for the tactical air defence role, and are 2-D and 3-D respectively. The two systems have more than 80 per cent common design, other than the antenna. They can be operated as either a local autonomous radar with single or dual displays provided for surveillance and control, or in a completely unattended mode as a sensor for a netted command and control system. Both equipments incorporate ECCM features which include frequency agility, random PRF and code agility, highly coded pseudo-random waveform, low antenna sidelobes and anti-chaff MTI processing.

The antenna of Astar-2 is a dual polarisation, double-curved parabolic reflector with mechanical azimuth scan. It is of lightweight fibreglass construction and can be mounted either on a tower or on the roof of the operations cabin. The Astar-3 antenna is a phased array with multiple pencil beams and phase/frequency elevation scan. It employs mechanical azimuth scan and is normally mounted on a tower or a tripod. The transceiver is common to both systems and uses a solid-state TWT driver amplifier with a dual-conversion, high dynamic range receiver and microprocessor control of subsystem functions.

The processor incorporates flexible multiprocessor architecture that combines both special purpose dedicated hardware and microprocessor-based computing and control elements. Full colour raster scan control/displays are available which provide alpha-numeric, graphic, video and real-time data with touch panel system control.

CHARACTERISTICS

	Astar-2	Astar-3
Peak power output	160 kW	160 kW
Antenna		
Polarisation	Horizontal/circular	Horizontal
Weight (with IFF)	500 kg	864 kg
Rotation	12 rpm	6 rpm
Coverage		
Range	100 nm	200 nm
Azimuth	360°	360°
Elevation	10 000/40 000 ft	100 000 ft
Data rate	5 s	10 s
Accuracy		
Range	89 ft	89 ft
Azimuth	0·156°	0·233°
Height	—	27 560 ft

CONTRACTOR

Aydin Corporation, Radar and EW Division, 32 Great Oaks Boulevard, San Jose, California 95119, USA.

2535.153

AN/TPX-42 PIDP IFF-ATCRBS EQUIPMENT

The PIDP (programmable indicator data processor) is an advanced sophisticated version of the AN/TPX-42 secondary radar system which was built for US Air Force, Navy, civil ATC and military air defence purposes. This latest state-of-the-art version nomenclatured AN/TPX-42A(V)10 is a secondary radar system comprising interrogator/receiver, data processor and display equipment installed in over 100 AN/FPN-47, AN/GPN-12, AN/GPN-20 and AN/FPS-67D airport surveillance radars. The heart of the PIDP, which provides a significant automated extension of existing ATC capabilities, is a newly-developed programmable digital processing system that will provide the controller with more useful information consisting of flight identification, aircraft type, altitude, and ground speed. The PIDP system utilises a NOVA 3 mini-computer (utilising only 26 000 words of programmed storage), new vertical displays (OD-153/T) and/or indicator modification kits (OD-152/T or OD-152A/T) to upgrade existing OD58 and OD58A indicators to accept programmable features. Each system is capable of driving 16 indicators and provides the following salient features:

(1) directly compatible with the existing TPX-42 systems
(2) modular system concept facilitates system interface with other existing ATC facilities
(3) on-line diagnostic displays for routine and system tests
(4) operational software includes advanced tracking algorithms
(5) full NAS interface
(6) reflection identification and filtering
(7) minimum safe altitude monitoring and warning (MSAW)
(8) altitude deviation monitoring and warning.

Keyboards at each display are used for message entry and control of the display formats. Additional expansion features available include provisions for digitising primary radar, BRITE interface equipment for converting PIDP data into high-resolution TV video for presentation on BRITE indicators in the daylight ambient or tower cab environment, generation of digital maps and ATC simulators that permit mixing of live and synthetic targets at the facilities consoles.

Main units of the system are the SSR interrogator/receiver, the synchroniser/coder, the interference blanker (defruiter), the video signal processor (VSP), the indicator data processor (hard-wired for the original TPX-42 and a NOVA 3 computer for the PIDP) and the display consoles. The displays feature simultaneous display of PPI radar video and stroke written synthetic alpha-numeric data. Coded pulse trains appropriate either to the Mk X IFF/SIF or to the ATCRBS system are transmitted by the interrogator which is triggered by the synchroniser/coder; the latter providing either internally generated pulse or pulses counted down from associated primary radar. The defruiter accepts incoming signals from the receiver and applies automatic three-mode interlace defruiting. It can operate over a wide PRF range of from 150 to 450 Hz. The defruiter output is applied to the VSP which standardises and decodes all replies in the interrogator coverage area (active decoding). The VSP also identifies potential garble situations, detects true target position for range and azimuth, correlates and validates identity and altitude codes, and combines all this information into a single message for each aircraft once per antenna revolution.

These messages are received by the display processor computer which in addition to performing the functions of tracking, keyboard command processing, MSAW, reflection filtering, etc, also converts and corrects the altitude according to the prevailing conditions, converts the polar radar co-ordinates into Cartesian co-ordinates, and provides the converted data to the displays. Display refresh is locally provided at 30 times per second via a micro-processor located in each display.

STATUS

322 basic AN/TPX-42 military and civil systems were built by the Command Systems Division and are presently in place at various sites in the United States and overseas bases. Basic and programmable versions of the AN/TPX-42 have been supplied to the civil/military authorities of Brazil, Bulgaria, Canada, Czechoslovakia, Iran, the Netherlands, Norway, Philippines, Poland, Spain and Taiwan. The PIDP production contract, calling for over 100 systems, was awarded to the Command Systems Division in August 1966 and was completed in 1983.

CONTRACTOR

Eaton Corporation, Command Systems Division, 815 Broad Hollow Road, Farmingdale, Long Island, New York 11735, USA.

3703.153

AN/TPX-46(V) IFF INTERROGATOR

The Hazeltine interrogator set AN/TPX-46(V) is compatible with a wide range of missile systems and associated radars, including the Hawk and Nike-Hercules configurations and most versions of the AN/FPS and AN/TPS radar sets. Interface capabilities for other radar systems are incorporated. An easily transportable ground IFF (secondary surveillance radar) interrogator, the AN/TPX-46(V) interrogates radar targets and, when the aircraft replies correctly, provides indications of aircraft identity for display on the associated radar PPI. The interrogator also has the ability, when its associated radar has been disabled - except for the PPI and its power supplies - to generate its own main trigger, to rotate its own antenna producing antenna synchronising signals, and to display on the radar indicator IFF replies from suitably equipped aircraft. Even when subjected to environmental extremes, the interrogator antenna can synchronise with the radar antenna at speeds up to 25 rpm. In addition, the interrogator transmitter power can be reduced, making it suitable for use with ground control approach radar systems.

The interrogator consists of four basic operating units: the receiver/transmitter, the coder-decoder group, the control box and the antenna group. The antenna consists of an array capable of a beamwidth of 5·5° (nominal). This is achieved by means of sum and difference antenna pattern techniques providing interrogator sidelobe suppression and receiver sidelobe suppression. Until now, production of so narrow a beamwidth has required the use of arrays approximately twice as long.

The AN/TPX-46(V) provides a clean display by means of the defruiting action of its processor unit. Other circuits make possible the automatic countdown of the repetition rate of the radar trigger, when necessary, to a frequency suitable for use by the interrogator set. Also provided is a gain time control circuit.

A solid-state transmitter module is now available as a direct replacement for the original electron tube version, resulting in reduced maintenance costs of labour. The AN/TPX-46(V) operates in Modes 1, 2, 3/A and C or in the Mk XII configuration on Mode 4 in conjunction with a KIR-1A/TSEC computer, and if additional circuits are installed, the AIMS mode also can be provided.

CHARACTERISTICS

Receiver frequency: 1090 MHz

Sensitivity: 80 dBm
Transmitting frequency: 1030 MHz
Peak power: 1000 or 2000 W, selectable; lower power model available
Antenna: 2·23 m long; 22·7 kg weight
STATUS
In service with US Army Improved Hawk and Nike-Hercules missile systems, AN/TSQ-38 radars, and AN/TSQ-51 AADCPs; US Marine Corps Improved Hawk missile batteries. Also in service with a number of foreign states. The AN/TPX-46(V)7 configuration is now in production for the US Army Patriot air defence system (**2800.131**). In January 1983, Hazeltine received a $2·5 million contract for component modernisation and technical improvements to the system.
CONTRACTOR
Hazeltine Corporation, Greenlawn, New York 11740, USA.

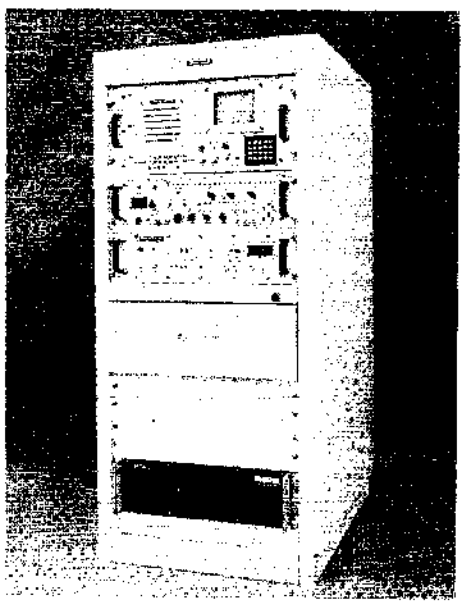
3705.153
AN/TPX-54 IFF/SSR INTERROGATOR
Using a modular building block approach, the AN/TPX-54(V) provides an interrogator which meets military and civil needs of secondary surveillance radar users in ground and shipborne applications. The modular system provides sufficient flexibility for a single compact interrogator to meet a diverse range of mission requirements, including those of ground and shipborne air defence and military and civil ATC. The AN/TPX-54 is designed to military specifications and operates in up to four SIF modes from Modes 1 or B, 2 or D, 3A and C and also in Mode 4. The unit is capable of operating with up to a five mode interlace when used with a KIR-1A/TSEC computer in Mode 4. The mode selection may be made remotely at an external decoder or at a remote control box. The interrogator front panel also provides mode selection for maintenance purposes.

The AN/TPX-54(V) includes a number of options to make it suitable for a variety of applications. The basic system consists of five plug-in printed circuit boards in addition to the modular power supply and the receiver/transmitter. It has a predicted MTBF given as 3800 hours. Space in the unit allows the addition of up to 11 more circuit boards for various standard options or special requirements.

More detailed information is given under this entry number in previous editions of *Jane's Weapons Systems*.
STATUS
The AN/TPX-54(V) is in use in the United States as well as other countries. It is being supplied for use in a standard 19 inch (48 cm) rack and meets DoD-AIMS 65-1000, NATO STANAG 5017 and ICAO Annex 10 requirements.
CONTRACTOR
Hazeltine Corporation, Greenlawn, New York 11740, USA.

4317.153
OX-60/FPS-117 IFF INTERROGATOR
The Hazeltine IFF interrogator OX-60/FPS-117 is the beacon processor group for the FPS-117 minimally attended radar. The OX-60 is a 200 nautical miles system with sidelobe suppression and interrogator sidelobe suppression. It is capable of interlacing Modes 2, 3, C and 4 and parallel processing the replies. The system is all solid-state and to meet the requirements of a minimally attended site, it is designed in a redundant, automatic switch-over configuration. The configuration consists of a control processor, two processors, signal data and two receiver/transmitters which provide an MTBF given as 118 765 hours. The automatic fault test and isolation is extensive and under the control of an 8086 microprocessor. Self-test of the beacon system is carried out on a continuous basis and consists of both a local circuits self-check as well as a full test accomplished by the generation of simulated targets. This function occurs in parallel to normal operation and is completely transparent to it.

Once a fault has been detected the microprocessor goes into a fault-isolation function to isolate automatically the fault to a single or group line replaceable unit. A status message is then passed to the computer indicating which module is at fault and needs to be replaced. This automatic fault isolation reduces MTTR and simplifies maintenance procedures.
CHARACTERISTICS
Receiver frequency: 1090 ±3 MHz
Sensitivity: -83 dBm decoding
Transmitter frequency: 1030 ±0·2 MHz
Peak transmitter power: 2 MW
Duty cycle: 1%
Range: 200 nm
Effective beamwidth: 2·75 - 0·5°
Power input: 115/200 V AC 50 - 400 Hz, 3-phase. Single channel 350 W, dual channel 700 W
Specification: Designed to MIL-E-4158
STATUS
Being procured by the US Air Force under the Seek Igloo programme for the Alaskan Air Command. Meets DoD-AIMS 65-1000 and FAA 101051A requirements.
CONTRACTOR
Hazeltine Corporation, Greenlawn, New York 11740, USA.



4632.053
MODEL 2679 IFF INTERROGATOR
Model 2679 IFF interrogator is a compact, rugged equipment designed to operate and survive in the battlefield. It provides weapon systems with an all-weather fire capability permitting rapid engagement of enemy aircraft at maximum system range. It is particularly suitable for land mobile systems, helicopters and small ships, where the need is for short range identification, smallness, lightness and low power consumption. The equipment includes both interrogator side lobe suppression and receiver sidelobe suppression capability for good azimuth accuracy while using small antennas. The model 2679 interrogator can be controlled directly from an associated fire control system computer or an associated control box.

The system consists of a receiver/transmitter, video processor, reply processor (sequential observer), timing and control, self-test, memory module and power supply. It has operator controls that allow mode selection, initiation of challenges and target identification.

CHARACTERISTICS
Transmitting frequency: 1030±0·2 MHz
Receiver frequency: 1090±0·2 MHz
Peak power output: 200 W
Sensitivity: -76 dBm
Weight: 28 lb (12·7 kg)
CONTRACTOR
Hazeltine Corporation, Greenlawn, New York 11740, USA

5776.153
AN/MSQ-117 IFF TRACKING SYSTEM
The AN/MSQ-117 is a lightweight IFF tracking system which provides advanced target acquisition and tracking for tactical and fast deployment applications. The equipment is completely self-contained and is based on microprocessor technology with a high power solid-state transmitter/receiver.

The system consists of an L-band antenna, a receiver, interrogator/processor and a display. Interrogations generated by the system elicit responses from transponder-equipped aircraft. From these replies, the position, altitude and identity of each aircraft within the system coverage is extracted and displayed on a random access PPI. The equipment also incorporates an adaptive α–β tracker which provides smoothed position and predictions for a selected aircraft. The tracking algorithm supports high speed manoeuvres by tactical aircraft. The digital output of the tracker can be used to position the antennas of other systems, eg ECM/ECCM.
CHARACTERISTICS
Peak power: 1 kW
Range: 60 n miles
Coverage: 360° azimuth; -30° to +85° elevation
Accuracy: ±0·5° azimuth; 300 ft rms range
Operating temperature: -40° to +62°C antenna; 0 to 50°C electronics
Dimensions
Antenna: 62 × 14 inches (157 × 16·5 cm)
Antenna control unit: 20 × 19 × 4 inches (50·8 × 48 × 10 cm)
Coder/processor: 20 × 19 × 5·5 inches (50·8 × 48 × 13·8 cm)
Display processor: (16 × 19 × 8·75 inches (40·6 × 48 × 22·2 cm)
Weights
Antenna: 37 lb (16·8 kg)
Antenna control unit: 36 lb (16·4 kg)
Coder/processor: 25 lb (11·4 kg)
Display/processor: 20 lb (9·1 kg)
STATUS
In production.

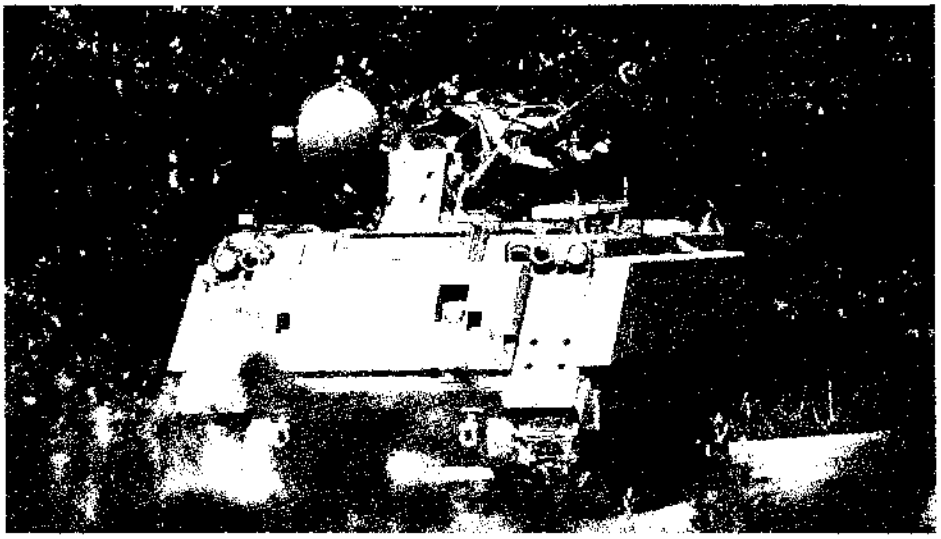
AN/MSQ-117 IFF tracking system

2547.153
AN/VPS-2 RANGING RADAR



This coherent pulse-doppler MTI radar is the range sensor of the Vulcan forward area air defence system (**2850.131**). Targets are acquired and tracked optically in this system but high-speed range and range rate data are required as inputs to the lead computing sub-system.

The axis of the radar antenna is servoed to the optical line of sight. The sight case and gun bore are physically fixed in alignment, but the sight reticle, which defines the optical line of sight, can move relative to the sight cage and is controlled by the gunner (see PIVADS **4015.131**). As the gunner tracks the target, the angular tracking rate and the radar-measured range and range rate are computed to predict future target position and then to control the gun position, introducing between the optical and firing axes the lead angle and super elevation required for successful target engagement.

Although primarily directed by optical means, the AN/VPS-2 radar has an automatic search and lock-on characteristic so that it tracks the target accurately.

CHARACTERISTICS

Frequency: 9200 – 9250 MHz, 6 crystal-controlled channels
Peak power: 1·4 kW
Average power: 10 W
Antenna: 4° conical beam ±20° in azimuth and elevation
Search range: 5000 m
Tracking capability: 15 – 310 m/s
Sub-clutter visibility: 40 dB or better

AN/VPS-2 range-only radar on a self-propelled multi-barrel gun

STATUS

Operational. The radar was developed under a US Government contract placed in 1966. The first prototype was completed in the same year and the equipment entered US Army service in 1969. In 1973, General Electric was awarded a product reliability improvement programme (PRIP) contract to study ways of increasing performance and the MTBF of the AN/VPS-2 radar, and as a result the latter characteristic rose from 37 to 122 hours. This led to the award of a further contract in 1975 for the production of modification kits for 2600 radars at US Army bases throughout the world. All sets have now been modified.

CONTRACTOR

Lockheed Electronics Company, US Highway 22, Plainfield, New Jersey 07061, USA.

2499.153
HIPAR (HIGH POWER ACQUISITION RADAR)

HIPAR (high power acquisition radar) is designed specifically for use with the United States Army's improved Nike Hercules surface-to-air missile system. The improved Nike Hercules system is deployed in key areas in the United States and overseas as a defence against high-performance aircraft, air-to-ground missiles, and tactical ballistic missiles. HIPAR was developed as an integral part of the system to provide significantly increased detection capabilities. It supplies long-range coverage and extremely precise azimuth data on small supersonic targets.

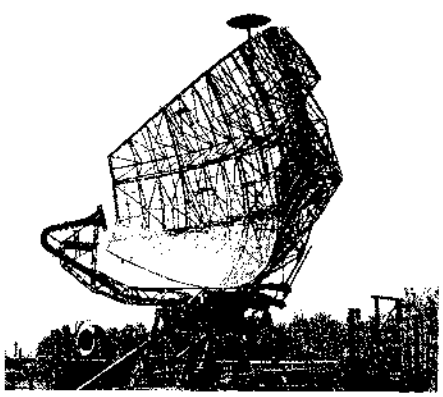
In addition to long range, the high-gain narrow-beam antenna used by HIPAR provides high-angle coverage. Its high-altitude coverage is said to be appreciably better than that of most present-day acquisition or surveillance radars.

To permit the full detection capabilities of the high-gain antenna to be realised despite the presence of enemy jamming, what are said to be unique MTI and receiver circuits have been developed for use with HIPAR. These circuits employ anti-jamming techniques that are said to provide capabilities not previously possible with conventional MTI techniques.

Both static and mobile HIPAR systems have been produced for the Army's use in both the United States and Europe. The mobile version (AN/MPQ-43), which uses the same electronics and components as the static version, is said to be the highest-powered mobile radar of its kind in the West. An important feature of the antenna for the mobile version is its ability to be changed quickly from cosec² coverage to fan-beam coverage.

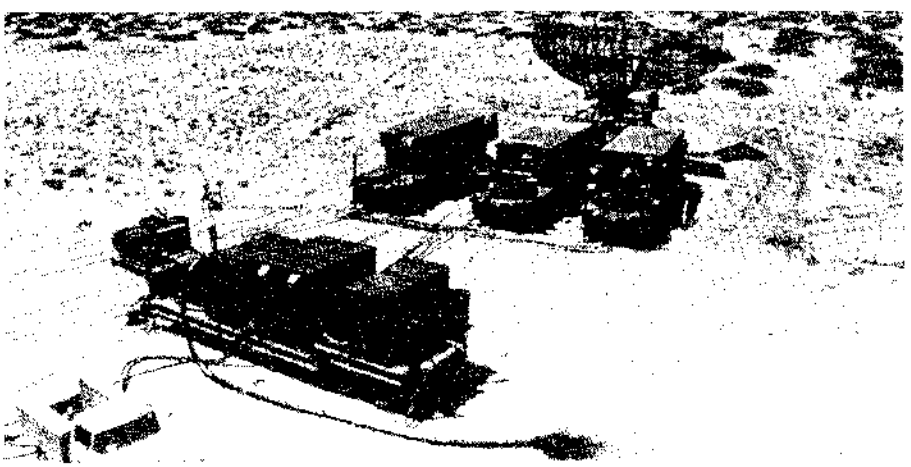
Mobile HIPAR is transported on five flat-bed trailers and can be emplaced by field army personnel after minimum training.

CHARACTERISTICS



Peak power: Classified
Average power: Classified
Frequency: 1350 – 1450 MHz
PRF: 417 – 438 pps
Pulse width: 6 μs
Receiver sensitivity: –113 dBm
Beam characteristics: Cosec² or fan
Beamwidth: Azimuth 1·2°; elevation 0 – 60°
Antenna azimuth rate: 6 or 10 rpm

STATUS



Operational. A total of 91 fixed HIPAR systems and 23 mobile HIPAR systems have been completed.

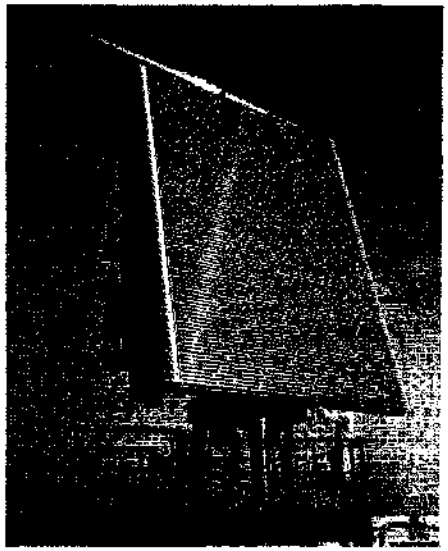
CONTRACTOR

General Electric Company, Electronic Systems Division, Syracuse, New York 13201, USA.

HIPAR

Mobile HIPAR

3721.153
HUGHES AIR DEFENCE RADAR (HADR)



HADR is the acronym by which Hughes refers to an advanced three-dimensional multi-mode radar designed for use in national air defence networks, either to replace ageing equipment, to enhance system performance or to fill gaps in the existing system. One version of the system is known as the H-3000. It is understood that many of the advanced features of this radar are a result of experience gained within the AN/TPQ-36 and AN/TPQ-37 mortar and artillery locating radars (**2848.153** and **1976.153**).

Designed to meet new NATO ACE (Allied Command Europe) standard radar specifications, HADR will automatically detect, classify and report on all targets in its area of coverage. Operation is in the E/F-band (former S-band) of the spectrum and a 4·8 × 6 m planar array antenna is used, generally protected within a radome.

The HADR is a member of the same family as the VSTAR (**4080.153**) and there may be commonality of certain parts of equipment as well as operating principles.

The HADR primary radar operates over a bandwidth greater than 12 per cent. The radar achieves a detection range of at least 320 km for a 1 m² target. The instrumented range coverage is 500 km. Versatile computer control enables radar coverage to 30 000 m altitude and up to 24° elevation. False target reports are controlled to prevent ADGE system computer overloads.

Target positional data is provided in three dimensions. Target range is measured to the nearest range cell while target azimuth and elevation are obtained by beam splitting. Performance in clutter is achieved by a digital mean velocity clutter tracker in

HADR antenna

conjunction with a single or double delay MTI canceller. A range gated pulse doppler waveform and associated processing implementation also is provided. An antenna rotation period of 10 or 12 seconds is consistent with ADGE system data rate requirements. Primary or secondary radar target report rates can exceed 400 per scan at the radar output. However, transmission rates to the remote command and control site may be limited by data link capacity.

The HADR antenna sub-system scans a single pencil beam in the elevation plane under computer control by controlling the phase shifters of the antenna. By properly positioning this beam in sequential steps, complete elevation coverage is provided. The elevation scan is completed before the antenna moves one beamwidth in azimuth, providing complete coverage of the surveillance volume with no holes. Antenna beamwidth and the transmitted waveform are controlled at each beam position to optimise management of the radar time and energy resources. Beamwidth is 1·1° in elevation and 1·7° in azimuth.

The operational modes in the HADR system are defined by tables stored in the computer memory. The computer controls the following elements for each beam in the search raster:

(1) Instrumented range
(2) Peak power
(3) Pulse length
(4) Elevation beamwidth
(5) Waveform
(6) Elevation angle
(7) Frequency
(8) Detection criteria
(9) Plot extraction criteria
(10) Operation changed by software

The secondary surveillance radar (SSR) sub-system incorporates an IFF interrogator and antenna. The HADR antenna makes provisions for mounting the primary IFF antenna as well as the sidelobe blanking IFF antenna and for routeing the RF signals through the rotary joint. The beacon video processor which is part of the multi-function processor provides extraction of IFF video and provides active and passive decoding. It also provides SSR target report outputs to the radar controller. The radar controller provides a correlation of these plot reports with primary radar plot reports for a consolidated output to the command control site.

The HADR primary radar utilises several techniques to reduce the effectiveness of ECM. Sophisticated jammers are thwarted by the radar operational characteristics including frequency agility, coded pulses, multiple pulsewidths and multiple PRFs. The primary radar design has low susceptibility to jamming through the use of pencil beams, a low sidelobe level antenna design, high receiver dynamic range and sharp channel selectivity. Automatic threshold control, target detection correlation and sidelobe blanking are techniques provided to handle any residual jamming which does get into the system. The burn-through mode and automatic frequency selection are special modes available for use in an ECM environment. Single pulse MTI is provided out to 60 nautical miles and two-pulse MTI out to 100 nautical miles. Seven-pulse range-gated pulse doppler is used to suppress rain or chaff clutter.

The system is capable of selecting operating frequency under computer control, and each frequency can be selected in about 40 μs, and may be changed on pulse-to-pulse or dwell-to-dwell basis. When selected by the operator, the system will automatically measure the interference level in each of the available operational channels and select that which is least affected.

The normal surveillance mode can be interrupted, at the operator's discretion, by a special mode which will intensify the energy on a specific target location. Normal surveillance volume is interrupted and all of the energy available is concentrated in a high energy waveform with a long dwell time in a sector automatically centred around the jam strobe which has been measured by the system and which indicates jammer direction. At high elevation angles, full antenna gain will be employed on the target even through the normal surveillance volume might call for a broadened beam.

STATUS

Hughes is building four HADR equipments for use by the Federal Republic of Germany, two to be used in conjunction with the NATO Air Defence Ground Environment (NADGE), and known as GEADGE (German ADGE), where they will replace AN/FPS-7 radars of the 412L radar network now in use. The first system went on-line at an unnamed site in the Federal Republic of Germany in October 1982. Two more systems became operational in 1983 and the fourth in 1984. HADR is also a contender for the NATO bulk buy of 10 cm radars to update the organisation's air defence system on the southern flank. It was announced at the 1985 Paris Air Show that a version of HADR, known as the H-3000, had been selected for the update of NATO's air defence system on the southern flank. This version will incorporate a number of modifications to the basic HADR, including monopulse operation and a 4 MHz processor. Eight systems will be supplied, with an option for a further six.

In January 1981 Hughes announced a contract for the supply of radars for Norwegian air defence. All three of these are to be used in shelters built into the tops of mountains. The antennas will be on elevators so that they can be retracted into environmentally controlled areas for routine maintenance. Two systems had been delivered to Norway by mid-1985.

One HADR system has been sold to Malaysia as part of the Malaysian Air Defense Ground Environment (MADGE) programme. Hughes is prime contractor on this programme.

CONTRACTOR

Hughes Aircraft Company, Ground Systems Group, Fullerton, California 92634, USA.

4080.153

VSTAR/VSTAR-PT AIR DEFENCE RADAR

Hughes has introduced a new air defence radar based on the operating principle of the company's AN/TPQ-36 and AN/TPQ-37 weapon locating radars (**2848.153** and **1976.153**) and incorporating some elements of the hardware of the latter, thus achieving common logistic support between the two radars. The new radar, VSTAR (variable search and track air defence radar), is an E/F-band (former S-band) equipment designed for rapid deployment and is configured in a variety of transportable forms and is primarily intended as a mobile system and secondly for static use in a gap-filler role. VSTAR has a wide instantaneous field of view (90°) and a 30° elevation field of view. The precision tracking (PT) variant has 90° elevation and 30° azimuthal field of view.

The planar antenna array measures approximately 7 × 11 metres and employs a combination of electronic scanning and mechanical rotation for target search and detection, although multiple targets can be tracked by electronic beam steering with the antenna array stationary. While rapidly rotating, the radar scan covers the entire aircraft penetration envelope, and a precision radar beam searches to a range of 250 km and up to 30 000 metres in altitude. Simultaneously, a beam also scans medium range at a faster rate to provide a quick reaction to low-flying or pop-up targets. The electronically scanned beam can search and track any point within the large azimuth-elevation sector while the antenna is being rotated. This allows electronic back and forward scan for immediate target verification and track initiation, multiple target tracking in high traffic density, variable track update rates, long dwell for non-co-operative identification, and ECM burn-through.

STATUS

VSTAR was demonstrated in three nations in 1980-82 and it is understood that this radar has been submitted for a number of other air defence requirements in NATO and elsewhere. Production contracts have been received but no details are available.

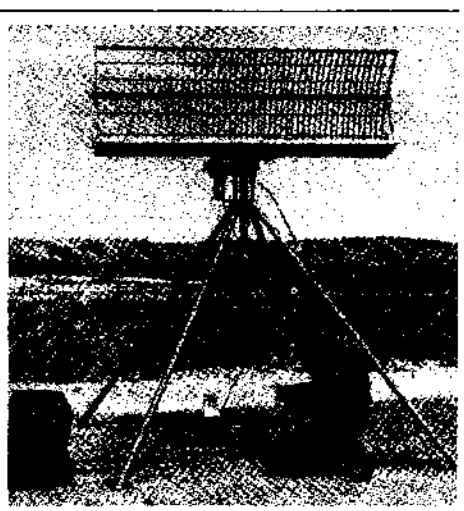
Hughes Aircraft Company, Ground Systems Group, Fullerton, California 92634, USA.



VSTAR air defence radar mounted on a tracked vehicle

5777.153

SENTRY TACTICAL DEFENCE RADAR

The Sentry tactical defence alert radar has been designed to meet the requirement for a short-range air defence command and control sensor for all-weather surveillance and detection of low flying targets. It is a licensed production version of the Elta EL/M-2106H radar (**3648.153**). It operates as a tactical alerting and cueing sensor well forward in the battle area. The system is a D-band lightweight, portable and relatively simple radar that normally operates autonomously in the field. It can also form part of a netted system as a gap-filler, or as an extension to other radar coverage.

The system consists of a rotating antenna assembly mounted on a pedestal and quadripod, a transceiver also positioned on the quadripod, and a display unit. An array of multiple display units, up to four, can be operated remotely from the equipment, with one display being the master by the attachment of a remote control unit. The antenna elevation angle can be adjusted from –5° to 10° for coverage up to 8000 feet. The display presents target azimuth and range information on an LED display. Range accuracy is 1

Sentry tactical radar deployed in the field

or 2 km, depending whether the 10 or 20 km scale is selected, and azimuth is defined in 10° sectors.

CHARACTERISTICS

Frequency: D-band, eight crystal frequencies selectable
Peak power: 140 W
Average power: 12 W
MTI improvement factor: 55 dB
Antenna
Beamwidth: 5° horizontal; 17° vertical
Rotation speed: 90°/s
Gain: 24 dB
Accuracy/resolution: Range 1 km on 10 km scale, 2 km on 20 km scale; 10° azimuth
Weights
Antenna: 108 lb (49 kg), including antenna, reflector and feeder, pedestal and quadripod
Transceiver: 57 lb (26 kg)
Display: 18 lb (8·2 kg)
Remote control unit: 2 lb (0·9 kg)

STATUS

In production.

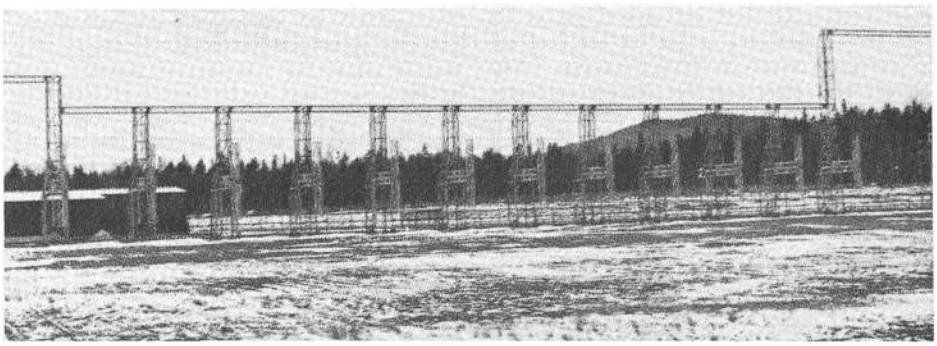
CONTRACTOR

Lear Siegler Inc, Astronics Division, 3400 Airport Avenue, Santa Monica, California 90406, USA.

5607.153
MULTI-FUNCTION RADAR (MFR)

The Multi-Function Radar (MFR) is a next generation land-based weapon control system that has been developed from the naval FLEXAR programme (**3258.253**). It uses technology derived from this programme and is intended for use with existing I-HAWK and other short-to-medium range missiles to provide a significant reduction in manpower and equipment, improved mobility and transportability, improved operation in ECM conditions and reduced life cycle costs. Further information is given under the FLEXAR entry in the naval radar section.

STATUS



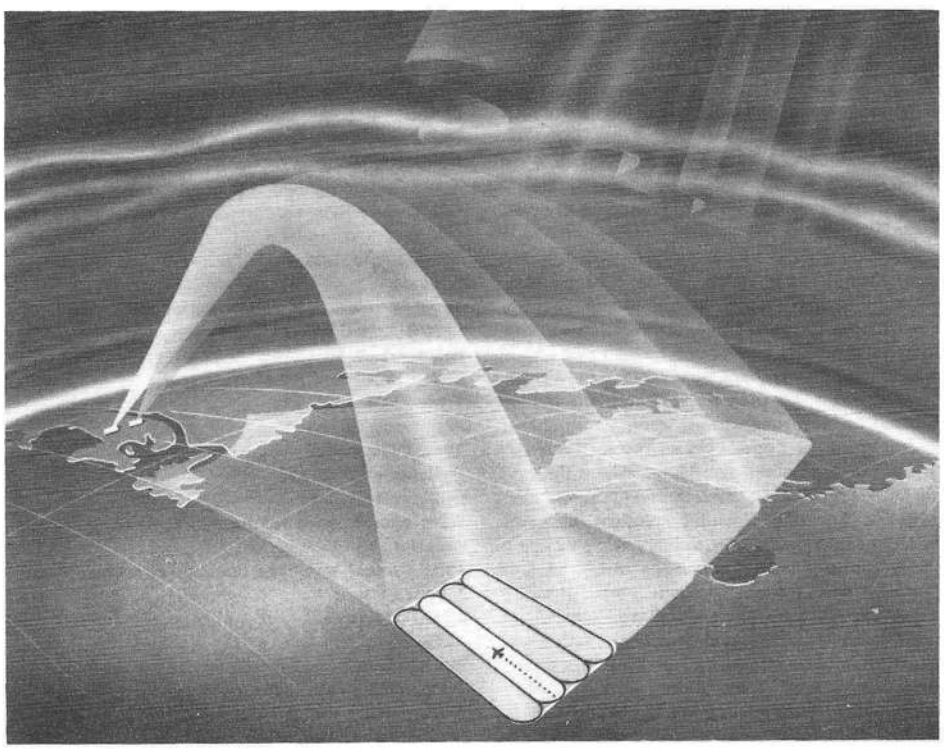
Development is proceeding in parallel with FLEXAR. During 1983, the system successfully completed testing with the Improved Hawk missile and US Navy Standard.

