## TILLAGE PRACTICES AND EFFECT OF SOWING METHODS ON GROWTH AND YIELD OF MAIZE CROP

MEMON S.Q., MIRZA B. BAIG, MARI G.R.

### Abstract

An experiment was carried out at Latif Experimental Farm, Sindh Agriculture University, Tando Jam during 2004, in order to assess the effect of tillage on soil physical properties growth and yield of maize under different sowing methods. The maize variety Akbar was planted on clay loam soil under three different methods ridge, drilling and broadcasting using RCBD. It was found that soil moisture content was higher in ridge sowing method as compared to other sowing methods. While bulk density and soil strength were relatively lower in ridge sowing plots as compared to seed drill and seed broadcasting plots. The results of agronomic observations revealed that plant height, number of leaves/plant, number of cobs/plant, dry cob weight, seed index, root length and total grain yield/ha were superior in ridge sowing, the second best was seed drilling, while seed broadcasting was found to be less effective. Maize sown on ridges resulted in greater seed emergence 89%, plant height 155.1 cm, weight of hulled dry cob 177.67 g, de-hulled dry cob 127.53 g and seed index 198.26 g, which in turn caused greater grain yield 6.35 t/ha, the next best was seed drilling, while seed broadcasting was not effective as other two methods.

**Key words:** tillage practices, sowing methods, emergence, growth, yield, maize

### INTRODUCTION

Many developing countries strive for an increase of their agriculture production in order to feed the rapidly growing population. Contrary to many other countries, Pakistan still has the possibility to expand the cultivated area since there is no lack of suitable land. Maize is most important cereal crop of the world, it is used for three main purposes as human food, feed for poultry and livestock. Maize being the highest yielding cereal crop in the world is of significant importance, where rapidly increasing population has already outstripped the available food supplies to use for direct human consumption, the other major outlets are the wet-milling industry and livestock feed. The maize crop categorized as cereal having starch in the grain, production of starch is the major objective of wet-milling industry, the production of maize oil is then very dependent on the demand for the starch component. Thousands of years recorded history, groups of human being have been tilling in order to increase the production of food, tillage includes any physical manipulation of soil, usually done in preparation for some aspect of crops production. The most favorable crop production requires a suitable soil condition, while the suitable soil condition can be obtained by best tillage practices. Kapner (1982) defined the tillage as the mechanical manipulation of soil, the goal of proper tillage is to provide a suitable environment for seed germination, weed control, excess moisture removed and reduction of surface runoff by increasing infiltration. The degree of soil compaction, soil bulk density and soil moisture condition are important factors that influence seedling emergence and crop yield.

The tillage equipment may cause soil compaction and upset the balance between the air and water components of soil, the compaction cause due to tillage implements may increase the soil strength and restrict root growth. However, a slight compaction is needed to gain good contact between seed and soil particles. This can be achieved by well planed tillage practices that can provide means for creating congenial soil environment, which is particularly necessary for seed germination and effective plant growth. Frequent traffic of machinery and equipment, in irrigated field cause a breakdown of soil structure in the topsoil layer, and considerable compaction of the lower layers. As a result, it is difficult to prepare a good seedbed, germination is affected, and irregular stands are obtained.

### MATERIAL AND METHODS

The study was conducted at Latif Experimental Farm, Sindh Agriculture University, Tando Jam, during 2004. The experimental area is located at distance of about ½ km in north of Sindh Agriculture University, Tando Jam. The soil at the site was medium textured clay loam, it has an average bulk density of 1.21 g/cm<sup>3</sup>, retains 19.45% moisture. The experiment was laid out in a Randomized Complete Block Design with three treatments, each replicated three times for the study, the treatment consisted of T-1 (Ridge sowing method), T-2 (drilling sowing method), T-3 (broadcasting method). Seedbed was prepared according to the treatments. Ridges were prepared by ridger, keeping 75 cm distance between ridge to ridge, while for seed drilling the plots were leveled by using leveler, for broadcasting the plots

Although a general phone number is provided, customer support remains But the combination of seed bank history, guarantees of delivery and germination, and generous 10 + 10
