

# Intravascular large B-cell lymphoma (IVL)

58-year-old man.

Symptoms of stroke, weakness in the left hand and epileptic seizure (grand mal).  
Also, 3-month of recurrent fever.

### Normal tests:

Cerebral CT and MR.  
EEG and LP.  
Physical examination.  
Laboratory studies.  
Blood cell counts.  
Chest radiography.  
Tests for viruses, bacteria and autoimmune diseases.  
Bone marrow biopsy.

### Abnormal tests:

Elevate LDH at 4000 U/L  
Hb level of 7.0 g/dL.

#### **FDG PET/CT:**

- diffuse uptake in the bilateral lung,
- slightly heterogeneous uptake in the bone marrow,
- slightly elevated uptake in the renal cortex.

### Skin biopsy:

CD20+ large lymphoid cells filling the small vessels in the subcutaneous tissues.

**IVL was diagnosed**

FDG PET

CT

- 1) **Diffuse** FDG **uptake** in the **bilateral lung**
- 2) Slightly **heterogeneous uptake** in the **bone marrow** with small focal accumulation sites
- 3) Elevated **uptake in the cortex** of the kidneys

*The blood vessel shown in the center of this section is lined with lymphoma cells (arrows), with red blood cells in the lumen. .*

## IVL

- rare subtype of large B cell lymphoma.

- **proliferation of lymphoma cells within the lumina of small blood vessels**, particularly capillaries and post-capillary venules, without an obvious extravascular tumor mass or readily observable circulating lymphoma cells in the peripheral blood.

*Purpuric lesions on arms of deceased 70-year-old patient with IVL*

**The diagnosis of IVL is made **postmortem** in over 50% of the cases.**

IVL can affect virtually any organ in the body:

CNS - 60%.

Skin - 8%.

Bone marrow and spleen - 11%.

Lung - 7%.

### *Patient distribution at initial diagnosis.*

*Among the newly diagnosed IVL patients, 308 (41%) presented in the CNS, 145 (20%) in skin, 124 (17%) in BM and spleen, 50 (7%) in lungs, 101 (13%) in other sites and 12 (2%) unknown. Among the 250 patients diagnosed at postmortem, IVL affecting the CNS was highest compared to other organ sites: 151 (60%) CNS, 21 (8%) skin, 28 (11%) BM and spleen, and 17 (7%) lung and 33 (13%) other organs.*

Histopathological analysis of skin biopsy from the left thigh.

(a) Large lymphoma cells in the small vessels (hematoxylin and eosin staining).

(b) Tumor cells were positive for CD20 (CD20 immunostain)

**FDG-PET findings**  
demonstrated **diffuse**  
**FDG uptake in the lung**  
**(47.8%)**.

The other reported abnormal foci of FDG uptake were in the bone marrow (57.0%), spleen (30.0%), renal cortex (22.0%), uterus/vagina (17.4%), adrenals (13.0%), lymph nodes (8.7%) and stomach (4.0%).

*D-F, Uptake of FDG with diffuse and intense accumulation in the bilateral lung of a 69-year-old woman (D and E), accumulation in the bilateral renal cortex (F), and multiple accumulations in the bones (D [red arrows]).*

*G-H, Uptake of FDG with diffuse accumulation in the bilateral lung of a 64-year-old man, especially in the lower lung field (G [blue arrows] and H), and multiple accumulations in the bones (G, red arrows). FDG uptake was not observed in the bilateral renal cortex (G).*