CONTRACTOR

Hughes Aircraft Company, Ground Systems Group, Fullerton, California 92634, USA.

5617.153
AN/FPS-118 OVER-THE-HORIZON RADAR

A new generation radar system, known as CONUS OTH-B (Continental United States over-the-horizon-backscatter) has been developed to provide electronic surveillance of aircraft at extended ranges of 500 to 1800 nautical miles (800 to 2880 km). Operating in the high frequency band, where the radar energy is reflected by the ionosphere, this ground-based radar is capable of over-the-horizon detection and tracking of aircraft and cruise missiles at any altitude. The system operates between 6·7 and 22·3 MHz, although this frequency range will be extended to 5 to 28 MHz later, and has two separate (bistatic) transmit and receive sites. On the United States eastern seaboard a prototype system has been in operation, the transmitter being located at Moscow US Air Force Station, Maine, with the receive site at Columbus Falls US Air Force Station, Maine, 110 miles (177 km) away. The latter also houses the operations centre although it is eventually due to be transferred to Bangor International Airport. Southward-looking and western seaboard systems are also planned. To adapt continuously in real-time to the prevailing ionospheric conditions, both the transmit and receive functions are completely computer controlled. Operation of the transmit and receive sites is synchronised in absolute time to better than one microsecond accuracy by Loran-C. The experimental transmissions from the Maine site covered an arc from 016·5 to 076·5° and 500 to 1800 nautical miles (800 to 2880 km) in range. This region was selected to evaluate the radar performance in an area where propagation will be most likely affected by the aurora, and to provide surveillance of the busy North Atlantic routes where aircraft targets are readily available at all times. Full-scale development is now taking place and the eastern seaboard system will become operational in three 60° phases. The first, covering the north-eastern sector, will be ready by mid-1986, and the second by the end of 1986. The entire OTH-B project is due for completion by 1989 and will consist of a three-sector eastern seaboard system covering 180°, a similar western seaboard system and a two-sector southward-looking coverage of 120°.



CONUS OTH-B E-band transmit antenna section

The transmit antenna array consists of four separate side-by-side 12-element sub-arrays, each optimised to cover a different portion of the total operating range. Together they provide the capability to operate anywhere between 6·7 and 22·3 MHz and present low voltage-standing-wave-ratios to the transmitters at all scan angles. The highest frequency sub-array (Band E) uses vertical dipole elements, the other three sub-arrays use canted dipoles. This arrangement provides elevation patterns which match that required for propagation to the desired ranges via ionospheric reflections. The elements are mounted in front of a common backscreen ranging from 45 to 100 feet (14 to 30·5 m) high and approximately 2265 feet (690 m) long. This will be extended to 3630 feet (1106 m). A common groundscreen extends 750 feet (230 m) in front of the arrays.

Twelve transmitters operate simultaneously into the 12 elements of a selected sub-array. Each transmitter contains four band-tuned tank circuits which respectively match the four antenna sub-arrays. Each transmitter produces up to 100 kW average power, with very high spectral purity at any operating frequency between 6·7 and 22·3 MHz. A 100 kW water-cooled tetrode is used in the final high-power amplifier stage of each transmitter. The 12 transmitters are driven by a beamformer at low power level which causes the transmitter/array combination to collimate the desired 7·5° beam and steer it to the selected positions. In operation the transmit site generates up to 100 MW of effective radiated power.

The receive antenna is a broadside array of 137 fan monopole elements mounted in front of a backscreen which is 3906 feet (1190 m) long and 50 feet (15 m) high. In an operational antenna, the length will be increased to 5230 feet (1594 m). As in the transmit array, a groundscreen extends 750 feet (230 m) in front of the entire receive array. Two bands are used to cover the 6·7 to 22·3 MHz range, a low band covering 6·7 to 11·2 MHz and a high band from 11·2 to 22·3 MHz. On the low band, every other element is used across the array giving a total of 68 active elements. Dividing the array in this fashion and using variable aperture weights in beamforming results in virtually constant receive beamwidths of 2·75° with no grating lobes over the full 60° azimuth coverage.

The active receive elements are fed via buried coaxial lines to elemental receivers, one for each active element, for a total of 82. Each elemental receiver employs 16 RF preselectors to cover the frequency range. In each receiver, the received signals are amplified, filtered and digitised before

OTH-B range/azimuth sectors

being passed to the beamformer/signal processor group. The beamformer combines the outputs to form four simultaneous receive beams spatially coincident with the range/azimuth sector. This four-beam cluster scans synchronously with the transmit beam. Beamwidth, beam spacing, pointing angle correction for frequency and real-time measured receive sub system errors are controlled by the receive control computer. The signal processor processes the four receive beams virtually simultaneously. Functions include MTI, interference suppression, range and doppler resolution processing, non-coherent integration, peak detection and parameter estimation.

At the heart of the system are very high speed computer, data processing and display systems which are used to control the radar, process the returned signals, monitor the HF propagation environment and display the information in a variety of formats to the operator. These displays are both alpha-numeric and graphic types to provide the operator with the maximum amount of information on target speed, track, position, altitude and other special characteristics, and also to adjust the transmission frequency to suit the prevailing HF environmental conditions. When the system is fully operational it is designed to give advanced warning of at least 1 to 1½ hours, even for supersonic aircraft, and, since it uses skywave propagation techniques, it can track very low-flying aircraft and cruise missiles at the same ranges as those flying at higher altitudes.

CONUS OTH-B has three modes of operation:

Normal mode

In this mode a surveillance barrier is established up to 30° wide, anywhere within the 60° azimuth sector, and up to 500 nautical miles (800 km) deep. A step-scan technique is used to illuminate this barrier on a regular, periodic basis by sequential illumination of four contiguous range azimuth sectors. Each sector normally covers a 7·5° by 500 nautical miles (800 km) area, thus four sectors form the 30° wide barrier. Four parallel receive beams, with 2·5° centre spacings, are formed to be coincident with each range azimuth sector and collect the signals reflected from targets in the coverage area. The starting range for each sector in the barrier can be chosen independently.

Interrogate mode

The interrogate mode illuminates one particular range azimuth sector and can be positioned anywhere within the 60° azimuth by 500 to 1800 nautical miles (800 to 2880 km) range capability of the radar. The interrogate range azimuth sector is illuminated by contiguous coherent dwells. As with the normal mode, four parallel receive beams, spaced on 2·5° fixed centres, collect the reflected target energy. The interrogate mode is a special mode intended to provide extra detection energy, contiguous illumination, and high range, velocity and azimuth resolution. It is used in circumstances to enhance the characterisation of particular targets.

Interleaved mode

This combines the interrogate and normal modes. One interrogate mode dwell is provided after each full scan of the normal mode barrier. Separate radar operating parameters can be selected independently for the interrogate and normal mode portions of the scan. This mode allows the barrier surveillance to be retained while focusing on special target situations anywhere in the coverage region.

DEVELOPMENT

A contract for the prototype system was awarded to General Electric in 1975 and, after the contract was restructured in 1977, an experimental system was developed to demonstrate technical feasibility. Initial testing took place from June 1980 to June 1981 and about one year later General Electric received a contract from the US Air Force to begin full-scale development of the project. The first part of this, the initial operating sector (IOS), was approximately 30 per cent complete in January 1984 and is scheduled to be fully operational by mid 1986. The IOS is a 60° wide sector, located in Maine, and is orientated north-east to illuminate the same geographic region as that used for testing of the experimental system. Funding for the second 60° sector was approved in 1983 but that for Sector 3 was proposed for 1985. When the complete system is operational it will cover 180° of the United States eastern seaboard.

For the proposed western seaboard system, sites have been chosen at Mountain Home Air Force Base, Idaho for the operations centre, Klamath Falls, Oregon for system support, Buffalo Flat site near Christmas Valley, Oregon for the transmitter and Rimrock Lake near Alturas, California for the receiver. The first west coast sector will be commenced in 1985 with procurement for the other two sectors in 1986. Long term planning for the two south-looking sectors envisages deployment in the late 1980s. Consideration was also given to a northwards looking sector but the wider irregularities of the ionosphere and the effects of the aurora preclude a reliable system. This region is already covered by the DEW line and the Seek Igloo chain. The cost of the complete OTH-B system has been estimated at $1300 million with a completion date of 1989. It is understood that Raytheon is also likely to put in a bid for the western and southern sectors.

STATUS

In full scale development. The first 60° sector, looking north-east, is due to be operational in 1986.

CONTRACTOR

General Electric Company, Electronic Systems Division, Syracuse, New York 13201, USA.

5781.153

RELOCATABLE OVER-THE-HORIZON RADAR

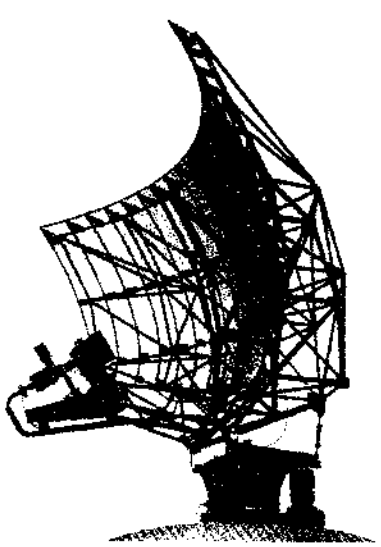
To complement the CONUS OTH-B system described under **5617.153**, the US Navy requires a relocatable over-the-horizon radar (ROTHR). Although classified as relocatable, the transmitter and receiver antenna systems are basically similar in construction and size to those of OTH-B and are, therefore, not easily relocated, although the operations centre and control station is intended to be a mobile unit. The ROTHR equipment is intended primarily for tactical use in deployments such as the perimeter of hostile countries to monitor aircraft and/or missiles beyond the normal radar horizon.

Raytheon has received an initial $18 million contract from the US Navy for a prototype model with software support. The programme calls for additional research and development expenditure of $77 million over the following three years to produce development models. TRW Defense Systems Group has also received an $18 million subcontract to design and develop an operations control centre for the system. In addition to the design and development work, TRW will provide hardware and software support for the project.

STATUS

In development.

CONTRACTOR



Raytheon Company, Equipment Division, Wayland, Massachusetts 01778, USA.

4082.153

CARDION COASTAL RADAR SYSTEM

Cardion has developed and produced a new E/F-band (formerly S-band) coastal defence radar under a contract awarded in 1979 by NATO with the code-name Baltic Approach. A number of these radars will be installed around the Danish coast, and the system is also known by the initials DCR (Danish coast radar). It includes an E/F-band primary search radar and a D-band (formerly L-band) secondary surveillance radar (SSR).

The system was designed for use at unattended sites with automatic reporting of data and control signals. Because the equipment is normally unattended, an extensive self-monitoring system has been incorporated into the design. Alerts are sent out immediately upon the first indication of trouble or abnormal situations.

Cardion coastal radar antenna

The antenna is a double curvature reflector with integral primary and secondary feed assemblies. An omni-directional antenna mounted on top of the main reflector is used for sidelobe suppression in the SSR system. Since the radar is normally used as a gap filler, the vertical beam shape has been specifically tailored to provide high detection probability of low-level aircraft and surface targets. A tilt mechanism allows adjustment of the beam above and below the horizon.

The transmitter employs a liquid-cooled, coupled cavity TWT, powered by an all solid-state high voltage power supply, to produce a highly stable coded waveform. The transmitter is versatile allowing operation in fixed, burst or full frequency agile operation. All operating modes are sector driven, ie a different mode may be selected for any of the four azimuth sectors, each of adjustable size. As the antenna rotates, the preset operating mode will be automatically turned on in each sector. The transmitter may also be silenced in a sector if desired.

Addition of an automatic detection and tracking unit (ADIT) provides the system with full automation capability. The ADIT features coherent and non-coherent signal processing, primary and secondary plot extraction, automatic track initiation and telephone line interface for data remoting. Video processing concepts allow automatic detection of targets in clutter and ECM environments, with a well regulated false alarm rate. The data processing portion of ADIT extracts plot data on both primary and secondary targets, merging the data into a single report when target correlation can be established. An integrated tracking system provides automatic initiation and continuous track update on all plot data.

One of the main functions performed by the ADIT is the separation and identification of all targets as either surface or air. Either or both types may be selected for transmission. The ADIT also extracts other non-target information such as a clutter map and jamming strobes. This data is transmitted, together with target messages, to the operations centre.

The remote control unit (RCU) is able to control and monitor an entire network of radars using bi-directional communication over telephone lines. Current status information is sent back to the RCU from each of the radar heads where it is displayed. The RCU is equipped with a CRT overlayed with a touch-sensitive screen which serves as the man/machine interface.

CHARACTERISTICS

Antenna
Type: Double curvature, integral with IFF
Polarisation: Circular
Rotation rate: 10 rpm
Size: 16 × 8 ft (4·88 × 2·44 m)
Transmitter
Frequency: E/F-band
Type: MOPA, TWT
Peak power: >100 kW
Duty cycle: 1%
Waveform: Phase coded pulse for pulse compression
Receiver
Type: Superheterodyne, double conversion with image rejection
MTI: Digital (I&Q)
ADIT
Plot handling capacity: 400 plots
Track handling capacity: 275 tracks

STATUS

Production and installation.

CONTRACTOR

Cardion Electronics, Long Island Expressway, Woodbury, New York 11797, USA.

3648.153
STARTLE

STARTLE is a prototype surveillance and target acquisition radar for tank location and engagement, under development by Martin Marietta for the US Army Night Vision and Electro-Optics Laboratories, the Combat Surveillance and Target Acquisition Laboratory and the Defense Advanced Research Projects Agency. Martin Marietta is applying advances made in 94 GHz radar technology to demonstrate its ability to enhance target acquisition, location, and engagement under conditions of rain, snow, dense fog, or smoke which characteristically reduce visibility and limit these capabilities both by day and night.

The system has been installed and tested on an M60A3 tank, and it avoids undue complexity and increased tank gunner workload by integrating radar information with the thermal sight display. The gunner can therefore locate and fire on targets using radar acquisition as easily as he can using the thermal sight. The integrated display also avoids the need for additional space for displays in the tank interior.

STARTLE operates with low power consumption in either of two modes: coherent MTI is used to detect radially-moving targets; area MTI permits acquisition of creeping and tangential targets. The spread spectrum waveform, used with area MTI processing, also provides smoothing of clutter, glint, and multi-path effects. The solid-state transmitter operates with a mirror-scanned paraboloid antenna located on the left of the tank turret. A rotating closure and armoured housing protects this component from indirect artillery fire, and accidental damage from trees or other obstructions. With the lid open the antenna can scan 3·75° up or down and 20° left or right independent of the movement of the gun.

STATUS

Development programme is now completed. No further activity at present.

CONTRACTOR

Martin Marietta Orlando Aerospace, Orlando, Florida 32855, USA.

5778.153
DR 810 Mk II MUZZLE VELOCITY RADAR

The DR 810 Mk II muzzle velocity radar is a small CW doppler system that measures the velocity of a projectile at several points in its trajectory. It is intended for use with tactical weapons and can be used with a variety of these, including artillery, small arms and machine guns, air defence weapons, shipborne guns, mortars and fire control systems. It has been tested with a variety of weapon systems from 5·56 to 203 mm calibre.

The equipment is mounted on the weapon concerned and consists of the antenna which contains an integral transmitter/receiver and includes quick-disconnect fitting for weapon mounting, a data unit/display connected by cable to the antenna, and a test unit for system test in the field. Data is fed to the data unit which calculates the actual projectile velocity at the muzzle to an accuracy better than ±0·2% and presents the measurement on a five-digit display in metres per second. Transmitter power is automatically cut-off after each round is fired. The DR 810 has a velocity data memory for the last eight rounds and will compute average velocity for up to eight rounds.

CHARACTERISTICS

Frequency: 10·525 ±0·03 GHz
Power output: 130-240 mW
Velocity range: 50-1750 m/s
Accuracy: ±0·2%

Dimensions
Antenna: 315 × 217 × 100 mm
Data unit: 256 × 402 × 200 mm
Test unit: 185 × 95 × 80 mm
Weights
Antenna: 8·2 kg
Data unit: 10·9 kg
Test unit: 0·45 kg

STATUS

In production. The DR 810 Mk II has been selected by the US Army and designated the M-90 Radar Chronograph.

NAVAL RADAR

CANADA

5677.253
AN/SPS-503 SURVEILLANCE RADAR

The AN/SPS-503 is a high performance, lightweight surveillance and target indicating radar operating in the E/F-band. In its standard configuration it is suitable for naval ships with displacement of 500 tons upwards. It is of rugged construction and has been designed to operate in very hostile electronic environments.

The main features of this radar are a coherent E/F-band transmitter with broadband frequency agility; pulse compression; a narrow beam, low sidelobe cosecant² antenna; and digital MTI with adaptive velocity compensation. The transmitter employs a TWT amplifier fed by a frequency synthesiser with high stability giving very good MTI performance. The low noise, high dynamic range receiver compresses target returns to provide high jamming resistance and range resolution. This pulse compression system has been optimised to ensure very low range sidelobes, even in the presence of large doppler shifts.

The signal processor is an all-digital unit providing MTI, CFAR and PRF discrimination facilities. Two independent signal channels are provided, one for MTI data and one for non-MTI data. The MTI system embodies adaptive velocity compensation which

AN/SPS-503 transmitter/receiver/signal processor assembly

shifts the notch of the MTI filter to compensate for the average clutter velocity. This is done independently for each area cell within the scan coverage to compensate for gross clutter motion. In addition a fast response loop is used to compensate for antenna movements due to the ship's motion. The optional plot extractor outputs digital reports of the range and azimuth of target centroids. The thresholding system employed gives maximal detection probability for targets and minimal probability of clutter-induced false alarms.

The SPS-503 uses a double curvature reflector antenna with horn feed. The reflector is configured to give a cosec² pattern in the elevation plane. Polarisation is variable from linear to circular and dual rotation rates of 10 and 20 rpm are provided. Antenna stabilisation is available and an IFF antenna is integral with the main antenna. A smaller, lightweight antenna is also available for applications where mastread weight is critical.

STATUS

This system has been ordered by the Canadian Armed Forces for fitment during the Destroyer Life Extension Programme (DELEX). Initial deliveries took place in 1984. Both this radar and the CMR-3 (**5678.153**) were developed in co-operation with the Marconi Company, England, where they are known under the nomenclature S1800 series (**3687.253**). Other company products include C-band naval air search radar and land-based mobile low-level air defence systems.

CONTRACTOR

Canadian Marconi Company, 415 Legget Drive, PO Box 13330, Kanata, Ontario, Canada K2K 2B2.

CHINA

5842.253
CHINESE NAVAL RADAR

As with ground radar, see entry **2019.153**, information on operational naval radar in Chinese ships is very sketchy. A small amount of detail has been released recently, although with the exception of entry **4808.253** which follows, the information provided is insufficient to produce meaningful entries. The Chinese authorities state that a series of navigation radars have been developed for installation on several classes of ships, including torpedo boats, missile equipped destroyers, escort ships, high speed gunboats and submarines, and are known as Types 752a, 756 and 757. No information has been made available on any surveillance, missile tracking or fire control radar systems which may be in use. Much of the radar currently fitted to Chinese naval vessels is Soviet in origin, some of it being of early design.

The main fire control radar in current use is the Sun Visor system (**1326.253**), known to the Chinese as Wok Won. The Jianghu class frigates are fitted with an air/surface warning equipment, called MX-902, which appears to be a modified version of the Slim Net system (**1322.253**). Other Soviet designed equipments observed on Chinese ships include the Square Tie short-range search radar (**1329.253**), the Knife Rest A long-range equipment, the High Pole and Square Head IFF interrogators (**1595.253**), and the Skin Head system (**1614.253**). In addition, a new prototype planar-array installation, similar to the Hughes AN/SPS-39A 3-D air surveillance radar (**1249.253**), has recently been seen on a frigate. It has become apparent, however, that an indigenous radar development programme covering naval, ground and airborne systems is under way, with priority on the shipborne equipment being given to air surveillance and fire-control systems. No doubt these systems will be observed on new classes of warships, although it seems very unlikely that information will be generally released.

4808.253
TYPE 756 NAVAL RADAR

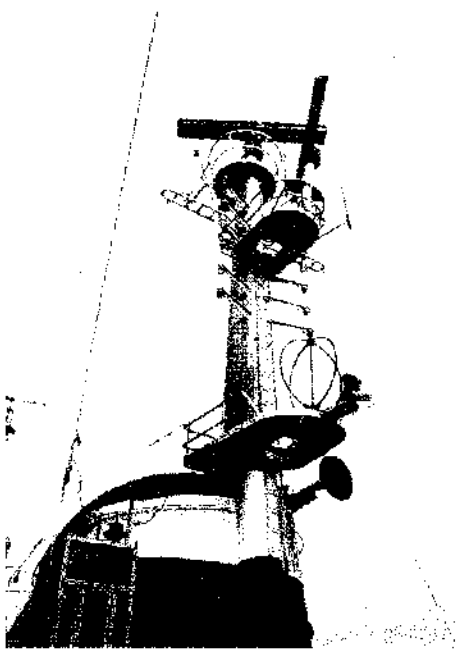
The Type 756 (Kaige 756 Series) naval radar is a marine navigation radar that offers dual band operation in the X- and S-bands. Of modern design, this equipment offers such facilities as inter-switching, dual displays, automatic plotting, etc. The system is designed to meet IMCO regulations and is of solid-state modular construction.

Design features include AFC, digital defruiter and performance monitor, 40 and 31 cm dual displays, and the inter-switching unit permits six different operating modes: either of the two radars can be operated independently, or both can be operated simultaneously. Two sizes of X-band slotted waveguide antenna are available (2 or 3 metres), and the S-band unit is 3·8 metres long. Separate (unstabilised) turning gear is provided for both.

CHARACTERISTICS

Antenna: Slotted waveguide
Rotation rate: 18 - 22 rpm

Frequency band	X	X	S
Length	2 m	3 m	3·8 m
Horizontal beamwidth	1·3°	0·8°	2°
Vertical beamwidth	20°	18°	22°
Gain	30 dB	32 dB	27 dB



Transmitter/receiver
Peak power: 50 kW
Noise figure: 10 dB

STATUS

Production.

CONTRACTOR

Fourth Shanghai Radio Factory, 1001 Zhao Jia Bang Road, Shanghai, People's Republic of China.

Type 756 naval radar

DENMARK

TERMA SCANTER MIL NAVIGATION AND SURVEILLANCE RADARS

The Terma navigational radar systems are designed to form an integral part of the total radar system on board naval vessels. They operate in S- and X-bands and are suitable for both navigation and surveillance. A multi-display system capable of operating in various master/slave combinations is available. The operational mode is selected on either display by illuminated push-buttons.

All units are autonomous, containing their own power conditioning circuits, and are built up as a modular system using accessible plug-in modules for ease of servicing. The system can be single X-band, single S-band, combined S- and X-bands, double X- and S-bands, or synchronised twin X-band. The modular technique also facilitates system extension. The following features can be supplied as options: electronic bearing line, sector transmission, reflection plotter, and true motion.

Terma Scanter Mil display

Terma Scanter Mil X-band antenna

Scanner Unit

The antenna is a horizontally-polarised slotted waveguide antenna with narrow beam and low sidelobe level. The antenna feed system (including a waveguide rotary joint) offers a low standing wave ratio at the input flange. Two scan rates may be selected by electronic switching of the drive system. The scanner position information is given through synchro transmitters and heading marker signal. The unit is driving-rain proof and a de-icing system is included.

Receiver/Transmitter Unit

The transmitter tube is a pulsed magnetron which is controlled from a solid-state magnetic modulator. Two pulse repetition rates and two pulsewidths may be selected individually. The modulator is divided into two separate assemblies with common input and output circuits, one for long and one for short pulse. The trigger assembly synchronises the total system and selects automatically internal or external synchronising mode. A trigger-pulse shaper and delay assembly perform compensation for transit times in the waveguide and receiver system. The RF system is integrated in one assembly and includes the waveguide duplexer, the T/R switch, the IF mixer, the AFC mixer and the solid-state local oscillator.

Display Unit

A whole range of displays is available all of which have the same physical size and common basic circuitry. The 16-inch tiltable display is flat-faced with all controls and readouts available from the front.

Deflection is based on the fixed coil principle. Presentation of radar video and synthetic video presentation such as vectors, target number, electronic bearing lines, etc are performed simultaneously. A series of displays ranging from navigational to complex tactical with automatic target tracking and target assignment to weapon systems of medium complexity is available.

All displays are fitted for operation from three independent radar sources of virtually any kind.

CHARACTERISTICS

Antenna: 2·1 m slotted waveguide (X-band), 4 m (S-band)
Scanner rotation: Switchable between 24 and 48 rpm ± 10% at 60 Hz or 20 and 40 rpm ± 10% at 50 Hz input frequency
Horizontal beamwidth: <1° within 3 dB points (X-band), 2° (S-band)
Vertical beamwidth: 20° within 3 dB points
Polarisation: Horizontal
Gain: >30 dB (X-band), >28·5 dB (S-band)
Receiver/Transmitter unit
Transmitter frequency: 9 GHz (X-band), 3 GHz (S-band)
PRF
Short pulse: Nom. 4000 Hz ± 200 Hz
Long pulse: Nom. 2000 Hz ± 200 Hz
Pulse length: 0·06 ± 0·01 μs, or 0·6 ± 0·1 μs
Peak power: 20 kW ± 1 dB measured at the output flange

STATUS

In service with the Danish and Swedish Navies.

Terma Elektronik AS, Hovmarken 4, 8520 Lystrup, Denmark.

4633.253
TERMA SCANTER MIL PLOT DATA SYSTEM

The Plot Data System (PDS) is a modular Command, Control, Communications and Information system (C3I) designed to replace electro-mechanical plotting tables and to provide data link communication capability in naval vessels not equipped with Tactical Data Systems (TDS).

The system enables NATO data link communication but can also be supplied for customer specified data link. Naval vessels fitted with PDS are able to exchange tactical data as well as with other TDS with compatible data link capability.

The system provides high speed plot correlation and tactical situation assessment and displays simultaneously raw radar video, synthetic video, IFF and computer generated colour graphics on two special purpose display systems.

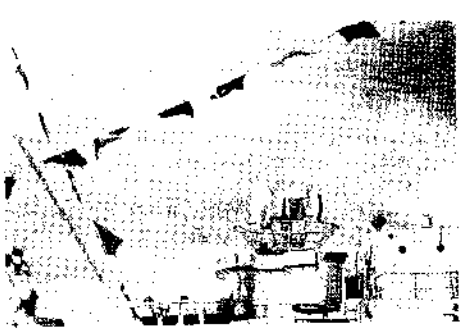
PDS consists of the following basic modules:

(1) a central system processor which contains all interfaces to navigation instrumentation, ships sensors, communication systems and weapon systems in addition to all PDS system units. It also serves as the main PDS co-ordination unit
(2) a local operation plot (LOP) display which is a 16-inch plan position indicator with its own tracking and display processors. The LOP will display raw radar video and IFF video as well as synthetic video such as target symbols, measurement vectors, alpha-numeric characters, small maps and index lines
(3) a general operational plot (GOP) display consisting of a high resolution 19-inch raster scan colour monitor and a graphic processor which compiles and controls the picture complete with maps, tracks, plots, target vectors, target symbols and measurement vectors
(4) a system terminal forming the operator's interface and consisting of a keyboard with a high precision trackerball and dual alpha-numeric displays. Each display provides 12 lines of 40 alpha-numeric characters. One display is used for PDS command menus, the other for own ship data, track information, pointer position and measurement vector information, as well as for high priority messages
(5) peripheral equipment which includes a dual tape station for instant dumping of the GOP picture, a printer and a graphic colour printer.

STATUS

In production and sold to a number of NATO and non-NATO countries for installation on small and medium naval and surveillance vessels.

CONTRACTOR



Terma Elektronik AS, Hovmarken 4, 8520 Lystrup, Denmark.

FRANCE

1894.253
DRBC 32 NAVAL RADAR

The DRBC 32 designation embraces a family of I/J-band fire control radars, of which there are at least five variants (denoted by suffix letters running from A to E) in use in French Navy ships, and which are associated with a variety of director units. The latter may or may not include optical direction facilities. Weapons associated with these directors normally are either 100 mm or 57 mm guns.

A stabilised mount is usual for DRBC 32 installations and, in all but the DRBC 32 A the radar dish is protected by a radome attached to the antenna assembly itself. The 'A' model, as seen on the helicopter-cruiser, *Jeanne d'Arc*, has exposed circular reflector and feed assemblies. However, the DRBC 32 A as seen on anti-submarine 'T 47' class escorts do have a protective radome for the antenna. The *Aconit* anti-submarine corvette is fitted with the DRBC 32 B. The 'C 70' class corvettes, the *Colbert* and the *Duperré* have the DRBC 32 C, and the DRBC 32 D installation is aboard the 'F 67' class frigates. The 'A 69' class of Avisos are fitted with the DRBC 32 E.

DRBC 32 D fire control radar

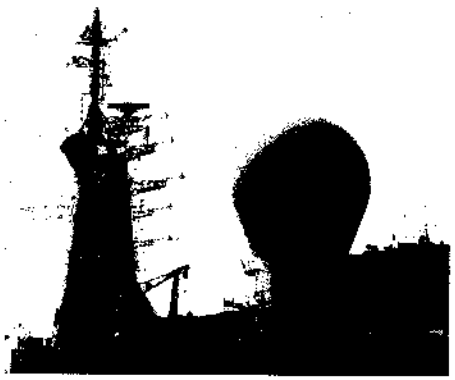
5843.253
DRBC 33 NAVAL RADAR

The DRBC 33 is a fully coherent monopulse tracking and fire-control I-band radar which is in current operational service with the French Navy. The weapon associated with this equipment is the 100 mm gun, although the system can also be used with both 76 mm and 57 mm weapons.

The DRBC 33 will be fitted to the new French Navy air defence corvettes, and the last anti-submarine corvette. It is also intended to be refitted to the *Suffren* and *Duquesne* missile frigates.

STATUS
In operational service with the French Navy.
CONTRACTOR
Thomson-CSF, Division Systèmes, Defénse et Contrôle, 40 rue Grange Dame Rose - BP 34, 92360 Meudon-la-Foret, France.

1593.253
DRBI 10 3-D NAVAL RADAR



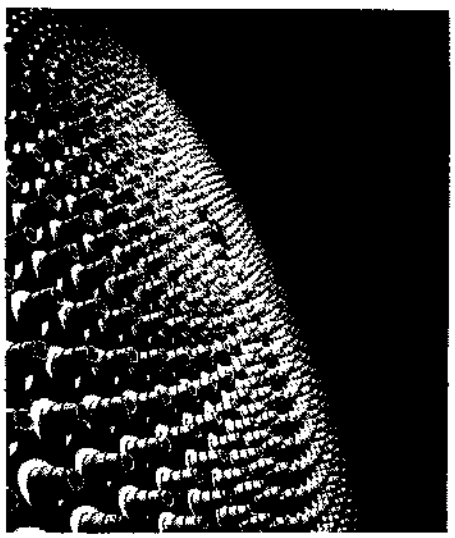
The DRBI 10 is a three-dimensional, E/F-band naval air surveillance radar for search and interceptor control functions. It is believed to be a naval version of the land-mobile radar Picador (TH.D 2200) (**2119.153**), which in turn evolved from the TH.D 1940.

More detailed information is given under this entry number in *Jane's Weapon Systems 1982-83*.
STATUS
The only known fittings are aboard French vessels. These include the aircraft carriers *Clémenceau* and *Foch*, which each have two; the helicopter carrier *Jeanne d'Arc*; the guided missile cruiser *Colbert* and the trials ship *Ile d'Oléron*.
CONTRACTOR
Thomson-CSF, Division Systèmes, Défense et Contrôle, 40 rue Grange Dame Rose - BP 34, 92360 Meudon-la-Foret, France.

1889.253
DRBI 23 3-D NAVAL RADAR

The DRBI 23 naval radar is a D-band (23 cm) three-dimensional air search and target designation radar forming the main detection element of the French Navy Masurca surface-to-air missile system (**1177.231**). Transmitter peak power is quoted as several MW, and it incorporates a carcinotron oscillator. Six amplification stages are provided, these being capable of virtually identical gain at any frequency within the range of the carcinotron oscillator.

The antenna, which is protected by a large radome, is of the inverse cassegrain type. An array of feed horns directs radiation to a semi-reflective parabolic mirror which in turn returns the energy to a flat plate reflector. This imparts a 45° polarisation change which permits the formed beams to pass through the semi-reflector. Vertical angular information is obtained by the use of monopulse techniques, these data being processed to provide corrected height information on aircraft targets. This information, together with plan position data, is available for use in the ship's action data system and weapon systems. Stabilisation against ship's motion is incorporated, and the antenna assembly includes an IFF antenna unit. The system provides for auto plot extraction and the DRBI 23 is interfaced with a digital computer. Associated with it are the Masurca missile tracking and guidance radar groups DRBR 51.
STATUS
In service with the French Navy missile frigates *Suffren* and *Duquesne*.
CONTRACTOR
Thomson-CSF, Division Systèmes, Défense et Contrôle, 40 rue Grange Dame Rose - BP 34, 92360 Meudon-la-Foret, France.



DRBI 23 radome on the Suffren (Stefan Terzibaschitsch)

3741.253
DRBJ 11 NAVAL RADAR

The DRBJ 11 is a new shipboard electronic phase scanned radar being developed by Thomson-CSF for the French Navy. Few technical details have been released for publication, but some indications can be gathered from the company's previous extensive work in this area of radar technology, and from a picture of the experimental antenna unit of the new radar. From the latter it will be seen that the array is composed of numerous separate radiating elements arranged concentrically on a disc surface. The active elements are connected in lines to be fed; in-situ computers determine their phases.

Thomson-CSF has revealed a preference for the use of diode phase-shifters for beam steering in electronically scanned arrays, and in this technique each source element (or reflector) has an associated module which offers the microwaves several alternative paths corresponding to different propagation times. Diodes controlled by DC voltages perform the switching needed to select required phase shifts. In addition, each source contains its own control logic which receives instructions from the beam steering computer circuitry. From the photograph, the individual elements appear to consist of spirals, supported by ceramic bases, but in the absence of anything from which to obtain an indication of scale it is not possible to deduce the likely frequency employed with any certainty.
STATUS
The system is being operationally tested and will be fitted to the 'C70' anti-aircraft destroyer class.
CONTRACTOR
Thomson-CSF, Division Systèmes, Défense et Contrôle, 40 rue Grange Dame Rose - BP 34, 92360 Meudon-la-Foret, France.

1890.253
DRBR 51 NAVAL RADAR

The DRBR 51 radar group provides for the tracking and missile guidance functions of the French Navy's Masurca surface-to-air missile system (**1177.231**). Search and target designation facilities are provided by the DRBI 23 three-dimensional air search radar (**1889.253**). The DRBR 51 is a multi-mode equipment and associated with the antenna assembly is a TV camera for optical tracking of low-flying targets. The complete system provides for the control of the Masurca missile.

Command signals are transmitted at frequencies in the 7 cm-band, and two missiles may be simultaneously controlled. There are two 5 cm radar tracking channels, 'blue' and 'yellow', one for each missile, and each radio command Masurca round is equipped with a 5 cm transponder to facilitate missile tracking.

When firing the Mk 2 Mod 3 radar homing version of Masurca, the main dish of the DRBR 51 operates as target tracker and I-band illuminator.
STATUS
The missile cruiser, *Colbert*, and the two missile frigates, *Suffren* and *Duquesne*, each have two DRBR 51 systems.
CONTRACTOR
Thomson-CSF, Division Systèmes, Défense et Contrôle, 40 rue Grange Dame Rose - BP 34, 92360 Meudon-la-Foret, France.

DRBR 51 radar group on the Suffren (Stefan Terzibaschitsch)

1893.253
DRBV 13 NAVAL RADAR

The DRBV 13 naval radar is pulse doppler equipment, believed to operate in the E/F band. It is stated to be a multi-mode radar providing both search and tracking facilities for the SENIT action data automation system installed in the *Aconit* anti-submarine corvette, which is the only vessel known to be fitted with the DRBV 13. The antenna array and turning gear are completely enclosed by a large plastic radome, itself mounted atop a prominent structure which is presumed to house the associated electronics, in an almost amidships location. No technical or performance data have been obtained.

1892.253
DRBV 20 NAVAL RADAR

The DRBV 20 is a long-range search radar operating in the metric waveband. Two antenna outfits are employed. The smaller, DRBV 20 A, version is installed in a variety of French Navy vessels and can be identified by its large open lattice antenna, of rectangular outline, slightly curved, and with a horizontal array of dipole feed elements. The larger, DRBV 20 C, is fitted on French aircraft carriers and has a flat, rectangular antenna array comprising three horizontal rows of dipole feed elements. No performance or other details of technical characteristics have been obtained.

STATUS

The DRBV 20 A is installed in the Tartar-armed 'T 47' escorts. The DRBV 20 C is fitted in the aircraft carriers *Clémenceau* and *Foch* and on the missile cruiser *Colbert*.

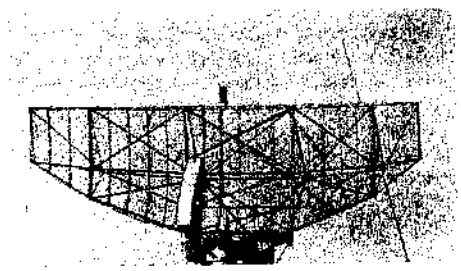
CONTRACTOR

Thomson-CSF, Division Systèmes, Défense et Contrôle, 40 rue Grange Dame Rose - BP 34, 92360 Meudon-la-Foret, France.

1891.253
DRBV 22 NAVAL RADAR

The DRBV 22 is a conventional naval search radar, having a L-band operating frequency and possibly incorporating dual-beam (high- and low-cover) facilities in some cases. It is widely fitted, both in French Navy vessels and in the ships of other countries. Different versions that have been identified are the DRBV 22 'A', 'C' and 'D' models.

The antenna assembly is very similar in appearance to the American SPS-6 and SPS-12 radars (**1744.253** and **1566.253**, respectively) but the French equipment can be readily distinguished from both US radars by the two supporting stays for the feed horn that are attached to the upper edge of the reflector of the DRBV radar.



STATUS

Known fittings in French Navy vessels include:
DRBV 22 A: five 'T 47' anti-submarine escorts; nine 'A 69' Aviso escorts; and the 'C 65' corvette *Aconit*.
DRBV 22 C: the trials ship *Ile d'Oléron*
DRBV 22 D: the helicopter-cruiser *Jeanne d'Arc*; the missile tracker ship *Henri Poincaré*.

Ships of several other nations have been fitted with the DRBV 22, in most, if not all, cases the 'A' version.

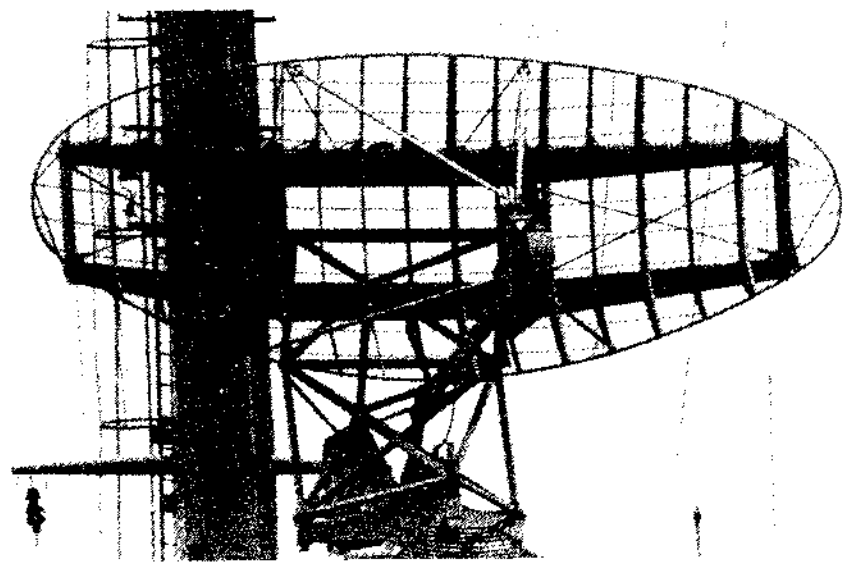
CONTRACTOR

Thomson-CSF, Division Systèmes, Défense et Contrôle, 40 rue Grange Dame Rose - BP 34, 92360 Meudon-la-Foret, France.

DRBV 22 A radar antenna on Aconit (X Taibo)

1594.253
DRBV 23 NAVAL SURVEILLANCE RADAR

The DRBV 23 is a L-band (23 cm) long-range naval air search and surveillance radar, similar in appearance to the Jupiter naval radar (**1236.253**). The most readily discerned external difference is the prominent tubular horizontal supports for the DRBV 23 scanner, compared with the lighter structure of the Jupiter.



Two versions have been identified, the DRBV 23 B and DRBV 23 C, the former being that fitted in aircraft carriers of the French Navy, and the latter being a solid-state version fitted in the missile cruiser *Colbert*.

STATUS

The only known fittings are on the following French Navy ships: the aircraft carriers *Clémonceau* and *Foch*, the missile cruiser *Colbert* and the command cruiser *De Grasse*.

CONTRACTOR

Thomson-CSF, Division Systèmes, Défense et Contrôle, 40 rue Grange Dame Rose - BP 34, 92360 Meudon-la-Foret, France.

DRBV 23 L-band air surveillance radar

1062.253
TRITON II SURVEILLANCE RADAR
TRS 3030/TRS 3035

This is a C-band, 5 cm, air and surface surveillance radar for shipboard mounting, and is used for surveillance and target designation functions in the Thomson-CSF Thomsea naval combat systems (**4572.281**). In these systems, Triton can be used for target designation to the fire control units (Castor or Pollux), and with a TWS for surface-to-surface missiles and/or torpedo launching. It may also be used alone as a surveillance and navigation radar. Triton is produced in an MTI version (TRS 3035).

More detailed information is given under this entry number in *Jane's Weapon Systems 1982-83*.

STATUS

The Triton radar is in production for use in systems being supplied to French and other navies.

CONTRACTOR

Thomson-CSF, Division Systèmes, Défense et Contrôle, 40 rue Grange Dame Rose - BP 34, 92360 Meudon-la-Foret, France.

Triton naval surveillance radar

3685.253
TRITON C DOPPLER SURVEILLANCE RADAR
TRS 3050

TRS 3050 is designed for ships of 150 tons upwards to perform air and surface surveillance, low altitude missile detection, target designation to weapon systems, and emergency navigation under adverse conditions. It is suitable for either original fitting in new ships, or for use during refits.

It is a C-band radar, fully coherent synthesiser driven, with two receiver channels:

(1) air with digital doppler processing, burst-to-burst frequency agility, automatic tracking and initialisation of targets
(2) surface, with pulse compression, pulse-to-pulse frequency agility, and advanced anti-clutter and anti-jamming processing.

As the adjacent photograph shows, Triton C employs the normal radar reflector of the Triton series of radars but can be fitted with a new antenna allowing detection of modern threats such as diving and sea-skimming missiles. Most of the operational advantages are apparently the result of advances in transmitter/receiver and processor design and/or the antenna feed arrangements.

CHARACTERISTICS

Frequency: C-band

Max detection range: 30 km (Pd = 0·5, 2 m² aircraft target, doppler operation) or 60 km
SCV: At least 45 dB
First blind speed: Over 800 m/s
Antenna gain: At least 27·5 dB
Elevation pattern: 22°

STATUS
No details of development state or sales of the Triton C have been released for publication.
CONTRACTOR
Thomson-CSF, Division Systèmes, Défense et Contrôle, 40 rue Grange Dame Rose – BP 34, 92360 Meudon-la-Foret, France.

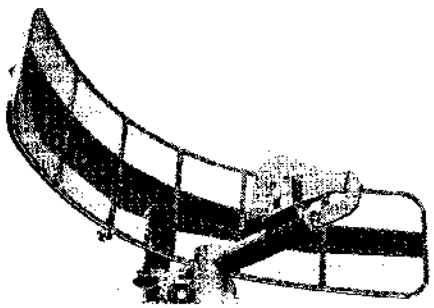
Triton C radar antenna

5844.253
TRITON G NAVAL RADAR TRS 3050

Triton G is a C-band medium range combined air and surface surveillance radar with a lightweight antenna system for high installation on the mast.

It features pulse compression, while the radiation pattern, frequency agile transmitter and doppler filter receiver are designed to provide accurate detection of targets at very low altitude in high clutter and/or jamming conditions.

CHARACTERISTICS
Frequency: C-band
Detection range: Greater than 28 km on a 2 m² fluctuating target
Clutter improvement factor: 40 dB
Antenna
Rotation speed: 40 rpm
Aperture: 2°
Gain: 28 dB
Transmitter: Coherent with TWT
CONTRACTOR
Thomson-CSF, Division Systèmes, Défense et Contrôle, 40 rue Grange Dame Rose – BP 34, 92360 Meudon-la-Foret, France.



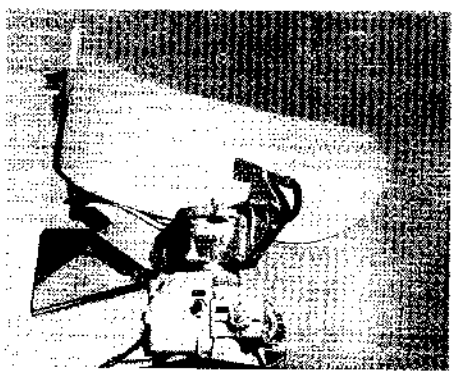
3254.253
TRITON S SURVEILLANCE RADAR TRS 3033

Triton S is an S-band air and surface surveillance radar for shipboard mounting, used for surveillance and target designation functions in the Thomson-CSF Vega II series of ships' fire control systems.

Specially developed for detection of small air targets (aircraft and missiles) in a heavy clutter environment, Triton S is a fully coherent, digital processing, pulse doppler radar which includes an independent pulse compression, frequency-agile receiver for detection of surface targets.

The antenna is of the non-stabilised type with a broad elevation lobe to counteract the effects of ship motion. The transmitter comprises a TWT and the average power is quoted as 250 W. The radar provides two video signals; an air surveillance video and a surface video, which can be used for display, target designation and track while scan processing.

CHARACTERISTICS
Frequency: S-band - frequency agile
Average power: 250 W
Two receivers: Pulse doppler (processed range 1·5 – 26·5 km); pulse compression
Antenna rotation: 24 rpm
Detection range: Air target (fighter), 33 km; surface target, radar horizon
SCV: At least 50 dB
STATUS
In production. Ordered by Nigeria, Tunisia and other navies.
CONTRACTOR
Thomson-CSF, Division Systèmes, Défense et Contrôle, 40 rue Grange Dame Rose – BP 34, 92360 Meudon-la-Foret, France.



Triton S radar antenna

3481.253
TRITON X NAVAL RADAR TRS 3040

This is an X-band air and surface surveillance radar for shipboard mounting, used for navigation, surveillance and target designation functions in the Thomson-CSF Vega-Canopus series of ships' fire control units (Pollux or Optronic directors) and with a TWS for surface-to-surface missiles and/or torpedo launching.

CHARACTERISTICS
Frequency: 300 MHz in X-band
Peak power: 200 kW with 0·3 μs pulse
PRF: 1500 Hz
Noise ratio: 9 dB

Antenna
Dimensions: 2·3 × 1·4 m
Weight: 175 kg
Azimuth beamwidth (3 dB): 1·2°
Rotation: 24 rpm
Transmitter/receiver: 1 × 0·6 × 0·4 m; weight 80 kg
Detection range: Air target (fighter), 20 km; surface target, radar horizon
STATUS
In production for foreign navies.
CONTRACTOR
Thomson-CSF, Division Systèmes, Défense et Contrôle, 40 rue Grange Dame Rose – BP 34, 92360 Meudon-la-Foret, France.

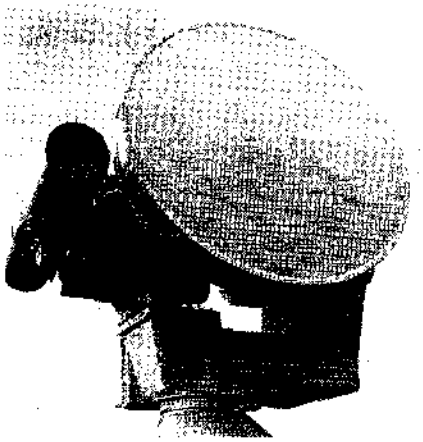
Triton X antenna

1063.253
CASTOR II FIRE CONTROL RADARS

Three versions of Castor II are available, Castor IIB, Castor IIC and Castor IIJ. All versions are compact, lightweight and suitable for installation on both small and large vessels.

Castor IIB is an X-band monopulse and MTI tracking radar for weapons control. The radar is managed by a microprocessor which ensures high performance, even in severe environmental conditions against low altitude targets and jamming, by the use of monopulse techniques, broadband operation, high efficiency anti-clutter filters and an integrated TV tracker.

Operationally Castor IIB performs the following functions:
(1) fully automatic acquisition enabling very short reaction times
(2) accurate tracking of targets in the radar mode, TV mode and a combined radar/TV mode
(3) passive tracking of a jammer with range information sent from a tracking device linked to a surveillance radar
(4) display of splashes in the case of anti-surface firing
(5) autonomous surveillance, continuous and by sector, with set absolute elevation.



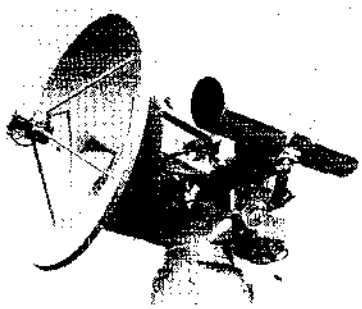
Castor IIC is an X-band doppler filtering tracking radar for weapons control which is able to acquire and track targets in conditions of active jamming, chaff and heavy clutter. The high performance of the system is achieved by the use of fully coherent transmission, frequency agility, analysis of received jamming signals within all the useful bandwidth, auto-adaptive doppler filtering and central management by computer which matches the radar to the environmental conditions at all times.

Operationally Castor IIC provides:
(1) fully automatic acquisition enabling very short reaction times
(2) short bursts operation (1·5 ms) with simultaneous frequency agility and doppler processing
(3) pulse-to-pulse operation giving true frequency agility
(4) TV tracking or combined TV/radar tracking
(5) passive tracking of a jammer with range information sent from a tracking device linked to a surveillance radar
(6) display of the angular error between the shells and the target
(7) display of the angular tracking error on a jammer
(8) autonomous surveillance, continuous and by sector.

Castor IIJ is a radar TV/IR director which forms the basis of an all-weather anti-missile system (see entry **4572.281**). It has been specifically designed for accurate tracking in a high clutter and jamming environment, even against very low altitude targets.

Operationally Castor IIJ provides
(1) fully automatic acquisition enabling very short reaction times
(2) frequency agility and doppler processing
(3) complementary TV or IR tracking
(4) passive tracking of a jammer with range information provided by a tracking device linked to a surveillance radar
(5) autonomous surveillance, continuous and by sector.

CHARACTERISTICS
Castor IIB and IIC
Frequency: X-band
Peak power: More than 30 kW
Range: 0 - 30 km
Acquisition mode: Fully automatic
Dimensions
Antenna: 1 m diameter
Transmitter: 1 × 0·6 × 0·42 m
Receiver and servo: 1·92 × 0·6 × 0·75 m
Weight: 620 kg
Castor IIJ
Frequency: Ku band for tracking; X-band for illumination channel
Range: More than 25 km
Acquisition mode: Fully automatic
Tracking accuracy: 0·8 mrad (20 m)
Dimensions
Antenna: 2 × 1 m
Transmitter: 1·2 × 1·4 × 0·75 m
Receiver and Servo: 1·2 × 11·8 × 0·75 m
System weight: 850 kg
STATUS
In production. Supplied to a number of foreign navies.
CONTRACTOR
Thomson-CSF, Division Systèmes, Défense et Contrôle, 40 rue Grange Dame Rose – BP 34, 92360 Meudon-la-Foret, France.



Castor IIC tracker radar head

1064.253
POLLUX TRACKER RADAR TRS 3220

This is a shipborne tracker radar used in the Thomson-CSF Vega series of naval fire control systems and usually operated in conjunction with a Triton 5 cm surveillance and target designation radar. It is mainly for gun control operations.

The Pollux radar operates on a frequency in the X-band, 3 cm region, and is a fast conical scan tracker radar. Circular polarisation and solid-state circuitry, using silicon semi-conductors, are employed, and peak transmitter power is quoted as 200 kW. Range finding capability extends to 30 km, and target acquisition is stated to remain reliable to 20 km under the most adverse weather conditions.

CHARACTERISTICS
Frequency: X-band
Circular polarisation
Peak power: 200 kW
Rangefinder: 0 - 30 km
Precision
Range: 20 m
Azimuth: 0·5 mrd
Display: Type A/R, A/B or A/E
TV tracking: Optional
Dimensions and weight
Antenna: 450 kg
Transmitter and servo cabinet: 1850 × 600 × 600 mm
Receiver cabinet: 1850 × 600 × 600 mm
Fire control console: 1850 × 600 × 600 mm (computer included)
STATUS
Details of users have not been revealed but contracts for Vega fire control systems have been placed by both French and foreign navies. Known fittings include four Portuguese corvettes of the 'João Roby' class and West German, Greek, and Malaysian fast missile patrol boats. No longer in production.

Pollux tracking radar, with opto-electronic sensor

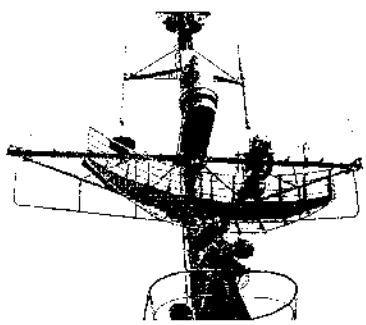
1687.253
SEA TIGER II SURVEILLANCE RADAR TRS 3001



Sea Tiger II is a shipborne S-band combined surveillance radar, which can be used in the Thomson-CSF Thomsea naval combat systems. It has been developed to provide detection and tracking of missiles, including sea-skimming anti-ship weapons. By virtue of modular design and operating flexibility, Sea Tiger II can be supplied with either of two antenna types, thus allowing fitting aboard medium or large tonnage ships, or small fast patrol boats. It is designed to perform the following functions in a very severe clutter and jamming environment.

(1) air surveillance
(2) surface surveillance
(3) anti-missile surveillance
(4) target designation for weapon systems (guns; missiles)

Visibility in clutter is achieved through the use of complementary techniques such as circular polarisation, pulse compression, doppler filtering, and an anti-clutter reception chain.

A typical Sea Tiger II installation comprises:

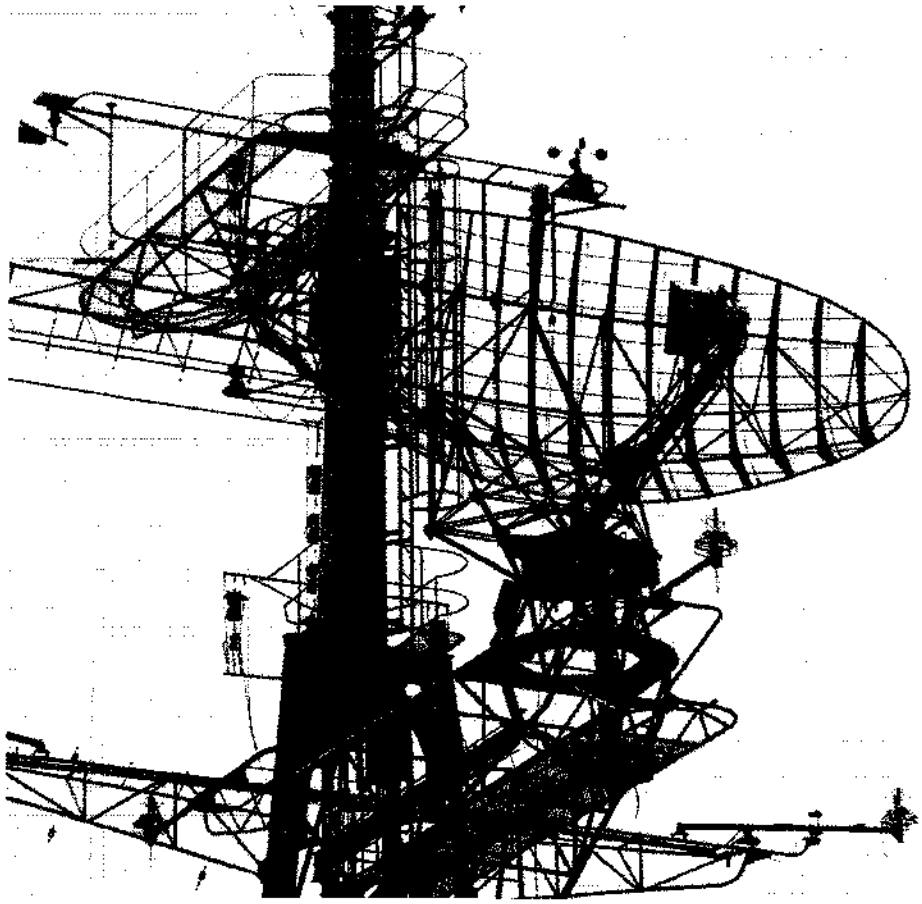
(1) a transmitter with coherent amplifier chain emitting frequency-modulated pulses (pulse compression) over a wide frequency range
(2) a receiver with multiple reception chains: MTI, in/log, CFAR. The MTI is a digital linear device whose characteristics, associated with the stability of the amplifier chain, make it possible to detect a missile in the most severe clutter environment
(3) an antenna appropriate to the class of ship, either:
(A) stabilised double-curvature antenna with switchable circular/linear polariser and integrated IFF for medium tonnage ships and above
(B) non-stabilised lightweight antenna with a broad elevation lobe to counteract the effects of ship's motion (FPBs).

Sea Tiger stabilised radar antenna head

CHARACTERISTICS
Operational performance
Detection range: 60 nm on 2 m² (fluctuation) target with Pc = 50%
Altitude detection: 50 000 ft (15 240 m)
Elevation pattern: Cosecant up to 50°
Sub-clutter visibility: >42 dB
First blind speed: Mach 2
Antenna
Gain: 30 dB
Polarisation: Circular/linear, switchable
Rotation speed: 15 and 30 rpm
Stabilisation: Better than ± 1·5%
Transmitter: Frequency agility, pulse compression, average power 1 kW, 66 kW peak
Receiver: Noise figure better than 5·5 dB, 4 different reception chains - MTI, in, log, CFAR anti-clutter
STATUS
Derived from the Tiger radar (**2156.153**). In production. Ordered by the French Navy (DRBV 15), installed in Colbert and F1500 frigates built in West Germany, and the Saudi Arabian F 2000 frigates.
CONTRACTOR
Thomson-CSF, Division Systèmes, Défense et Contrôle, 40 rue Grange Dame Rose – BP 34, 92360 Meudon-la-Foret, France.

1236.253
JUPITER NAVAL AIR SURVEILLANCE RADAR TRS 3010

The Jupiter is a L-band (23 cm), long-range air surveillance radar with a peak transmitter output power of 2 MW with a 2·5 microsecond pulse and a PRF of 450 pulses/second. The antenna measures 7·5 × 3 m and has two rotation speeds: 7·5 and 15 rpm. Weight is approximately 1000 kg. Both primary and secondary (IFF) radar functions are provided by the one antenna system. Beamwidth at half power points of the primary radar pattern is 2·5° or less. The elevation pattern is cosecant² up to 50°.



Range performance figures quoted give detection out to at least 200 km on a fluctuating target of two m² cross-section with a detection probability of 50 per cent, and under the same conditions a target with ten metres cross-section can be observed out to 275 km.

Solid-state circuitry is used throughout, with the exception of the microwave stages, and a fixed-frequency, water-cooled magnetron is used in the transmitter. Comprehensive signal processing facilities are incorporated to provide maximum protection from natural interference (such as sea clutter) and ECM.

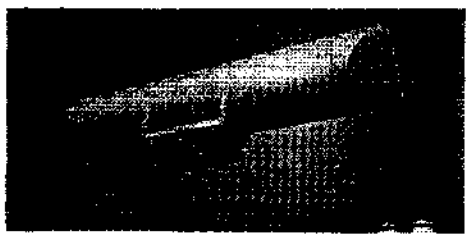
The receiver section provides multiple reception chains, wide dynamic range receiver and anti-clutter circuits for surface surveillance and detection of low-speed targets. Jupiter is produced in both non-MTI and MTI versions. The latter is equipped with a linear digital MTI receiver for operation in clutter environment.

STATUS
The Jupiter is in use with medium and large vessels of the French Navy, as the DRBV 26 with different antenna, and on South African frigates. A solid-state transmitter version is in late development for the French Navy (DRBV 27).

CONTRACTOR
Thomson-CSF, Division Systèmes, Défense et Contrôle, 40 rue Grange Dame Rose - BP 34, 92360 Meudon-la-Foret, France.

Jupiter long-range surveillance radar antenna

5845.253
TRISKEL MULTI-FUNCTION NAVAL RADAR



Triskel is a multi-function naval C-band radar employing a phased-frequency planar array which is being developed by Thompson-CSF. No technical details have been released, although it is believed that the system is being designed around the specification for the radar requirements of the future NATO frigate (NFR90). The system is understood to be compatible with the illuminating radars of a number of shipborne area defence missiles.

STATUS
In early design stage and will probably be one of several candidates for the proposed NATO frigate.

CONTRACTOR
Thomson-CSF, Division Systèmes, Défense et Contrôle, 40 rue Grange Dame Rose - BP 34, 92360 Meudon-la-Foret, France.

3255.253
IFF INTERROGATOR ANTENNA 3973-A

The type 3973-A antenna is designed for transmission and reception of IFF signals. The antenna has a double radiation pattern to prevent identification of transponders outside the main lobe direction (side lobe suppression). It consists essentially of a radiation plane to which networks are supplied, via a distributor, either on phase conjunction for a directional pattern (sum pattern for transmission of interrogation pulses), or on phase opposition for a non-directional pattern (difference pattern for transmission of ISLS pulses). Part of the signal difference is directed towards a rear dipole which provides additional cover needed to complete the rear lobe of the difference pattern.

IFF radar antenna 3973-A

The antenna mounting attachment is designed for assembly to various radar antenna structures or to a pedestal.

CHARACTERISTICS
Frequency: 1030 and 1090 MHz
Power: 3 kW peak for 1% duty cycle
Input impedance: 50Ω
Beamwidth: Horizontal pattern 10° for sum channel; 30° for difference channel; vertical pattern 40° for sum and difference
Dimensions: 2 × 0·36 × 0·355 m
Weight: 20 kg

STATUS
In production.

LMT Radio Professionnelle, 46-47 quai Alphonse Le Gallo, 92103 Boulogne-Billancourt, France.

1933.453
CALYPSO III SUBMARINE RADAR TRS 3100

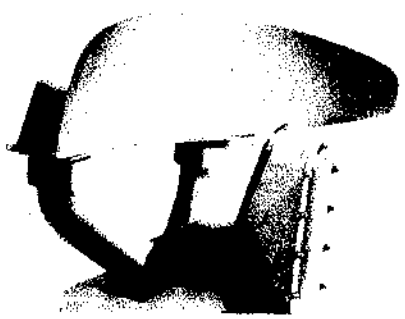
Calypso III is a higher performance radar than Calypso II (**1240.453** in 1979-80 and earlier editions), but with the same general characteristics and same functions (navigation, surveillance, target designation) with a greater detection range and the additional capability of accurate range measurement. It is also of compact design and well fitted to the severe environment characteristics of a submarine.

Calypso III results from the joint studies of a submarine mast specialist (IKL - Ingenieur Kontor Lubeck) and a radar specialist (Thomson-CSF).

Its main features are as follows.

The periscope mast does not rotate, the antenna rotation being achieved by a pressure-tight drive mechanism fitted at the top of the mast. The upper part of the mast is streamlined. The transmitter/receiver is integral with the mast, which allows:

(1) simpler connection and reduced RF losses between T/R and antenna
(2) simpler connection with the fixed part of equipment (flexible cables).



Calypso III comprises four main parts: an antenna (the Calypso II antenna); a non-rotating periscopic mast (hoisting is achieved using the ship's hydraulic system pressure); a transmitter/receiver cabinet (secured at the foot of the mast); and an operational console.

The transmitter is a conventional magnetron transmitter with a frequency adjustable magnetron and the same I/J-band transmitter as Calypso II is employed. The receiver is fitted with RF elements of long service life, a modern mixer and a logarithmic anti-clutter chain. The operational console comprises: the control panel for radar and antenna; the display (16 inch (406 mm) CRT) with an accurate digital rangefinding device; and an operational panel. The optical-periscope direction and the ESM and sonar data can be displayed on the PPI. The accurate range measurement of a detected target can be made during short-time transmission.

The detection range capability of Calypso III for a typical ASW aircraft at 2500 metres altitude is 18 nautical miles, and for a surface vessel depends on the radar horizon.

STATUS

In production and supplied to three foreign navies.

Scanner of the TH.D 1030 Calypso II submarine radar. Span is 1 metre

The earlier Calypso II radar was supplied to at least 13 foreign navies.

CONTRACTOR

Thomson-CSF, Division Systèmes, Défense et Contrôle, 40 rue Grange Dame Rose - BP 34, 92360 Meudon-la-Foret, France.

3684.453
CALYPSO IV SUBMARINE RADAR TRS 3110

The TRS 3110 Calypso IV radar is an I/J-band equipment designed to provide surveillance and navigation facilities for submarines. It is comprised of three units: an antenna, a transmitter/receiver cabinet and an operating console. Antenna and operating console are similar to Calypso III. To fulfil its functions, the Calypso IV is built around a simple navigation radar equipment, and modular design enables it to carry out additional functions merely by the addition of appropriate functional circuit cards, without changing the basic equipment.

Using a 1 ms pulse, it has a good detection range, limited only by the radar horizon (at least 10 nautical miles in free space), and using the narrow (50 ns) pulse, it has very high resolution over shorter detection ranges (down to about 15 metres). The receiver design has been developed to give good capabilities and performance in the presence of clutter.

The transmitter is a 25 kW (peak) klystron-driven unit providing several transmission options (continuous, sectoral, burst, or receive only - radar silence) giving maximum operational flexibility to meet specific requirements. The overall radar transmission parameters have been chosen to enhance the submarine's security by arranging for them to be similar to those of merchant ship radars, frequency and pulse length, in particular.

The operating console and its data processor permit the presentation, in either raw radar or synthetic form, of information such as target echoes, range and bearing labels, transmission sectors etc, as well as providing for operational control of the radar equipment itself.

STATUS

Development of the TRS 3110 Calypso IV was carried out by Thomson-CSF in 1978, and the first production deliveries were made in 1980 for various foreign navies.

CONTRACTOR

Thomson-CSF, Division Systèmes, Défense et Contrôle, 40 rue Grange Dame Rose - BP 34, 92360 Meudon-la-Foret, France.

INTERNATIONAL

3312.253
Mk95 MOD 0 RADAR SET

This radar set provides search, acquisition, tracking and illumination for the NATO Sea Sparrow point defence missile system Mk57 developed by Denmark, Italy, Norway and the USA (**2770.231** in 1983-84 and earlier editions). As such, the radar forms part of the Mk91 guided missile fire control system; Mk91 Mod 0 has a single director group, and the Mk91 Mod 1 has dual directors. Each radar has separate antennas for transmission and reception, the dishes of which are protected by radome covers. The radar receiver is carried on the antenna unit. The antennas share a common mounting on the Mk78 Mod 0 missile director. An on-mount TV camera is also provided.

Operation is probably in the I/J-band part of the spectrum.

The receiver is the responsibility of the Danish Radartronics Company, and this unit's functions include clutter filtering, ECM channel, signal conversion and amplification. The Mk83 Mod 0 radar set console has search and tracking displays, status and fault indicators, radar operating controls and built-in test equipment. Operating controls provide for such functions as scan pattern selection, ECM facility selection, check-out etc. The transmitter group Mk73 Mod 0 provides RF power for search acquisition, and tracking in air and surface modes, target illumination and modulation for the Sea Sparrow missile; a reference signal for missile tuning; local oscillator for the receiver; range reference for the radar target data processor which provides target detection, doppler tracking, range tracking and angle track signals; visual and aural indications to the radar set console; ECCM; and test functions.

DEVELOPMENT

Development was initially undertaken in the late 1960s by Raytheon, and subsequently on a joint basis by companies in four of the seven nations which form the NATO Sea Sparrow group. The four were Denmark, Italy, Norway and the USA.

STATUS

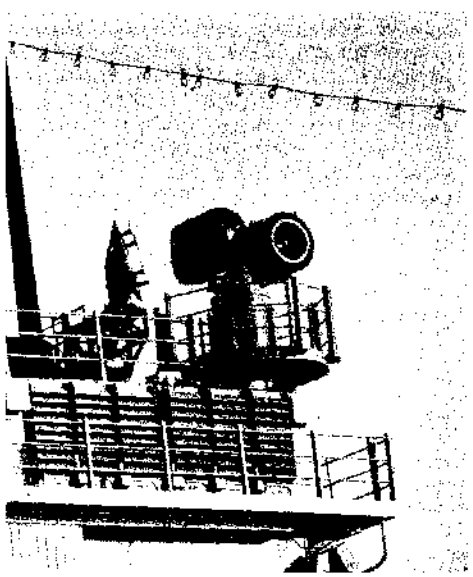
In production.

CONTRACTORS

Raytheon, USA - Main contractor.

MBLE Société Anonyme - Printed circuit boards.

Radartronics, Denmark - Radar receiver.



NEA-Lindpert, Denmark - Static frequency converter.

Selenia, Italy - Firing officers console.

Brownswerk-Amersfoort, Netherlands - Liquid cooler group.

ISRAEL

3709.253
EL/M-2221 NAVAL FIRE CONTROL RADAR

The Elta EL/M-2221 is an I/J-band monopulse tracking radar for naval fire control applications. Its operational roles include: surface and air search and acquisition; surface-to-surface missile fire control; surface-to-air missile fire control; gun fire control against surface targets; and gun fire control against air targets. Low weight and compact dimensions make it suitable for installation aboard ships of all sizes, including small patrol craft and missile boats. In addition to its ability to control the Israeli Gabriel anti-ship missile (**6019.221**), both active and semi-active homing missiles can be controlled.

Dvora fast missile boat uses Elta EL/M-2221 fire control radar to control Gabriel SSMs and guns

Target acquisition can be initiated by designation from a search radar, other sensors (eg optical, ESM etc), or can occur automatically within a given sector. In the tracking mode there is automatic lock-on, and the radar is TV/optical tracker compatible. In the search mode, the radar performs track-while-scan, and miss-evaluation and ranging facilities are available.

CHARACTERISTICS
Frequency: I/J-band
Antenna: Monopulse
Diameter: 1 m
Height: 1·5 m
Weight: 230 kg
Radar cabinet
Height: 1·2 m
Width: 70 cm
Depth: 50 cm
Weight: 120 kg

STATUS
Production and in service

CONTRACTOR
Elta Electronics Industries Ltd. (a subsidiary of Israel Aircraft Industries Ltd), Ashdod, Israel.

AUTOMATIC MISSILE DETECTION RADAR

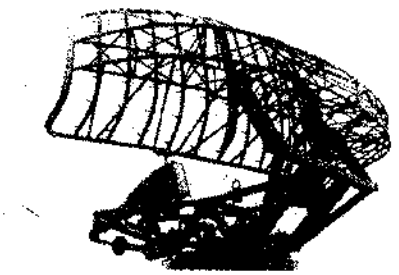
The Automatic Missile Detection Radar (AMDR) has been developed by Elta as a shipborne radar designed to automatically detect incoming sea skimming missiles in addition to normal air surveillance with automatic detection and TWS capability. It is designed for installation on ships from 450-tons upwards.

AMDR is a coherent pulse doppler radar operating in S-band to give fast alarm warning at ranges of over 30 km with a very high probability of detection. The system will detect and warn of an approaching 0·1 m² missile at 15 km with 90 per cent probability of detection. Velocity coverage is 0·3 to 3 Mach. The antenna is a lightweight, stabilised cosecant² unit with a total weight of 220 kg at the masthead. Coherent pulse doppler technique, combined with discrete Fourier transform doppler filtering processing and programmable data processing enable apriori filtering out of slow moving targets (below Mach 0·2) and target radial velocity measurement during a single antenna scan. Display options include a 16-inch PPI, digital scan converter colour TV display and an alpha-numeric tabulated data display.

The AMDR may be installed as a stand-alone system or added to the EL/M-2207, EL/M-2208, or other naval search radars.

CONTRACTOR
Elta Electronics Industries Ltd (a subsidiary of Israel Aircraft Industries Ltd), Ashdod, Israel.

3264.253
ELTA EL/M-2207 NAVAL RADAR



Elta Electronics Industries Ltd produces a number of military radars, details of most of which are classified. However some particulars have been released concerning the EL/M-2207 S-band general purpose naval radar, which is one of the EL/M-2200 range of shore and shipboard radars. The same basic transmitter/receiver unit (either singly or duplicated for diversity operation) is assumed to be used throughout the range, with differences in the antenna employed and the extent of additional facilities incorporated accounting for the main variations between models.

The EL/M-2207 is a medium power equipment offering high performance in both air and surface search roles. A lightweight stabilised antenna is used, the AT-101, which is claimed to require a reflector area only 66 per cent of that required by a conventionally designed antenna to achieve the same performance characteristics.

Operational roles include air early warning surface surveillance, target indication, and navigation. Other features are operator selection of transmitter pulse width, single knob frequency tuning, true motion display, and integrated IFF.

One or two IF-33 41 cm diameter PPI display consoles are normally fitted. Antenna polarisation is switchable linear/circular and there is remote control of antenna elevation angle.

CHARACTERISTICS
Transmitter
Peak power: 425 kW typical
Average power: 425 W typical
Frequency: 3·1 – 3·3 GHz tunable
PRF: 500 – 700 pps, long pulse; 1000 – 1500 pps short pulse
Pulse length: 1·4 or 0·4 μs
Receiver
Type: Linear, with switchable STC, FTC, IAGC, Log-FTC-A Log, CFAR
Noise: 2 dB
IF frequency: 60 MHz
IF bandwidth: 1·4 MHz, long pulse; 3 MHz, short pulse
Antenna
Polarisation: Vertical/circular
Gain: 28 dB (F-band); 17 dB (IFF)
Beamwidth (3 dB): 3·3° azimuth; 10° elevation, cosec² to 30°
Rotation rate: 12 or 24 rpm, selectable
Stabilisation: ±15°
Dimensions: 2·4 × 1 m (reflector)

AT-101 antenna used in EL/M-2207 naval radar system

Performance
Detection range: 55 km, against fighter aircraft size target
Resolution: <75 m, short pulse; <230 m, long pulse

STATUS
No details of ship fittings have been released for publication

CONTRACTOR

4610.253
EL/M-2208 SHIPBORNE SEARCH RADAR

The EL/M-2208 is another member of the EL/M-2200 family and is a dual band shipborne radar, with integral IFF, for simultaneous air and surface surveillance. Two transceivers (S- and X-band) use a common lightweight, small size antenna mounted at masthead. Full automatic stabilisation provides complete coverage even in adverse sea states.

Long pulse and DVTI are provided for long range and air surveillance functions. A navigation facility is included by selection of a short pulse. Either separate or combined S- and X-band presentation, plus IFF, can be selected on a 16 inch display.

CHARACTERISTICS
Antenna
Stabilisation: ±15°
Polarisation: Linear/circular
Detection range: 32 nm (59 km)
Resolution: 1° (azimuth); 50 m (range)

Technical specification	S-band	X-band
Frequency	3·1 – 3·3 GHz (tunable)	9·345 – 9·405 GHz (fixed)
Peak power	425 kW	25 kW
Pulse length	1·4 or 0·4 μs	0·25 μs
PRF	500 – 750 pps (long pulse) 1000 – 1500 pps (short pulse)	1000 – 1500 pps

CONTRACTOR
Elta Electronics Industries Ltd (a subsidiary of Israel Aircraft Industries Ltd), Ashdod, Israel.

AT-101A TRIPLE BAND SURVEILLANCE ANTENNA

The AT-101A surveillance antenna is a triple band unit used in a number of Elta shipborne and land mobile applications. It consists of an S band cosec antenna with a reflector area only ⅓ the size of a conventional unit, plus X- and L-band feeds which use the same reflector as the S-band. Switchable linear/circular polarisation is incorporated with remote control of antenna elevation angle. The shipborne version is fully stabilised.

CHARACTERISTICS

	S-Band	X-band	L-band
Frequency (MHz)	3100-3300	9345-9405	1030-1090
Gain	28 dB	34 dB	17 dB
Azimuth beamwidth	3°	1°	7°
Elevation beamwidth	10°	5°	20°
Polarisation	Vertical/ Circular	Horizontal	Vertical

Rotation rate: 12/24 rpm, remotely selectable
Stabilisation: ± 15°
Reflector dimensions: 2·4 × 1 m
Overall height: 1·75 m (including pedestal)
Weight: 245 kg

STATUS
In service

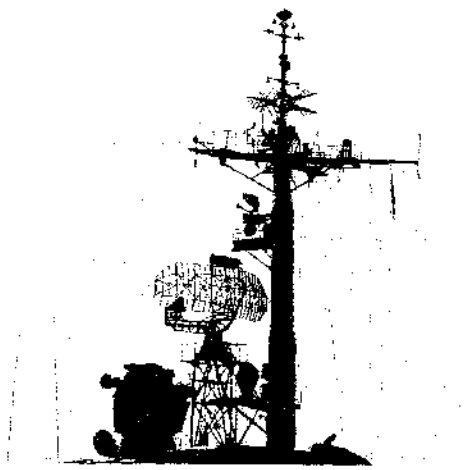
ITALY

1364.253
RAN-3L NAVAL RADAR (MM/SPS-768)

The Selenia RAN-3L (Italian Navy MM/SPS-768) is a long range, early warning radar, specifically designed for service in naval vessels in the frigate/destroyer/cruiser class.

The radar is of advanced design and provides air/surface warning and target identification for a modern shipborne defence system. A double curvature reflector with double channel IFF/radar feed is used. A new concept in radar design is the use of a composite coded waveform. This offers the following main advantages:

(1) ability to obtain great range accuracy and discrimination together with long range detection and a good overall reliability
(2) ability to maintain an adequate target visibility in the presence of either deliberate or natural interference, through the codification of information
(3) ability to take advantage of the diversified information contained in each packet of RF energy in order to extract the doppler components within a single repetition period. This provides the improved capability for cancelling clutter echoes while performing an RF agile transmission
(4) ability to ensure a CFAR condition and SCV in a clutter environment (also against clutter received through antenna sidelobes when the ship is underway).



Digital techniques are used extensively and applications of this include: transfer of functions, coping with weather and clutter returns, verifying false alarms, mode changeover etc. The RF generation and amplification process is entirely compatible because of a fully coherent transmitter/receiver chain. Therefore, changes in radar waveform, repetition interval, transmission frequency, pulse phase, and gain level are accomplished in real-time thereby giving greatly enhanced performance. A multi-pulse coded radiation in frequency agile operation is used in transmission. Code-matched filtering and pulse compression is performed in reception together with doppler discrimination to enhance echoes from genuine targets relative to noise or jamming.

CHARACTERISTICS
Frequency: D-band
Antenna: 3·6 × 7·6 m
Rotation: 6 rpm
Polarisation: Linear
Range: Approx 280 km
Range accuracy: 70 m
Angular accuracy: 0·4°
Outputs: Main video to air plots; normal video to surface plots; synthetic video to computer

DEVELOPMENT
Development was started in 1968 under Italian Navy contract.

STATUS
In current production, a number of systems are in service with the Italian Navy. An upgrade modification was developed in 1982 and is currently being introduced to achieve improved performance.

CONTRACTOR
Selenia-Elsag Consortium for Naval Systems, Via Panama, 52, 00198 Rome, Italy.

Antenna complex (large antenna on lattice structure) of the early warning search radar MM/SPS-768 (Selenia type RAN-3L) installed on board the Italian Navy cruiser Doria. *The same equipment is installed on* Veneto *and* Audace/Ardito, *and will be fitted on the* Garibaldi *and the new* DDGs

1699.253
RAN-10S NAVAL RADAR (MM/SPS-774)

The RAN-10S (Italian Navy designation, MM/SPS-774) is an advanced E/F-band coded radar for combined air and surface surveillance. The radar design philosophy is the same as that of the RAN-3L early warning radar (**1364.253**), and a number of items are common to both systems. Basic characteristics that the two radars share include:

(1) improved accuracy and resolution due to time compression of the radiated waveform
(2) excellent sub-clutter visibility in natural or deliberate interference
(3) clutter cancellation simultaneous with RF agility
(4) advanced CFAR under varying environmental conditions.

The antenna assembly is a pitch and roll stabilised reflector with double channel radar/IFF feed. The transmitter is medium powered coherent equipment, and the receiver incorporates a parametric amplifier, frequency programmer, quadrature IF channels, and digital processing.

The MM/SPS-774 is intended for fitting in vessels of medium tonnage such as corvettes, frigates, or fast destroyers. Typical operational roles include air warning, tactical air control, helicopter direction, surface surveillance, navigation, and anti-ship missile direction.

The radar is optimised for target designation to gun and/or missile weapon control systems and for interfacing with automatic or semi-automatic command and control systems. Use of a coded waveform and digital processing of returns gives excellent clutter and jamming rejection performance. Frequency agility operation is available.

CHARACTERISTICS
Frequency: E/F-band
Antenna: 3·2 × 4·5 m
Rotation: 15 and 30 rpm
Polarisation: Linear and circular
Range: Approx 75 km
Range accuracy: 20 m
Angular accuracy: 0·35°

STATUS
In current production on behalf of several navies, and various systems are in service in 'Lupo' and 'Maestrale' class frigates as well as in CNR 600-ton corvettes.

CONTRACTOR
Selenia-Elsag Consortium for Naval Systems, Via Panama, 52, 00198 Rome, Italy.

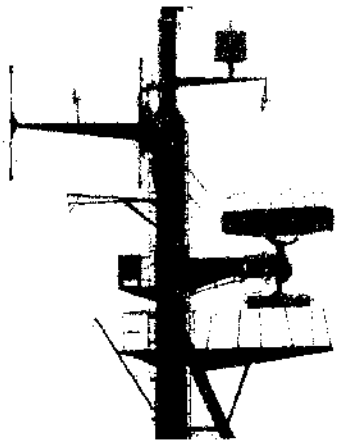
RAN-11 L/X AND RAN-12 L/X INTEGRATED NAVAL RADAR SYSTEM

The Selenia/SMA RAN-11 L/X and RAN-12 L/X are combined naval search radar systems for fitment to ships ranging from fast patrol boats to multi-purpose corvettes as the primary search radar, or on larger ships as complementary close range radar.

The system consists of two radar sets, one operating in D-band (formerly L-band) and the other in I band (formerly X-band), mutually synchronised and radiating through a common stabilised antenna. The antenna can also accommodate IFF. The D-band equipment is a pulse-doppler radar based on fully digitised techniques and utilising a coherent transmitter/receiver chain with final transistor power amplifier stage. The I-band equipment is a well proven, ruggedised system in the family of pulsed oscillator radars, employing a reliable magnetron as the power source and fitted with completely updated signal processing facilities.

The video signals from the two radars are comprehensively processed through an interface unit providing selectable output radar channels to feed the display system. The output channels comprise the I-band video for surface surveillance, the MTI video from the D band radar and the combined D/I-bands video for air surveillance.

The system can be supplied in the RAN-11 L/X basic configuration or RAN-12 L/X extended range configuration. The former employs the D-band transceiver RTM-11 L and uses an add-on solid-state power amplifier to provide a power output three times greater for the extended range version. The I band radar, as well as the antenna group, remains unchanged in both configurations.



STATUS

In production. Operational with the Royal Danish Navy 260-ton fast attack craft, and on the CNR 2400-ton frigates and CNR 600-ton corvettes.

CONTRACTORS

Selenia-Elsag Consortium for Naval Systems, Via Panama, 52, 00198 Rome, Italy.

SMA – Segnalamento Marittimo ed Aereo, Via del Ferrone Soffiano, PO Box 200, 50100 Florence, Italy.

1368.253
ORION RTN-10X NAVAL TRACKING RADAR

The Orion RTN-10X is a conical-scan pulse radar operating in the I/J-band. It has been especially developed for one man operation, and installation with gun or missile fire control systems in naval vessels. Specifically, the Orion is used in conjunction with Selenia equipment (see Albatros system) or with other equipment (El San Giorgio, Ferranti, Galileo etc). Operational range is about 40 km.

The antenna system consists of a slatted parabolic reflector and feed, with integral trunnion box, mounted on an elevation over train director. Elevation coverage is +90 to -30°. The trunnion box contains the feed drive motor for high-speed conical scanning, and the assembly which performs the target acquisition scanning mode. The unit is fitted to accept a CCTV camera and camera control unit.

Acquisition of a target is initiated by external designating input sources. The radar then switches to the acquisition phase and upon detection of the target, automatic tracking is started. As an alternative, the radar can perform an autonomous search programme, in this way further complementing the surveillance system with the low altitude detection capability inherent to the Orion equipment.

More detailed information is given under this entry number in *Jane's Weapon Systems 1982-83*.

DEVELOPMENT

The development of the Orion series started in the early 1960s on behalf of the Italian Navy. Significant improvement in technology and design has been successfully introduced into the original project. The last series, which is named Orion-10X, was developed in 1970 and series production began in 1972. A further design upgrade was introduced in 1982.

STATUS

The radar has been extensively supplied to the Italian Navy and to many other navies. In series production. Orders by Ferranti Limited for the Royal Navy and Brazilian Navy were revealed in 1982.

CONTRACTOR

Selenia-Elsag Consortium for Naval Systems, Via Panama, 52, 00198 Rome, Italy.

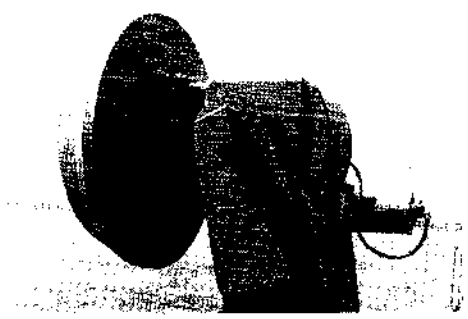
Orion RTN-10X radar antenna director

1935.253
ORION RTN-20X NAVAL RADAR

The Orion RTN-20X is another of the family of I/J-band tracking radars that has evolved from the Orion-10X. It has been developed particularly for use in the Darcio ships' close-in weapon system (**1920.281**). In this application it is used for the automatic acquisition of air targets and spotting of rounds. It is a digital coherent monopulse radar, featuring high ECCM, sub-clutter visibility, and tracking performance.

Autonomous, automatic acquisition occurs at ranges from 5 to 12 km depending on target size and relative altitude of the radar antenna and target. Fully automatic, self-adaptive target tracking takes place thereafter, using monopulse techniques. Among its main features are:

(1) Hooding free operation during tracking
(2) automatic spotting of the rounds
(3) automatic acquisition and tracking of a missile launched by the tracked platform.



Much consideration has been given in design to the reliability of the radar and to the rapid location of faults.

STATUS

Operational. The equipment is in production for installation on board 'Lupo' class frigates of the Italian, Peruvian and Venezuelan Navies.

CONTRACTOR

Selenia-Elsag Consortium for Naval Systems, Via Panama, 52, 00198 Rome, Italy.

Orion RTN-20X tracking radar

1936.253
ORION RTN-30X NAVAL RADAR

The Orion RTN-30X is a monopulse acquisition and tracking radar operating in the I/J-band. Its performance specifications have been dictated by the requirement of integration with advanced weapon systems having an intercept capability up to 15 km and particularly optimised to counter the low and very low altitude threat in an environment characterised by rain, sea, and land clutter, and consequent electronic countermeasures. The RTN-30X antenna is implemented with a cassegrain type twisted polarisation reflector, which avoids aperture blocking, thereby optimising antenna gain while reducing the side-lobe level.

The RTN-30X employs a coherent chain for RF generation and operates in frequency agility with simultaneous MTI processing. This gives the radar an excellent anti-clutter capability, denying the jamming threat and improving the tracking accuracy. Independent search and acquisition patterns are automatically performed according to computer programs. After radar lock-on, the radar switches to automatic tracking, in which regeneration is provided by the computer.

This radar is particularly designed for integration with the Albatros Mk 2 missile and gun fire control system.

DEVELOPMENT

Its research and development programme was commissioned by the Italian Defence Technical Scientific Committee within a wider development programme for a new GFCS. Now in production.

MM/BPS-704 SUBMARINE RADAR

The MM/BPS-704 is a naval search and navigation radar for use aboard submarines. The general characteristics are similar to the MM/SPN 703 surface ship version (**3482.253**), using the same 20 kW transmitter and with the same pulse length/PRI combinations. A specially designed very deep resistant antenna (up to 60 kgm/cm²) is part of the equipment. The principal differences are indicated in the following table.

CHARACTERISTICS

Antenna span: 1 m

Beamwidth: 2·9° horizontal; 11° vertical

Gain: At least 27 dB

Noise figure: Better than 11 dB

STATUS

Italian Navy 'Sauro' class submarines are fitted with the BPS 704.

CONTRACTOR

SMA – Segnalamento Marittimo ed Aereo, Via del Ferrone Soffiano, PO Box 200, 50100 Florence, Italy.

1702.253

3RM SERIES NAVAL RADARS

The 3RM Series are I-band navigation and surface warning radars, with some air target capability. The equipment has been tested and qualified in full accordance with MIL-E-16400F specifications. The antennas used are of the slotted waveguide type and provide horizontal beamwidths from 0·8° to 2°, depending upon the antenna length, and a vertical beam pattern of 26°, shaped to 40°. Scanner rotation rate is 25 rpm. Two transmitters are available, with outputs of 7 or 20 kW. The display unit has a nine-inch (23 cm) diameter PPI.

CHARACTERISTICS

Frequency: 9375 MHz

Peak power: 7 or 20 kW

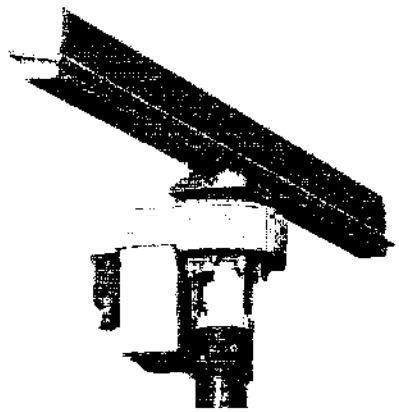
Antenna: Slotted waveguide

Rotation rate: 25 rpm

Pulse length/PRF: 0·05 μs/6000 Hz; 0·15 μs/3000 Hz; 0·5 μs/1500 Hz; 1·5 μs/750 Hz

Receiver: Linear f.m. log

Display: 9 inch (23 cm) PPI; 8 ranges 0·25 – 40 nm



True motion unit: On request

STATUS

In production and fitted to ships of a number of navies, and notably those of the Italian Navy, and on the West German fast patrol boats of the '143' and '148' classes. The US Navy has officially approved introduction of this equipment into its inventory under the military nomenclature AN/SPS-63. A submarine version (3RM20 SMG) is a standard product option.

SMA – Segnalamento Marittimo ed Aereo, Via del Ferrone Soffiano, PO Box 200, 50100 Florence, Italy

3RM antenna group

3482.253

MM/SPN-703 NAVIGATION RADAR

The Italian Navy MM/SPN-703 is the latest version of the 3RM navigation radar (**1702.253**), incorporating the latest state-of-the-art developments in electronic design. Most characteristics are similar or identical to those of the 3RM, above; known differences are listed in the following table.

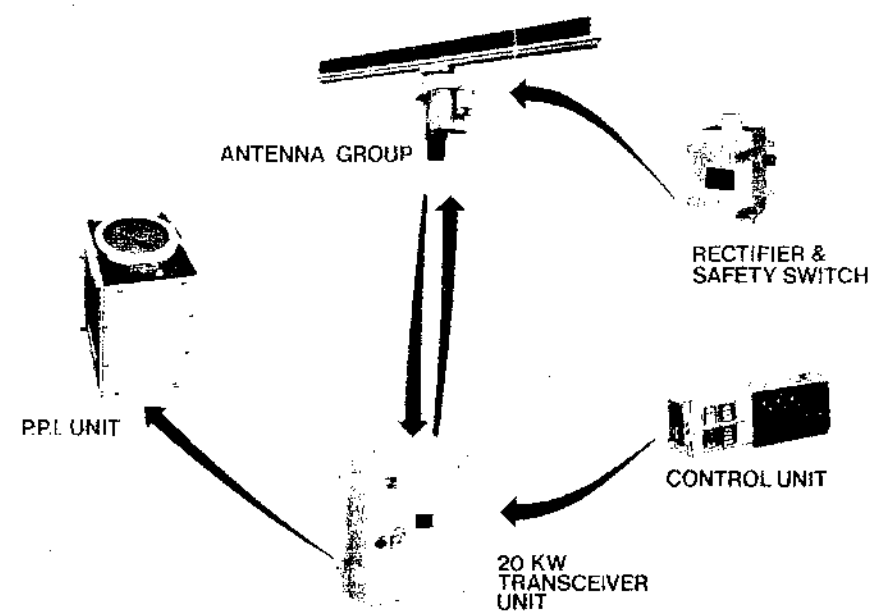
CHARACTERISTICS

Peak power: 20 kW

Antenna: Low profile slotted waveguide with cylindrical-parabolod depolarising reflector

Beamwidth: 1·2° azimuth; 25° vertical

Pulse length/PRF: 0·05 μs/5200 Hz; 0·15 μs/2600 Hz; 0·5 μs/1300 Hz; 1·5 μs/650 Hz



Noise figure: 9 dB

STATUS

Adopted by Italian Navy and others.

MM/SPN-703 navigation and surface search radar

1703.253

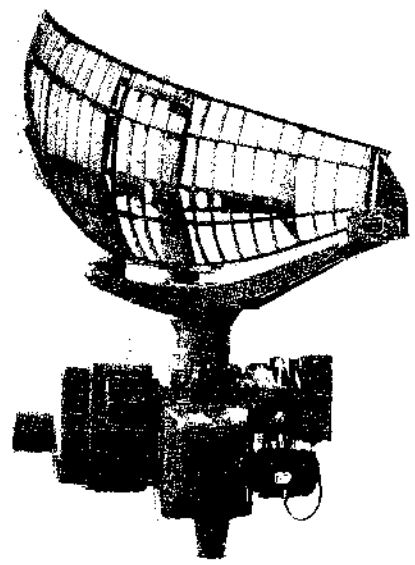
SPQ-2D/F NAVAL RADAR

The SPQ-2D/F is a medium power I/J-band radar the principle operation of which is based on time shared transmission of long and short pulses to achieve simultaneous video signals with high sensitivity for surface search and short-range air search, or with high resolution for navigation and close in control. The last feature is particularly appropriate for rescue operations and the direction of ASW helicopters.

The SPQ-2D equipment is currently integrated as the target designation radar in various electronic combat systems. A later model is the SPQ-2F.

Two control units which include all the operational controls of the radar permit use of remote or local controlling facilities by either CIC or LW operators. The SPQ-2D/F is designed for IFF compatibility and there is provision for 'Beacon' operation in conjunction with an I/J band transponder. Among the optional additional facilities which are available are: TWS operation at an antenna rotation rate of 40 rpm; frequency agility; MTI; D-band transceiving section integrated with the I/J-band (and with a common SPQ-2 type antenna group) for low-flying target detection and varying modes of operation.

The antenna assembly is produced in both roll and pitch stabilised and non-stabilised forms. The reflector is a double-curvature lattice and mesh structure of about three metres span, and is illuminated by a feed horn carried by an underslung support boom.



The sensor's output signals can be processed for different types of plot extraction and displayed on SMA-designed and manufactured weapons management consoles.

STATUS

The SPQ-2D/F has been in production for several years and is fitted on ships of several navies including the Italian Navy ('Alpino' class frigates), Canadian Navy (DDH 280 frigates), and the Venezuelan Navy (Vosper LPB).

CONTRACTOR

SMA – Segnalamento Marittimo ed Aereo, Via del Ferrone Soffiano, PO Box 200, 50100 Florence, Italy.

3262.253
MM/SPQ-701 NAVAL RADAR

The SMA MM/SPQ-701 naval radar is an I-band equipment designed for surface and air target detection and primarily intended for fitting in small vessels such as hydrofoils and fast patrol boats. It is essentially a combined system that includes navigational and search components and the roll-stabilised mount carries both antennas.

Reportedly of advanced design, the MM/SPQ-701 employs frequency agility and is provided with digital MTI. Good performance is claimed, including long and short range target detection in ECM. Provisions include an antenna and appropriate rotary joints etc.

STATUS
In production.

CONTRACTOR
SMA - Segnalamento Marittimo ed Aereo, Via del Ferrone Soffiano, PO Box 200, 50100 Florence, Italy.

MM/SPQ-701 antenna group

3263.253
MM/SPS-702 NAVAL RADAR

The SMA MM/SPS-702 naval radar is derived from the MM/SPQ-701 described above (**3262.253**), and is essentially comprised of the search components of that equipment. An I-band system, it provides assistance in missile guidance, supplying data for TWS processing and also providing a mount for the command guidance antenna. IFF facilities are incorporated.

STATUS
In production.

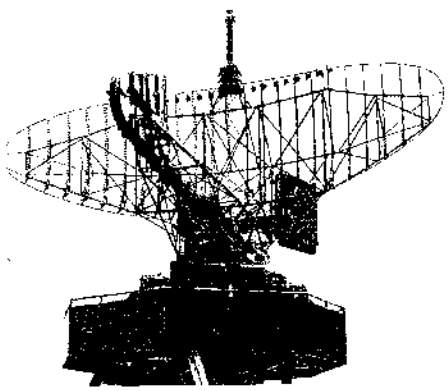
SMA - Segnalamento Marittimo ed Aereo, Via del Ferrone Soffiano, PO Box 200, 50100 Florence, Italy.

NETHERLANDS

1973.253
LW.08 NAVAL EARLY WARNING AND WEAPON DIRECTION RADAR

The LW.08 is a high-power D-band frequency synthesiser-driven travelling-wave tube (TWT) radar with pulse-to-pulse coherence, designed to fulfil the following functions:

(1) long-range air warning with high definition
(2) long-range surface surveillance
(3) target designation for weapon control radars and systems.



It is used in both naval and land-based applications.

Long-range performance is aided by use of a high mean-power TWT in the transmitter. A pulse-compression receiver with MTI provides for good performance in rain and in the presence of ground clutter. For naval use, the antenna is mounted on a platform which is stabilised in roll and pitch against ships motion. As is general practice with Signaal radars, a stainless steel antenna reflector is used to counteract the effects of the salt atmosphere and corrosive exhaust gases. The electronics are solid-state. Other technical features include: frequency agility over a wide band; linear and circular polarisation; frequency synthesiser-controlled coherent transmitter; MTI with digital quadrature canceller; digital video processor, and provision for integration of IFF. Range performance against a 2 m² air target is 145 nautical miles. Peak power is 150 kW and mean power is 5·2 kW.

STATUS
LW.08 systems have been delivered for fitting in Royal Netherlands Navy S-type frigates and for the RN anti-submarine cruisers and 'Type 42' frigates as well as the Argentinian aircraft carrier *Veinticinco de Mayo*. In the RN installation a Marconi antenna is employed, and the radar is designated Type 1022 (**3486.253**).

LW.08/3 systems (land-based) are employed in the Netherlands and Portugal, at Changi Airport in Singapore and at two airfields in Paraguay.

An extended range version of the LW.08 has been designated for the command-and-control air-defence version of the S-type frigate for the RNN.

LW.08/2S early warning and weapon direction radar

3484.253
SIGNAAL STIR

The Signaal STIR tracking radar is a lightweight two-axis tracker capable of rapid and accurate target tracking down to sea-skimmer missile heights, without the aid of TV. The initials STIR denote Signaal track and illuminating radar. The modular tracker system with its electric servo drives was originally developed as a short/medium-range I-band monopulse tracker with illumination for the Seasparrow missile. A later version has a concentric I/K-band monopulse radar for improved tracking, as well as J-band illumination. Another variant is a long-range I-band monopulse tracker with illumination and a larger antenna dish for standard missile control. A variety of MTI and ESM/ECCM features are incorporated.

The antenna feed assembly is weather protected by a polyamide radome, with all the electronics equipment for transmission, reception, control and power supply housed in a container. A containerised version is available for fitment to merchant ships, etc.

STATUS
By the end of 1984 more than 55 sets had been ordered for fitment to the ships of the Netherlands, the Federal Republic of Germany, Argentina, Canada and other unspecified navies. The Royal Netherlands Navy has fitted STIR systems to its 'Kortenaer' class frigates and has ordered units for the 'Jacob van Heemskerck' class frigates. The West German Navy has fitted STIR to its 'F122' class frigates and the equipment is also installed on the 'Meko 360' destroyers of the Argentinian Navy. The 'Paliot' frigates for the Canadian Navy will be equipped with STIR systems in a double-headed configuration.

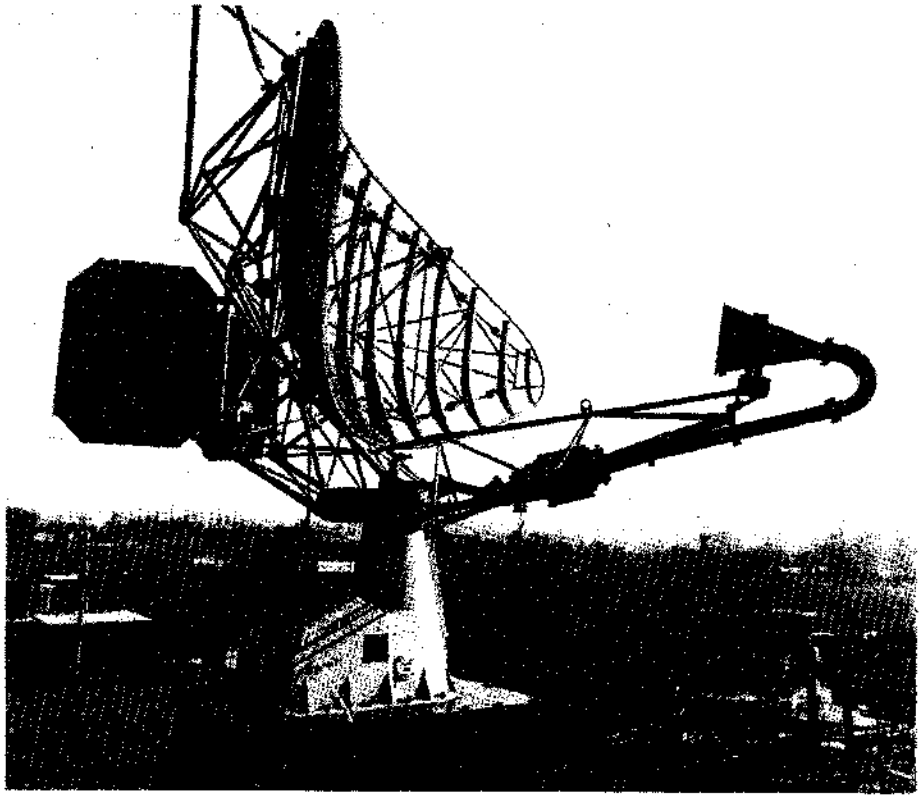
Hollandse Signaalapparaten BV, PO Box 42, Hengelo, Netherlands.

Signaal STIR, VM40 naval tracking and illumination radar

1554.253
DA.05 NAVAL SURVEILLANCE RADAR

The DA.05 is an E/F-band surveillance radar transmitter/receiver for shipboard and land-based applications. Various antenna types are available, both stabilised and unstabilised. It provides for air surveillance, surface warning, target designation for fire control radars, and weapon director systems. A solid-state transmitter/receiver is used, a tunable magnetron providing for operation on any one of a number of pre-set frequencies with a peak power of 1·2 MW. Facilities are provided for an on-mounted secondary radar (IFF) antenna on the main radar scanner. The latter is constructed of stainless steel to permit operation in adverse salt and exhaust environments.



Range performance for the naval DA.05/4 is typically 135 km against a 2 m² target. Operational features include high discrimination; medium-range air cover and good surface detection; two rates of antenna rotation; linear and circular polarisation; low-noise receiver; video processing, including MTI with digital cancellation and digital interference suppression; automatic test facilities. The naval DA.05/5 includes a lightweight antenna and is designed for FPBs and refit programmes.

STATUS

Signaal has reported that over 50 DA.05 systems are in use with, or ordered for, the navies of Belgium, Malaysia, Netherlands, Finland, Indonesia, South Korea, Ireland, Morocco, Spain, Thailand and Argentina.

CONTRACTOR

Hollandse Signaalapparaten BV, PO Box 42, Hengelo, Netherlands.

Scanner and turning gear of the Signaal DA.05/4 radar

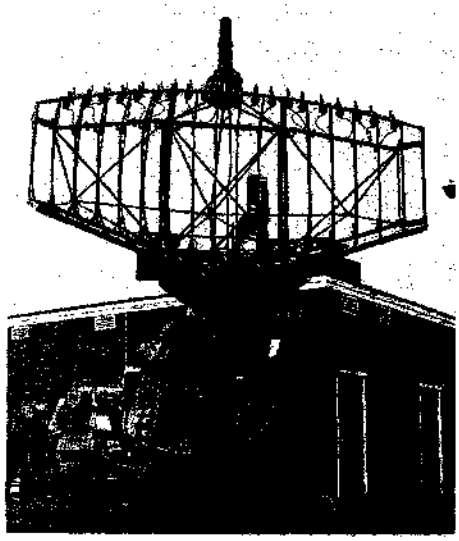
3479.253
DA.08 NAVAL WARNING AND WEAPON DIRECTION RADAR

The DA.08 is a high-power F-band frequency synthesiser-driven TWT radar with pulse-to-pulse coherence, designed to fulfil the following functions:

(1) medium-range air warning with high definition and high elevation coverage
(2) medium-range surface surveillance
(3) target designation for weapon control
(4) en route and terminal area control.

The combination of functions depends on the antenna version employed.

The design is a derivative of the LW.08 D-band radar (**1973.253**). Consequently, the main characteristics of the DA.08 are the same as for the LW.08. In addition to MTI, an FFT-processor is available for the DA.08. The range performance against a 2 m² air target is approximately 200 km for the DA.08/1S model. Peak power is 145 kW and mean power 5 kW.



A variant, known as the DA.08/5S, with lightweight stabilised antenna is available for FPBs and small corvettes.

STATUS

The DA.08/2S system has been fitted to the type 'F122' class frigates of the Federal Republic of Germany. The DA.08/1S is being fitted to the Argentinian Navy type 'Meko 360' frigates, the aircraft carrier *Veinticinco de Mayo* and also to Royal Malaysian frigates.

1555.253
ZW.06/2 SURFACE SEARCH AND NAVIGATION RADAR

The ZW.06 is an I-band naval surface search and navigation radar providing surveillance, navigation, helicopter control, and limited air surveillance facilities. Of compact and lightweight construction, it is suitable for installation on very small vessels. The transmitter/receiver is of solid-state design, and the scanner is of stainless steel construction to permit siting in adverse environments.

Operational features include: surface coverage to radar horizon; air coverage sufficient for helicopter guidance; high resolution for navigation, provision for integration of helicopter transponder systems; digital video processor. Anti-clutter measures and ECCM provisions include: circular polarisation; logarithmic receiver with pulse length discrimination; sensitivity time control; suppression of non-correlated pulses; tunable transmitter.

Signaal ZW.06 surface search and navigation radar antenna

CHARACTERISTICS

ZW.06
Antenna: Parabolic reflector 2·7 m wide, 1·2 m high, with off-set feed horn
Polarisation: Horizontal or circular, selectable
Vertical beamwidth (at -3 dB): 19°
Horizontal beamwidth (at -3 dB): 0·9°
Sidelobe level: -25 dB
Gain: 31 dB
Rotation speed: 24 rpm
Max windspeed: 185 km/h
Transmitter
Type: Tunable magnetron
Frequency band: 8600 - 9500 MHz
Receiver
Overall noise: 9 dB
Intermediate frequency: 60 MHz
Receiver channels: Linear, or logarithmic with PLD. Pulse interference suppression on both channels. Digital video processor

DEVELOPMENT

The ZW.06/2 version was announced in 1975. This model embodies improvements resulting from the

application of value engineering, and is stated to be of lower cost.

ZW.06/2 fittings include: Brazilian 'Niteroi' class frigates and 'Aratu' class minesweepers, Netherlands 'Kortenaer' class frigates; Spanish 'F 30' class frigates; Indian Navy 'Leander' class frigates; Moroccan Navy 'Lazaga' class missile patrol boats and one F 30' class corvette, the South Korean frigate 'Ulsan', the Thailand Navy, the 'Moko 360' class frigates of the Argentinian Navy, and the LST of the Indonesian Navy.

CONTRACTOR

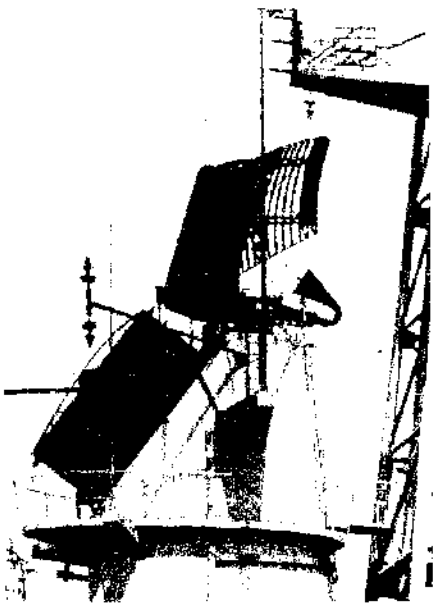
Hollandse Signaalapparaten BV, PO Box 42, Hengelo, Netherlands.

1256.253

LW.02 NAVAL AIR SURVEILLANCE RADAR

The LW.02 is a D-band (23 cm), high-power long-range air surveillance radar for use on vessels of frigate size or above. Peak transmitter power is 500 kW and maximum detection range about 100 nautical miles. Vertical cover extends to 18 000 metres.

A double curvature reflector measuring 7 m by 2·9 m is used and a distinguishing feature of this radar is the large 'trunk' at the rear of the centre section of the scanner. There is also an LW.03 version of this radar, the only known difference between the two models being in the scanner rotation rates. The LW.02 rate is between one and ten rpm, and the LW.03 five or ten rpm.



STATUS

The LW.02 has been fitted to a large number of vessels in several countries. These include the navies of the Netherlands, Peru, West Germany, Sweden, Colombia, Malaysia, Australia and Argentina.

Production has ceased, the replacement model being the LW.08 (**1973.253**).

CONTRACTOR

Hollandse Signaalapparaten BV, PO Box 42, Hengelo, Netherlands.

LW.02 antenna

4051.253

ZW SERIES NAVAL RADARS

This range of general-purpose search radars, the so-called ZW series, has been extended with three new types, these being:

ZW07: submarine radar for navigation, distance measuring, surface search and limited air warning. The ZW07 is specially suited for use on board submarines. A single shot mode has been adapted for ranging of surface targets. Other operational features are: surface coverage up to radar horizon, limited air warning and high resolution for navigation. Anti-clutter measures and ECCM provisions include: sector scan facilities, logarithmic receiver with pulse length discriminator, suppression of non-correlated pulses and a tunable transmitter.

ZW08: low-level air warning and sea skimmer detection radar. The ZW08 is a newly developed radar system with the special capability of detecting accurately small, fast, low and very low-flying targets at such ranges that successful engagement and combatting of these targets is possible. The basic configuration of the radar system consists of a stabilised antenna fed by a high power TWT transmitter and a full coherent chain receiver. The system operates in the I-band.

Operational features include: surface search to the radar horizon, limited air warning and excellent sea-skimmer detection capability. Anti-clutter measures and ECCM provisions include: fully coherent receiver/transmitter system, pulse compression, adaptive waveform transmission, interpulse frequency diversity, pseudo-jumping frequency over bursts, FFT doppler processing, high average output power, and automatic selection of radar parameters.

ZW09: surface search and low-level air warning radar. The configuration comprises a stabilised antenna fed by a magnetron transmitter with matched receiver channels. Its application is on board small ships, giving the following operational features: surface search to the radar horizon, limited air warning and detection capability against low-flying targets. Anti-clutter measures and ECCM provisions are: circular polarisation, DMTI, pseudo jumping frequency, video correlator, linear, logarithmic, Dicke Fix and MTI receivers, pulse length discrimination and suppression of non-correlated pulses.

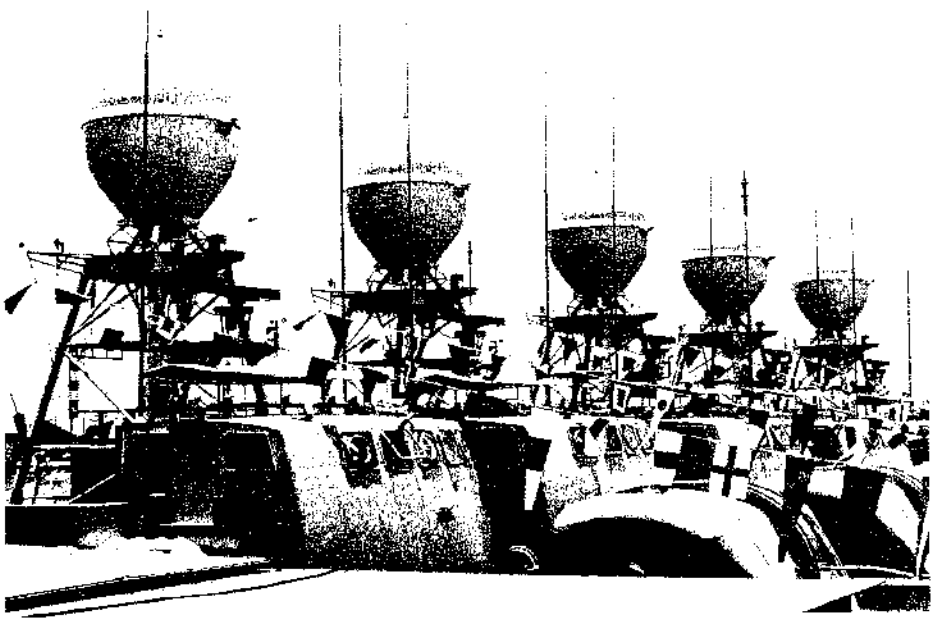
SIGNAAL WM20 SERIES FIRE CONTROL RADAR

This radar is the principal sub-system of the Signaal WM20 series of naval fire control systems, and in its full form consists of two radars sharing a common stabilised mount and housed in a near-spherical radome. In the double installation, the tracker/illuminator is carried above the search radar, with the gimbal and stabilising assembly in between. The general arrangement can be seen from the accompanying illustration.



Both antennas are fed from a common I/J-band transmitter or from separated transmitters for surveillance and air target tracking.

The search radar carries out the surface and air search functions, and automatic tracking of surface targets for weapon control purposes. The tracking radar performs tracking functions for weapon control against air targets.

One version of the WM20 series, the WM26, employs only the search antenna, this being mounted on top of the stabilised platform and enclosed in a hemispherical radome. In all other versions the tracking antenna is fitted in the upper position with the search antenna below.

STATUS

The WM20 series of fire control radars is widely fitted and details of known installations are given in the M20 series fire control systems entry (**1259.281**) in the Systems Section of this edition of *Jane's Weapon Systems*.

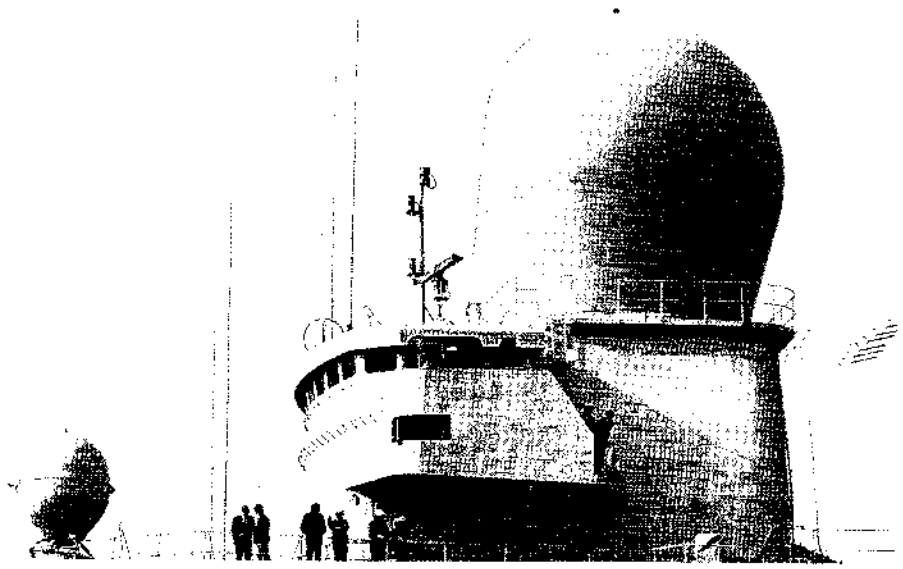
SIGNAAL 3D MULTI-TARGET TRACKING RADAR

The Signaal 3D multi-target tracking radar (MTTR) is an advanced air search and target tracking radar capable of handling more than 100 aircraft tracks. A very high data rate is achieved by the use of an antenna array consisting of back-to-back pairs of parabolic reflectors and planar electronically scanned antennas, all four of which have common turning gear. IFF/SIF secondary radar are integrated with the MTTR. The parabolic dishes are used for search and the electronic-scan antennas for target tracking. High and low cover is provided. Beam steering and data extraction are performed by an SMR series digital computer.



Operational functions include: long range search; search information with high data rate for low-flying aircraft; search information with high resolution of close-in air targets; automatic position and height information; simultaneous tracking of over 100 aircraft targets; target designation facilities for other systems. No performance or other technical details have been obtained. Estimated diameter of the parabolic dishes is in the region of six metres. Both land and naval uses are likely, and the latter is understood to incorporate full stabilisation.

STATUS

The 3D MTTR forms one of the major sensors of the SEWACO action information and fire control system for the 'Tromp' class of Royal Netherlands Navy guided weapon frigates. There are no other known fittings at this stage.

5626.253
SMART NAVAL SURVEILLANCE RADAR

SMART (Signaal Multibeam Acquisition Radar for Targeting) is an all-weather three-dimensional naval surveillance radar system intended for all types of naval vessel from fast patrol boats upwards, its prime application is as the main sensor for data handling and weapon system control and it has a very high performance in the presence of heavy clutter and electronic countermeasures. The equipment has been designed to cope with small high-speed anti-ship missiles, with radar cross sections down to 0·1 m² and approach speeds of Mach 3·1, which can be either sea skimmers or arriving from high angles of 70° or more.

The SMART system operates in F-band (formerly S-band) where it offers an optimum balance between range, clutter rejection and antenna dimensions. An alternative version operating in G-band is also available. It provides an uninterrupted search envelope from 0 to 90° in elevation with automatic detection followed by automatic initiation and target tracking. It incorporates anti-clutter and ECCM features such as multiple reception beams with ultra low side lobes in elevation and azimuth, a clutter analysis sensor, broadband transmission, PRF and RF agility per burst and a jamming analysis sensor which automatically changes PRF and transmit frequency.

The system comprises an antenna and four below-decks units. The antenna unit consists of a single horn transmitter array combined with a linear array of 16 strip line receiving antennas. It is hydraulically stabilised to ensure a low top weight. To ensure high sensitivity, pre-processing of the received signals takes place in the antenna unit itself. The output of the 16 antennas is fed to a digital beam forming network in which 12 independent elevation beams are produced. The transmitter is based on a high power, pulse-to-pulse coherent TWT. For the complete integration of any type of IFF, an IFF antenna, rotary joint and an IFF extractor are incorporated.

Signaal SMART naval surveillance antenna

CHARACTERISTICS

Antenna unit
Rotation speed: 27 rpm
Stabilisation: ±30° in roll; ±10° in pitch
Polarisation: Horizontal
Transmitting antenna
Type: Single horn antenna array
Beamwidth: 2° horizontal; up to 90° vertical
Receiving antenna
Type: 16 strip line radiators
Beamwidth: 2° horizontal; 100° vertical (processing beamwidth is 9° vertical)
Transmitter
Type: TWT with pulse compression
Peak power: 150 kW
Frequency: F-band
PRF: 3800 Hz average
Weight
Antenna: 200 kg
Below-deck units: 3200 kg
Antenna dimensions: 360 × 250 or 400 × 320 cm

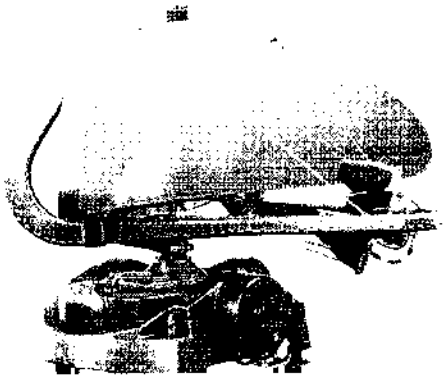
9GR 600 NAVAL RADAR

The 9GR 600 is an I-band radar transceiver extensively used in naval radar systems both in the Swedish and other navies.

With the 9GA 205 antenna it is used in the Marelo coastal radar system (**1548.181**). It is used in the 9LV 200 fire control system (**1542.281**), the 9LV 200 Mk 2 weapon control system (**3127.281**), the Sea Fire system (**1543.281** in 1979-80 and earlier editions), the Torc torpedo fire control system (**1541.281**), and with the 9GA 300 antenna in the Subfar submarine radar system (**1545.453**).



The radar can be used either in its broadband frequency agility mode, or in a fixed frequency mode for MTI operation.

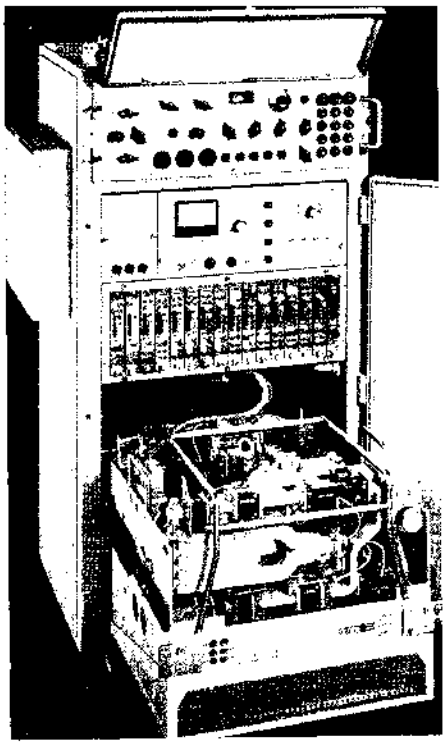
CHARACTERISTICS

Transmitter
Operating modes: Frequency agility/fixed frequency MTI
Transmitter tubes (2 off): Magnetron YJ 1180/YJ 1181
Frequency agility range: Minimum 400 MHz, typically 450 MHz within 8700 - 9500 MHz
Frequency shift: Randomly within the frequency agility range from pulse to pulse
Pulse peak power: 200 kW
Pulsewidth/PRF: Typically 1 μs/1000 Hz and 0·25 μs/3000 Hz

Receiver
Frequency range: 8500 - 9600 MHz
IF: 30 MHz
Noise figure: Typically 5·5 dB; 7 dB with low-noise preamplifier
Receiver characteristics: Lin and log, log/lin, STC
Operational features: Image reject mixer, Dicke-Fix receiver, PLD, IAGC, narrow-band jamming suppression, passive ECM mode
Transceiver
Dimensions: 1200 × 635 × 510 mm
Weight: Approx 225 kg

Antenna GA 209
Type: Parabolic, horn fed, stabilised
Reflector material: GRP and metal wires
Frequency range: 8·5 - 9·6 GHz
Rotation speed: Up to 60 rpm
Beamwidths

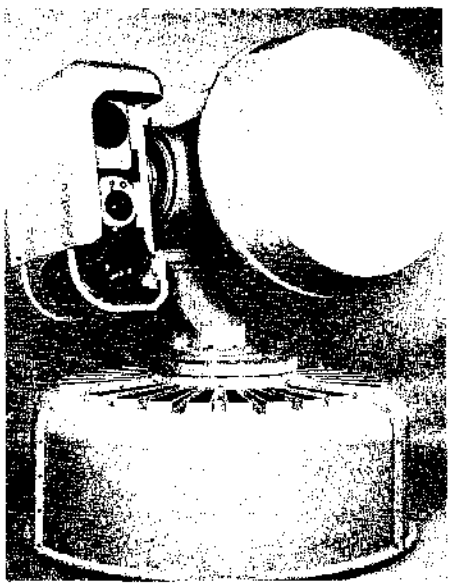
Dual-frequency, I- and D-band, stabilised surveillance antenna 9GA 218, for the 9GR 600 naval radar



Horizontal: 1·1°
Vertical: 7°
Gain: 35·5 dB
Sidelobes: -21 dB at ±1·5°; -33 dB beyond ±1·5°
Spiral scan coverage: Up to 40°
Stabilisation: Direct driving hydraulic motors
Stabilisation limits: Roll ±32°, pitch ±12°
Aperture: 2100 × 300 mm
Weight (including turntable): 260 kg

Antenna 9GA 218
Type: Parabolic, dual frequency, stabilised
Reflector type: GRP and metal wires

PEAB 9GA 209 I-band stabilised surveillance antenna



Frequency range
I-band: 8·5 - 9·6
D-band: 1·01 – 1·11 and 1·25 - 1·35 GHz
Beamwidths
Horizontal: 1° at I-band, 6/8° at D-band
Vertical: 3° at I-band, 20/25° at D-band
Gain
8·5 – 9·6 GHz: 38 dB
1·25 - 1·35 GHz: >20 dB
1·01 – 1·11 GHz: >17 dB
Stabilisation: Direct driving hydraulic motors
Stabilisation limits: Roll ±30°, pitch ±10°
Aperture: 2700 × 700 mm
Weight (including turntable): 260 kg

9LV 200 Mk 2 TRACKING RADAR
This is a J-band frequency-agile naval fire control radar forming part of the 9LV 200 fire control system (**3127.281**) in which it is used with an I-band search radar. The main role is that of target tracking for gun fire control, and the radar is monopulse equipment with stabilised antenna and a cassegrain scanner system. The radar mounting can also carry TV, IR camera and laser rangefinder for autonomous electro-optical (optronic) tracking. A feature of the mounting is a new type of direct drive hydraulic motor capable of a slewing speed of 85°/s, and an initial acceleration of 500°/s².
CHARACTERISTICS
Type: J-band frequency-agile MTI monopulse

Frequency range: Random pulse-to-pulse in J-band
Magnetron type: Philips YJ 1321
Pulse peak power: 65 kW
PRF: About 2000 Hz
Pulsewidth: About 0·2 μs
Receiver noise: 11 dB
Antenna
Diameter: 1 m
Beamwidth (at 3 dB): 1·3°
Gain: 40 dB
Sidelobes: 22 dB
STATUS
In service.

4299.253
SEA GIRAFFE NAVAL SEARCH RADAR
The Giraffe family of air defence search radars is based on the fully coherent TWT transmitter concept featuring an extremely good sub-clutter visibility of moving targets. Various versions of the Giraffe radar are in operation in different system configurations in ten countries. The latest version, Sea Giraffe, is a multi-purpose naval search radar designed to meet the operational requirements of a variety of warships from small fast patrol boats to frigate sized ships. There are five different versions (HC denotes extra height coverage versions):
(1) Sea Giraffe 50 and 50HC for small and medium-sized patrol boats and fast attack craft
(2) Sea Giraffe 150HC for large fast attack craft, corvettes and frigates
(3) Sea Giraffe 50 and 100 for off-shore patrol vessels.

All versions of the Sea Giraffe are essentially repackaged versions of the Giraffe family to satisfy a variety of requirements in the area defence and point defence roles. They provide all-weather anti-ship missile detection to enable successful defence, long range aircraft detection in severe environmental conditions and ECM, and surface target detection up to the radar horizon. For area defence, Sea Giraffe supplies air and surface data to the ship's fire control system, target information to own surface-to-surface missiles and surface gun fire control with accurate fall-of-shot observations. Ancillary uses for the system include long range navigation and helicopter guidance.

Low altitude coverage is obtained at a considerable range with obvious benefits in the detection of low-flying aircraft and sea skimming missiles.

The radar uses a broadband fully coherent TWT transmitter giving 15 kW output power for Sea Giraffe 50 and 100, and 60 kW for Sea Giraffe 150HC. The antenna for the Sea Giraffe 50 is the standard Giraffe family version while a special antenna has been developed for the 100 and 150HC. The 50HC and 150HC have an optional antenna for extra high cover to detect steep diving missiles (60 to 80° dive angle). A high MTI improvement factor ensures excellent low-level detection capability, and frequency agility in both MTI and non-MTI operation is used for high ECCM performance. Agility is on a pulse-to-pulse

Modified Spica II class fast attack boat of the Swedish Navy fitted with Sea Giraffe

basis in non-MTI mode and on a pulse burst basis in MTI mode. The adaptive computer based coherent MTI is used to give optimised suppression of mixed clutter from sea, land, rain and chaff. Digital pulse compression is used for high range resolution and improved clutter performance. G/H-band operation enables optimum detection of both air and surface targets.

(1) Sea Giraffe 50 and 50HC to 15 km for missiles and 35 km for aircraft
(2) Sea Giraffe 150HC to 25 and 55 km respectively.

All versions are normally supplied with a stabilised platform and for operation in extreme winds the antenna should be enclosed in a radome.

CHARACTERISTICS
Frequency: 5·4 – 5·9 GHz
MTI improvement factor: 45 – 50 dB
Antenna rotation rate: 30/60 rpm
Output power (peak): 15 kW (50 & 100 versions); 60 kW (150 version)
Output power (mean): 300 W (50 & 100 versions); 1200 W (150 version)
Antenna size: 2·3 × 0·7 m (50 version); 2·4 × 0·8 m (50HC and 150HC); 2·4 × 1·8 m (100 and 150HC)
Masthead weight: 250 kg (50 version); 700 kg (100 and 150HC versions, radome included)

STATUS
Sea Giraffe was first ordered in 1980 by the Swedish Navy for the mid-life refit of the Spica II attack craft, and has been subsequently ordered for the new Spica III 'Stockholm' class fast missile vessels, as well as for the minelayer/training ship *HMS Carlskrona*. Sea Giraffe has been in full operational use with the Swedish Navy since early 1983 in the modified Spica IIs.

At the end of 1983, Sea Giraffe 150HC was ordered for the new Canadian patrol frigate programme. On this vessel, Sea Giraffe will be used as the medium range surveillance radar and as target indication radar to the fire control system.

Negotiations are also being conducted with a number of other customers for various applications of Sea Giraffe.

SUBFAR 100 SUBMARINE RADAR

The Subfar 100 equipment is an air and surface search radar for submarines and comprises the 9GA 300 antenna, a 9GR 600 I-band frequency-agile transceiver, and a display system.

The 9GA 300 antenna is designed for mounting with its hydraulic turntable on top of the submarine radar mast. This way of mounting eliminates bearing error sources from torsion effects in the radar mast. The hydraulic turntable gives a very low noise level as well as flexible control of antenna rotation speed. The antenna direction can be manually set or slaved to external sources such as the periscope.

Sector transmission as well as short time transmission down to emitting a single pulse can be selected. Automatic target detection can be incorporated, which facilitates automatic target tracking by an external fire control computer.

CHARACTERISTICS
9GA 300 antenna
Frequency range: 8·5 – 9·6 GHz
Rotation speed: 0·5 – 24 rpm, and pos. control
Beamwidths
Horizontal: 2·4°
Vertical: 16°
Gain: 26 dB
Sidelobes: 18 dB
Antenna aperture: 1000 × 140 mm
Height above mast tube: 600 mm
Rotating circle diameter: 1040 mm
Antenna system weight: 95 kg
9GR 600 transceiver
See **1546.253**, above, for full characteristics.
Display system
CRT diameter: 300 mm (12 inch)
Deflection: Magnetic, fixed coils
Scale factors: 1:20 000
1:50 000
1:100 000
1:200 000
True motion: Selectable
Range readout: Digital
Bearing readout: Digital

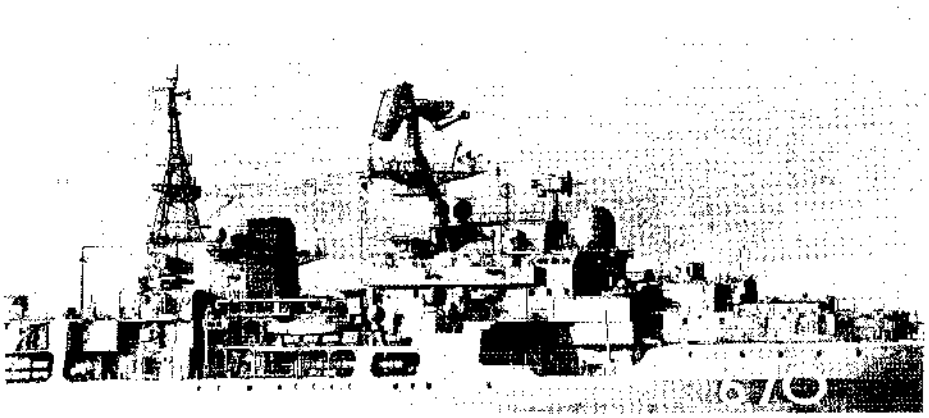
4090.253
BAND STAND NAVAL RADAR

Band Stand is the name given to the radar identified by its large dome shaped radome, and considered to be associated with the ship's overall air surveillance requirements, although there may be some connection with the vessel's main armament.

The latter is thought to be less likely in the light of the continued fitting of the Band Stand radar (or its radome, at least) in the 'Nanuchka' class missile corvettes supplied by the USSR to India, although the latter ships are armed with SS-N-2B anti-ship missiles instead of the six SS-N-9 missiles which arm the Soviet vessels of this class. However, it is possible that in the Soviet ships the Band Stand radar may be employed in a complementary fashion in the SS-N-9 system in addition to having air surveillance as its main role. This might include tracking of the outgoing SS-N-9 missiles, with guidance signals being transmitted via the two Fish Bowl equipments (which smaller radomes are missing from Indian examples of 'Nanuchka' ships).

Both Indian and Soviet ships of the class are fitted with SAN-4 anti-aircraft missile systems and an air surveillance function of the Band Stand radar, with a fairly high data rate, would be a valuable complement to this system.



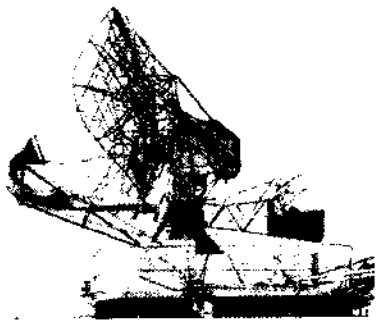
The Soviet ship Sovremenny *includes a Band Stand radar in its radar fit. Other items seen here include a Kite Screech fire control radar and Top Steer group*

4085.253
BASS TILT FIRE CONTROL RADAR

Bass Tilt is a Soviet naval fire control radar which resembles Drum Tilt (**1330.253**) and Muff Cob (**1611.253**) in both general appearance and broad functional purpose. Of these three radars, Bass Tilt is the most modern, having entered service in the mid-1970s; it is also decidedly larger than the oldest of the three types, Drum Tilt. They all share a common main operational function of radar direction of small or medium calibre anti-aircraft guns, with Muff Cob generally being associated with Soviet twin 57 mm gun mounts. Both Drum Tilt and Bass Tilt are usually used with smaller calibre weapons, particularly multiple turret twin or single Gatling-type installations. Drum Tilt fittings are mostly confined to smaller ships with a single gun turret such as the common-place 'Osa' class missile boats.

Bass Tilt fittings have been noted on one ship of the 'Kresta I' class (which underwent modernisation in 1975), 'Kresta II' class and 'Kara' class cruisers, some 'Kashin' class destroyers, 'Nanuchka II' and 'Grisha III' class corvettes, and various miscellaneous types of vessel such as the 'Ivan Rogov' class of amphibious assault ship and the *Berezina* fleet replenishment ship. 'Kresta II' class ships present one of the best opportunities to make direct visual comparisons between the most difficult pair of these three types of fire control radar to identify accurately, Muff Cob and Bass Tilt, as two of each type are fitted in these ships; two Bass Tilt forward for control of four Gatling-gun AA turrets, and two Muff Cob athwart the funnel for the aft twin 57 mm gun turrets. More recent

examples of Bass Tilt fittings are the new *Kirov* cruiser and the Sovremenny class destroyers, the first of which emerged into the Baltic briefly in the summer of 1980. The latter ship has both Muff Cob and Bass Tilt radars fitted in some profusion, offering something of a challenge to radar 'spotters'. The 'Kiev' class of aircraft carriers each have four Bass Tilt radars for their eight Gatling-gun AA mounts.



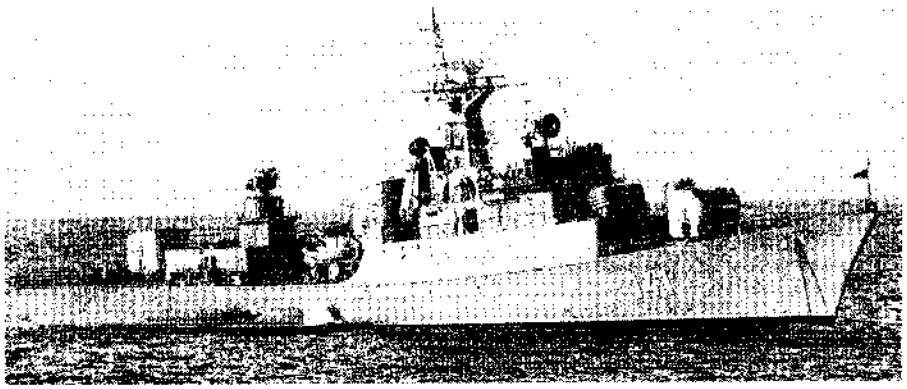
The Sovremenny presents a radar identification challenge with multiple fittings of both Muff Cob and Bass Tilt fire control radars (plus one other redome of similar size which is neither of these types but more probably a communications satellite terminal). Other radars are Top Steer air search radar pair, Kite Screech fire control radar, and Band Stand missile director radar

---

1608.253
BIG NET SEARCH RADAR

Big Net is a very large, long-range air surveillance radar operating in either the E/F- or D-band, probably the latter although even C-band operation has been suggested. The open lattice reflector is of elliptical parabolic form, illuminated by an underslung horn feed, carried on a solid boom. Behind the reflector are two balance vanes. Range performance is estimated as more than 100 nautical miles (185 km) against an aircraft at medium altitude, and up to 200 nautical miles (370 km) at higher altitudes.

According to the latest information, all four of the 'Kresta I' class of guided missile cruisers carry Big Net, on which ships it is mounted over the funnel. Some of the 'Kashin' class of guided missile destroyers are fitted with this radar, in which cases it is mounted on a pylon type mast aft of the forward funnel. The cruiser *Dzerzhinsky* has also been seen with Big Net and some of the 'T43/AGR' class of radar picket ships (converted from minesweepers of the 'T43' class) have a Big Net search radar. Other vessels of this class have either a Squat Eye or Knife Rest radar instead of the Big Net.

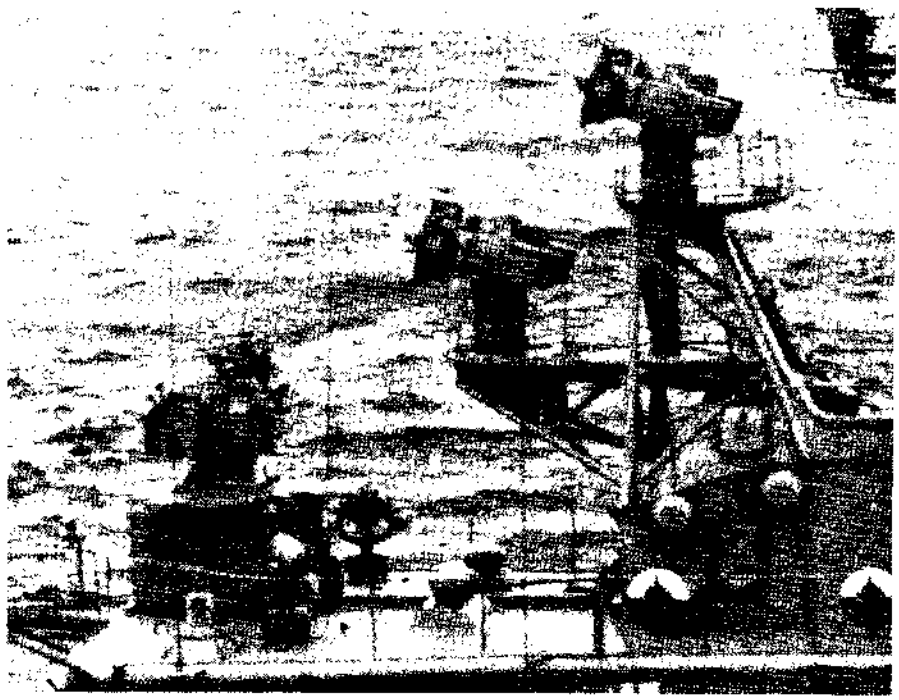


Big Net long-range search radar

1330.253
DRUM TILT FIRE CONTROL RADAR

This is a pedestal-mounted fire control radar which probably provides acquisition and tracking functions only for AA guns. It is housed in a weather-proof container which is attached to the scanner assembly tilted at about 25°. Maximum acquisition range of aerial targets is approximately 22 nautical miles. Operating frequency is almost certainly in the I-band. It is principally fitted aboard 'Osa' class missile boats, on a platform between the two aft missile launchers, for the direction of four 30 mm AA guns carried by these craft.

Drum Tilt fittings have also been noted on some 'Sverdlov' cruisers, and ships of the 'Kanin', 'Kotlin', 'Shershen', 'Stenka', 'Turya', 'Natya', 'Yurka', 'Senyarin', and 'Polnochniy' classes. The type is gradually being supplanted by later radars such as Muff Cob and Bass Tilt which are fitted in more recent classes of Soviet ship.



This East German 'Koni' class escort vessel, at anchor off the Shetland Islands is equipped with a Drum Tilt and a Hawk Screech fire control radar for gun direction, and a Pop Group for use with the SAN-4 missile system. The air search radar is a Slim Net or Strut Curve (RN photo)

4089.253
EYE BOWL NAVAL RADAR

The Eye Bowl radar is associated with the Soviet SS-N-14 naval missile system fitted aboard 'Krivak' class frigates and the Soviet cruiser *Kirov*, although other classes thought to be fitted with the SS-N-14 system have not yet been noted with the Eye Bowl radar. The precise function of the Eye Bowl radar tends to remain as problematical as that of the SS-N-14 missile with which it is associated. The latter is generally thought to be somewhat similar to the Australian/British Ikara (**6002.241**) in that the payload/warhead is believed to comprise a torpedo, thus making the SS-N-14 principally an anti-submarine weapon although there will also be a certain surface ship target capability. On these assumptions, the main role of the Eye Bowl radar is probably that of tracking and guidance of the outgoing SS-N-14 missile to ensure that it reaches a previously designated target position determined by another of the ship's sensors and the combat information system. This seems to be confirmed by what is discernible from photographs of the Eye Bowl radar. The reflector dish is comparatively small and there appear to be several auxiliary (possibly electro-optical) sensors mounted immediately behind the reflector dish. Command signals to the SS-N-14 missile are probably transmitted as coded information within the radar transmissions, as no separate command antennas can be seen.

The operating frequency is most likely in the I-band of the radar spectrum, although the G/H-band is also feasible. Either would suffice for the estimated range of the SS-N-14 system, which is generally thought to be in the neighbourhood of 30 nautical miles.

Beam view of the two Eye Bowl guidance radars on a Soviet 'Krivak' class destroyer, abaft and above the Pop Group radar for the ship's SA-N-4 anti-aircraft missile system (HMS Londonderry)

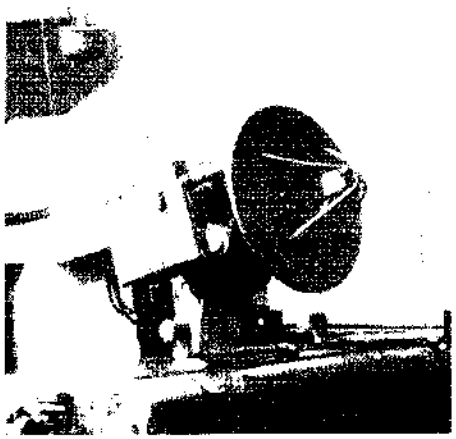
1605.253
FAN SONG E NAVAL RADAR

This is a shipboard version of the Guideline (SA-N-2) surface-to-air missile fire control and guidance radar (**2868.153**) which is widely used by Soviet and forces in place of the mobile housing used on land, the shipboard installation is mounted on a stabilised gun mount.

Fan Song E operates in the G/H-band range of frequencies with a maximum acquisition range of 80 nautical miles. The antenna array consists of horizontal and vertical scan Lewis antennas, and three circular parabolic dishes. Two of the latter are for lobe on receive only (LORO) ECCM, and the third dish is for command guidance purposes. Operation of Fan Song E is described more fully in **2868.153**

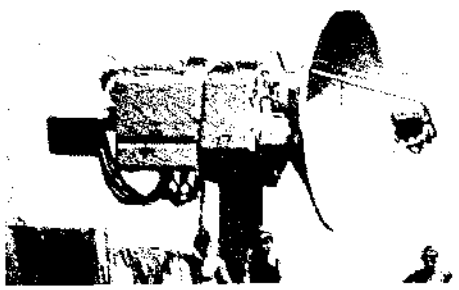
The only known fitting of this radar is on the Soviet Cruiser *Dzerzhinsky*, on which ship the Fan Song E is mounted on a platform aft of the after funnel and forward of the twin Guideline missile launcher.

1325.253
HAWK/OWL SCREECH FIRE CONTROL RADARS



Hawk Screech and Owl Screech are fire control radars of conventional design, widely used in many classes of Soviet vessels. They are distinguished by a circular dish scanner, behind which are mounted fairly bulky housings which are assumed to contain transmitter and receiver, and probably turning and stabilisation gear. The complete radar is pedestal mounted. The 2·3 metre diameter scanner has a central feed supported by a four-leg structure. Feed arrangements could incorporate a rotating dipole to provide a conical-scan search pattern. Dish diameter is approximately two metres, with Owl Screech somewhat larger than Hawk Screech and the operating frequency is probably in the G-band for both types.

The NATO designations, Hawk Screech and Owl Screech, are apparently derived from signal characteristics noted in the course of Elint monitoring. They appear to refer to two versions of the same basic radar, and close examination of photographs of this equipment does reveal external differences to support this. These visible variations do not as yet permit positive identification of either with one of the NATO names although information has been obtained suggesting that Owl Screech is an improved version of Hawk Screech.



The two most obvious physical differences between the two types are in the arrangement of equipment behind the dish and in the mounting of the feed. In Owl Screech, the hardware behind the dish is contained in more numerous housings, giving a less tidy appearance than in the other version. Also, the four legs of the feed support are fixed to the dish at points nearer its centre than in the other radar. The pedestals also differ, Owl Screech being tubular, and that of Hawk Screech being slightly tapered. In the photographs studied by *Jane's Weapon Systems* it has been noticed that the feed housing in the Owl Screech version is at an angle of about 45°, whereas in the other version it is orthogonally mounted. This may be a clue to the signal characteristics of the two types. There is one other feature, which is less obvious, that distinguishes the two types. That believed to be Hawk Screech has a small aperture in the dish, on the centre line and near the upper edge. This could be for a closed-circuit TV camera, and there is a small housing on the rear of the reflector. This could be used for optical target acquisition and/or tracking.

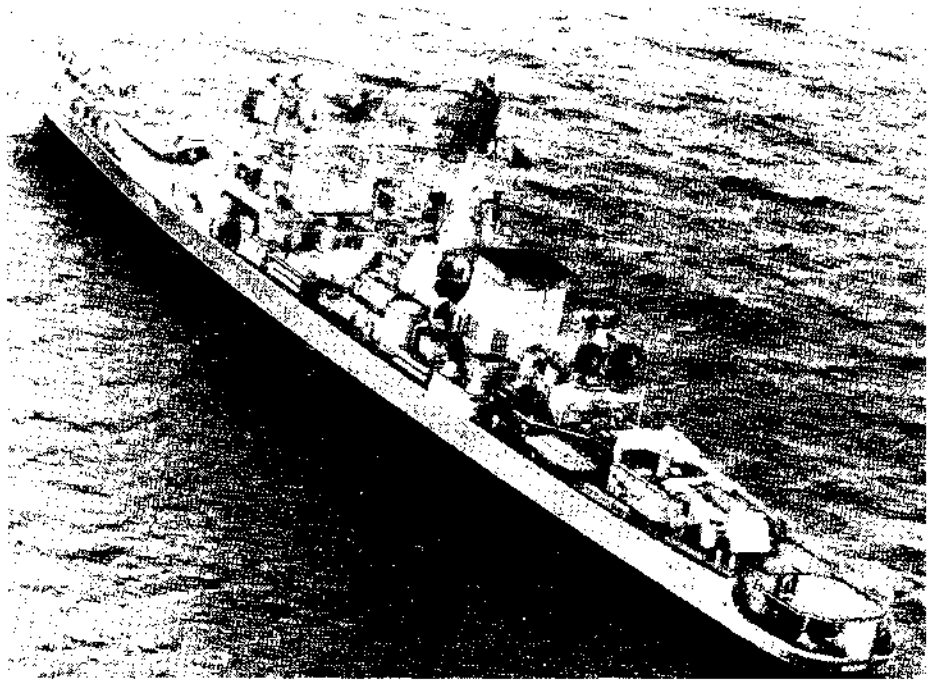
The principal function is that of gun fire director against aircraft targets, although this type probably also has a certain capability against surface targets, and possibly splash detection.

Hawk Screech is associated with quadruple 45 mm, twin and quadruple 57 mm, and twin 76 mm guns, while Owl Screech is employed with 76 mm twin gun installations. Classes of Soviet Fleet vessels fitted with Hawk Screech include: 'Kanin' (one), 'Kotlin' SAM (one), modified 'Kildin' (two), 'Kotlin' (two), modified 'Skory' (two), 'Lama' (two), 'Koni' (one), 'Don' (one), 'Petya' (one), 'Mirka' (one). Owl Screech fittings include: 'Kiev' (two), 'Kara' (two), 'Kynda' (two), 'Kashin' (two), some 'Kildin' (two), 'Krivak' (two), 'Ivan Rogov' (one)

Fire control radar for main guns, believed to carry NATO designation Hawk Screech. Compare feed arrangements with those of Owl Screech

Gun fire control radar believed to carry the NATO designation Owl Screech. Note the angled feed housing, numerous separate equipment housings behind the reflector, tubular pedestal, and feed mounting, which distinguish this radar from that known as Hawk Screech, shown in an adjacent photograph

1328.253
HEAD LIGHT GROUP



This group of radars was first seen on the cruiser helicopter carrier, *Moskva*, but has subsequently made its appearance on its sister ship *Leningrad* and on the 'Kresta II' and 'Kara' classes of guided missile cruisers. Two of these groups of radars are fitted, fore and aft on the 'Kresta II' and 'Kara' vessels, and two forward on the *Moskva*. In very general configuration, and possibly function to some degree, this group resembles the Peel Group missile control radar group for Goa surface to air missiles on other Soviet vessels. The Head Light group consists of a group of four radars, apparently comprising two identical pairs of equipment combined on a common mounting. There is a fifth, smaller dish, possibly fulfilling a command link or IFF function. Two versions have been identified, designated Head Light A and Head Light B, respectively. The former is associated with Goblet surface-to-air missiles and the latter with the SS-N-14 missile system.

The four main reflectors of the group are circular dishes, of open mesh construction, one small and one large to each pair with the smaller in the upper position, and all being disposed symmetrically about the central mounting pillar. Estimated dish sizes are 1·8 and 3·8 m. The electronics for each radar, transmitter/receiver etc, are carried behind the individual reflectors and the whole assembly of four radars is supported from the top of the pedestal turning gear on a yoke of triangulated tube construction.

The whole assembly rotates in azimuth, and can also move in elevation. The two upper radars also appear to have provision for individual movement in both axes, possibly limited, and the dynamic balancing vanes fitted to them could support this suggestion.

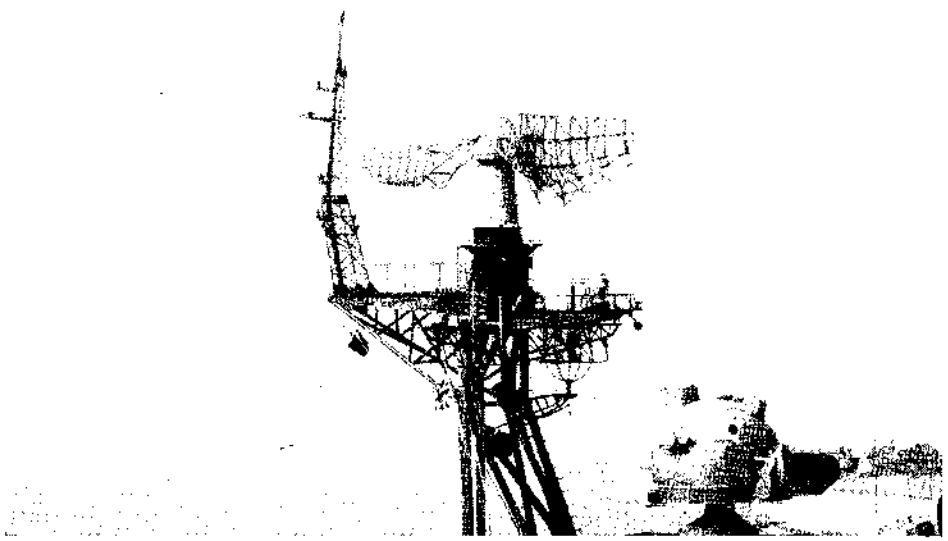
The upper dishes have unusually large feed arrangements which may be of the cassegrain type, and the larger dishes appear to be front fed. Operating frequencies are reported to be in the G-band for acquisition and H/I-band for tracking.

On the *Moskva* and *Leningrad* there is one Head Light group to each of two surface-to-air missile launchers, each for two missiles. On 'Kresta II' class ships there is one Head Light group associated with similar launchers fore and aft. The arrangement on 'Kara' class ships is similar.

This photograph of the 'Kara' class cruiser Nikolaev *shows Head Light radar groups for SAM guidance and control, fore and aft. Air surveillance radars are the big Top Sail on the mainmast and a Head Net C back-to-back system* (RAF)

1318.253
HEAD NET A AIR SURVEILLANCE RADAR

This appears to be the most widely fitted of the numerous radars employed by the Soviet Navy, and appears to be of fairly conventional construction. It has a large (about 6 × 1·5 m) elliptical paraboloid reflector of open lattice construction. This is illuminated by a horn feed carried by a boom projecting from below the lower edge of the scanner. An unusual visual feature compared with practice outside the USSR, is a pair of prominent 'butterfly' vanes extending behind the scanner which are for dynamic balancing.



The scanner mounting is also quite distinctive and has a rather 'lighthouse' like appearance, being quite regular and with a domed top. It is possible, though considered unlikely, that this accommodates some form of scanner stabilisation against ship's motion. It is possible that a relatively high rotation rate is employed.

Operating frequency is in either the D- or E/F-band, probably the latter, with a detection range, on aircraft at medium altitude, of 60–70 nautical miles. No details of the radiated power are available.

The principal function of the Head Net A is assumed to be air search and surveillance and it can be expected to provide target designation facilities for other fire control radars for guns and missiles, carried by the vessel.

It is normally mounted on a mast-top location, or other high positions, and both single and double installations have been seen on various classes of Soviet vessel. 'Kynda' and 'Kashin' class guided missile destroyers have one on each of the two masts; the *Bravy* ('Sam Kotlin' class destroyer) has a single installation on the mainmast.

Head Net mountings and scanners are also employed in two types of dual installation. One is a back-to-back configuration (**1319.253**) with one of the scanners at a larger elevation angle (about 15° more than the companion scanner) to provide separate high and lower cover antennas. The second dual configuration (**1320.253**) is also a back-to-back arrangement, but in this case one scanner is tilted laterally from the horizontal with the probable objective of providing a three-dimensional capability.

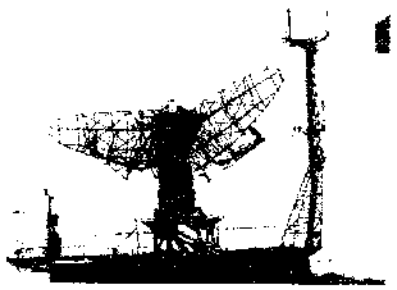
Head Net A surveillance radar, with Sun Visor radar director below and to right. Note also High Pole IFF and assorted direction-finding and ESM antennas

1319.253
HEAD NET B AIR SURVEILLANCE RADAR

This is a dual installation of the Head Net A radar (**1318.253**) in which two scanners are mounted in a back-to-back configuration. One is tilted at an angle of about 15° elevation in relation to the other scanner to provide separate high and low cover. Operating frequency probably lies within the E/F-band of the spectrum, although D-band is a possibility also.

Functions of the radar are search and surveillance, and target designations for the fire control radars carried for the direction of surface-to-air missiles and guns.

This radar has been seen on a 'Krupny' class destroyer (No 229 since renumbered), but does not appear to be in widespread use. The general mechanical arrangement is very similar to the Head Net C (**1320.253**), which is also a back-to-back system using dual Head Net A arrays, and it is possible that individual vessels have been converted from one version to the other. Latest information is that of the five 'Krupny' class ships, *Gnevnyi* now has Head Net C and the others have a Head Net A. The only known remaining Head Net B installations are on two Soviet range instrumentation ships, *Chazma* and *Chumikan*, which entered service in the early 1960s.



1320.253
HEAD NET C AIR SURVEILLANCE RADAR

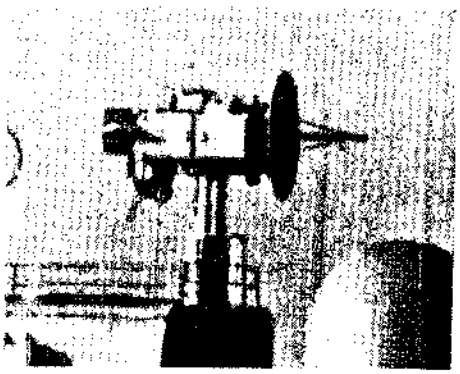
This radar is apparently a back-to-back combination of two Head Net A scanners (**1318.253**), similar to Head Net B (**1319.253**) but with the significant difference that one of the scanners has its aperture (ie. its 'span' dimension) tilted from the horizontal by approximately 30°. This has the effect of displacing the resulting fan-shaped elevation beam by the same amount from the vertical. This beam, in combination with the vertical beam produced by the companion scanner, thus provides the means for heightfinding by the so-called 'V-beam' technique, such as is used in the American AN/TPS-34.

There are important differences, however, in the way in which these two radars employ this principle, apart from other variations between them. The most significant is that the US equipment has both beams (slant and vertical) radiating along a common azimuth, rotating in synchronism, whereas in the Head Net C the beams are separated in azimuth by 180° as a result of the back-to-back configuration employed.

In practice, the vertical beam fulfils the search function and the operator selects a target for which height data is required, and by placing a marker on this target (or similar technique) this places a range gate in the second (inclined) beam and excludes other targets. Computation to give a height readout can be performed by analogue or digital methods.

This radar has been seen on both 'Kresta I' and 'II' classes of guided missile cruisers, the *Moskva* and *Leningrad* cruiser helicopter carriers, some 'Kashin', 'Kanin' and 'Krupny' GMDs, and 'Kotlin SAM II' GMDs. The newest class of vessel to carry Head Net C is the 'Krivak' general-purpose leader type.

Head Net back-to-back three-dimensional air-surveillance radar on 'Kresta II'

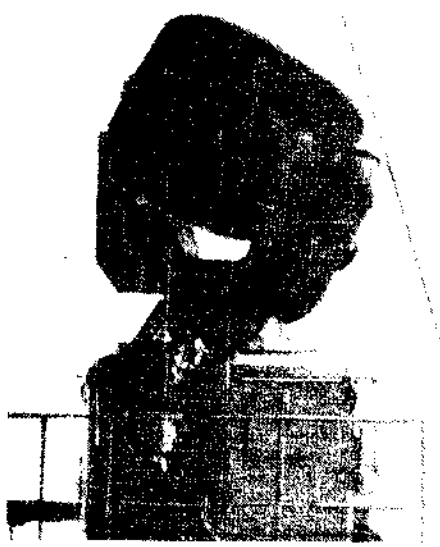


4084.253
KITE SCREECH FIRE CONTROL RADAR

Kite Screech is a gun fire control radar, probably an evolutionary development of the Hawk Screech and Owl Screech family of fire control radars (**1325.253**). A distinguishing feature that enables the Kite Screech to be identified from the other two types is the antenna illuminating feed support assembly which has a noticeably more 'pointed' appearance compared with the Hawk and Owl Screech radars. The latter types also have a comparatively large dielectric housing protecting the actual radiator element, whereas the equivalent item on the Kite Screech is much less prominent. G- or I-band operation is probable, and possibly this recently introduced radar incorporates monopulse tracking instead of conical scan tracking.

The only fittings noted to date are aboard the new 'Kirov' class cruisers, where the Kite Screech radar is used for the direction of two 100 mm gun turrets mounted aft, the 'Sovremenny' class destroyers and the new guided missile cruiser *Slava*.

Kite Screech fire control radar on the Soviet ship Sovremenny showing the very pointed appearance of the antenna feed assembly (see text)



Aboard the Soviet cruiser Kirov a single Kite Screech radar is used for direction of two single 100 mm dual-purpose gun turrets

1611.253
MUFF COB FIRE CONTROL RADAR

The Muff Cob fire control radar is similar in general appearance to the Drum Tilt fire control radar (**1330.253**), but the former has provision for elevation motion, being supported by a trunnion yoke carried on the traversing mounting. The operating frequency is probably in the G/H- or I-band part of the spectrum. Some drawings of Muff Cob show what appears to be an on-mounted TV or optical tracking sub-system, but this has not been confirmed.

In all the installations of Muff Cob studied, this radar is employed for gun fire control purposes only. On the helicopter carriers *Moskva* and *Leningrad* there are two Muff Cobs mounted high on each side of the main superstructure for direction of the twin 57 mm guns on either side of these ships. Both 'Kresta I' and 'Kresta II' classes of guided missile cruiser have two Muff Cobs each, carried on platforms on the sides of the funnel. These are for control of twin 57 mm guns on each side. Some of the 'Ugra' and 'Lama' classes of support ships have two Muff Cob installations, and there are single fittings on ships of the 'Poti' class of coastal escorts. The 'T58' class of fleet minesweepers carry a single Muff Cob on top of the bridge house. Some 'Polnochniy' amphibious landing craft (Type IX) carry a Muff Cob for direction of anti-aircraft guns.

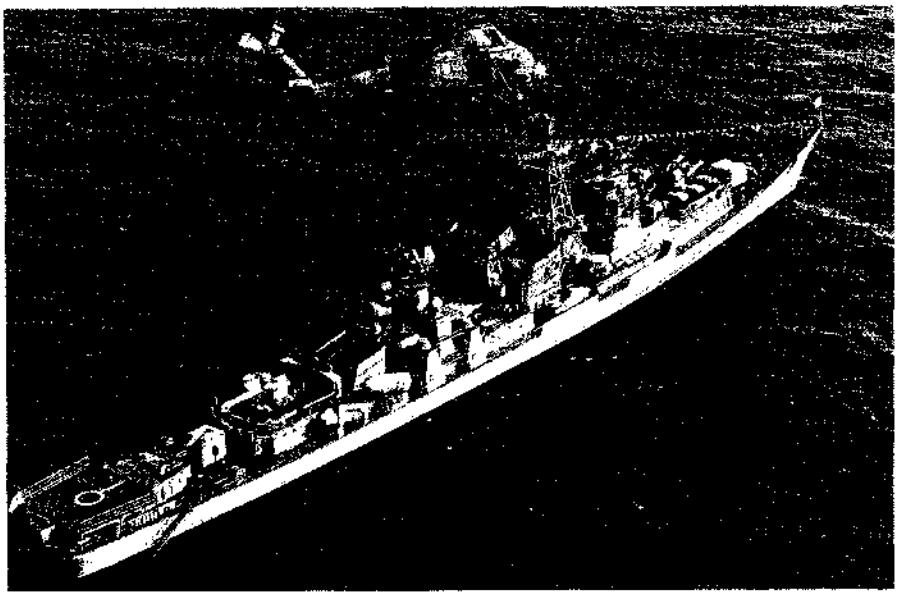
Muff Cob fire control radar

1323.253
PEEL GROUP FIRE CONTROL RADAR

This group comprises four distinct radars on a common mounting and is associated with the Goa surface-to-air armament of Soviet vessels. The radars entered operational service in the early 1960s. Within the group are an H/I-band tracking radar for high altitude targets and an E-band guidance radar for lower altitudes. The maximum range is reported as 30 to 40 miles (55 to 75 km). All four scanners are of solid-reflector construction and of elliptical parabaloid shape. There are two large and two small scanners in each group, one of each size being disposed with its major axis horizontal and the other vertical.

The central mounting has noticeably rounded proportions and appears to provide a common axis about which the group rotates in azimuth, and the forward side of this mounting is another large housing providing for rotation of the group in elevation. It cannot positively be ascertained if this provides for separate elevation rotation of the individual elements of the group. Viewed from the front, the large vertically disposed scanner is to the right of the central mounting and the other three scanners are to the left of it.

Although unrestricted rotation of the individual vertical and horizontal elements of the Peel Group is unlikely, sector scanning is probable for the performance of air target tracking. Target designation is probably provided by one of the Head Net series of air surveillance radars, and the Peel Group does not seem to have been designed to give a search capability.



The feed arrangements are a matter of some conjecture. Those of the two smaller scanners are distinguished by large offset boom-mounted illuminator housing boxes the shape of which seems to suggest that they contain multiple horns. One feasible explanation for this is that a monopulse tracking technique is used, with separate radars for each co-ordinate, azimuth and elevation. Operating frequency of the two smaller radars of the group is probably in the I-band.

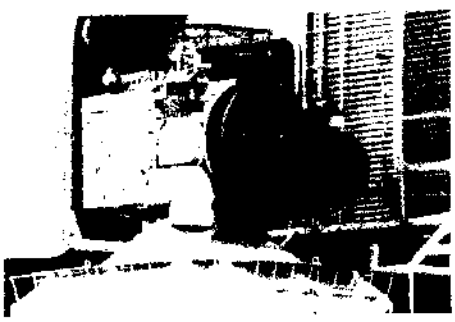
The feeds of the two larger radars are smaller than those of the other two radars of the group and are not offset. The feed housings are of cylindrical form and may contain devices such as a quarter-wave plate to provide circular polarisation as an aid to higher weather penetration.

Information is too limited to draw firm conclusions concerning the functions of the individual elements of the Peel Group in tracking the target and directing the missile. A likely assessment is that the two larger scanners are employed for the longer range target acquisition and coarse tracking, while the two smaller scanners provide precision tracking.

Between the large vertically oriented scanner and the central mounting a further unit of uncertain function is located. This could be a radiator for guidance signals to the missile until its own homing system comes into operation. It is also a reasonable assumption that some provisions for IFF are made within the system.

The normal deployment arrangements associate one Peel Group unit with one dual Goa surface-to-air missile launcher. 'Kresta I' class guided missile cruisers have two installations, one forward above the bridge and the other aft, atop a short tower, and 'Kashin' class GMDs are similarly fitted. The 'Kynda' class GMDs have a Peel Group installation above the bridge, and on 'Kotlin' class GMDs there is a Peel Group on a square, tapered tower amidships.

The two Peel Group missile control radars stand out, fore and aft, on this modified 'Kashin' class destroyer, at anchor off the Libyan coast. Also prominent are the air search radars Head Net C and Big Net on the two lattice masts, Bass Tilt fire control radars for the Gatling-gun turrets, fore and aft Owl Screech fire control radars for twin dual-purpose gun turrets, and the ship's impressive armament (HMS Intrepid)



1609.253
PLINTH NET SEARCH RADAR

Plinth Net is a medium-range E-band general-purpose search radar with an elliptical lattice reflector illuminated by an underslung boom-mounted feed horn. Functions include air search and target designation. Range against air targets at medium attitudes is about 80 nautical miles (150 km), and 20 nautical miles (37 km) against surface ship targets. There are no balance vanes behind the scanner. The turning gear is housed in a tapered cylindrical mounting, from which the NATO name for this radar is derived. Plinth Net is fitted in certain ships of the 'Kynda' and 'Kresta I' class, 'Talin' class, and 'Sverdlov' class cruisers.

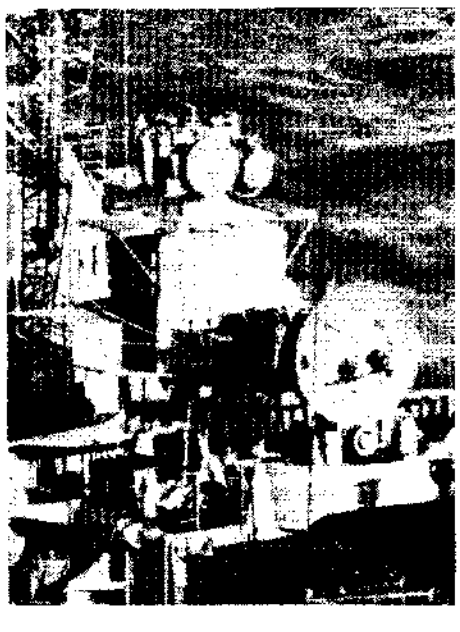
1897.253
POP GROUP FIRE CONTROL RADAR

Pop Group is the NATO code-name for the fire control radar group associated with the Soviet Navy's SAN-4 surface-to-air missile system (**2954.231**). The name has its origin in the fact that the launcher for this missile system pops up from a silo-type housing preparatory to launching.

Few details have been obtained regarding the operation of the Pop Group radar but at least two antennas are used for radar functions, with a third for the transmission of command signals to the missile. The arrangement consists of a cube-shaped container with sides of about 2·2 m in which is probably housed the bulk of the electronics such as transmitter/receiver units, power supplies, and turning gear, and on the top of this is a trainable radar head assembly. The latter unit, so far as can be ascertained from the limited evidence available, has a parabolic antenna of about two metres aperture which is probably for target search and which may rotate independently of the rest of the radar head (which, as noted above, can be trained in azimuth). On the front face of the head are two circular arrays that are assumed to be for target tracking and missile guidance. Operating frequencies are likely to lie in that part of the spectrum contained within the G- to J-band region.

Pop Group fire control radar

The public display by the Soviet Union in November 1975 of the land-mobile SA-8 missile system, complete with its associated radar group, rapidly led observers to comment upon the similarities between this radar and Pop Group. The theory that the two recent sea and land air-defence missiles are related is an attractive one, but it should be noted that whereas the SA-8's radar group has two antennas which are assumed to be for command link signals, the Pop Group set has only one. The fact that the main tracking array of the land radar has cropped sides is not significant, and this measure was probably adopted to enable the overall dimensions of the radar to be reduced to measurements compatible with those of the carrier vehicle.



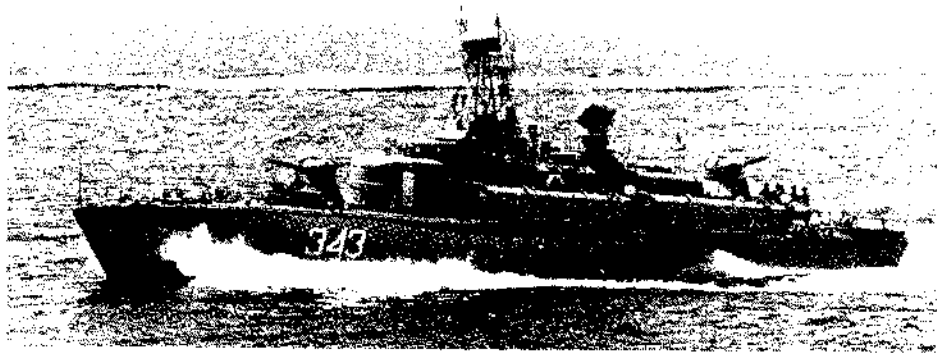
Operating frequencies for SA-8 are conjectured to be G- or H-band for search and target acquisition with I-band for tracking.

STATUS

Since Pop Group was first detected on Soviet 'Nanuchka' class missile frigates in the late 1960s, it has been fitted to an increasing number of types of vessel of widely differing sizes.

'Nanuchka' class ships have a single Pop Group installation on top of the bridge housing, and a similar arrangement is employed in the 'Grisha' escorts, the SAN-4 launcher 'bin' being located in the forecastle on both types of vessel. The 'Krivak' missile destroyers have SAN-4 installations fore and aft, with a Pop Group radar for each system, one on top of the bridgehouse and the other on a raised mounting amidships. 'Kara' class missile cruisers have two SAN-4 systems, located one on each side of the mast and with their associated Pop Group radars are two automatic anti-aircraft gun turrets on each side, and these would appear to be directed by the Pop Group radars to form (with the SAN-4 missile launchers) port and starboard integrated close-in autonomous air defence weapon systems.

In the case of the converted 'Sverdlov' cruisers, the largest vessels equipped with SAN-4, various arrangements exist. *Zhdanov* had its SAN-4 silo fitted in place of the original 'X' 152 mm gun turret, and the associated Pop Group radar was installed on a platform attached to the aft mast. The *Admiral Senyavin* has its SAN-4 installation incorporated in the helicopter hangar, with the Pop Group in the same position as on the *Zhdanov*. In the former ship, however, there are four automatic AA gun turrets mounted adjacent to the SAN-4 system.



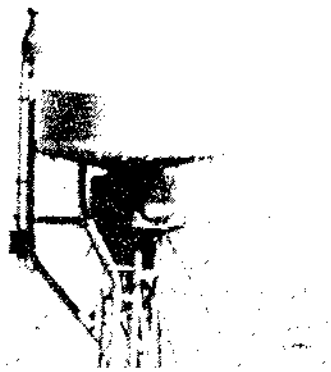
A similar view of the Pop Group radar on a 'Krivak' class destroyer. The Owl Screech gun fire control radar below the Pop Group is facing the opposite way showing the feed arrangements more clearly

The 'Nanuchka' class fittings were the first to appear in quantity, but since those early days many classes and individual ships of the Soviet Fleet have appeared armed with the SAN-4 missile system and equipped with Pop Group radar. A single Pop Group is fitted to ships of the 'Koni', 'Grisha I' and 'III', and 'Sarancha' classes, as well as the *Ivan Rogov* landing ship and the fleet replenishment ship *Berezina*. Two Pop Group installations are found on ships of the 'Kara', 'Kiev', 'Kirov', and 'Krivak I' and 'II' classes.

1612.253
POT DRUM NAVAL RADAR

Pot Drum is a small surface search radar, probably operating in H/I-band and protected by a flat, slightly domed, radome from which its NATO code name is derived. The diameter of the radome is about 1·5 m and the unit is typically installed at the masthead of small patrol boats. This radar is probably of conventional design with the possible exception of a rather higher than usual rate of scanner rotation and the inclusion of ECCM and perhaps a passive direction finding mode of operation. The transmitter/receiver is housed below decks. The display unit has a small CRT display (about 15 cm), so that short range operation of the radar is likely. In addition to surface target detection, Pot Drum probably is used for pilotage purposes also and may have a limited air warning capability. The principal operational role is that of surface search and fire control for torpedoes carried by fast MTBs. Range is about 20 nautical miles (37 km).

Coastal escorts of the 'Stenka' and 'Kronstadt' classes are fitted with Pot Drum, as are torpedo boats of the 'Shershen' class, some 'P6' class boats, and the 'Pchela' class of hydrofoil craft.



Soviet 'Shershen' class torpedo boat with Pot Drum surface search radar and Drum Tilt fire control radars for guns

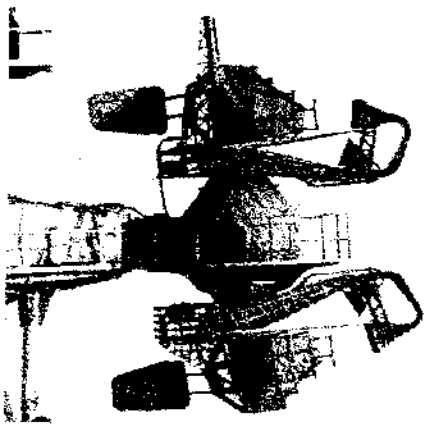
1613.253
POT HEAD NAVAL RADAR

Pot Head is similar in appearance to the Pot Drum surface search radar (**1612.253**) but is slightly smaller with an estimated diameter of 1·2 m. Another distinguishing feature is that the top of Pot Head is flatter than that of Pot Drum. The operating frequency is probably in the I-band but the possibility of E-band operation has been quoted by certain sources. The main function will be that of surface target detection, with pilotage and limited air warning facilities as supplementary capabilities.

Fittings appear to be confined to torpedo boats of the 'P6', 'P8' and 'P4' classes operated by the Soviet and East German Navies.

Pot Head short-range surface radar with IFF antenna

1324.253
SCOOP PAIR SURFACE TARGET RADARS



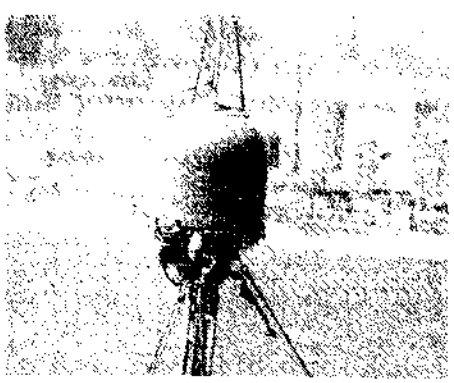
This radar system is a feature of Soviet vessels equipped with Shaddock surface-to-surface missile launcher tubes. It consists of two apparently identical radars mounted above and below a spherical housing supported at the end of a sponson. Photographs indicate that these sponsons, which are aligned with the ship's fore-and-aft axis, may include provision for rotating the radar group to provide stabilisation against roll motion, and there may also be pitch stabilisation but this is not known for certain.

The scanners are of open lattice construction and of essentially elliptical parabolic form, although the contours are rather angular. They have quite a high span/depth ratio and the former dimensions are estimated at approximately 4·2 m. They each have the typical Soviet balance vanes behind the scanners, in this case of almost square outline. Each scanner is illuminated by a double horn assembly carried on a boom, coming from beneath the scanner in the case of the upper radar of the group, and above in the case of the lower radar. The disposition of the horns suggests that they are arranged to provide maximum elevation coverage from the combined pair of radars. A further possibility for the use of double horns is that they are associated with special signal processing equipment to provide optimum target detection in the presence of sea clutter returns.

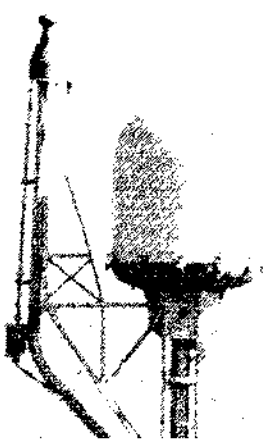
It is not known if the two radars comprising the Scoop Pair group are rotated in azimuth independently, although there is no mechanical reason why they should not be.

Operating frequencies are in the E-band. Probable functions include surface search, and target detection to provide range and bearing data for the Shaddock missile fire control system, and tracking of the missile after launch.

All Shaddock-carrying Soviet vessels appear to be equipped with one or two Scoop Pairs, depending upon the Shaddock launching arrangements. 'Kresta I' class guided missile cruisers have a single installation, high on the main 'tower', and this serves two twin launchers below, and on each side of the bridge. 'Kynda' class ships have two groups, fore and aft, each serving a four-tube launcher.



Scoop Pair radars for surface-to-surface Shaddock missiles. The projection above the upper-scanner could be for IFF. The scanners can be seen to employ a solid reflector in front of which is a parallel grid, presumably to improve clutter rejection

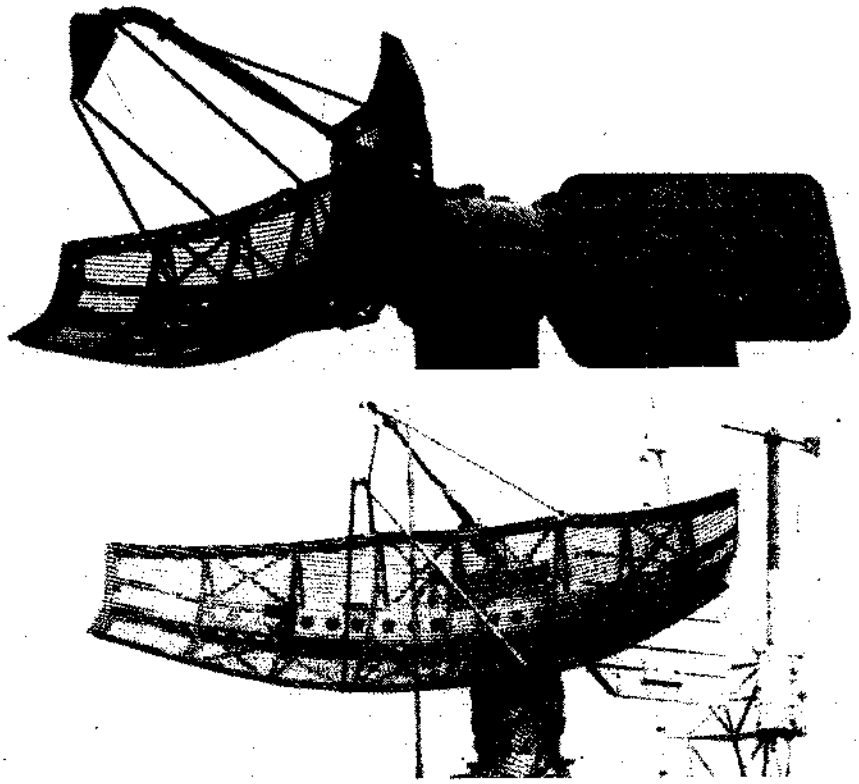


1614.253
SKIN HEAD NAVAL RADAR

The Skin Head radar is principally associated with Soviet torpedo boats and its function is assumed to be surface target detection for use in association with torpedo fire control systems. Its appearance is characterised by a thimble shaped dome from which the NATO code-name is derived, and generally a masthead mounting. Diameter of the radome is estimated to be about 0·8 m. The nature of the scanner assembly inside is not known but a high rotation rate is assumed. Operating frequency is probably in the I-band.

Although Skin Head is mostly associated with torpedo boats of the 'P4' and 'P6' classes, used by the Soviet and friendly navies, the 152 mm gun turrets of Soviet 'Sverdlov' cruisers carry a radome of similar proportions (NATO code-name Egg Cup) which suggests that the same radar may be used for fall-of-shot measurement or other purposes on these ships.

Skin Head radar on masthead of 'P'-type Soviet torpedo boat. The array on top may be an alternative IFF antenna



Skin Head radar used for surface target detection on Soviet torpedo boats. Small antenna is for IFF

1322.253
SLIM NET SURFACE WARNING RADAR

Slim Net is a surface warning, high definition, radar of generally conventional naval design, plus the typical Soviet characteristic of balancing vanes behind the scanner. It also has an air search capability. The scanner is of open lattice construction and approximately 5·5 m span and 1·8 m maximum depth. The general shape is of a tapered rectangle, and the balance vanes also are rectangular. The horn feed is mounted on a boom overhangng the scanner. Operating frequency probably lies within the E/F-band of the spectrum.

Vessels seen with this radar include some ships of the 'Kildin' class of guided missile destroyers (in which it may be associated with the Strela surface-to-surface missile launcher); 'Kotlin' class destroyers; and 'Tallin' class destroyers. In all three cases it is carried on top of the rear tripod mast. It is believed that some 'Riga' class and 'Petya' class escorts have been equipped.

Slim Net scanner assembly, with Yard Rake rotating Yagi array (right)

5849.453
SNOOP CLASS SUBMARINE SURVEILLANCE RADARS

A number of surveillance radars have been fitted to Soviet submarines since World War II, some of which have been given a NATO designation starting with Snoop. The early Soviet submarines were equipped with a small antenna designated Snoop Plate. This was apparently fitted to all boats up to the 'Golf/Foxtrot/Romeo' classes and was reputed to have a range of 25 nautical miles against aircraft and 12 nautical miles against surface vessels. Later 'Foxtrot' class vessels and the 'Hotel' generation were fitted with a larger and more powerful radar known as Snoop Tray which entered service in the early 1960s.

Since the early 1960s, all new Soviet submarine have been fitted with Snoop Tray, with the exception of the 'Juliet' and 'Echo' classes of cruise missile submarines which are equipped with a much larger antenna known as Snoop Slab. This antenna is twice the size of the Snoop Tray unit and must be capable of greater definition at longer ranges. Both the 'Juliet' and 'Echo' classes are armed with the surface-launched SS-N-3 Shaddock missile and it is assumed that the Snoop Slab radar will also provide back-up cover for the Front Door/Front Piece missile guidance equipment.

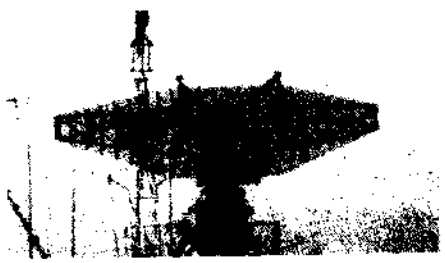
STATUS

In operational service.

1595.253
SQUARE HEAD NAVAL RADAR

The antenna of this system consists of a broadside array of dipoles with a rectangular reflector/support frame measuring about 1·4 m high by 2 m wide. It was originally thought to be a long wavelength search radar of modest power, but later evidence confirms that its function is that of an IFF interrogator antenna, or a directional array for the transmission of guidance signals to surface-to-surface missiles. It is most frequently seen on Soviet missile carrying boats of the 'Osa' class (but apparently not on craft of this class of the navies of countries friendly to the USSR), and these generally have two such arrays carried on sponsons fore and aft of the tubular mainmast. Some 'Kotlin' class destroyers of the Soviet fleet carry four, and Square Head has been seen on vessels of the 'Skory' class.

Recent information suggests that the Square Head antenna is associated with an IFF system operating in the G-band.



1329.253
SQUARE TIE NAVAL RADAR

Square Tie is a small lightweight search radar, probably operating in the I-band to provide short range air and surface search facilities. It is extensively fitted on Soviet vessels of the 'Osa' class armed with anti-ship missiles. The scanner is an elliptical paraboloid reflector illuminated by an overhung horn feed. Functions will include target detection and tracking for anti-ship missile direction and possible target designation for the Drum Tilt gun fire control radar carried by 'Osa' class craft. Maximum range is believed to be about 70 nautical miles (130 km).

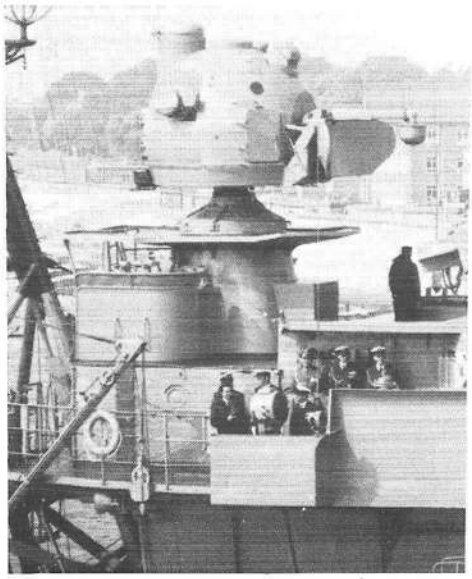
1331.253
STRUT CURVE SEARCH RADAR

Strut Curve is a medium-range general-purpose air search radar, probably operating in the E/F-band to provide both air and surface search facilities. An elliptical lattice reflector is used, illuminated by a horn feed carried by a boom projecting from the lower edge of the scanner. The boom is supported by two struts which attach to stays at the upper edge of the reflector. Somewhat unusual for Soviet naval radars, the Strut Curve has no balance vanes behind the reflector.

Range performance against an aircraft target at medium altitude is about 60 nautical miles (110 km) with a likely maximum range of 150 nautical miles (280 km).

Strut Curve search radar

Strut Curve antenna profile



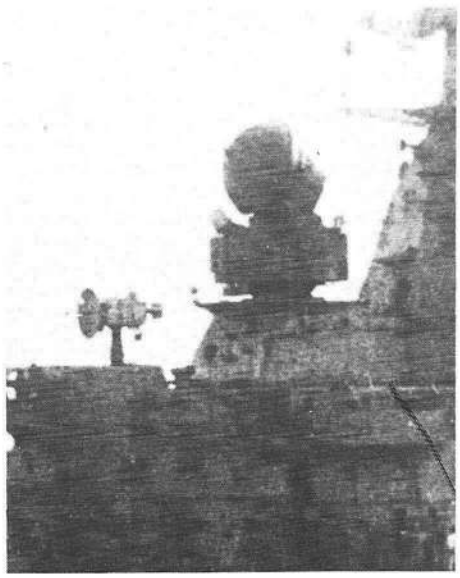
Soviet vessels fitted with Strut Curve include the 'Poti' class of escorts and certain support ships.

1326.253
SUN VISOR FIRE CONTROL RADAR

Sun Visor is identified as a solid paraboloid scanner fixed to the front of a spherical shaped gun fire director station. Two types of director have been identified carrying this type of radar. These have the NATO code names Round Top and Wasp Head, and in the former the radar is carried near the top of the unit compared with a lower location on Wasp Head, which is stabilised. Span of the dish is estimated at approximately 2·2 m, and the depth at 1·3 m. Operating frequency is probably I- or G/H-band. The reflector is illuminated by a dielectric-enclosed feed carried on a solid boom structure projecting from over the upper edge of the reflectors. The disposition of these components suggests that surface target detection is the principal role of this radar.

The fire director units on which Sun Visor is mounted are capable of 360° rotation, but since they are manned units incorporating optical rangefinding equipment also, it is unlikely that it is normally used for target search and surveillance on a continuous basis. A more likely mode of operation is for target co-ordinates to be passed to the system by another of the ship's radars and for the former to operate in a target acquisition and lock-on role to provide either range and bearing data for blind firing or to assist the operator in the training of optical sighting systems.

Sun Visor has been seen on certain vessels of the 'Krupny' class of GMDs, the 'Kanin' class, 'Kotlin' class, 'Talin' class, and 'Sverdlov' class cruisers.

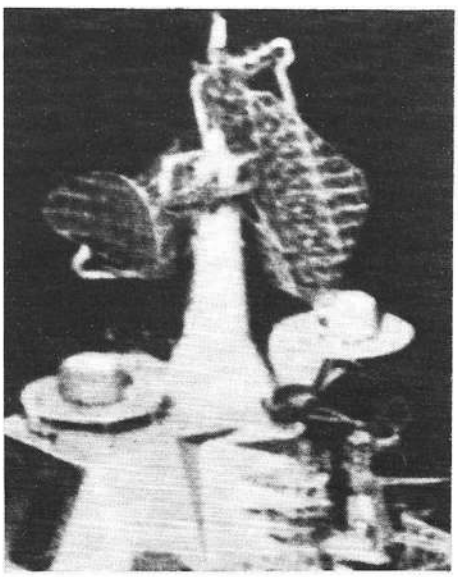


Sun Visor gun fire control radar

4088.253
TOP DOME RADAR GROUP

Top Dome is the name of the radar group associated with the SA-N-6 naval area air defence weapon system fitted in the Soviet cruisers *Kirov* and *Frunze*. This system is thought likely to be an approximate Soviet equivalent of the American Aegis surface-to-air naval air defence missile system, in which case the Top Dome radar group will embody long-range tracking and guidance functions, probably incorporating multi-mode operating facilities of one sort or another. At this early stage it is possible only to embark on preliminary conjecture concerning the functioning of the Top Dome radar group. The *'Kirov'* class has two such director groups located fore and aft, this being more to achieve an all-round engagement capability rather than by any requirement to associate the individual directors with missile launcher installations in specific parts of the ship. The SA-N-6 is believed to employ a vertical launch technique so that once missiles are launched from the magazine on the foredeck of the ship and are clear of the ship's superstructure, they can be commanded to turn onto any course required to engage the specified target.

Targets are probably detected by either passive means (of which *Kirov* has an ample selection) or the Top Pair radar group, and targets are designated to either of the two Top Dome director groups which are then laid on to the necessary threat direction. When the Top Dome radar (or passive detection sub-system) acquires the target and locks on and when the target has reached an appropriate engagement range one or more SA-N-6 missiles are launched and commanded to the proper direction, after which automatic guidance to interception takes place. The Top Dome radar group is probably capable of tracking both the SA-N-6 missile and the designated target simultaneously, and there is also the possibility of a combined mode of guidance involving target tracking through the SA-N-6 seeker with the command link relaying data back to the ship. In any event, the new system is likely to incorporate several guidance options to cater for changing circumstances and to deal with opposing countermeasures.



The Top Dome group mounting is obviously designed to rotate in azimuth and probably has some horizontal stabilisation against ship's motion also, but continuous rotation of the mount is thought unlikely. Stabilisation gear is possibly housed within the hexagonal portion of the mounting. The 'front' face of the latter carries three antenna housings of hemi-cylindrical shape; these are thought to contain passive sensors or command link elements. A similar purpose is also possible for the small 'thimble' shaped housing carried above the hemi-cylindrical units, at an angle. The contents of the main dome remains uncertain at this stage.

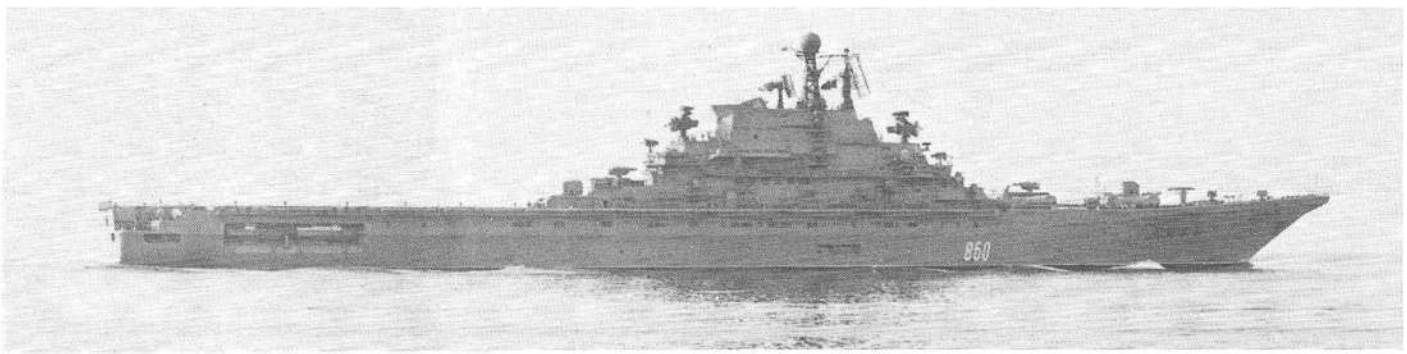
Top Dome radar director group on the Soviet cruiser Kirov *with Kite Screech gun fire control radar to the left*

4087.253
TOP PAIR RADAR GROUP

Top Pair is the name of a back-to-back configuration of two very different naval radar types employed for long-range air surveillance. One is the well-known Top Sail 3-D radar which is associated in this configuration with what appears to be the Big Net long-range search radar (or a derivative of it). All known fittings are aboard recent ships known to have a major air role, such as the aircraft carriers of the 'Kiev' class. The Top Pair group has also been noted more recently fitted in the Soviet guided missile cruiser *Slava*, as well as the cruisers *Kirov* and *Frunze*, which in addition to carrying their own helicopters are fitted with the new SA-N-6 surface-to-air missile system and are thought to have an important anti-air escort role in support of the Soviet carrier force. Operating frequencies in the D-band, and possibly E/F-bands, are thought likely for the Top Pair radars. Detection ranges of several hundred kilometres can be expected.

Enlargement of Top Pair radar group on the Soviet cruiser Kirov

Soviet cruiser Kirov, *showing the Top Pair air surveillance radar group at the very highest position on the ship's superstructure, with another new radar group, Top Steer, to be seen further aft on top of the pyramidal mast. The ship also displays two Top Dome fire control radar groups (fore and aft) for the ship's SA-N-6 vertical launch area defence anti-aircraft missile system. Numerous ESM and EW antennas are clearly visible*



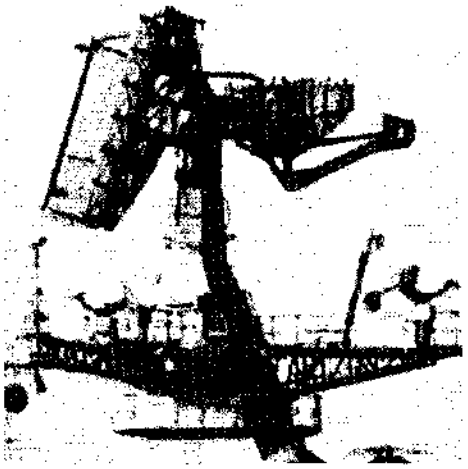
1327.253
TOP SAIL THREE-DIMENSIONAL RADAR

Top Sail is a very large air surveillance radar, first seen on the Soviet cruiser helicopter carrier, *Moskva*, and her sister ship *Leningrad*, but later on the new 'Kresta II' and 'Kara' classes of guided missile cruisers. In all installations the radar is mounted at the highest point of the vessel; in the case of the 'Kresta II' class on a large diameter tubular pedestal atop the principal tower, and on the helicopter cruisers supported by a tubular tripod. In the 'Kara' installation the scanner surmounts a typically Soviet pyramid shaped structure amidships.

The scanner is of cylindrical cross-section, the axis of which is tilted from the vertical at an angle of about 20°. It is of lattice construction and has a frontal aspect of rhombic shape (estimated 5·5 m sides), with 'cropped' corners. Illumination of the reflector is by a linear radiating element located parallel to the reflector's cylindrical axis, and supported top and bottom. The feed appears to be from the upper end. It may consist of multiple horns to provide three-dimensional air target data by the 'stacked-beam' method, or some form of electronic scanning in elevation (such as the ridged waveguide) may be used to achieve the same result. Operating frequency is probably in the D-band, although one authority has quoted G-band operation, with high transmitter power. The theoretical maximum range is more than 300 nautical miles (555 km).

The photograph of a 'Kresta II' Top Sail antenna shows what appears to be a second system of waveguide, of smaller dimensions than the main system, apparently feeding a horn at the top of the main illuminator. This might indicate dual band operation facilities for some purposes. There is a subsidiary antenna fixed to the top of the Top Sail scanner which could be for IFF. In addition to the two plates which are the most prominent feature of this secondary antenna there are also three dipoles. Near the bottom of the illuminator of the main Top Sail are what could be a similar group of three dipoles. The function of these elements has not been ascertained.

In all three classes of vessel equipped with Top Sail it is associated with similar radars, a Head Net C back-to-back 'V-beam' set, and Head Light group missile fire control director radars. The Top Sail is probably used for long-range air surveillance and target designation.



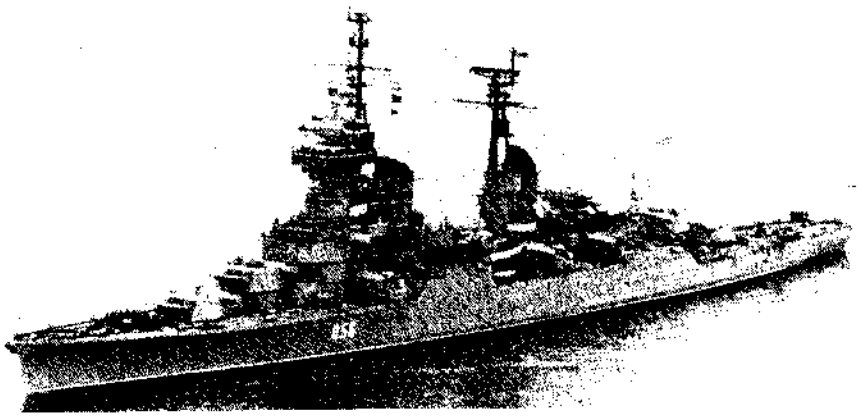
The profile of the Soviet aircraft carrier Kiev *clearly illustrates the ship's comprehensive radar fit. Ahead and abaft of the Top Globe on its mast are Top Sail and Top Steer air surveillance radars, respectively, emphasising their size difference; below these radars are fore and aft Head Light missile control radar groups, Owl Screech gun fire control radars, with a navigation radar between the forward Head Light and Owl Screech*

4086.253
TOP STEER RADAR GROUP

Top Steer is the name given to what appears to be a new generation Soviet air search radar group comprising a pair of scanners mounted back-to-back, usually high up on the superstructure of the ship. The two scanners are not the same and one is somewhat similar in appearance to the well-known Top Sail 3-D air surveillance radar fitted to several classes of recent major Soviet ships. However the Top Steer antenna is noticeably smaller, as can be seen on ships such as the new *Kirov* cruiser which has both Top Sail and Top Steer fitted. The other scanner appears to be either a standard Head Net A search radar or a modified derivative of it. It is not known if the two radars are operated together as part of a single complex system of a new type, or if the two scanners are merely co-mounted as a matter of structural convenience with either one of the two radars being capable of independent operation on its own (apart, of course, from having common turning gear and/or stabilisation).

Operating frequencies of both radars are likely to be in the D/E/F-bands of the radar spectrum and it is possible that the larger antenna may incorporate some form of frequency scanning of the beam in elevation to provide a heightfinding capability. The probable function of this radar group is that of air control of the ship's helicopters, or other aircraft operating with the ship.

Top Steer installations have been noted on the cruisers, *Kirov* and *Frunze*, on the *Sovremenny*, which is thought to be the lead ship of a new class, on the recent 'Kiev' class aircraft carriers, and the guided missile cruiser *Slava*.

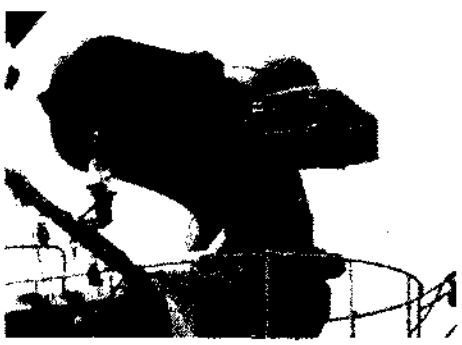


Top Steer radar group on the Sovremenny

This view of the Soviet aircraft carrier Kiev *clearly shows the considerable difference in size between the Top Sail 3-D radar and the Top Steer radar group mounted aft of the Top Sail and the flaired-in mast that carries the Top Dome* (RAF)

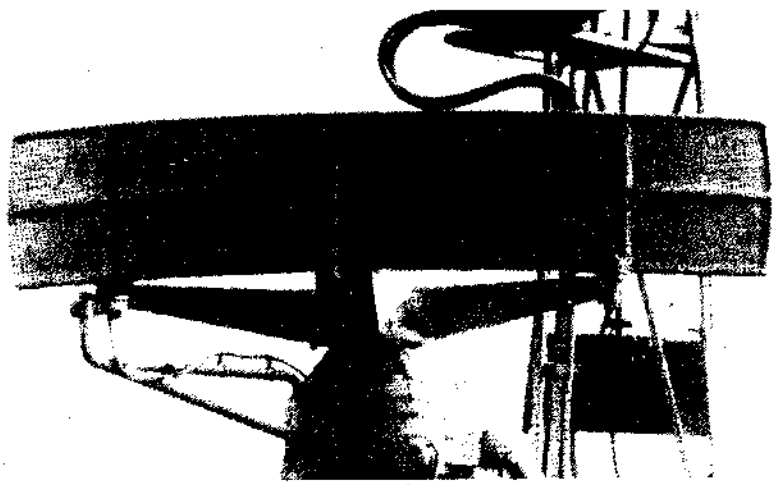
1610.253
TOP TROUGH SURVEILLANCE RADAR

Top Trough is a C-band long-range air search radar with a probable maximum range of up to 300 nautical miles (555 km). The only known installations are on some ships of the Soviet 'Sverdlov' class of cruisers, in particular *Mikhail Kutuzov, Senyavin and Zhdanov*.



Soviet 'Sverdlov' class cruiser, Mikhail Kutuzov, *showing Top Trough radar on aft mast. Knife Rest (Uda-Yagi) antenna for air warning can just be discerned forward of aft gun turrets*

1900.253
OTHER SOVIET NAVAL RADARS



Photographs have been obtained of a number of other radars fitted to ships of the Soviet Fleet additional to those described in the preceding entries. Insufficient information is available to make possible individual entries, but the photographs are reproduced to assist readers with identification.

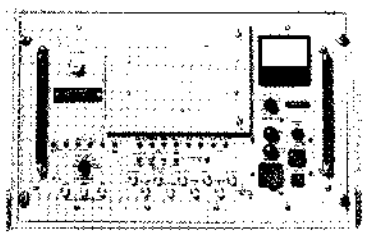
CEL 850 NAVAL INTERROGATOR



The Cossor CEL 850 naval IFF interrogator is the shipboard version of the CEL 850 general-purpose interrogator, and additional details will be found in **3692.153** in the Ground Radar section of this volume. In the naval application it is suitable for use in all classes of ship, down to fast patrol craft in size. The transmitter section has an output of 2 kW (peak), and the equipment can operate on Modes 1, 2, 3/A, C and External. It is designed to accommodate many different interfaces so that integration with numerous types of primary radar presents no problem.

STATUS

In production with deliveries to navies all over the world.

CONTRACTOR

Cossor Electronics Ltd, The Pinnacles, Harlow, Essex CM19 5BB, England.

Cossor CEL 850 general-purpose interrogator equipment

3701.253
IFF 2750 (TYPE 1013) NAVAL TRANSPONDER

Under contract to the Royal Navy, Cossor modified their IFF 2720 airborne IFF transponder (**3695.353**) for naval applications. The resulting equipment, IFF 2750, has a low magnetic profile, low weight and low volume, thus making it suitable for fitting in all classes of vessel, including minehunters. In the Royal Navy the IFF 2750 is designated the Type 1013. The key features of the IFF 2720, high reliability, ease of access for maintenance, and continuous on-line monitoring, have been retained in the IFF 2750.

CHARACTERISTICS

Modes: 1, 2, 3

Receiver frequency: 1030 MHz

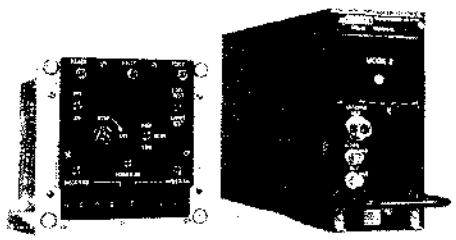
Receiver sensitivity: –76 dBm

Transmitter frequency: 1090 ±3 MHz under all service conditions

Transmitter power output: 750 W (nominal); 500 W (minimum)

Reply coding: 4096 on all modes

Dimensions: 91 × 193 × 381 mm



Weight: 4·6 kg

STATUS

In production and supplied to the Royal Navy and other customers.

CONTRACTOR

Cossor Electronics Ltd, The Pinnacles, Harlow, Essex CM19 5BB, England.

Cossor IFF 2750 naval transponder (Type 1013) and control unit Type IFF 2753

1941.253
RACAL SURVEILLANCE AND NAVIGATION RADARS

Racal navigational radars are now in service with some 90 navies, not only for general navigational purposes, but also as prime sensors for action information systems and weapon control. These standard commercial marine radars, in both the E- and I-bands, are frequently interfaced with a wide variety of fire control systems, surveillance radars, EW systems and computers.

The use of standard commercial equipment with transmitter emission characteristics indistinguishable from those of thousands of commercial users reduces the chances of identification by ESM.

Racal Clearscan video processing provides sea and rain clutter and radar interference suppression and echo stretching. The first anti-collision radar was introduced in 1968 and shows true and relative motion data simultaneously. Markers can be placed on five echoes to show the movement of targets which are being shadowed or attacked.

The Racal Command Tactical Console (CTC) is based on the well-tried all-weather commercial ARPA and autotracks up to 20 targets, air or surface, with ground stabilisation, true motion storage and target indication facilities.

The Racal 2459 F/I radar with its widely spaced dual frequency capability provides combined air and surface surveillance for warships fitted with guns and sea-to-air or -surface missiles.

CONTRACTOR

Racal Marine Radar Ltd, Burlington House, 118 Burlington Road, New Malden, Surrey KT3 4NW, England

1563.253
MRS3/GWS22 FIRE CONTROL RADARS TYPES 903/904

The MRS3/GWS22 is standard Royal Navy equipment for the control of guns (MRS3) and Seacat missiles (GWS22). The initial application was gun fire control for quick-firing medium guns of 3, 4·5, and 6 inch calibres. Following application of the system to the Seacat system, the MRS3/GWS22 has been the subject of steady modification and can be seen in several forms.

The radars carried by this director are known as the Types 903 and 904, and both are conventional I/J-band conical scan tracking radars.

More detailed information is given under this entry number in previous editions of *Jane's Weapon Systems*.

STATUS

The MRS3/GWS22 has been extensively fitted in many ships of the Royal Navy. A number of Commonwealth and other navies are equipped with the system, including ships of the Australian, Chilean, Indian, and New Zealand navies. Production is continuing. The systems have now been updated under a contract awarded to Sperry Gyroscope (now part of British Aerospace).

CONTRACTOR

British Aerospace Dynamics Group, Bracknell Division, Bracknell, Berkshire RG12 1QL, England.

1751.253
AWS-2 NAVAL RADAR

The Plessey AWS-2 naval tactical radar is a versatile E/F-band surveillance radar designed for installation on vessels of the destroyer, frigate, and corvette classes. The AWS-2 will detect small aircraft at a range of the order of 60 nautical miles at a height of 25 000 feet. The equipment can be readily integrated into a ship's gun or missile fire control systems.

STATUS

Numerous fittings of the AWS-2, and its predecessor AWS-1, have been made. There are about 20 of the former aboard the ships of five navies and there are about 30 AWS-1 in vessels of 11 navies. The AWS-2 has now been superseded in production by the AWS-4 and AWS-5.

CONTRACTOR

Plessey Radar Ltd, Oakcroft Road, Chessington, Surrey KT9 1QZ, England.

3171.253
AWS-4 NAVAL RADAR

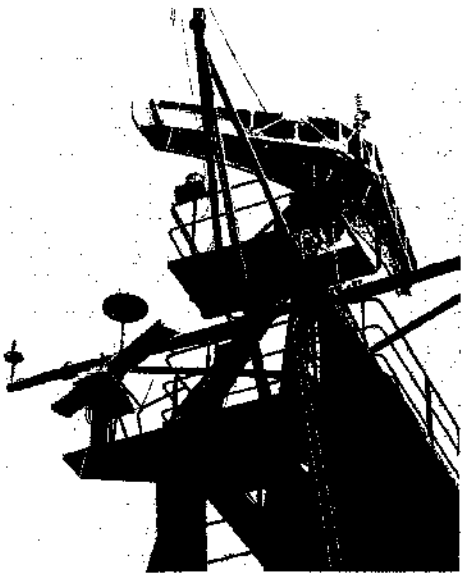
The Plessey AWS-4 naval search radar meets the operational needs for air and surface search, target indication and weapon control. It can perform effectively in conditions of jamming, sea clutter and precipitation. With a lightweight, compact antenna system the AWS-4 is readily installed in small ships, such as fast strike craft, and is equally suitable as the search radar for corvettes and light frigates, or as the tactical radar for larger vessels in association with a separate long-range air warning radar. The AWS-4 uses a tunable magnetron transmitter with a low-noise parametric amplifier and an ECCM receiver to give an effective anti-jamming performance.

A two-speed antenna, operating with dual pulse lengths and PRFs, optimises the performance of the AWS-4 in the roles of air and surface search and target indication. Variable antenna polarisation enables the operator to minimise the effect of bad weather. IFF facilities are provided by the incorporation of the D-band IFF radiator in the main feed horn. This irradiates the search radar reflector which allows an improved coverage pattern from a lower-power interrogator and reduces masthead weight and windage.

The optional digital moving target indicator (DMTI) provides further protection against clutter caused by sea, land or rain. The DMTI system is self-compensating for clutter velocity, hence also providing good discrimination against chaff. Data from ship's log and gyro is not required.

Radar coverage of the single transmitter version against a 4 m² target is 104 km and over 11 500 m free space range with a detection probability of 80 per cent. Against the same target a diversity system will provide increased coverage operationally, enhance anti-jamming performance, increase system reliability and improve availability as one transmitter/receiver may be closed down for maintenance without loss of radar service.

In addition to the optional features of DMTI and diversity operation mentioned above, a two-axis stabiliser is available to improve overall system performance in cases where AWS-4 is used with a computerised AIO/CIC. A modular data distribution rack is also available to provide optimised interfaces between the radar and the rest of the ship's weapon system.



DEVELOPMENT

The AWS-4 has been derived from extended experience with the preceding AWS-1 and AWS-2 radars in service with 14 navies. Programmes for the progressive up-dating of earlier radars to AWS-4 standards are available.

STATUS

Plessey Radar has supplied AWS-4 radars to a number of overseas customers including the Royal Norwegian Navy and the Sultan of Oman's Navy. Four stabilised diversity systems are being manufactured for the Brazilian Navy. Over 50 AWS-4 installations had been ordered or supplied as at the end of 1984.

The AWS-4 below-deck equipment is also extensively employed for modernising obsolescent radars such as the Type 293 and the Type 993 (see **3260.253** and **3261.253**). Conversely, AWS-4 antennas are being used to improve the performance of existing radar systems. Eight antennas are being fitted to Royal Canadian Navy ships as part of the DELEX (Destroyer Life Extension) programme.

AWS-4 masthead equipment fitted in Norwegian coastguard patrol ship K/V Nordkapp

CONTRACTOR

Plessey Radar Ltd, Oakcroft Road, Chessington, Surrey KT9 1QZ, England.

AWS-5 SERIES NAVAL RADAR

The Plessey AWS-5 is an advanced technology E/F-band tactical radar designed to provide comprehensive surveillance facilities for corvettes and frigates in the range 1000 to 4000 ton. It is also suitable as the search and target indication radar in larger ships, in conjunction with a long-range air warning radar. Advanced features of the AWS-5 enable it to combine the following functions:

(1) air and surface warning, with cosecant² coverage for typical air targets to 150 km in range and 20 km in altitude
(2) point-defence search, with enhanced missile detection capability against low level attack and detection beyond 30 km against small high elevation diving targets.

The AWS-5 provides excellent anti-jamming protection and clutter rejection principally through:

(1) high-low beam operation to counter stand-off jamming
(2) circular or linear polarisation by selection to improve rejection against rain
(3) pulse-to-pulse programmable/random frequency agility for ECCM protection and decorrelation of clutter
(4) frequency coded transmissions against deception jamming
(5) high ratio pulse compression for finer resolution and better clutter performance
(6) adaptive coherent DMTI to remove echo responses due to sea and land clutter, bad weather and chaff.

Nigerian frigate, NNS Aruda, *fitted with AWS-5 radar*

The lightweight masthead equipment of the AWS-5 comprises a compact two-axis stabilised mount on which is fitted a dual-beam antenna system incorporating variable polarisation and integral IFF facilities.

The main below-decks equipment comprises a compact transmitter/receiver cabinet in which are housed the wide-band frequency-modulated transmitter with its drive circuits, power supplies, and a programmable frequency agile source. The receiver chain incorporates pulse compression, CFAR processing, and adaptive MTI. Additional equipment in the AWS-5 outfit includes the stabiliser control system and a data distribution unit with a high-resolution video extractor and comprehensive interface facilities for supply of video and other data to the ship's operations room and AIO/CIC computer.

Time multiplexing and frequency coding techniques are used in both transmitter and receiver chains in conjunction with the dual-beam antenna. This enables the performance characteristics of two radars to be achieved simultaneously from a single AWS-5 outfit. Radar facilities which could previously be accommodated only in large ships are thus now available for ships of the corvette and light frigate categories.

The various modes of video processing provide good protection against clutter and jamming, enhanced by the programmable frequency agility, the clutter-free high beam, accurately controlled antenna characteristics with good sidelobe performance, and high-ratio equalisers giving an exceptionally short compressed pulse. Integrity of performance under hostile conditions was given priority in the development programme.

The AWS-5 is designed for maximum flexibility in use. A modular set of control panels gives the operator a wide choice of facilities including:

(1) independent control of main beam and high beam
(2) active or passive mode
(3) DMTI on either or both beams
(4) separate or combined videos
(5) fixed frequency, limited or full agility
(6) variable main beam polarisation
(7) two data rates.

Certain performance characteristics are programmable during manufacture, enabling the AWS-5 to be closely matched to the role of a particular class of ship.

AWS-5D

This is a single beam general-purpose surveillance radar for corvettes and frigates. Using a high gain horn-fed reflector on a stabilised mounting, the system provides good air target detection to over 100 nautical miles (185 km), and excellent performance against low-flying aircraft and sea-skimming missiles.

STATUS

Equipments are in service with the Royal Danish Navy and a containerised system is in use with the Nigerian Navy.

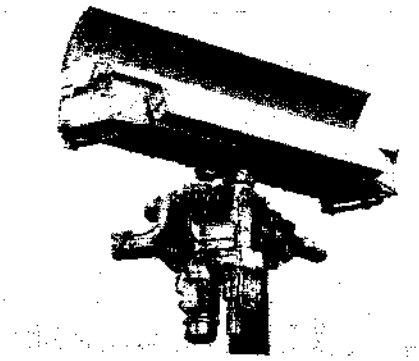
The AWS-5 is being developed to provide the new 3-D surveillance radar for the Royal Navy Type 996 programme.

CONTRACTOR

Plessey Radar Ltd, Oakcroft Road, Chessington, Surrey KT9 1QZ, England.

5620.253
AWS-6 SERIES NAVAL RADAR

The AWS-6 is a range of G-band radars designed for naval surveillance combined with maximum missile detection capability. It is intended to provide the multi-function of surveillance and point defence sensor in fast patrol boats, corvettes and other small ships generally. In larger vessels where multiple radar installations are provided, the AWS-6 will be used in a point defence role only. The equipment is offered in a wide range of configurations and signal processing options and can be profiled to specialised defensive requirements.



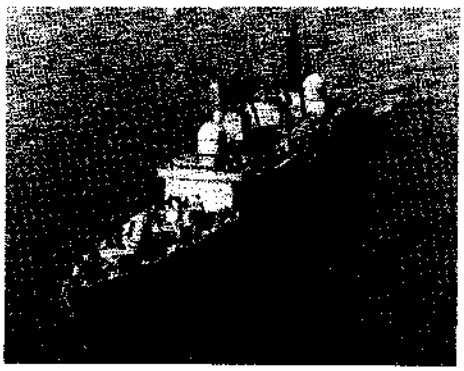
The antenna is small and lightweight which allows it to be mounted at masthead with dual-axis stabilisation. The optimum rotational rate is 60 rpm and IFF and navigational functions are integral. Single- or dual-beam configurations are available; the single beam is used for general surveillance operation and target designation while the dual beam mode enables near hemispherical coverage for threat detection at all angles of elevation. Incoming targets as small as 0·1 m² radar cross-section can be detected, typical of anti-ship missiles. The radar is then used to control the ship's defences - either guns or missiles. One version, the AWS-6/Dolphin missile detection radar, is the search radar module for Seaguard (**3509.281**), the Contraves close-in weapon system, and employs the dual beam configuration for the detection of high diving and sea-skimming missiles.

The AWS-6 has been designed to operate under severe environmental conditions; and frequency

agility, pulse compression and within-pulse coding have minimised the effects of ECM. This has been combined with adaptive MTI to give high performance against clutter, chaff and target glint.

The equipment is also available in containerised form for integration with other weapon systems on ships such as armed merchantmen.

STATUS
The equipment is in full production and trials with the Seaguard system are well advanced. Seven AWS-6 systems are being manufactured for delivery in 1985 for fitment to Danish fishery protection vessels.
CONTRACTOR
Plessey Radar Ltd, Oakcroft Road, Chessington, Surrey KT9 1QZ, England.



Antenna unit of the Plessey AWS-6/Dolphin surveillance radar

1559.253
RN TYPE 909 RADAR

The Royal Navy Type 909 radar provides target tracking and illuminating facilities for the Sea Dart, GWS-30 air defence missile (**6004.231**). This weapon has an anti-ship capability, and the radar is stated to be suitable for gun laying also, so that a surface target capability must be assumed. The antenna is of the cassegrain type and has a diameter of 2·44 m. A small dome mounted near the upper edge probably houses an associated IFF antenna. On board ship, the complete antenna assembly will be protected by a cupola radome. The radar head and the office cabin, containing transmitter/receiver unit and associated electronics, are constructed as a single pre-fabricated assembly to reduce installation and replacement time and to enable functional testing before fitting.

Few technical particulars have been revealed. A G/H-band operating frequency range is likely and a high transmitter power can be expected. It has been stated that elaborate ECCM are incorporated to counter both active and passive ECM. A photograph appears with the Sea Dart missile entry.
STATUS
The Type 909 is fitted to Type 42 destroyers for the Argentinian and British Navies, and for the RN Type 82 destroyer. Each ship has two radars of this type, mounted in fore and aft radomes. Full production started in 1971.
CONTRACTOR
Marconi Radar Systems Ltd, Writtle Road, Chelmsford, Essex CM1 3BN, England.

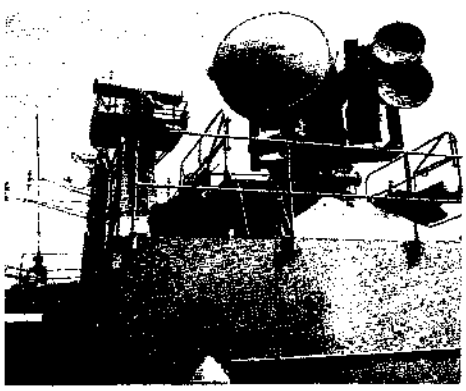
1752.253
RN TYPE 901 RADAR

The Royal Navy Type 901 radar equipment provides target tracking and missile guidance for the Seaslug shipborne surface-to-air missile system (**6003.231**). Each of the seven RN 'County' class guided missile destroyers is fitted with a single Type 901 radar, forward of the helicopter deck, for use with the twin Seaslug launcher aft. A stabilised mount is provided and the right-hand side of the director head carries equipment for initial 'gathering' of the beam-riding Seaslug missile. No performance details of the Type 901 have been released. Operation at G/H-band frequencies is probable.
CONTRACTOR
Marconi Radar Systems Ltd, Writtle Road, Chelmsford, Essex CM1 3BN, England.

1558.253
RN TYPE 912 RADAR



Type 912 is the Royal Navy designation for the Selenia Orion RTN-10X fire control radar fitted to RN ships. It is an I/J-band conical-scan pulse radar, and the mounting arrangements include facilities for a closed-circuit TV system for acquisition and missile gathering functions. More details will be found in **1368.253** among the Italian entries of this section.

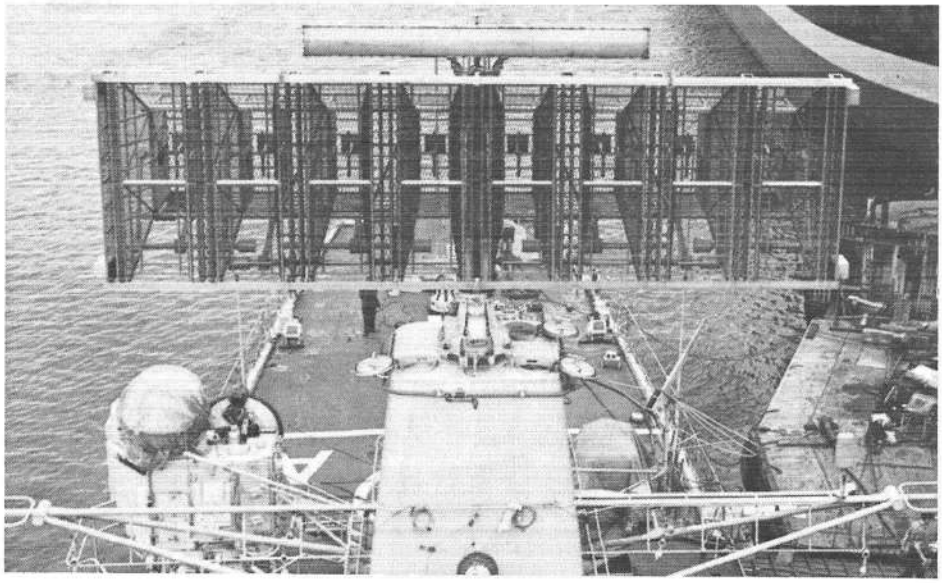
1562.253
RN TYPE 910 RADAR

The Type 910 is the radar tracking element of the GWS 25 Mod 0 Seawolf point defence missile system. It is used with, and receives target designation data from, the Types 967 and 968 air and surface surveillance radars (**1561.253**). It is a monopulse differential tracker radar, incorporating electronic angle tracking in the tracking loop as a means of correcting the missile guidance line-of-sight for small angles without calling for physical movement of the mount. This benefits both accuracy and the smoothness of tracking. After launch, the Seawolf missile is rapidly acquired by the Type 910 wide-angle antenna and automatically gathered onto the target line-of-sight. Subsequently, target and missile are tracked together, using the same antenna and receiver by means of time division multiplex techniques. Few technical details have been released but operation in the I/J-band has been confirmed.

The Seawolf system uses command to line-of-sight guidance with radar differential tracking and a microwave radio command link, and some of the related antennas can be seen flanking the main Type 910 antenna unit. This is a self-adaptive system and is capable of controlling and directing a number of Seawolf missiles to interception. The system also includes a differential tracking optical TV system which monitors the firing and is capable of taking over missile control during flight should circumstances demand.

Information from this tracker could be used for gun control also, and the TV tracker on the same pedestal could also be employed for gunnery purposes.
STATUS
In production. Fitted to all Type 22 and 'Leander' class frigates of the Royal Navy.
CONTRACTOR
Marconi Radar Systems Ltd, Writtle Road, Chelmsford, Essex CM1 3BN, England.

Type 910 tracking radar with type 967/968 antenna in the background



---

1560.253
RN TYPE 965 RADAR

The Type 965 long-range air search radar of the Royal Navy is widely used on ships of sizes ranging upwards from frigates. The operating frequency range lies in the metric wavelength band and output powers in the megawatt range are assumed. In addition to air surveillance, the Type 965 fulfils target designation functions for guided weapons systems, and on-mounted IFF Mk 10 facilities are provided.

The antenna array consists of a row of eight dipoles, each at the rear of a 'horn' formed of metal mesh, the whole having a characteristic 'bedstead' appearance. The complete antenna scanner assembly may consist of either one or two such groups, and both versions are extensively employed. An IFF antenna is usually mounted on the upper edge of the primary array.

STATUS
The Type 965 has been in production for several years and is widely deployed in either single or double array form on most ships of the Royal Navy from frigates upwards, including Type 42 and 82 destroyers. It is however being currently replaced in the Type 42 ships by the Type 1022 (**3486.253**).
CONTRACTOR
Marconi Radar Systems Ltd, Writtle Road, Chelmsford, Essex CM1 3BN, England.

1561.253
RN TYPES 967 AND 968 RADARS
The Royal Navy Type 967 is an air surveillance radar which is integrated with the Type 968 surface surveillance radar to form a very compact medium-to-short range defence radar. They provide high performance facilities to fulfil the requirements of air and surface warning, search and target designation, from sea level to high elevation angles. These radars with the Type 910 target tracker and missile guidance radar form the radar group for the Seawolf anti-aircraft and anti-ship missile weapon, GWS 25 (**2442.231**).

The waveguide antennas for both radars are mounted back-to-back in a common housing carried by a single fully stabilised mount protected by a radome. The Type 967 provides air surveillance with cover up to high elevation angles. Operating frequency is in the D-band of the radar spectrum and pulse doppler mode is employed. An enhanced version, known as the Type 967M, is now in production. The Type 968 provides low air cover and surface search, and operates in the E-band. The antenna rotation rate for both is 30 rpm. The Seawolf surveillance radar system is a high-power self-adaptive system, with sophisticated data handling, which resolves both velocity and range ambiguities, initiates track, carries out threat evaluation, takes the engagement decision, and performs attack allocation by assigning a tracker and feeding the track co-ordinates to it. IFF and system ECCM are incorporated. The system has its own digital processor, a Ferranti FM1600 series computer.

STATUS
In production. Fitted to all Type 22 and 'Leander' class frigates of the Royal Navy.
CONTRACTOR
Marconi Radar Systems Ltd, Writtle Road, Chelmsford, Essex CM1 3BN, England.

1253.253
RN TYPE 975 RADAR
The Type 975 is a lightweight, I/J-band, high definition surface warning radar designed for fitting on frigates, coastal and inshore minesweepers, and other naval craft of similar size. Its primary function is navigation, but in some installations it is specially adapted for minehunting in conjunction with a suitable plot and underwater detection equipment. This version is designated Type 975ZW, and incorporates true motion displays and provision for marking sonar targets on the display.

Transmitter power is 50 kW (nominal), and either a 182 or 304 cm slotted waveguide scanner is used. Two models of display unit are available, JUC/1 and JUC/2. The former is a watertight unit with magslip range and bearing, and the latter has synchro range and bearing transmission. Seven range scales provide displays of 0·75 to 48 nautical miles. Minimum detection of the radar is less than 32 metres, and bearing accuracy is within 1°.
STATUS
This radar has been extensively fitted to ships of the RN and other navies, and although now superseded by the Type 1006 (**1394.253**), many Type 975 units are still in use.
CONTRACTOR
Kelvin Hughes Division, Smiths Industries Ltd, New North Road, Hainault, Ilford, Essex IG6 2UR, England.

1753.253
RN TYPE 992Q RADAR
The Royal Navy Type 992Q radar is a fully stabilised 10 cm (E/F-band), high-power pulse radar equipment, fitted in destroyers and frigates. It is a prime source of surface/air target information for the action information organisation system, and provides space-stabilised output data which can be synchronised in pulse and rotation with that of other radars fitted in the ship. It is of solid-state electronic construction apart from certain circuit elements which retain vacuum tube devices.

STATUS
Fitted in RN 'County' class and Type 82 destroyers.
CONTRACTOR
Marconi Radar Systems Ltd, Writtle Road, Chelmsford, Essex CM1 3BN, England.

3260.253
RN TYPE 994 NAVAL RADAR

This new radar incorporates a transmitter/receiver based on the Plessey AWS-4 radar described in **3171.253**. It uses the existing antenna of its predecessor Type 993. The below-decks equipment is the same as for the Plessey AWS-4 radar system, for which Plessey supplies a new high performance lightweight antenna system. The transmitter/receiver is designed to occupy the same space as the original equipment. An interface unit is supplied to simplify the installation work. Widespread use of solid-state technology ensures better reliability and simplifies maintenance procedures.

The radar's performance can be further enhanced by the addition of a digital moving target indicator (DMTI), providing increased protection against clutter caused by sea, land or rain. The DMTI is self-compensating for clutter velocity, hence also providing good discrimination against chaff. Data from ship's log and gyro is not required.

Similar E/F-band tactical radars of various Royal Navy types, both search and heightfinders, are in service with other navies around the world. The introduction of Type 994 means that cost-effective and proven facilities are available for modernising tactical radars on board many different classes of ship, using either the antenna already fitted or the new AWS-4 antenna according to circumstances.

HMS Arethusa *fitted with one of the Type 993/994 conversions showing the antenna at the top of the foremast*

Trials carried out on a typical aircraft target at several different altitudes established clearly that the new equipment not merely matches the improved requirements but exceeds it by a significant margin.

STATUS

In quantity production for fitting aboard Royal Navy frigates and ships of other navies. The RN installation programme commenced in 1978.

CONTRACTOR

Plessey Radar Ltd, Oakcroft Road, Chessington, Surrey KT9 1QZ, England.

4634.253
TYPE 996 NAVAL SURVEILLANCE RADAR

Type 996 is the Royal Navy nomenclature for a new E/F-band, 3-D surveillance and target indication radar which is intended for fitment to the Type 23 frigates, and retrofitted into Type 42 destroyers, Type 21 frigates and the 'Invincible' class carriers.

No technical details of the Type 996 are available currently, other than that it is largely based on the AWS-5 (**3172.253**) with the addition of 3-D technology from the AR-320 system (**3649.153**).

STATUS

Plessey Radar received a contract, valued at approximately £70 million, from the UK MoD in September 1983 to develop the Type 996 radar. No information is available on deliveries for either new ships or retrofits.

CONTRACTOR

Plessey Radar Ltd, Oakcroft Road, Chessington, Surrey KT9 1QZ, England.

3486.253
RN TYPE 1022 NAVAL RADAR

The Type 1022 is a long-range D-band frequency synthesiser-driven travelling wave tube (TWT) radar with pulse-to-pulse coherence. It was developed as a replacement for the Royal Navy's Type 965 surveillance radar. Long-range performance is aided by the use of a high mean-power TWT in the transmitter. A pulse-compression receiver with MTI provides for good performance in rain and in the presence of surface clutter.

The antenna uses a squintless feed to provide tapered illumination of the main reflector. This results in good sidelobe performance across the band. Other technical features include solid-state electronics, frequency agility over a wide band, horizontal and circular polarisation, frequency synthesiser-controlled coherent transmitter, MTI with digital quadrature canceller and digital video processing.

It is understood that the Type 1022 is a joint Anglo/Dutch project in which Signaal is providing the transmitter/receiver and Marconi the antenna. This suggests that the finished equipment will appear on the vessels of both British and Netherlands fleets.

Type 1022 antenna on HMS Nottingham *Type 42 destroyer*

STATUS

In production and fitted to a number of Royal Navy ships.

CONTRACTOR

Marconi Radar Systems Ltd, Writtle Road, Chelmsford, Essex CM1 3BN, England.

1394.253
RN TYPE 1006 RADAR

The Type 1006 is the standard I-band navigational radar of the Royal Navy.

Antenna Outfit AZJ

The surface role antenna outfit consists of a 2·4 m slotted waveguide linear array rotated at 24 rpm by a turning mechanism. The array has a horizontal beamwidth of 1° and low sidelobe levels to give good bearing discrimination. The vertical beamwidth of 18° gives good performance in conditions of roll and pitch. To meet special ship fitting requirements the antenna outfit may be inverted and mounted on the underside of a mast spur.

Antenna Outfit AZK

This antenna outfit consists of a 3·1 m slotted waveguide linear array rotated by the same type of turning mechanism as outfit AZJ. It is used when the improved bearing discrimination given by the 0·75° beamwidth is required. The increased antenna gain also improves the range performance of the radar system. The remaining details of outfit AZK are similar to those for AZJ.

Transmitter/Receiver (Surface)

The equipment is non-thermionic with the exception of the magnetron, and operates at a frequency of approximately 9445 MHz. The solid-state modulator, which may be externally synchronised, provides three pulse lengths at two repetition frequencies to drive the magnetron which is coupled directly to the RF head. The advanced broadband design of the RF head ensures the best obtainable minimum range under adverse waveguide conditions. The three pulse lengths of 80, 250, and 750 ns ensure good short range discrimination and long range performance. A Gunn diode local oscillator is controlled by an AFC with tuning indication; the IF generated is fed to a combined linear/logarithmic receiving system. The linear video is used for navigational radar displays and the logarithmic video is used for weapon system data extraction. The receiver bandwidth is automatically optimised for the transmitter pulse length in use.

Transmitter/Receiver (Submarine)

In order to be compatible with the existing submarine antenna system a variant of the transmitter/receiver operating at 9650 MHz is available. It is otherwise identical to the surface role equipment. The design of the RF head prevents damage to the equipment from massive waveguide reflections which occur if the antenna is submerged while transmitting.

Display Unit JUD

This unit is non-thermionic with the exception of the cathode ray tube. The display unit uses a rotating scanning coil system to provide range scales from ½ to 96 data miles. The unit uses a 31 cm (12 inch) cathode ray tube. Fixed coils provide off-centring facilities of up to 75 per cent of a radius from either an external true motion unit or from internal sources.

Symbolic Data Display

The facilities of the display have been extended for surface role applications to operate in conjunction with computer systems such as CAAIS (computer assisted action information system). Additional symbol writing coils and amplifiers are provided together with pulsed off-centring amplifiers to enable the display of interscan symbolic data on appropriate range scales from analogue information inputs.

True Motion Outfit QAB

The outfit QAB is a solid-state electro-mechanical computer for the provision of true motion presentation on the radar 1006 JUD display.

The Type 1006 is compatible with the JQ submarine bridge display which is primarily used to assist conning when submarines enter or leave harbour.

STATUS

The Type 1006 radar has been in series production for the Royal Navy and other navies since 1971.

CONTRACTOR

Kelvin Hughes Division, Smiths Industries Ltd, New North Road, Hainault, Ilford, Essex IG6 2UR, England.

5847.253

RN TYPE 1007 RADAR

The Type 1007 is a new I-band radar for the Royal Navy. It is based on two Kelvin Hughes commercial systems, Radpak 16 and Series 1600, which have been in operational use for some time. The new system incorporates antenna outfits and a 25 kW transmitter/receiver coupled to 16-inch displays. The Type 1007 drives a number of main displays plus auxiliary displays installed in various parts of the ship, and is also interfaced with the ship's weapon systems.

The main displays operate in a true motion mode and include the Kelvin Hughes 'E Plot' electronic plotting system. This is a manually entered plotting system for up to ten targets providing true and relative vectors, together with the ability to draw fixed lines and mark hazards to navigation.

STATUS

Being delivered to the Royal Navy for a number of ships.

CONTRACTOR

Kelvin Hughes Division, Smiths Industries Ltd, New North Road, Hainault, Ilford, Essex IG6 2UR, England.

1508.253

ST 802 NAVAL TRACKING RADAR

The ST 802 is a lightweight I-band monopulse search and tracking radar for the direction of small and medium calibre guns, and for target tracking in guided missile systems. It is intended for use against air or surface targets, and the weight and dimensions of the system are appropriate to installation on all classes of vessel from patrol boats upwards. The ST 802 is designed with facilities for independent operation and control in weapon systems not equipped with a central computer complex, but can also interface with, and be controlled by, the weapon system's own computer.

The radar director head is a two-axis mount carrying a one metre diameter antenna, and optionally, a TV camera. The mount is controlled by electric servos in azimuth and elevation, with stabilisation of the sight line during tracking by means of rate gyros. The antenna is of the twist cassegrain type. A four-horn monopulse feed and comparator provide three separate RF outputs (sum, elevation difference, and training difference signals) for processing in the IF receivers to produce acquisition and auto-follow data. Accurate angular data result from the combination of a 2·4° pencil beam and monopulse signal processing. With TV camera, the director head weighs 532 kg.

The I-band transmitter incorporates a tunable magnetron, and a short pulse length is used in the interests of range resolution and tracking accuracy. The receiver employs monopulse tracking and embodies features such as the tunable magnetron, monopulse signal processing, MTI, passive tracking of targets using ECM, and CFAR, to reduce the effects of countermeasures. MTI (coherent on receive) provides discrimination against sea clutter when tracking small, low-flying targets.

A frequency agile version of this radar, known as the ST 1802 is also available. It includes a fully coherent transmitter to produce true random frequency agility across a wide bandwidth, offering significant performance advantages, particularly in jamming environments.

OPERATION

Weapons which can be associated with the ST 802 include Seacat, Exocet, and medium and small calibre guns of 20 mm upwards. Acquisition of air or surface targets is automatic, following target designation by search radar or other means. After acquisition, the target is automatically tracked and appropriate data supplied to weapon systems. The antenna head is able to rotate continuously in azimuth at 20 rpm, and this feature in conjunction with MTI is of value in providing additional surveillance cover at low elevation.

If the TV sub-system is fitted, it may fulfil either of two distinct roles, depending upon the weapon system employed. With command line-of-sight missiles, the TV system will permit automatic missile guidance after launch, from a below-decks position. Alternatively it may be used as a back-up to radar tracking in either daylight or low light-level mode. Other electro-optical sensors may also be fitted, such as infra-red or laser rangefinder.

ST 1802 naval tracking radar with IR camera

STATUS

The ST 802 is a private development in collaboration with L M Ericsson, and has been proposed to a number of navies with various gun and missile fire control systems. In production, it forms part of the Marconi/Sperry Sapphire gun control system of the Egyptian *'October'* and *'Ramadan'* fast missile craft.

CONTRACTOR

Marconi Radar Systems Ltd, Writtle Road, Chelmsford, Essex CM1 3BN, England.

1754.253

S810/820 NAVAL SURVEILLANCE RADARS

Lightweight surveillance radars in the S800 series are comprised of various combinations of two sizes of scanner, and two transmitter/receiver equipments. These are summarised in the table of characteristics.

The Marconi Type S810 is a lightweight stabilised I-band surveillance radar suitable for fitting in small warships down to the size of fast patrol boats where there are limitations of space and weight. I-band gives good performance against surface targets, a major requirement for fast patrol craft, while satisfactory coverage is maintained against air targets by the use of a stabilised antenna in a radome, with vertical fan beam shape. A narrow horizontal beamwidth ensures accurate target indication data for pointing weapons and for putting on a tracking radar.

Detection of surface targets such as fast patrol boats is horizon limited and strike aircraft of 5 m² can be detected at ranges in excess of 25 km with the smaller antenna and up to 40 km with the larger one. A DMTI system is provided to enhance the system performance against small high-speed targets in clutter and the magnetron transmitter is tunable to ECCM or other interference.

S810 series radars use a pulse transmitter of the same design as in the lightweight search/tracker radar Type ST 802 (**1508.253**), resulting in a reduction in the on-board spares if both radars are fitted in a ship. In all versions, the receiver provides either logarithmic/linear or integrated video for the operational displays.

The antenna head, stabilised in roll and pitch, rotates at 20 or 40 rpm and is enclosed in a radome for protection and minimum weight. An elliptical reflector is used, which measures 1·2 by 0·45 m, or 1·8 by 0·6 m. Both types are constructed of glass-reinforced plastic. A single horn feed is located at the focus of the reflector which is contoured to provide a narrow horizontal beam and a fan-shaped vertical beam. The turntable consists of an aluminium alloy centre tube and outer casing, azimuth bearing and azimuth drive and data units. The complete antenna/turntable assembly is supported on a platform giving stabilisation for roll angles up to 25° and pitch angles up to 10°, with acceleration up to 30° per second. The 1·8 or 2·7 m diameter radome which encloses the whole antenna assembly is constructed of a 12 mm thick sandwich of glass-reinforced plastic and foam.

The transmitter employs a tunable magnetron operating within the frequency band 8·6 to 9·5 GHz and delivers a typical peak power of 200 kW. All components are solid-state except the magnetron and the hydrogen thyratron in the pulse modulator.

Two receiver channels, one logarithmic, the other linear, are provided. The required channel is selected by a switch located near the PPI display. MTI processing is available, the DMTI filter being a double canceller employing shift-register storage and feedback. The radar operates with a staggered PRF in the MTI mode in order to overcome the disadvantages of 'blind speeds'. Compensation is provided for ship and wind velocity. When clutter cancellation is not required, the MTI can be switched out and the radar then operates with a jittered PRF of 1·5 kHz allowing a maximum displayed range of 80 km.

For the larger FPB, there is the radar Type S820 operating in the E/F-band. This employs a 2·4 m stabilised antenna enclosed in a radome giving a total masthead weight of 550 kg. The transmitter is tunable within one of two frequency bands. The receiver employs a parametric amplifier and has linear/logarithmic processing and can be supplied with or without MTI.

A recent development is a low cover version of the S810 which has a concentrated low-level beam and a high antenna rotation rate (40 rpm) which is intended for detection of sea-skimming targets.

STATUS

Radars of the S800 series are in production for the UK MoD and other unspecified customers. The S810 is fitted to the *'October'* class and the S820 to the *'Ramadan'* class fast missile craft of the Egyptian Navy.

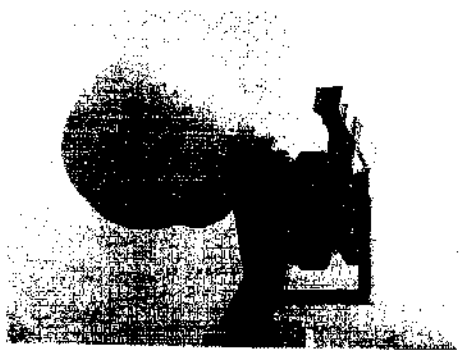
805 SERIES NAVAL TRACKING RADARS

The 805 series has been developed as lightweight naval tracking radars for the control of missiles and guns. They are intended for use primarily against air targets and are suitable for virtually any type of naval vessel from patrol boats upwards. There are five different types: 805SW, 805SD, 805AS, 805SS and 805G.

The 805SW has been designed for the lightweight Seawolf system and is currently being fitted to ships of the Royal Navy. Details are given under entry **5630.253**, RN Type 911 tracking radar.

The 805SD is designed for use with the lightweight Sea Dart system for smaller warships. The system uses standard modules from the 800 series radars (**1754.253**), and the RN Type 909 (**1559.253**) which is currently in operational use in Royal Navy Type 42 destroyers. The radar director carries a 2·1 metre antenna, which fulfils the functions of target tracking and illumination, plus an optronics package tailored to meet the particular requirement. The system is suitable for ships of 300 tons and above, a containerised fit is available. The 805SD is a private venture equipment intended for the export market.



The 805AS has been developed in co-operation with Selenia as a lightweight tracking radar for use with the surface-to-air version of the Aspide missile. It uses the Selenia 200 watt transmitter and has been designed so that it can take full advantage of the complete missile envelope. The 805AS Aspide system is known as the Albatros Mark 10. The radar can also be used for gun control.

The 805SS has been designed in co-operation with Raytheon for use with the Sea Sparrow missile. It uses the Raytheon illuminating transmitter, is extremely lightweight and can also be used for gun control.

The 805G is a millimetric radar system for controlling fast firing or medium calibre guns. The 805G employs a variant of the DN 181 Blindfire tracking radar (**2439.153**) to give high accuracy performance against low-level targets such as sea-skimming missiles and low-flying aircraft. The system includes facilities for correcting alignment against both air and surface targets.

STATUS

The 805SW has been selected as the tracking radar for the Royal Navy's lightweight Seawolf system and is being fitted aboard Type 22 and 23 frigates. The system is also the subject of considerable interest from a number of foreign countries for smaller types of warship.

805SD tracking radar for lightweight Sea Dart

The 805SD has been designed for the export market and is currently being studied by a number of defence forces as part of lightweight Sea Dart.

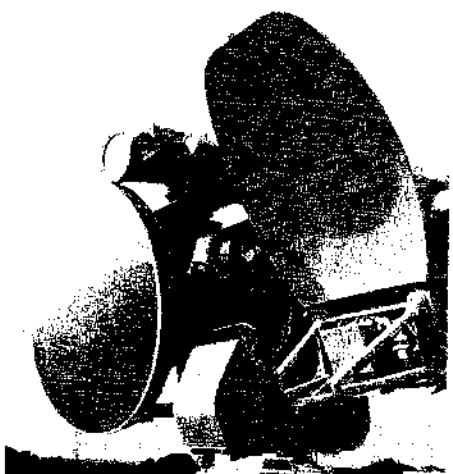
RN TYPE 911 TRACKING RADAR

The Marconi 805SW is a lightweight tracking radar for use with the Seawolf short-range point defence system. It is designated Type 911 by the Royal Navy and will be fitted on Type 22 and 23 frigates.

The radar is a dual frequency (I-band and millimetric wave) differential tracking system which includes a command link to control the Seawolf missile in flight. The I-band antenna and transmitter form part of the Marconi ST 800 range and the signal processing uses fast Fourier transform techniques to ensure effective operation in severe clutter environments. The millimetric part of the system is a version of the DN 181 Blindfire radar (**2439.153**) used with the BAe Rapier missile. It provides accurate tracking at low sight angles against targets close to the sea surface, such as sea-skimming missiles and low-flying aircraft. A system of independently illuminating the upper and lower parts of the millimetric antenna ensures that the missile receives good guidance data while flying at low level.



The radar is fully automatic to provide fast reaction time against small targets and is autonomous, requiring only the allocation of the fire control channel to the selected target and information on ship's motion. Excellent clutter rejection is provided on both bands for operation in both open and enclosed waters and ECCM facilities are incorporated to enable use in hostile electronic environments.

STATUS

In production. The system will be fitted to all Royal Navy Type 22 and 23 frigates, and delivery commenced in October 1984. Further contracts have been received for the GWS26 vertical-launch Seawolf and also for the new GWS27 system which will incorporate new developments to the radar.

S1800 SERIES NAVAL SURVEILLANCE RADARS

This range of modular surveillance radars has been developed by Marconi Radar Systems Ltd as a private venture, in association with Canadian Marconi, although some of the technology was developed as part of the RN Type 1030 STIR radar (**3485.253** in 1982-83 and earlier editions). Two of the range have been described to date, the S1820 and S1821, although other models have been designated.

S1820

This model has been described as the minimum configuration version within the ST800 series of equipments, the series itself comprising a range of modular elements, such as antennas, transmitter/receivers, signal processors. The S1820 antenna is a stabilised unit (pitch and roll) of 2·4 m span, very similar to that of the S820 (**1754.253**), housed in a protective radome and associated with a frequency agile transmitter. The latter unit incorporates pulse compression and operates at E/F-band frequencies, and alternative modes of frequency agile working are available. The use of long pulse techniques yields a high mean power which increases range performance while subsequent pulse compression restores range accuracy. Pulse compression on reception also gives additional noiseless gain to genuine echoes.

The MTI processor, particularly when fitted with adaptive velocity compensation, discriminates against land, sea and rain clutter. Combined frequency agility and MTI processing are provided, and CFAR circuits precede the automatic target tracking circuitry. The optional IFF can be integrated with the main antenna.

The S1820 is suitable for fitting aboard ships of 300 tons or above, and provides for air and surface tactical surveillance in addition to target indicator data for ship's weapons.

S1821

The S1821 uses the same transmitter, receiver and processing system as the S1820 but employs a higher gain 4-metre antenna to give higher elevation cover, increased range performance and improved angular resolution.

CHARACTERISTICS

Type: S1820

Frequency: E/F band, frequency agile

Transmitter power: 20 kW (peak); 800 W (mean)

Antenna: 2·4 m span stabilised with integral IFF

Antenna weight: 550 kg

Range: Approx 85 km (max)

STATUS
No details of ship fittings are available for publication although the S1820 system is in production for the Canadian Navy, by Canadian Marconi, under the nomenclature AN/SPS-503 (**5677.253**).

TRANSPONDER REPLY RECEIVER RRB

The reply receiver RRB has been developed to enable ships' radars operating with naval aircraft equipped with transponders (ARI 5983) or airborne radar (ARI 5954) to receive and display the responses from the latter.

The airborne transponders are principally employed to assist in navigation when aircraft are operating beyond visual range of the controlling unit, each aircraft or helicopter carrying an identical transponder which can be interrogated by the ship's ordinary radar system. This mode of operation considerably enhances range performance of the ship's radar.

The airborne transponder receives over a wide range of frequencies but replies on a single frequency only, and some types of shipboard radar incorporate a reply receiver so that either transponder (beacon) replies or normal radar returns may be displayed. Where this is not available, a separate reply receiver must be attached to the ship's radar to tune it to the transponder's frequency. This is the reply receiver RRB which enables a naval fixed-frequency receiver to receive pulse radar emissions from airborne radar ARI 5954 (**1027.353**) and ARI 5983 (**3310.353**).

An associated video code suppression unit (VCSU) processes the coded video pulse train output from the receiver so that the first framing pulse is passed and the remainder of the pulse train is suppressed. This enables coded replies to be displayed at will on the radar. The VCSU has facilities for three modes: permanent suppression, manual selection of suppression facility, and remote selection.

STATUS
In production for Royal Navy.

RADAR ANTENNA PEDESTALS

Radamec (formerly Bentley Engineering) is the largest supplier of stabilised and general surveillance antenna pedestals for the Royal Navy and has been a prime naval contractor for over 40 years. The company has full UK MoD approval to DEF STAN 05-21.

The illustration shows a reference model stabilised pedestal maintained by the company for the Royal Navy. In service the unit carries a 6·4 m medium-range surveillance antenna on vessels such as guided missile destroyers. A more recent development is a stabilised pedestal for mounting on top of a pole mast where low weight is essential. Unstabilised pedestals range from a small unit for 'half-cheese' antennas up to a heavyweight mounting for 1½ tonne arrays. Manufacture of this equipment includes production of RF components (rotating and nutating joints, tuners, attenuators, etc) and bearing data transmission units. Servo amplifier and micro-processor-based control equipment is also available.

STATUS
Radamec equipment is fitted to over 120 ships of frigate size and above in the navies of 14 nations.

AN/SPG-51 RADAR

The AN/SPG-51 pulse doppler radar forms a major element of the missile and gun fire control system Mk 74, with the Mk 73 gun and missile director system (**2632.281**) being intended mainly for use with the Tartar (**6006.231**) and Standard (**1122.231**) surface-to-air missile systems, for which it fulfils target tracking and missile guidance functions. Operating frequency is probably in the I-band. A circular parabolic dish reflector with offset horn feed is used, mounted on a gearless power drive produced by General Electric.

The radar line-of-sight can be rotated continuously in train, and can be elevated from -30 to +83° relative to the deck plane. Initial pointing information is supplied to the SPG-51 by a search and target designator radar. This information is received via the Raytheon Mk 72 signal data converter and digital fire control computer which generates a search pattern for the SPG-51 until target acquisition is accomplished. Automatic tracking is then initiated and the SPG-51 feeds angle and range information to the computer. The computer generates fire control data for transmission to gun mounts and missile launchers. It also provides missile seeker and angle data.
